    4.12.1.5 Interaction of script elements and XSLT ............................................................ 607
  4.12.2 The noscript element ........................................................................................... 608
  4.12.3 The template element .......................................................................................... 610
    4.12.3.1 Interaction of template elements with XSLT and XPath .................................. 612
  4.12.4 The slot element .................................................................................................. 613
  4.12.5 The canvas element ............................................................................................. 614
    4.12.5.1 The 2D rendering context .................................................................................. 618
      4.12.5.1.1 Implementation notes .................................................................................. 625
      4.12.5.1.2 The canvas state ......................................................................................... 625
      4.12.5.1.3 Line styles .................................................................................................. 625
6.7.3.2 The `DataTransferItem` interface
6.7.4 The `DragEvent` interface
6.7.5 Processing model
6.7.6 Events summary
6.7.7 The `draggable` attribute
6.7.8 Security risks in the drag-and-drop model

7 Loading Web pages

7.1 Browsing contexts
7.1.1 Nested browsing contexts
7.1.1.1 Navigating nested browsing contexts in the DOM
7.1.2 Auxiliary browsing contexts
7.1.2.1 Navigating auxiliary browsing contexts in the DOM
7.1.3 Security
7.1.4 Groupings of browsing contexts
7.1.5 Browsing context names

7.2 Security infrastructure for `Window`, `WindowProxy`, and `Location` objects
7.2.1 Integration with IDL
7.2.2 Shared internal slot: `[[CrossOriginPropertyDescriptorMap]]`
7.2.3 Shared abstract operations
7.2.3.1 `CrossOriginProperties (O)`
7.2.3.2 `IsPlatformObjectSameOrigin (O)`
7.2.3.3 `CrossOriginGetOwnPropertyHelper (O, P)`
7.2.3.4 `CrossOriginGet (O, P, Receiver)`
7.2.3.5 `CrossOriginSet (O, P, V, Receiver)`
7.2.3.6 `CrossOriginOwnPropertyKeys (O)`

7.3 The `Window` object
7.3.1 APIs for creating and navigating browsing contexts by name
7.3.2 Accessing other browsing contexts
7.3.3 Named access on the `Window` object
7.3.4 Garbage collection and browsing contexts
7.3.5 Closing browsing contexts
7.3.6 Browser interface elements
7.3.7 Script settings for `Window` objects

7.4 The `WindowProxy` exotic object
7.4.1 `[[GetPrototypeOf]] (O)`
7.4.2 `[[SetPrototypeOf]] (V)`
7.4.3 `[[IsExtensible]] (O)`
7.4.4 `[[PreventExtensions]] (O)`
7.4.5 `[[GetOwnProperty]] (P)`
7.4.6 `[[DefineOwnProperty]] (P, Desc)`
7.4.7 `[[Get]] (P, Receiver)`
7.4.8 `[[Set]] (P, V, Receiver)`
7.4.9 `[[Delete]] (P)`
7.4.10 `[[OwnPropertyKeys]] (O)`

7.5 Origin
7.5.1 Relaxing the same-origin restriction

7.6 Sandboxing

7.7 Session history and navigation
7.7.1 The session history of browsing contexts
### 8.1.2 Enabling and disabling scripting

- **8.1.2.1 Definitions**
- **8.1.2.2 Fetching scripts**
- **8.1.2.3 Creating scripts**
- **8.1.2.4 Calling scripts**

### 8.1.3 Processing model

- **8.1.3.1 Definitions**
- **8.1.3.2 Fetching scripts**
- **8.1.3.3 Creating scripts**
- **8.1.3.4 Calling scripts**
- **8.1.3.5 Realms, settings objects, and global objects**
  - **8.1.3.5.1 Entry**
  - **8.1.3.5.2 Incumbent**
  - **8.1.3.5.3 Current**
  - **8.1.3.5.4 Relevant**
- **8.1.3.6 Killing scripts**
- **8.1.3.7 Integration with the JavaScript job queue**
  - **8.1.3.7.1 EnqueueJob**
- **8.1.3.8 Integration with the JavaScript module system**
  - **8.1.3.8.1 HostResolveImportedModule**
  - **8.1.3.8.2 HostImportModuleDynamically**
  - **8.1.3.8.3 HostGetImportMetaProperties**
- **8.1.3.9 Integration with the JavaScript agent formalism**

### 8.1.3.10 Integration with the JavaScript agent cluster formalism

- **8.1.3.11 Runtime script errors**
  - **8.1.3.11.1 Runtime script errors in documents**
  - **8.1.3.11.2 The ErrorEvent interface**
- **8.1.3.12 Unhandled promise rejections**
  - **8.1.3.12.1 HostPromiseRejectionTracker**
  - **8.1.3.12.2 The PromiseRejectionEvent interface**
- **8.1.3.13 HostEnsureCanCompileStrings**

### 8.1.4 Event loops

- **8.1.4.1 Definitions**
- **8.1.4.2 Processing model**
- **8.1.4.3 Generic task sources**
- **8.1.4.4 Dealing with the event loop from other specifications**

### 8.1.5 Events

- **8.1.5.1 Event handlers**
- **8.1.5.2 Event handlers on elements, Document objects, and Window objects**
  - **8.1.5.2.1 IDL definitions**
- **8.1.5.3 Event firing**

### 8.2 The WindowOrWorkerGlobalScope mixin

### 8.3 Base64 utility methods

### 8.4 Dynamic markup insertion

- **8.4.1 Opening the input stream**
- **8.4.2 Closing the input stream**
- **8.4.3 document.write()**
- **8.4.4 document.writeln()**

### 8.5 Timers

### 8.6 Microtask queuing

### 8.7 User prompts

- **8.7.1 Simple dialogs**
- **8.7.2 Printing**

### 8.8 System state and capabilities

- **8.8.1 The Navigator object**
  - **8.8.1.1 Client identification**
  - **8.8.1.2 Language preferences**

1 Introduction

1.1 Where does this specification fit?

This specification defines a big part of the Web platform, in lots of detail. Its place in the Web platform specification stack relative to other specifications can be best summed up as follows:

<table>
<thead>
<tr>
<th>CSS</th>
<th>SVG</th>
<th>MathML</th>
<th>NPAPI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geo</td>
<td>Fetch</td>
<td>CSP</td>
<td>PNG</td>
</tr>
<tr>
<td>JPEG</td>
<td>GIF</td>
<td>PNG</td>
<td></td>
</tr>
<tr>
<td>HTTP</td>
<td>TLS</td>
<td>MQ</td>
<td>DOM</td>
</tr>
<tr>
<td>MIME</td>
<td>URL</td>
<td>XML</td>
<td>JavaScript</td>
</tr>
</tbody>
</table>

1.2 Is this HTML5?

This section is non-normative.

In short: Yes.
In more length: the term "HTML5" is widely used as a buzzword to refer to modern Web technologies, many of which (though by no means all) are developed at the WHATWG. This document is one such; others are available from the WHATWG specification index.

Although we have asked them to stop doing so, the W3C also republishes some parts of this specification as separate documents.

1.3 Background

This section is non-normative.

HTML is the World Wide Web's core markup language. Originally, HTML was primarily designed as a language for semantically describing scientific documents. Its general design, however, has enabled it to be adapted, over the subsequent years, to describe a number of other types of documents and even applications.

1.4 Audience

This section is non-normative.

This specification is intended for authors of documents and scripts that use the features defined in this specification, implementers of tools that operate on pages that use the features defined in this specification, and individuals wishing to establish the correctness of documents or implementations with respect to the requirements of this specification.

This document is probably not suited to readers who do not already have at least a passing familiarity with Web technologies, as in places it sacrifices clarity for precision, and brevity for completeness. More approachable tutorials and authoring guides can provide a gentler introduction to the topic.

In particular, familiarity with the basics of DOM is necessary for a complete understanding of some of the more technical parts of this specification. An understanding of Web IDL, HTTP, XML, Unicode, character encodings, JavaScript, and CSS will also be helpful in places but is not essential.

1.5 Scope

This section is non-normative.

This specification is limited to providing a semantic-level markup language and associated semantic-level scripting APIs for authoring accessible pages on the Web ranging from static documents to dynamic applications.

The scope of this specification does not include providing mechanisms for media-specific customization of presentation (although default rendering rules for Web browsers are included at the end of this specification, and several mechanisms for hooking into CSS are provided as part of the language).

The scope of this specification is not to describe an entire operating system. In particular, hardware configuration software, image manipulation tools, and applications that users would be expected to use with high-end workstations on a daily basis are out of scope. In terms of applications, this specification is targeted specifically at applications that would be expected to be used by users on an occasional basis, or regularly but from disparate locations, with low CPU requirements. Examples of such applications include online purchasing systems, searching systems, games (especially multiplayer online games), public telephone books or address books, communications software (e-mail clients, instant messaging clients, discussion software), document editing software, etc.

1.6 History

This section is non-normative.

For its first five years (1990-1995), HTML went through a number of revisions and experienced a number of extensions, primarily
With the creation of the W3C, HTML's development changed venue again. A first abortive attempt at extending HTML in 1995 known as HTML 3.0 then made way to a more pragmatic approach known as HTML 3.2, which was completed in 1997. HTML4 quickly followed later that same year.

The following year, the W3C membership decided to stop evolving HTML and instead begin work on an XML-based equivalent, called XHTML. This effort started with a reformulation of HTML4 in XML, known as XHTML 1.0, which added no new features except the new serialization, and which was completed in 2000. After XHTML 1.0, the W3C's focus turned to making it easier for other working groups to extend XHTML, under the banner of XHTML Modularization. In parallel with this, the W3C also worked on a new language that was not compatible with the earlier HTML and XHTML languages, calling it XHTML2.

Around the time that HTML's evolution was stopped in 1998, parts of the API for HTML developed by browser vendors were specified and published under the name DOM Level 1 (in 1998) and DOM Level 2 Core and DOM Level 2 HTML (starting in 2000 and culminating in 2003). These efforts then petered out, with some DOM Level 3 specifications published in 2004 but the working group being closed before all the Level 3 drafts were completed.

In 2003, the publication of XForms, a technology which was positioned as the next generation of Web forms, sparked a renewed interest in evolving HTML itself, rather than finding replacements for it. This interest was borne from the realization that XML’s deployment as a Web technology was limited to entirely new technologies (like RSS and later Atom), rather than as a replacement for existing deployed technologies (like HTML).

A proof of concept to show that it was possible to extend HTML4’s forms to provide many of the features that XForms 1.0 introduced, without requiring browsers to implement rendering engines that were incompatible with existing HTML Web pages, was the first result of this renewed interest. At this early stage, while the draft was already publicly available, and input was already being solicited from all sources, the specification was only under Opera Software’s copyright.

The idea that HTML’s evolution should be reopened was tested at a W3C workshop in 2004, where some of the principles that underlie the HTML5 work (described below), as well as the aforementioned early draft proposal covering just forms-related features, were presented to the W3C jointly by Mozilla and Opera. The proposal was rejected on the grounds that the proposal conflicted with the previously chosen direction for the Web’s evolution; the W3C staff and membership voted to continue developing XML-based replacements instead.

Shortly thereafter, Apple, Mozilla, and Opera jointly announced their intent to continue working on the effort under the umbrella of a new venue called the WHATWG. A public mailing list was created, and the draft was moved to the WHATWG site. The copyright was subsequently amended to be jointly owned by all three vendors, and to allow reuse of the specification.

The WHATWG was based on several core principles, in particular that technologies need to be backwards compatible, that specifications and implementations need to match even if this means changing the specification rather than the implementations, and that specifications need to be detailed enough that implementations can achieve complete interoperability without reverse-engineering each other.

The latter requirement in particular required that the scope of the HTML5 specification include what had previously been specified in three separate documents: HTML4, XHTML1, and DOM2 HTML. It also meant including significantly more detail than had previously been considered the norm.

In 2006, the W3C indicated an interest to participate in the development of HTML5 after all, and in 2007 formed a working group chartered to work with the WHATWG on the development of the HTML5 specification. Apple, Mozilla, and Opera allowed the W3C to publish the specification under the W3C copyright, while keeping a version with the less restrictive license on the WHATWG site.

For a number of years, both groups then worked together. In 2011, however, the groups came to the conclusion that they had different goals: the W3C wanted to publish a “finished” version of “HTML5”, while the WHATWG wanted to continue working on a Living Standard for HTML, continuously maintaining the specification rather than freezing it in a state with known problems, and adding new features as needed to evolve the platform.

Since then, the WHATWG has been working on this specification (amongst others), and the W3C has been copying fixes made by the WHATWG into their fork of the document (which also has other changes).

1.7 Design notes

This section is non-normative.
It must be admitted that many aspects of HTML appear at first glance to be nonsensical and inconsistent.

HTML, its supporting DOM APIs, as well as many of its supporting technologies, have been developed over a period of several decades by a wide array of people with different priorities who, in many cases, did not know of each other’s existence.

Features have thus arisen from many sources, and have not always been designed in especially consistent ways. Furthermore, because of the unique characteristics of the Web, implementation bugs have often become de-facto, and now de-jure, standards, as content is often unintentionally written in ways that rely on them before they can be fixed.

Despite all this, efforts have been made to adhere to certain design goals. These are described in the next few subsections.

### 1.7.1 Serializability of script execution

This section is non-normative.

To avoid exposing Web authors to the complexities of multithreading, the HTML and DOM APIs are designed such that no script can ever detect the simultaneous execution of other scripts. Even with workers, the intent is that the behavior of implementations can be thought of as completely serializing the execution of all scripts in all browsing contexts.

The exception to this general design principle is the JavaScript SharedArrayBuffer class. Using SharedArrayBuffer objects, it can in fact be observed that scripts in other agents are executing simultaneously. Furthermore, due to the JavaScript memory model, there are situations which not only are un-representable via serialized script execution, but also un-representable via serialized statement execution among those scripts.

### 1.7.2 Compliance with other specifications

This section is non-normative.

This specification interacts with and relies on a wide variety of other specifications. In certain circumstances, unfortunately, conflicting needs have led to this specification violating the requirements of these other specifications. Whenever this has occurred, the transgressions have each been noted as a "willful violation", and the reason for the violation has been noted.

### 1.7.3 Extensibility

This section is non-normative.

HTML has a wide array of extensibility mechanisms that can be used for adding semantics in a safe manner:

- Authors can use the `class` attribute to extend elements, effectively creating their own elements, while using the most applicable existing "real" HTML element, so that browsers and other tools that don’t know of the extension can still support it somewhat well. This is the tack used by microformats, for example.
- Authors can include data for inline client-side scripts or server-side site-wide scripts to process using the `data-*` attributes. These are guaranteed to never be touched by browsers, and allow scripts to include data on HTML elements that scripts can then look for and process.
- Authors can use the `<meta name="content"` mechanism to include page-wide metadata.
- Authors can use the `rel` mechanism to annotate links with specific meanings by registering extensions to the predefined set of link types. This is also used by microformats.
- Authors can embed raw data using the `<script type=""` mechanism with a custom type, for further handling by inline or server-side scripts.
- Authors can create `plugins` and invoke them using the `embed` element. This is how Flash works.
- Authors can extend APIs using the JavaScript prototyping mechanism. This is widely used by script libraries, for instance.
- Authors can use the microdata feature (the `itemscope="` and `itemprop="` attributes) to embed nested name-value
pairs of data to be shared with other applications and sites.

1.8 HTML vs XML syntax

This section is non-normative.

This specification defines an abstract language for describing documents and applications, and some APIs for interacting with in-memory representations of resources that use this language.

The in-memory representation is known as "DOM HTML", or "the DOM" for short.

There are various concrete syntaxes that can be used to transmit resources that use this abstract language, two of which are defined in this specification.

The first such concrete syntax is the HTML syntax. This is the format suggested for most authors. It is compatible with most legacy Web browsers. If a document is transmitted with the `text/html` MIME type, then it will be processed as an HTML document by Web browsers. This specification defines the latest HTML syntax, known simply as "HTML".

The second concrete syntax is XML. When a document is transmitted with an XML MIME type, such as `application/xhtml+xml`, then it is treated as an XML document by Web browsers, to be parsed by an XML processor. Authors are reminded that the processing for XML and HTML differs; in particular, even minor syntax errors will prevent a document labeled as XML from being rendered fully, whereas they would be ignored in the HTML syntax.

The DOM, the HTML syntax, and the XML syntax cannot all represent the same content. For example, namespaces cannot be represented using the HTML syntax, but they are supported in the DOM and in the XML syntax. Similarly, documents that use the `noscript` feature can be represented using the HTML syntax, but cannot be represented with the DOM or in the XML syntax. Comments that contain the string "-->" can only be represented in the DOM, not in the HTML and XML syntaxes.

1.9 Structure of this specification

This section is non-normative.

This specification is divided into the following major sections:

- **Introduction**
  - Non-normative materials providing a context for the HTML standard.
- **Common Infrastructure**
  - The conformance classes, algorithms, definitions, and the common underpinnings of the rest of the specification.
- **Semantics, structure, and APIs of HTML documents**
  - Documents are built from elements. These elements form a tree using the DOM. This section defines the features of this DOM, as well as introducing the features common to all elements, and the concepts used in defining elements.
- **The elements of HTML**
  - Each element has a predefined meaning, which is explained in this section. Rules for authors on how to use the element, along with user agent requirements for how to handle each element, are also given. This includes large signature features of HTML such as video playback and subtitles, form controls and form submission, and a 2D graphics API known as the HTML canvas.
- **Microdata**
  - This specification introduces a mechanism for adding machine-readable annotations to documents, so that tools can extract trees of name-value pairs from the document. This section describes this mechanism and some algorithms that can be used to convert HTML documents into other formats. This section also defines some sample Microdata vocabularies for contact information, calendar events, and licensing works.
User interaction

HTML documents can provide a number of mechanisms for users to interact with and modify content, which are described in this section, such as how focus works, and drag-and-drop.

Loading Web pages

HTML documents do not exist in a vacuum — this section defines many of the features that affect environments that deal with multiple pages, such as Web browsers and offline caching of Web applications.

Web application APIs

This section introduces basic features for scripting of applications in HTML.

Web workers

This section defines an API for background threads in JavaScript.

The communication APIs

This section describes some mechanisms that applications written in HTML can use to communicate with other applications from different domains running on the same client. It also introduces a server-push event stream mechanism known as Server Sent Events or EventSource, and a two-way full-duplex socket protocol for scripts known as Web Sockets.

Web storage

This section defines a client-side storage mechanism based on name-value pairs.

The HTML syntax

The XML syntax

All of these features would be for naught if they couldn't be represented in a serialized form and sent to other people, and so these sections define the syntaxes of HTML and XML, along with rules for how to parse content using those syntaxes.

Rendering

This section defines the default rendering rules for Web browsers.

There are also some appendices, listing obsolete features and IANA considerations, and several indices.

1.9.1 How to read this specification

This specification should be read like all other specifications. First, it should be read cover-to-cover, multiple times. Then, it should be read backwards at least once. Then it should be read by picking random sections from the contents list and following all the cross-references.

As described in the conformance requirements section below, this specification describes conformance criteria for a variety of conformance classes. In particular, there are conformance requirements that apply to producers, for example authors and the documents they create, and there are conformance requirements that apply to consumers, for example Web browsers. They can be distinguished by what they are requiring: a requirement on a producer states what is allowed, while a requirement on a consumer states how software is to act.

Example

For example, "the foo attribute's value must be a valid integer" is a requirement on producers, as it lays out the allowed values; in contrast, the requirement "the foo attribute's value must be parsed using the rules for parsing integers" is a requirement on consumers, as it describes how to process the content.

Requirements on producers have no bearing whatsoever on consumers.

Example

Continuing the above example, a requirement stating that a particular attribute's value is constrained to being a valid integer emphatically does not imply anything about the requirements on consumers. It might be that the consumers are in fact required to treat the attribute as an opaque string, completely unaffected by whether the value conforms to the requirements or not. It might be (as in the previous example) that the consumers are required to parse the value using specific rules that define how invalid (non-numeric in this case) values are to be processed.
1.9.2 Typographic conventions

This section is non-normative.

Note

This is a note.

Example

This is an example.

This is an open issue.

⚠ Warning!

This is a warning.

IDL

[Exposed=Window]

interface Example {
    // this is an IDL definition
};

For web developers (non-normative)

variable = object . method([ optionalArgument ])

This is a note to authors describing the usage of an interface.

CSS

/* this is a CSS fragment */

The defining instance of a term is marked up like this. Uses of that term are marked up like this or like this.

The defining instance of an element, attribute, or API is marked up like this. References to that element, attribute, or API are marked up like this.

Other code fragments are marked up like this.

Variables are marked up like this.

In an algorithm, steps in synchronous sections are marked with ⌛.

In some cases, requirements are given in the form of lists with conditions and corresponding requirements. In such cases, the requirements that apply to a condition are always the first set of requirements that follow the condition, even in the case of there being multiple sets of conditions for those requirements. Such cases are presented as follows:

← This is a condition
← This is another condition
    This is the requirement that applies to the conditions above.
← This is a third condition
    This is the requirement that applies to the third condition.

1.10 Privacy concerns

This section is non-normative.

Some features of HTML trade user convenience for a measure of user privacy.

In general, due to the Internet’s architecture, a user can be distinguished from another by the user’s IP address. IP addresses do not perfectly match to a user; as a user moves from device to device, or from network to network, their IP address will change; similarly,
NAT routing, proxy servers, and shared computers enable packets that appear to all come from a single IP address to actually map to multiple users. Technologies such as onion routing can be used to further anonymize requests so that requests from a single user at one node on the Internet appear to come from many disparate parts of the network.

However, the IP address used for a user’s requests is not the only mechanism by which a user’s requests could be related to each other. Cookies, for example, are designed specifically to enable this, and are the basis of most of the Web’s session features that enable you to log into a site with which you have an account.

There are other mechanisms that are more subtle. Certain characteristics of a user’s system can be used to distinguish groups of users from each other; by collecting enough such information, an individual user's browser's “digital fingerprint” can be computed, which can be as good as, if not better than, an IP address in ascertaining which requests are from the same user.

Grouping requests in this manner, especially across multiple sites, can be used for both benign (and even arguably positive) purposes, as well as for malevolent purposes. An example of a reasonably benign purpose would be determining whether a particular person seems to prefer sites with dog illustrations as opposed to sites with cat illustrations (based on how often they visit the sites in question) and then automatically using the preferred illustrations on subsequent visits to participating sites. Malevolent purposes, however, could include governments combining information such as the person's home address (determined from the addresses they use when getting driving directions on one site) with their apparent political affiliations (determined by examining the forum sites that they participate in) to determine whether the person should be prevented from voting in an election.

Since the malevolent purposes can be remarkably evil, user agent implementers are encouraged to consider how to provide their users with tools to minimize leaking information that could be used to fingerprint a user.

Unfortunately, as the first paragraph in this section implies, sometimes there is great benefit to be derived from exposing the very information that can also be used for fingerprinting purposes, so it’s not as easy as simply blocking all possible leaks. For instance, the ability to log into a site to post under a specific identity requires that the user’s requests be identifiable as all being from the same user, more or less by definition. More subtly, though, information such as how wide text is, which is necessary for many effects that involve drawing text onto a canvas (e.g. any effect that involves drawing a border around the text) also leaks information that can be used to group a user's requests. (In this case, by potentially exposing, via a brute force search, which fonts a user has installed, information which can vary considerably from user to user.)

Features in this specification which can be used to fingerprint the user are marked as this paragraph is.

Other features in the platform can be used for the same purpose, though, including, though not limited to:

- The exact list of which features a user agents supports.
- The maximum allowed stack depth for recursion in script.
- Features that describe the user’s environment, like Media Queries and the Screen object. [MQ] [CSSOMVIEW]
- The user’s time zone.

1.10.1 Cross-site communication

The postMessage() API provides a mechanism by which two sites can communicate directly. At first glance, this might appear to open a new way by which the problems described above can occur. However, in practice, multiple mechanisms exist by which two sites can communicate that predate this API: a site embedding another can send data via an iframe element's dimensions; a site can use a cross-site image request with a unique identifier known to the server to initiate a server-side data exchange; or indeed the fingerprinting techniques described above can be used by two sites to uniquely identify a visitor such that information can then be exchanged on the server side.

Fundamentally, users that do not trust a site to treat their information with respect have to avoid visiting that site at all.

1.11 A quick introduction to HTML

This section is non-normative.

A basic HTML document looks like this:
<!DOCTYPE html>
<html lang="en">
<head>
<title>Sample page</title>
</head>
<body>
<h1>Sample page</h1>
<p>This is a <a href="demo.html">simple</a> sample.</p>
<!-- this is a comment -->
</body>
</html>

HTML documents consist of a tree of elements and text. Each element is denoted in the source by a start tag, such as "<body>", and an end tag, such as "</body>". (Certain start tags and end tags can in certain cases be omitted and are implied by other tags.)

Tags have to be nested such that elements are all completely within each other, without overlapping:

```html
<p>This is <em>very</em> wrong!</p>
<p>This <em>is</em> <strong>correct</strong>.</p>
```

This specification defines a set of elements that can be used in HTML, along with rules about the ways in which the elements can be nested.

Elements can have attributes, which control how the elements work. In the example below, there is a hyperlink, formed using the <code>a</code> element and its <code>href</code> attribute:

```html
<a href="demo.html">simple</a>
```

Attributes are placed inside the start tag, and consist of a name and a value, separated by an "=" character. The attribute value can remain unquoted if it doesn’t contain ASCII whitespace or any of "'"=' '< or >. Otherwise, it has to be quoted using either single or double quotes. The value, along with the "=" character, can be omitted altogether if the value is the empty string.

```html
<!-- empty attributes -->
<input name="address" disabled=""/>
<!-- attributes with a value -->
<input name="address" maxlength="200" />
<input name="address" maxlength="'200'" />
<input name="address" maxlength=""200"" />
```

XML user agents (e.g. Web browsers) then parse this markup, turning it into a DOM (Document Object Model) tree. A DOM tree is an in-memory representation of a document.

DOM trees contain several kinds of nodes, in particular a <code>DocumentType</code> node, <code>Element</code> nodes, <code>Text</code> nodes, <code>Comment</code> nodes, and in some cases <code>ProcessingInstruction</code> nodes.

The markup snippet at the top of this section would be turned into the following DOM tree:
The document element of this tree is the html element, which is the element always found in that position in HTML documents. It contains two elements, head and body, as well as a Text node between them.

There are many more Text nodes in the DOM tree than one would initially expect, because the source contains a number of spaces (represented here by "␣") and line breaks ("⏎") that all end up as Text nodes in the DOM. However, for historical reasons not all of the spaces and line breaks in the original markup appear in the DOM. In particular, all the whitespace before head start tag ends up being dropped silently, and all the whitespace after the body end tag ends up placed at the end of the body.

The head element contains a title element, which itself contains a Text node with the text "Sample page". Similarly, the body element contains an h1 element, a p element, and a comment.

This DOM tree can be manipulated from scripts in the page. Scripts (typically in JavaScript) are small programs that can be embedded using the script element or using event handler content attributes. For example, here is a form with a script that sets the value of the form's output element to say "Hello World":

```html
<form name="main">
  Result: <output name="result"></output>
  <script>
    document.forms.main.elements.result.value = 'Hello World';
  </script>
</form>
```

Each element in the DOM tree is represented by an object, and these objects have APIs so that they can be manipulated. For instance, a link (e.g. the a element in the tree above) can have its "href" attribute changed in several ways:

```javascript
var a = document.links[0]; // obtain the first link in the document
a.href = 'sample.html'; // change the destination URL of the link
a.protocol = 'https'; // change just the scheme part of the URL
a.setAttribute('href', 'https://example.com/'); // change the content attribute directly
```

Since DOM trees are used as the way to represent HTML documents when they are processed and presented by implementations (especially interactive implementations like Web browsers), this specification is mostly phrased in terms of DOM trees, instead of the markup described above.

HTML documents represent a media-independent description of interactive content. HTML documents might be rendered to a screen, or through a speech synthesizer, or on a braille display. To influence exactly how such rendering takes place, authors can use a styling language such as CSS.

In the following example, the page has been made yellow-on-blue using CSS.

```html
<!DOCTYPE html>
<html lang="en">
<head>
  <title>Sample styled page</title>
  <style>
    body { background: navy; color: yellow; }
  </style>
</head>
```
For more details on how to use HTML, authors are encouraged to consult tutorials and guides. Some of the examples included in this specification might also be of use, but the novice author is cautioned that this specification, by necessity, defines the language with a level of detail that might be difficult to understand at first.

1.11.1 Writing secure applications with HTML

This section is non-normative.

When HTML is used to create interactive sites, care needs to be taken to avoid introducing vulnerabilities through which attackers can compromise the integrity of the site itself or of the site’s users.

A comprehensive study of this matter is beyond the scope of this document, and authors are strongly encouraged to study the matter in more detail. However, this section attempts to provide a quick introduction to some common pitfalls in HTML application development.

The security model of the Web is based on the concept of "origins", and correspondingly many of the potential attacks on the Web involve cross-origin actions. [ORIGIN]

Not validating user input

Cross-site scripting (XSS)

SQL injection

When accepting untrusted input, e.g. user-generated content such as text comments, values in URL parameters, messages from third-party sites, etc, it is imperative that the data be validated before use, and properly escaped when displayed. Failing to do this can allow a hostile user to perform a variety of attacks, ranging from the potentially benign, such as providing bogus user information like a negative age, to the serious, such as running scripts every time a user looks at a page that includes the information, potentially propagating the attack in the process, to the catastrophic, such as deleting all data in the server.

When writing filters to validate user input, it is imperative that filters always be safelist-based, allowing known-safe constructs and disallowing all other input. Blocklist-based filters that disallow known-bad inputs and allow everything else are not secure, as not everything that is bad is yet known (for example, because it might be invented in the future).

Example

For example, suppose a page looked at its URL's query string to determine what to display, and the site then redirected the user to that page to display a message, as in:

```html
<ul>
  <li><a href="message.cgi?say=Hello">Say Hello</a></li>
  <li><a href="message.cgi?say=Welcome">Say Welcome</a></li>
  <li><a href="message.cgi?say=Kittens">Say Kittens</a></li>
</ul>
```

If the message was just displayed to the user without escaping, a hostile attacker could then craft a URL that contained a script element:

```
https://example.com/message.cgi?say=%3Cscript%3Ealert%28%27Oh%20no%21%27%3C/script%3E
```

If the attacker then convinced a victim user to visit this page, a script of the attacker's choosing would run on the page. Such a script could do any number of hostile actions, limited only by what the site offers: if the site is an e-commerce shop, for instance, such a script could cause the user to unknowingly make arbitrarily many unwanted purchases.

This is called a cross-site scripting attack.

There are many constructs that can be used to try to trick a site into executing code. Here are some that authors are encouraged to consider when writing safelist filters:
• When allowing harmless-seeming elements like `<img>` , it is important to safelist any provided attributes as well. If one allowed all attributes then an attacker could, for instance, use the `onload` attribute to run arbitrary script.

• When allowing URLs to be provided (e.g. for links), the scheme of each URL also needs to be explicitly safelisted, as there are many schemes that can be abused. The most prominent example is `javascript:` , but user agents can implement (and indeed, have historically implemented) others.

• Allowing a `base` element to be inserted means any `script` elements in the page with relative links can be hijacked, and similarly that any form submissions can get redirected to a hostile site.

Cross-site request forgery (CSRF)
If a site allows a user to make form submissions with user-specific side-effects, for example posting messages on a forum under the user's name, making purchases, or applying for a passport, it is important to verify that the request was made by the user intentionally, rather than by another site tricking the user into making the request unknowingly.

This problem exists because HTML forms can be submitted to other origins.

Sites can prevent such attacks by populating forms with user-specific hidden tokens, or by checking `Origin` headers on all requests.

Clickjacking
A page that provides users with an interface to perform actions that the user might not wish to perform needs to be designed so as to avoid the possibility that users can be tricked into activating the interface.

One way that a user could be so tricked is if a hostile site places the victim site in a small `iframe` and then convinces the user to click, for instance by having the user play a reaction game. Once the user is playing the game, the hostile site can quickly position the iframe under the mouse cursor just as the user is about to click, thus tricking the user into clicking the victim site's interface.

To avoid this, sites that do not expect to be used in frames are encouraged to only enable their interface if they detect that they are not in a frame (e.g. by comparing the `window` object to the value of the `top` attribute).

11.2 Common pitfalls to avoid when using the scripting APIs

This section is non-normative.

Scripts in HTML have "run-to-completion" semantics, meaning that the browser will generally run the script uninterrupted before doing anything else, such as firing further events or continuing to parse the document.

On the other hand, parsing of HTML files happens incrementally, meaning that the parser can pause at any point to let scripts run. This is generally a good thing, but it does mean that authors need to be careful to avoid hooking event handlers after the events could have possibly fired.

There are two techniques for doing this reliably: use `event handler content attributes` , or create the element and add the event handlers in the same script. The latter is safe because, as mentioned earlier, scripts are run to completion before further events can fire.

Example

One way this could manifest itself is with `<img>` elements and the `load` event. The event could fire as soon as the element has been parsed, especially if the image has already been cached (which is common).

Here, the author uses the `onload` handler on an `<img>` element to catch the `load` event:

```html
<img src="games.png" alt="Games" onload="gamesLogoHasLoaded(event)"/>
```

If the element is being added by script, then so long as the event handlers are added in the same script, the event will still not be missed:

```html
<script>
  var img = new Image();
  img.src = 'games.png';
</script>
```
1.11.3 How to catch mistakes when writing HTML: validators and conformance checkers

This section is non-normative.

Authors are encouraged to make use of conformance checkers (also known as validators) to catch common mistakes. The WHATWG maintains a list of such tools at: https://whatwg.org/validator/

1.12 Conformance requirements for authors

This section is non-normative.

Unlike previous versions of the HTML specification, this specification defines in some detail the required processing for invalid documents as well as valid documents.

However, even though the processing of invalid content is in most cases well-defined, conformance requirements for documents are still important: in practice, interoperability (the situation in which all implementations process particular content in a reliable and identical or equivalent way) is not the only goal of document conformance requirements. This section details some of the more common reasons for still distinguishing between a conforming document and one with errors.

1.12.1 Presentational markup

This section is non-normative.

The majority of presentational features from previous versions of HTML are no longer allowed. Presentational markup in general has been found to have a number of problems:

The use of presentational elements leads to poorer accessibility

While it is possible to use presentational markup in a way that provides users of assistive technologies (ATs) with an acceptable experience (e.g. using ARIA), doing so is significantly more difficult than doing so when using semantically-appropriate markup. Furthermore, even using such techniques doesn't help make pages accessible for non-AT non-graphical users, such as users of text-mode browsers.

Using media-independent markup, on the other hand, provides an easy way for documents to be authored in such a way that they work for more users (e.g. users of text browsers).
Higher cost of maintenance

It is significantly easier to maintain a site written in such a way that the markup is style-independent. For example, changing the color of a site that uses `<font color="">` throughout requires changes across the entire site, whereas a similar change to a site based on CSS can be done by changing a single file.

Larger document sizes

Presentational markup tends to be much more redundant, and thus results in larger document sizes.

For those reasons, presentational markup has been removed from HTML in this version. This change should not come as a surprise; HTML4 deprecated presentational markup many years ago and provided a mode (HTML4 Transitional) to help authors move away from presentational markup; later, XHTML 1.1 went further and obsoleted those features altogether.

The only remaining presentational markup features in HTML are the `style` attribute and the `style` element. Use of the `style` attribute is somewhat discouraged in production environments, but it can be useful for rapid prototyping (where its rules can be directly moved into a separate style sheet later) and for providing specific styles in unusual cases where a separate style sheet would be inconvenient. Similarly, the `style` element can be useful in syndication or for page-specific styles, but in general an external style sheet is likely to be more convenient when the styles apply to multiple pages.

It is also worth noting that some elements that were previously presentational have been redefined in this specification to be media-independent: `<b>`, `<i>`, `<hr>`, `<s>`, `<small>`, and `<u>`.

1.12.2 Syntax errors

This section is non-normative.

The syntax of HTML is constrained to avoid a wide variety of problems.

Unintuitive error-handling behavior

Certain invalid syntax constructs, when parsed, result in DOM trees that are highly unintuitive.

Example

For example, the following markup fragment results in a DOM with an `<hr>` element that is an earlier sibling of the corresponding `<table>` element:

```
<table><hr>...
```

Errors with optional error recovery

To allow user agents to be used in controlled environments without having to implement the more bizarre and convoluted error handling rules, user agents are permitted to fail whenever encountering a parse error.

Errors where the error-handling behavior is not compatible with streaming user agents

Some error-handling behavior, such as the behavior for the `<table><hr>...` example mentioned above, are incompatible with streaming user agents (user agents that process HTML files in one pass, without storing state). To avoid interoperability problems with such user agents, any syntax resulting in such behavior is considered invalid.

Errors that can result in infoset coercion

When a user agent based on XML is connected to an HTML parser, it is possible that certain invariants that XML enforces, such as element or attribute names never contain multiple colons, will be violated by an HTML file. Handling this can require that the parser coerce the HTML DOM into an XML-compatible infoset. Most syntax constructs that require such handling are considered invalid. (Comments containing two consecutive hyphens, or ending with a hyphen, are exceptions that are allowed in the HTML syntax.)

Errors that result in disproportionately poor performance

Certain syntax constructs can result in disproportionately poor performance. To discourage the use of such constructs, they are typically made non-conforming.

Example

For example, the following markup results in poor performance, since all the unclosed `<i>` elements have to be reconstructed in each paragraph, resulting in progressively more elements in each paragraph:
Errors involving fragile syntax constructs

There are syntax constructs that, for historical reasons, are relatively fragile. To help reduce the number of users who accidentally run into such problems, they are made non-conforming.

Examples

For example, the parsing of certain named character references in attributes happens even with the closing semicolon being omitted. It is safe to include an ampersand followed by letters that do not form a named character reference, but if the letters are changed to a string that does form a named character reference, they will be interpreted as that character instead.

In this fragment, the attribute's value is "?bill&ted":

```html
<a href="?bill&ted">Bill and Ted</a>
```

In the following fragment, however, the attribute's value is actually "?art©", not the intended "?art&copy", because even without the final semicolon, "&copy" is handled the same as "©" and thus gets interpreted as "©":

```html
<a href="?art&copy">Art and Copy</a>
```

To avoid this problem, all named character references are required to end with a semicolon, and uses of named character references without a semicolon are flagged as errors.

Thus, the correct way to express the above cases is as follows:

```html
<a href="?bill&ted">Bill and Ted</a> <!-- &ted is ok, since it's not a named character reference -->
```

```html
<a href="?art&amp;copy">Art and Copy</a> <!-- the & has to be escaped, since &copy is a named character reference -->
```

Errors involving known interoperability problems in legacy user agents

Certain syntax constructs are known to cause especially subtle or serious problems in legacy user agents, and are therefore marked as non-conforming to help authors avoid them.
Errors that risk exposing authors to security attacks

Certain restrictions exist purely to avoid known security problems.

Example

For example, the restriction on using UTF-7 exists purely to avoid authors falling prey to a known cross-site-scripting attack using UTF-7. [UTF7]p1277

Cases where the author's intent is unclear

Markup where the author's intent is very unclear is often made non-conforming. Correcting these errors early makes later maintenance easier.

Example

For example, it is unclear whether the author intended the following to be an h1 p183 heading or an h2 p183 heading:

```
<h1>Contact details</h2>
```

Cases that are likely to be typos

When a user makes a simple typo, it is helpful if the error can be caught early, as this can save the author a lot of debugging time. This specification therefore usually considers it an error to use element names, attribute names, and so forth, that do not match the names defined in this specification.

Example

For example, if the author typed `<capton>` instead of `<caption>`, this would be flagged as an error and the author could correct the typo immediately.

Errors that could interfere with new syntax in the future

In order to allow the language syntax to be extended in the future, certain otherwise harmless features are disallowed.

Example

For example, "attributes" in end tags are ignored currently, but they are invalid, in case a future change to the language makes use of that syntax feature without conflicting with already-deployed (and valid!) content.

Some authors find it helpful to be in the practice of always quoting all attributes and always including all optional tags, preferring the consistency derived from such custom over the minor benefits of terseness afforded by making use of the flexibility of the HTML syntax. To aid such authors, conformance checkers can provide modes of operation wherein such conventions are enforced.

1.12.3 Restrictions on content models and on attribute values §p38

This section is non-normative.

Beyond the syntax of the language, this specification also places restrictions on how elements and attributes can be specified. These restrictions are present for similar reasons:

Errors involving content with dubious semantics

To avoid misuse of elements with defined meanings, content models are defined that restrict how elements can be nested when such nestings would be of dubious value.
Errors that involve a conflict in expressed semantics

Similarly, to draw the author's attention to mistakes in the use of elements, clear contradictions in the semantics expressed are also considered conformance errors.

Example
In the fragments below, for example, the semantics are nonsensical: a separator cannot simultaneously be a cell, nor can a radio button be a progress bar.

```html
<hr role="cell">
<input type=radio role=progressbar>
```

Another example is the restrictions on the content models of the `ul` element, which only allows `li` element children. Lists by definition consist just of zero or more list items, so if a `ul` element contains something other than an `li` element, it's not clear what was meant.

Cases where the default styles are likely to lead to confusion

Certain elements have default styles or behaviors that make certain combinations likely to lead to confusion. Where these have equivalent alternatives without this problem, the confusing combinations are disallowed.

Example
For example, `div` elements are rendered as block boxes, and `span` elements as inline boxes. Putting a block box in an inline box is unnecessarily confusing; since either nesting just `div` elements, or nesting just `span` elements, or nesting `span` elements inside `div` elements all serve the same purpose as nesting a `div` element in a `span` element, but only the latter involves a block box in an inline box, the latter combination is disallowed.

Another example would be the way interactive content cannot be nested. For example, a `button` element cannot contain a `textarea` element. This is because the default behavior of such nesting interactive elements would be highly confusing to users. Instead of nesting these elements, they can be placed side by side.

Errors that indicate a likely misunderstanding of the specification

Sometimes, something is disallowed because allowing it would likely cause author confusion.

Example
For example, setting the `disabled` attribute to the value "false" is disallowed, because despite the appearance of meaning that the element is enabled, it in fact means that the element is disabled (what matters for implementations is the presence of the attribute, not its value).

Errors involving limits that have been imposed merely to simplify the language

Some conformance errors simplify the language that authors need to learn.

Example
For example, the `area` element's `shape` attribute, despite accepting both `circle` and `circ` values in practice as synonyms, disallows the use of the `circ` value, so as to simplify tutorials and other learning aids. There would be no benefit to allowing both, but it would cause extra confusion when teaching the language.

Errors that involve peculiarities of the parser

Certain elements are parsed in somewhat eccentric ways (typically for historical reasons), and their content model restrictions are intended to avoid exposing the author to these issues.

Example
For example, a `form` element isn't allowed inside phrasing content, because when parsed as HTML, a `form` element's start tag will imply a `p` element's end tag. Thus, the following markup results in two paragraphs, not one:
Errors that would likely result in scripts failing in hard-to-debug ways
Some errors are intended to help prevent script problems that would be hard to debug.

Example
This is why, for instance, it is non-conforming to have two `id` attributes with the same value. Duplicate IDs lead to the wrong element being selected, with sometimes disastrous effects whose cause is hard to determine.

Errors that waste authoring time
Some constructs are disallowed because historically they have been the cause of a lot of wasted authoring time, and by encouraging authors to avoid making them, authors can save time in future efforts.

Example
For example, a `script` element's `src` attribute causes the element's contents to be ignored. However, this isn't obvious, especially if the element's contents appear to be executable script — which can lead to authors spending a lot of time trying to debug the inline script without realizing that it is not executing. To reduce this problem, this specification makes it non-conforming to have executable script in a `script` element when the `src` attribute is present. This means that authors who are validating their documents are less likely to waste time with this kind of mistake.

Errors that involve areas that affect authors migrating between the HTML and XML syntaxes
Some authors like to write files that can be interpreted as both XML and HTML with similar results. Though this practice is discouraged in general due to the myriad of subtle complications involved (especially when involving scripting, styling, or any kind of automated serialization), this specification has a few restrictions intended to at least somewhat mitigate the difficulties. This makes it easier for authors to use this as a transitional step when migrating between the HTML and XML syntaxes.

Example
For example, there are somewhat complicated rules surrounding the `lang` and `xml:lang` attributes intended to keep the two synchronized.

Example
Another example would be the restrictions on the values of `xmlns` attributes in the HTML serialization, which are intended to ensure that elements in conforming documents end up in the same namespaces whether processed as HTML or XML.

Errors that involve areas reserved for future expansion
As with the restrictions on the syntax intended to allow for new syntax in future revisions of the language, some restrictions on the content models of elements and values of attributes are intended to allow for future expansion of the HTML vocabulary.

Example
For example, limiting the values of the `target` attribute that start with an U+005F LOW LINE character (_) to only specific predefined values allows new predefined values to be introduced at a future time without conflicting with author-defined values.

Errors that indicate a mis-use of other specifications
Certain restrictions are intended to support the restrictions made by other specifications.

Example
For example, requiring that attributes that take media query lists use only `valid` media query lists reinforces the importance of following the conformance rules of that specification.

1.13 Suggested reading

This section is non-normative.
The following documents might be of interest to readers of this specification.

**Character Model for the World Wide Web 1.0: Fundamentals [CHARMOD] p1221**

This Architectural Specification provides authors of specifications, software developers, and content developers with a common reference for interoperable text manipulation on the World Wide Web, building on the Universal Character Set, defined jointly by the Unicode Standard and ISO/IEC 10646. Topics addressed include use of the terms 'character', 'encoding' and 'string', a reference processing model, choice and identification of character encodings, character escaping, and string indexing.

**Unicode Security Considerations [UTR36] p1227**

Because Unicode contains such a large number of characters and incorporates the varied writing systems of the world, incorrect usage can expose programs or systems to possible security attacks. This is especially important as more and more products are internationalized. This document describes some of the security considerations that programmers, system analysts, standards developers, and users should take into account, and provides specific recommendations to reduce the risk of problems.

**Web Content Accessibility Guidelines (WCAG) 2.0 [WCAG] p1227**

Web Content Accessibility Guidelines (WCAG) 2.0 covers a wide range of recommendations for making Web content more accessible. Following these guidelines will make content accessible to a wider range of people with disabilities, including blindness and low vision, deafness and hearing loss, learning disabilities, cognitive limitations, limited movement, speech disabilities, photosensitivity and combinations of these. Following these guidelines will also often make your Web content more usable to users in general.

**Authoring Tool Accessibility Guidelines (ATAG) 2.0 [ATAG] p1221**

This specification provides guidelines for designing Web content authoring tools that are more accessible for people with disabilities. An authoring tool that conforms to these guidelines will promote accessibility by providing an accessible user interface to authors with disabilities as well as by enabling, supporting, and promoting the production of accessible Web content by all authors.

**User Agent Accessibility Guidelines (UAAG) 2.0 [UAAG] p1227**

This document provides guidelines for designing user agents that lower barriers to Web accessibility for people with disabilities. User agents include browsers and other types of software that retrieve and render Web content. A user agent that conforms to these guidelines will promote accessibility through its own user interface and through other internal facilities, including its ability to communicate with other technologies (especially assistive technologies). Furthermore, all users, not just users with disabilities, should find conforming user agents to be more usable.
2 Common infrastructure

This specification depends on the WHATWG Infra standard. [INFRA][1224]

2.1 Terminology

This specification refers to both HTML and XML attributes and IDL attributes, often in the same context. When it is not clear which is being referred to, they are referred to as content attributes for HTML and XML attributes, and IDL attributes for those defined on IDL interfaces. Similarly, the term "properties" is used for both JavaScript object properties and CSS properties. When these are ambiguous they are qualified as object properties and CSS properties respectively.

Generally, when the specification states that a feature applies to the HTML syntax or the XML syntax, it also includes the other. When a feature specifically only applies to one of the two languages, it is called out by explicitly stating that it does not apply to the other format, as in "for HTML, ... (this does not apply to XML).

This specification uses the term document to refer to any use of HTML, ranging from short static documents to long essays or reports with rich multimedia, as well as to fully-fledged interactive applications. The term is used to refer both to Document objects and their descendant DOM trees, and to serialized byte streams using the HTML syntax or the XML syntax, depending on context.

In the context of DOM structures, the terms HTML document and XML document are used as defined in the DOM specification, and refer specifically to two different modes that Document objects can find themselves in. [DOM][1223] (Such uses are always hyperlinked to their definition.)

In the context of byte streams, the term HTML document refers to resources labeled as text/html, and the term XML document refers to resources labeled with an XML MIME type.

For simplicity, terms such as shown, displayed, and visible might sometimes be used when referring to the way a document is rendered to the user. These terms are not meant to imply a visual medium; they must be considered to apply to other media in equivalent ways.

2.1.1 Parallelism

To run steps in parallel means those steps are to be run, one after another, at the same time as other logic in the standard (e.g., at the same time as the event loop). This standard does not define the precise mechanism by which this is achieved, be it time-sharing cooperative multitasking, fibers, threads, processes, using different hyperthreads, cores, CPUs, machines, etc. By contrast, an operation that is to run immediately must interrupt the currently running task, run itself, and then resume the previously running task.

To avoid race conditions between different in parallel algorithms that operate on the same data, a parallel queue can be used.

A parallel queue represents a queue of algorithm steps that must be run in series.

A parallel queue has an algorithm queue (a queue), initially empty.

To enqueue steps to a parallel queue, enqueue the algorithm steps to the parallel queue's algorithm queue.

To start a new parallel queue, run the following steps:

1. Let parallelQueue be a new parallel queue.
2. Run the following steps in parallel:
   1. While true:
      1. Let steps be the result of dequeuing from parallelQueue's algorithm queue.
2. If `steps` is not nothing, then run `steps`.

3. Assert: running `steps` did not throw an exception, as steps running in parallel\[^{p42}\] are not allowed to throw.

---

**Note**

Implementations are not expected to implement this as a continuously running loop. Algorithms in standards are to be easy to understand and are not necessarily great for battery life or performance.

3. Return `parallelQueue`.

---

**Note**

Steps running in parallel\[^{p42}\] can themselves run other steps in in parallel\[^{p42}\]. E.g., inside a parallel queue\[^{p42}\] it can be useful to run a series of steps in parallel with the queue.

---

**Example**

Imagine a standard defined `nameList` (a list), along with a method to add a `name` to `nameList`, unless `nameList` already contains `name`, in which case it rejects.

The following solution suffers from race conditions:

1. Let \( p \) be a new promise.

2. Run the following steps in parallel\[^{p42}\]:
   1. If `nameList` contains `name`, reject `p` with a `TypeError` and abort these steps.
   2. Do some potentially lengthy work.
   3. Append `name` to `nameList`.
   4. Resolve `p` with undefined.

Two invocations of the above could run simultaneously, meaning `name` isn’t in `nameList` during step 2.1, but it might be added before step 2.3 runs, meaning `name` ends up in `nameList` twice.

Parallel queues solve this. The standard would let `nameListQueue` be the result of starting a new parallel queue\[^{p42}\], then:

1. Let \( p \) be a new promise.

2. Enqueue the following steps in parallel\[^{p42}\] to `nameListQueue`:
   1. If `nameList` contains `name`, reject `p` with a `TypeError` and abort these steps.
   2. Do some potentially lengthy work.
   3. Append `name` to `nameList`.
   4. Resolve `p` with undefined.

The steps would now queue and the race is avoided.

---

### 2.1.2 Resources \[^{p43}\]

The specification uses the term **supported** when referring to whether a user agent has an implementation capable of decoding the semantics of an external resource. A format or type is said to be **supported** if the implementation can process an external resource of that format or type without critical aspects of the resource being ignored. Whether a specific resource is **supported** can depend on what features of the resource's format are in use.
What some specifications, in particular the HTTP specification, refer to as a representation is referred to in this specification as a resource. [HTTP]\[123\]

A resource's critical subresources are those that the resource needs to have available to be correctly processed. Which resources are considered critical or not is defined by the specification that defines the resource's format.

2.1.3 XML compatibility §\[p44\]

To ease migration from HTML to XML, UAs conforming to this specification will place elements in HTML in the http://www.w3.org/1999/xhtml namespace, at least for the purposes of the DOM and CSS. The term "HTML elements" refers to any element in that namespace, even in XML documents.

Except where otherwise stated, all elements defined or mentioned in this specification are in the HTML namespace ("http://www.w3.org/1999/xhtml"), and all attributes defined or mentioned in this specification have no namespace.

The term element type is used to refer to the set of elements that have a given local name and namespace. For example, button elements with the element type button, meaning they have the local name "button" and (implicitly as defined above) the HTML namespace.

Attribute names are said to be XML-compatible if they match the Name production defined in XML and they contain no U+003A COLON characters (:). [XML]\[1228\]

2.1.4 DOM trees §\[p44\]

When it is stated that some element or attribute is ignored, or treated as some other value, or handled as if it was something else, this refers only to the processing of the node after it is in the DOM. A user agent must not mutate the DOM in such situations.

A content attribute is said to change value only if its new value is different than its previous value; setting an attribute to a value it already has does not change it.

The term empty, when used for an attribute value, Text node, or string, means that the length of the text is zero (i.e., not even containing controls or U+0020 SPACE).

A node A is inserted into a node B when the insertion steps are invoked with A as the argument and A's new parent is B. Similarly, a node A is removed from a node B when the removing steps are invoked with A as the removedNode argument and B as the oldParent argument.

A node is inserted into a document when the insertion steps are invoked with it as the argument and it is now in a document tree. Analogously, a node is removed from a document when the removing steps are invoked with it as the argument and it is now no longer in a document tree.

A node becomes connected when the insertion steps are invoked with it as the argument and it is now connected. Analogously, a node becomes disconnected when the removing steps are invoked with it as the argument and it is now no longer connected.

A node is browsing-context connected when it is connected and its shadow-including root has a browsing context. A node becomes browsing-context connected when the insertion steps are invoked with it as the argument and it is now browsing-context connected. A node becomes browsing-context disconnected either when the removing steps are invoked with it as the argument and it is now no longer browsing-context connected, or when its shadow-including root no longer has a browsing context.
2.1.5 Scripting

The construction "a Foo object", where Foo is actually an interface, is sometimes used instead of the more accurate "an object implementing the interface Foo".

An IDL attribute is said to be **getting** when its value is being retrieved (e.g. by author script), and is said to be **setting** when a new value is assigned to it.

If a DOM object is said to be **live**, then the attributes and methods on that object must operate on the actual underlying data, not a snapshot of the data.

2.1.6 Plugins

The term **plugin** refers to a user-agent defined set of content handlers used by the user agent that can take part in the user agent's rendering of a Document object, but that neither act as child browsing contexts of the Document, nor introduce any Node objects to the Document's DOM.

Typically such content handlers are provided by third parties, though a user agent can also designate built-in content handlers as plugins.

A user agent must not consider the types text/plain and application/octet-stream as having a registered plugin.

**Example**

One example of a plugin would be a PDF viewer that is instantiated in a browsing context when the user navigates to a PDF file. This would count as a plugin regardless of whether the party that implemented the PDF viewer component was the same as that which implemented the user agent itself. However, a PDF viewer application that launches separate from the user agent (as opposed to using the same interface) is not a plugin by this definition.

**Note**

This specification does not define a mechanism for interacting with plugins, as it is expected to be user-agent- and platform-specific. Some UAs might opt to support a plugin mechanism such as the Netscape Plugin API; others might use remote content converters or have built-in support for certain types. Indeed, this specification doesn't require user agents to support plugins at all.

**Warning!**

Browsers should take extreme care when interacting with external content intended for plugins. When third-party software is run with the same privileges as the user agent itself, vulnerabilities in the third-party software become as dangerous as those in the user agent.

Since different users having different sets of plugins provides a fingerprinting vector that increases the chances of users being uniquely identified, user agents are encouraged to support the exact same set of plugins for each user.

2.1.7 Character encodings

A **character encoding**, or just **encoding** where that is not ambiguous, is a defined way to convert between byte streams and Unicode strings, as defined in the WHATWG Encoding standard. An encoding has an **encoding name** and one or more **encoding labels**, referred to as the encoding's **name** and **labels** in the Encoding standard.

A UTF-16 encoding is **UTF-16BE** or **UTF-16LE**.

An ASCII-compatible encoding is any encoding that is not a UTF-16 encoding. [ENCODING]
2.1.8 Conformance classes

This specification describes the conformance criteria for user agents (relevant to implementers) and documents (relevant to authors and authoring tool implementers).

Conforming documents are those that comply with all the conformance criteria for documents. For readability, some of these conformance requirements are phrased as conformance requirements on authors; such requirements are implicitly requirements on documents: by definition, all documents are assumed to have had an author. (In some cases, that author may itself be a user agent — such user agents are subject to additional rules, as explained below.)

User agents fall into several (overlapping) categories with different conformance requirements.

Web browsers and other interactive user agents

Web browsers that support the XML syntax must process elements and attributes from the HTML namespace found in XML documents as described in this specification, so that users can interact with them, unless the semantics of those elements have been overridden by other specifications.

Example

For example, if a requirement states that "authors must not use the foobar element", it would imply that documents are not allowed to contain elements named foobar.

Example

A conforming Web browser would, upon finding a script element in an XML document, execute the script contained in that element. However, if the element is found within a transformation expressed in XSLT (assuming the user agent also supports XSLT), then the processor would instead treat the script element as an opaque element that forms part of the transform.

Web browsers that support the HTML syntax must process documents labeled with an HTML MIME type as described in this specification, so that users can interact with them.

User agents that support scripting must also be conforming implementations of the IDL fragments in this specification, as described in the Web IDL specification. [WEBIDL]

Example

Unless explicitly stated, specifications that override the semantics of HTML elements do not override the requirements on DOM objects representing those elements. For example, the script element in the example above would still implement the HTMLScriptElement interface.

Non-interactive presentation user agents

User agents that process HTML and XML documents purely to render non-interactive versions of them must comply to the same conformance criteria as Web browsers, except that they are exempt from requirements regarding user interaction.

Typical examples of non-interactive presentation user agents are printers (static UAs) and overhead displays (dynamic UAs). It is expected that most static non-interactive presentation user agents will also opt to lack scripting support.

Example

A non-interactive but dynamic presentation UA would still execute scripts, allowing forms to be dynamically submitted, and so forth. However, since the concept of "focus" is irrelevant when the user cannot interact with the document, the UA would not need to support any of the focus-related DOM APIs.
Visual user agents that support the suggested default rendering

User agents, whether interactive or not, may be designated (possibly as a user option) as supporting the suggested default rendering defined by this specification.

This is not required. In particular, even user agents that do implement the suggested default rendering are encouraged to offer settings that override this default to improve the experience for the user, e.g. changing the color contrast, using different focus styles, or otherwise making the experience more accessible and usable to the user.

User agents that are designated as supporting the suggested default rendering must, while so designated, implement the rules the rendering section defines as the behavior that user agents are expected to implement.

User agents with no scripting support

Implementations that do not support scripting (or which have their scripting features disabled entirely) are exempt from supporting the events and DOM interfaces mentioned in this specification. For the parts of this specification that are defined in terms of an events model or in terms of the DOM, such user agents must still act as if events and the DOM were supported.

Note

Scripting can form an integral part of an application. Web browsers that do not support scripting, or that have scripting disabled, might be unable to fully convey the author's intent.

Conformance checkers

Conformance checkers must verify that a document conforms to the applicable conformance criteria described in this specification. Automated conformance checkers are exempt from detecting errors that require interpretation of the author's intent (for example, while a document is non-conforming if the content of a `blockquote` element is not a quote, conformance checkers running without the input of human judgement do not have to check that `blockquote` elements only contain quoted material).

Conformance checkers must check that the input document conforms when parsed without a browsing context (meaning that no scripts are run, and that the parser's scripting flag is disabled), and should also check that the input document conforms when parsed with a browsing context in which scripts execute, and that the scripts never cause non-conforming states to occur other than transiently during script execution itself. (This is only a "SHOULD" and not a "MUST" requirement because it has been proven to be impossible. [COMPUTABLE])

The term "HTML validator" can be used to refer to a conformance checker that itself conforms to the applicable requirements of this specification.

Note

XML DTDs cannot express all the conformance requirements of this specification. Therefore, a validating XML processor and a DTD cannot constitute a conformance checker. Also, since neither of the two authoring formats defined in this specification are applications of SGML, a validating SGML system cannot constitute a conformance checker either.

To put it another way, there are three types of conformance criteria:

1. Criteria that can be expressed in a DTD.
2. Criteria that cannot be expressed by a DTD, but can still be checked by a machine.
3. Criteria that can only be checked by a human.

A conformance checker must check for the first two. A simple DTD-based validator only checks for the first class of errors and is therefore not a conforming conformance checker according to this specification.

Data mining tools

Applications and tools that process HTML and XML documents for reasons other than to either render the documents or check them for conformance should act in accordance with the semantics of the documents that they process.

Example

A tool that generates document outlines but increases the nesting level for each paragraph and does not increase the nesting level for each section would not be conforming.

Authoring tools and markup generators

Authoring tools and markup generators must generate conforming documents. Conformance criteria that apply to authors also apply to authoring tools, where appropriate.
Authoring tools are exempt from the strict requirements of using elements only for their specified purpose, but only to the extent that authoring tools are not yet able to determine author intent. However, authoring tools must not automatically misuse elements or encourage their users to do so.

**Example**

For example, it is not conforming to use an `address` element for arbitrary contact information; that element can only be used for marking up contact information for its nearest `article` or `body` element ancestor. However, since an authoring tool is likely unable to determine the difference, an authoring tool is exempt from that requirement. This does not mean, though, that authoring tools can use `address` elements for any block of italics text (for instance); it just means that the authoring tool doesn't have to verify that when the user uses a tool for inserting contact information for an `article` element, that the user really is doing that and not inserting something else instead.

**Note**

In terms of conformance checking, an editor has to output documents that conform to the same extent that a conformance checker will verify.

When an authoring tool is used to edit a non-conforming document, it may preserve the conformance errors in sections of the document that were not edited during the editing session (i.e. an editing tool is allowed to round-trip erroneous content). However, an authoring tool must not claim that the output is conformant if errors have been so preserved.

Authoring tools are expected to come in two broad varieties: tools that work from structure or semantic data, and tools that work on a What-You-See-Is-What-You-Get media-specific editing basis (WYSIWYG).

The former is the preferred mechanism for tools that author HTML, since the structure in the source information can be used to make informed choices regarding which HTML elements and attributes are most appropriate.

However, WYSIWYG tools are legitimate. WYSIWYG tools should use elements they know are appropriate, and should not use elements that they do not know to be appropriate. This might in certain extreme cases mean limiting the use of flow elements to just a few elements, like `div`, `b`, `i`, and `span` and making liberal use of the `style` attribute.

All authoring tools, whether WYSIWYG or not, should make a best effort attempt at enabling users to create well-structured, semantically rich, media-independent content.

User agents may impose implementation-specific limits on otherwise unconstrained inputs, e.g. to prevent denial of service attacks, to guard against running out of memory, or to work around platform-specific limitations.

For compatibility with existing content and prior specifications, this specification describes two authoring formats: one based on XML, and one using a custom format inspired by SGML (referred to as the HTML syntax). Implementations must support at least one of these two formats, although supporting both is encouraged.

Some conformance requirements are phrased as requirements on elements, attributes, methods or objects. Such requirements fall into two categories: those describing content model restrictions, and those describing implementation behavior. Those in the former category are requirements on documents and authoring tools. Those in the second category are requirements on user agents. Similarly, some conformance requirements are phrased as requirements on authors; such requirements are to be interpreted as conformance requirements on the documents that authors produce. (In other words, this specification does not distinguish between conformance criteria on authors and conformance criteria on documents.)

### 2.1.9 Dependencies

This specification relies on several other underlying specifications.

**Infra**

The following terms are defined in the WHATWG Infra standard: [INFRA](https://infra.spec.whatwg.org).

- The general iteration terms `while`, `continue`, and `break`.
- `code point` and its synonym `character`.
- `surrogate`.
- `scalar value`.
- `noncharacter`.
- `JavaScript string`, `code unit`, and `JavaScript string length`.
- `scalar value string`.
- `string length`.
- `ASCII whitespace`.
- `control`.
The Unicode character set is used to represent textual data, and the WHATWG Encoding standard defines requirements around character encodings. [UNICODE]

The following terms are used as defined in the WHATWG Encoding standard: [ENCODING]

- **Getting an encoding**
- **Get an output encoding**
- The generic **decode** algorithm which takes a byte stream and an encoding and returns a character stream
- The **UTF-8 decode** algorithm which takes a byte stream and returns a character stream, additionally stripping one leading UTF-8 Byte Order Mark (BOM), if any
- The **UTF-8 decode without BOM** algorithm which is identical to **UTF-8 decode** except that it does not strip one leading UTF-8 Byte Order Mark (BOM)
- The **encode** algorithm which takes a character stream and an encoding and returns a byte stream
- The **UTF-8 encode** algorithm which takes a character stream and returns a byte stream

**XML and related specifications**

Implementations that support the XML syntax for HTML must support some version of XML, as well as its corresponding namespaces specification, because that syntax uses an XML serialization with namespaces. [XML] [XMLNS]

Data mining tools and other user agents that perform operations on content without running scripts, evaluating CSS or XPath expressions, or otherwise exposing the resulting DOM to arbitrary content, may “support namespaces” by just asserting that their DOM node analogues are in certain namespaces, without actually exposing the namespace strings.

**Note**

In the HTML syntax, namespace prefixes and namespace declarations do not have the same effect as in XML. For instance, the colon has no special meaning in HTML element names.

The attribute with the tag name **xml:space** in the XML namespace is defined by the XML specification. [XML]

The **Name** production is defined in the XML specification. [XML]

This specification also references the **<?xml-stylesheet?>** processing instruction, defined in the **Associating Style Sheets with XML documents** specification. [XMLSSPI]
This specification also non-normatively mentions the XSLTProcessor interface and its transformToFragment() and transformToDocument() methods. [XSLTP]p1228

URLs

The following terms are defined in the WHATWG URL standard: [URL]p1227

- host
- public suffix
- domain
- IPv4 address
- IPv6 address
- URL
- Origin of URLs
- Absolute URL
- Relative URL
- The URL parser and basic URL parser as well as these parser states:
  - scheme start state
  - host state
  - hostname state
  - port state
  - path start state
  - query state
  - fragment state
- URL record, as well as its individual components:
  - scheme
  - username
  - password
  - host
  - port
  - path
  - query
  - fragment
  - cannot-be-a-base-URL flag
  - object
- valid URL string
- The cannot have a username/password/port concept
- The URL serializer
- The host parser
- The host serializer
- Host equals
- URL equals
- serialize an integer
- Default encode set
- UTF-8 percent encode
- String percent decode
- set the username
- set the password
- The application/x-www-form-urlencoded format
- The application/x-www-form-urlencoded serializer

A number of schemes and protocols are referenced by this specification also:

- The about: scheme [ABOUT]p1221
- The blob: scheme [FILEAPI]p1223
- The data: scheme [RFC2397]p1226
- The http: scheme [HTTP]p1223
- The https: scheme [HTTP]p1223
- The mailto: scheme [MAILTO]p1224
- The sms: scheme [SMS]p1226
- The urn: scheme [URN]p1227

Media fragment syntax is defined in the Media Fragments URI specification. [MEDIAFRAG]p1224

HTTP and related specifications

The following terms are defined in the HTTP specifications: [HTTP]p1223

- `Accept` header
- `Accept-Language` header
- `Cache-Control` header
- `Content-Disposition` header
- `Content-Language` header
- `Last-Modified` header
- `Referer` header

The following terms are defined in the Cookie specification: [COOKIES]p1221

- cookie-string
- receives a set-cookie-string
• `Cookie` header

The following term is defined in the Web Linking specification: [WEBLINK]^{p1227}

• `Link` header

The following terms are defined in the WHATWG MIME Sniffing standard: [MIMESNIFF]^{p1224}

- MIME type
- valid MIME type string
- valid MIME type string with no parameters
- HTML MIME type
- JavaScript MIME type and JavaScript MIME type essence match
- JSON MIME type
- XML MIME type

**Fetch**

The following terms are defined in the WHATWG Fetch standard: [FETCH]^{p1223}

- about:blank
- An HTTP(s) scheme
- A network scheme
- A fetch scheme
- HTTPS state value
- CORS protocol
- default `User-Agent` value
- extract a MIME type
- fetch
- HTTP-redirect fetch
- ok status
- navigation request
- network error
- `Origin` header
- process response
- set
- terminate
- the RequestCredentials enumeration
- the RequestDestination enumeration
- the fetch() method

**response** and its associated:
  - type
  - url
  - uri list
  - status
  - header list
  - body
  - internal response
  - CSP list
  - HTTPS state
  - location URL

**request** and its associated:
  - url
  - method
  - header list
  - body
  - client
  - reserved client
  - target client id
  - initiator
  - destination
  - potential destination
  - translating a potential destination
  - script-like destinations
  - priority
  - origin
  - referrer
  - synchronous flag
  - mode
  - credentials mode
  - use-URL-credentials flag
  - unsafe-request flag
  - cache mode
  - redirect mode
  - referrer policy
  - cryptographic nonce metadata
  - integrity metadata
  - parser metadata
  - reload-navigation flag
  - history-navigation flag

The following terms are defined in Referrer Policy: [REFERRERPOLICY]^{p1225}
The `Referrer-Policy` HTTP header

The parse a referrer policy from a `Referrer-Policy` header algorithm

The "no-referrer", "no-referrer-when-downgrade", "no-referrer-when-downgrade", and "unsafe-url" referrer policies

The following terms are defined in *Mixed Content*: [MIX]1224

**a priori authenticated URL**

**Web IDL**

The IDL fragments in this specification must be interpreted as required for conforming IDL fragments, as described in the Web IDL specification. [WEBIDL]1227

The following terms are defined in the Web IDL specification:

- extended attribute
- named constructor
- array index property name
- supported property indices
- determine the value of an indexed property
- set the value of an existing indexed property
- set the value of a new indexed property
- support named properties
- supported property names
- determine the value of a named property
- set the value of an existing named property
- set the value of a new named property
- delete an existing named property
- perform a security check
- platform object
- legacy platform object
- primary interface
- interface object
- interface prototype object
- global environment associated with a platform object
- callback context
- frozen array and creating a frozen array
- callback this value
- converting between Web IDL types and JS types
- invoking and constructing callback functions
- converting to a sequence of Unicode scalar values

The Web IDL specification also defines the following types that are used in Web IDL fragments in this specification:

- ArrayBuffer
- ArrayBufferView
- boolean
- DOMString
- double
- enumeration
- Error
- Function
- long
- object
- Uint8ClampedArray
- unrestricted double
- unsigned long
- USVString

The term `throw` in this specification is used as defined in the Web IDL specification. The `DOMException` type and the following exception names are defined by Web IDL and used by this specification:

- "IndexSizeError"
- "HierarchyRequestError"
- "InvalidCharacterError"
- "NotFoundError"
- "NotSupportedError"
- "NotFoundError"
- "SyntaxError"
- "InvalidAccessError"
- "SecurityError"
- "NetworkError"
- "AbortError"
- "QuotaExceededError"
- "DataCloneError"
- "EncodingError"
- "NotAllowedError"

When this specification requires a user agent to create a `Date` object representing a particular time (which could be the special
value Not-a-Number), the milliseconds component of that time, if any, must be truncated to an integer, and the time value of the newly created `Date` object must represent the resulting truncated time.

Example

For instance, given the time 23045 millionths of a second after 01:00 UTC on January 1st 2000, i.e. the time 2000-01-01T00:00:00.023045Z, then the `Date` object created representing that time would represent the same time as that created representing the time 2000-01-01T00:00:00.023Z, 45 millionths earlier. If the given time is NaN, then the result is a `Date` object that represents a time value NaN (indicating that the object does not represent a specific instant of time).

JavaScript

Some parts of the language described by this specification only support JavaScript as the underlying scripting language.

Users agents that support JavaScript must also implement the `ECMAScript Internationalization API Specification`. [JSINTL]

The following terms are defined in the JavaScript specification and used in this specification:

- active function object
- agent and agent cluster
- automatic semicolon insertion
- The current Realm Record
- early error
- Directive Prologue
- invariants of the essential internal methods
- JavaScript execution context
- JavaScript execution context stack
- JavaScript realm
- running JavaScript execution context
- Use Strict Directive
- Well-Known Symbols, including `@@hasInstance`, `@@IsConcatSpreadable`, `@@toPrimitive`, and `@@toStringTag`
- Well-Known Intrinsic Objects, including `%ArrayBuffer%`, `%ArrayPrototype%`, and `%ObjProto_valueOf%`
- The `FunctionBody` production
- The `Module` production
- The `Pattern` production
- The `Script` production
- The `Type` notation
- The `Completion Record` specification type
- The `List` and `Record` specification types
- The `PropertyDescriptor` specification type
- The `Script Record` specification type
- The `Source Text Module Record` specification type and its `Evaluate` and `Instantiate` methods
- The `ArrayCreate` abstract operation
- The `Call` abstract operation
- The `Construct` abstract operation
- The `CopyDataBlockBytes` abstract operation
- The `CreateByteDataBlock` abstract operation
- The `CreateDataProperty` abstract operation
- The `DetachArrayBuffer` abstract operation
- The `EnqueueJob` abstract operation
- The `EnumerableOwnProperties` abstract operation
- The `FunctionCreate` abstract operation
- The `Get` abstract operation
- The `GetActiveScriptOrModule` abstract operation
- The `GetFunctionRealm` abstract operation
- The `HasOwnProperty` abstract operation
- The `HostEnsureCanCompileStrings` abstract operation
- The `HostPromiseRejectionTracker` abstract operation
- The `InitializeHostDefinedRealm` abstract operation
- The `IsAccessorDescriptor` abstract operation
- The `IsCallable` abstract operation
- The `IsConstructorDescriptor` abstract operation
- The `IsDataDescriptor` abstract operation
- The `IsDetachedBuffer` abstract operation
- The `IsSharedArrayBuffer` abstract operation
- The `NewObjectEnvironment` abstract operation
- The `NormalCompletion` abstract operation
- The `OrdinaryGetPrototypeOf` abstract operation
- The `OrdinarySetPrototypeOf` abstract operation
- The `OrdinaryIsExtensible` abstract operation

Note

The term "JavaScript" is used to refer to ECMA-262, rather than the official term ECMAScript, since the term JavaScript is more widely known. Similarly, the MIME type used to refer to JavaScript in this specification is `text/javascript`, since that is the most commonly used type, despite it being an officially obsoleted type according to RFC 4329. [RFC4329]
User agents that support JavaScript must also implement the `import()` proposal. The following terms are defined there, and used in this specification: [JSIMPORT]$$^{1224}$$

- `import()`
- The `HostImportModuleDynamically` abstract operation
- The `FinishDynamicImport` abstract operation

User agents that support JavaScript must also implement the `import.meta` proposal. The following term is defined there, and used in this specification: [JSIMPORTMETA]$$^{1224}$$

- The `HostGetImportMetaProperties` abstract operation

User agents that support JavaScript must also implement the `BigInt` proposal. [JSBIGINT]$$^{1224}$$

### DOM

The Document Object Model (DOM) is a representation — a model — of a document and its content. The DOM is not just an API; the conformance criteria of HTML implementations are defined, in this specification, in terms of operations on the DOM. [DOM]$$^{1223}$$

Implementations must support DOM and the events defined in UI Events, because this specification is defined in terms of the DOM, and some of the features are defined as extensions to the DOM interfaces. [DOM]$$^{1223}$$ [UIEVENTS]$$^{1227}$$

In particular, the following features are defined in the WHATWG DOM standard: [DOM]$$^{1223}$$
The following features are defined in the UI Events specification: [UIEVENTS]¹²²
The following are defined in the Touch Events specification: [TOUCH]¹227

- Touch interface
- Touch point concept
- touchend event

The following are defined in the Pointer Events specification: [POINTEREVENTS]¹225

- pointerup event

This specification sometimes uses the term name to refer to the event's type; as in, "an event named click" or "if the event name is keypress". The terms "name" and "type" for events are synonymous.

The following features are defined in the DOM Parsing and Serialization specification: [DOMPARSING]¹223

- DOMParser
- innerHTML
- outerHTML

The Selection interface is defined in the Selection API specification. [SELECTION]¹226

Note
User agents are encouraged to implement the features described in the execCommand specification. [EXECCOMMAND]¹222

The following parts of the WHATWG Fullscreen API standard are referenced from this specification, in part to define the rendering of dialog elements, and also to define how the Fullscreen API interacts with HTML: [FULLSCREEN]¹223

- top layer (an ordered set) and its add operation
- requestFullscreen()
- run the fullscreen steps

The High Resolution Time specification provides the current high resolution time and the DOMHighResTimeStamp typedef. [HRT]¹222

**File API**
This specification uses the following features defined in the File API specification: [FILEAPI]¹223

- The Blob interface and its type attribute
- The File interface and its name and lastModified attributes
- The FileList interface
- The concept of a Blob's snapshot state
- The concept of read errors
- Blob URL Store

**Indexed Database API**
This specification uses cleanup Indexed Database transactions defined by the Indexed Database API specification. [INDEXEDDB]¹224

**Media Source Extensions**
The following terms are defined in the Media Source Extensions specification: [MEDIASOURCE]¹224

- MediaSource interface
- detaching from a media element

**Media Capture and Streams**
The following terms are defined in the Media Capture and Streams specification: [MEDIASTREAM]¹224

- MediaStream interface
- getUserMedia() method

**XMLHttpRequest**
The following features and terms are defined in the XMLHttpRequest specification: [XHR]¹228

- XMLHttpRequest interface
- XMLHttpRequest.responseXML attribute
- ProgressEvent Interface
• **ProgressEvent.lengthComputable** attribute
• **ProgressEvent.loaded** attribute
• **ProgressEvent.total** attribute
• Fire a progress event named e
• The concept of entry
• create an entry

**Battery Status**

The following features are defined in the Battery Status API specification: [BATTERY]¹²²¹

• getBattery() method

**Media Queries**

Implementations must support Media Queries. The `<media-condition>` feature is defined therein. [MQ]¹²²⁶

**CSS modules**

While support for CSS as a whole is not required of implementations of this specification (though it is encouraged, at least for Web browsers), some features are defined in terms of specific CSS requirements.

When this specification requires that something be parsed according to a particular CSS grammar, the relevant algorithm in the CSS Syntax specification must be followed, including error handling rules. [CSSSYNTAX]¹²²²

**Example**

For example, user agents are required to close all open constructs upon finding the end of a style sheet unexpectedly. Thus, when parsing the string "rgb(0,0,0" (with a missing close-parenthesis) for a color value, the close parenthesis is implied by this error handling rule, and a value is obtained (the color 'black'). However, the similar construct "rgb(0,0," (with both a missing parenthesis and a missing "blue" value) cannot be parsed, as closing the open construct does not result in a viable value.

To parse a CSS `<color>` value, given a string input with an optional element element, run these steps:

1. Let color be the result of parsing input as a CSS `<color>`. [CSSCOLOR]¹²²²
2. If color is failure, then return failure.
3. If color is 'currentColor', then:
   1. If element is not given, then set color to opaque black.
   2. Otherwise, set color to the computed value of the 'color' property of element.
4. Return color.

The following terms and features are defined in the CSS specification: [CSS]¹²²¹

• viewport
• line box
• out-of-flow
• in-flow
• replaced element
• intrinsic dimensions
• content area
• content box
• border box
• margin box
• border edge
• margin edge
• collapsing margins
• containing block
• inline box
• block box
• The 'margin-top', 'margin-bottom', 'margin-left', and 'margin-right' properties
• The 'padding-top', 'padding-bottom', 'padding-left', and 'padding-right' properties
• The 'top', 'bottom', 'left', and 'right' properties
• The 'float' property
• The 'clear' property
• The 'width' property
• The 'height' property
• The 'line-height' property
• The 'vertical-align' property
• The 'content' property
• The 'inline-block' value of the 'display' property
• The 'visibility' property

The CSS specification also defines the following border properties: [CSS]¹²²¹
The terms **intrinsic width** and **intrinsic height** refer to the width dimension and the height dimension, respectively, of intrinsic dimensions.

The basic version of the 'display' property is defined in the CSS specification, and the property is extended by other CSS modules. ([CSS][1221] [CSSRUBY][1222] [CSSTABLE][1222])

The following terms and features are defined in the CSS Logical Properties specification: ([CSSLOGICAL][1222])
- The 'margin-block-start', 'margin-block-end', 'margin-inline-start', and 'margin-inline-end' properties
- The 'padding-block-start', 'padding-block-end', 'padding-inline-start', and 'padding-inline-end' properties

The following terms and features are defined in the CSS Color specification: ([CSSCOLOR][1222])
- named color
- <color>
- The 'color' property
- The 'currentcolor' value
- opaque black
- transparent black

The term **paint source** is used as defined in the CSS Image Values and Replaced Content specification to define the interaction of certain HTML elements with the CSS 'element()' function. ([CSSIMAGES][1222])

The term **default object size** and the **object-fit** property are also defined in the CSS Image Values and Replaced Content specification. ([CSSIMAGES][1222])

The following features are defined in the CSS Backgrounds and Borders specification: ([CSSBG][1222])
- The 'background-color' property
- The 'background-image' property

The term **block-level** is defined in the CSS Display specification. ([CSSDISPLAY][1222])

The following features are defined in the CSS Fonts specification: ([CSSFONTS][1222])
- The 'font-family' property
- The 'font-weight' property
- The 'font-size' property
- The 'font' property

The 'list-style-type' property is defined in the CSS Lists and Counters specification. ([CSSLISTS][1222])

The 'overflow' property and its 'hidden' value are defined in the CSS Overflow specification. ([CSSOVERFLOW][1222])

The following features are defined in the CSS Positioned Layout specification: ([CSSPOSITION][1222])
- The 'position' property and its 'static' value

The 'ruby-base' value of the 'display' property is defined in the CSS Ruby Layout specification. ([CSSRUBY][1222])

The following features are defined in the CSS Table specification: ([CSSTABLE][1222])
- The 'border-spacing' property
- The 'border-collapse' property
- The 'table-cell', 'table-row', 'table-caption', and 'table' values of the 'display' property

The following features are defined in the CSS Text specification: ([CSSTEXT][1222])
- The 'text-transform' property
- The 'white-space' property
- The 'text-align' property
- The 'letter-spacing' property

The following features are defined in the CSS Writing Modes specification: ([CSSWM][1223])
- The 'direction' property

<table>
<thead>
<tr>
<th>Top</th>
<th>Bottom</th>
<th>Left</th>
<th>Right</th>
</tr>
</thead>
<tbody>
<tr>
<td>Width</td>
<td>'border-top-width'</td>
<td>'border-bottom-width'</td>
<td>'border-left-width'</td>
</tr>
<tr>
<td>Style</td>
<td>'border-top-style'</td>
<td>'border-bottom-style'</td>
<td>'border-left-style'</td>
</tr>
<tr>
<td>Color</td>
<td>'border-top-color'</td>
<td>'border-bottom-color'</td>
<td>'border-left-color'</td>
</tr>
</tbody>
</table>
• The ‘unicode-bidi’ property
• The block flow direction, block size, inline size, block-start, block-end, inline-start, inline-end, line-left, and line-right concepts

The following features are defined in the CSS Basic User Interface specification: [CSSUI]¹²²²

• The ‘outline’ property
• The ‘cursor’ property
• The ‘appearance’ property

The algorithm to update animations and send events is defined in the Web Animations specification. [WEBANIMATIONS]¹²²⁷

Implementations that support scripting must support the CSS Object Model. The following features and terms are defined in the CSS specifications: [CSSOM]¹²²², [CSSOMVIEW]¹²²²

• Screen interface
• LinkStyle interface
• CSSStyleDeclaration interface
• cssText attribute of CSSStyleDeclaration
• StyleSheet interface
• create a CSS style sheet
• remove a CSS style sheet
• associated CSS style sheet
• CSS style sheets and their properties:
  ◦ type
  ◦ location
  ◦ parent CSS style sheet
  ◦ owner node
  ◦ owner CSS rule
  ◦ media
  ◦ title
  ◦ alternate flag
  ◦ disabled flag
  ◦ CSS rules
  ◦ origin-clean flag

• CSS style sheet set
• CSS style sheet set name
• preferred CSS style sheet set name
• change the preferred CSS style sheet set name
• Serializing a CSS value
• run the resize steps
• run the scroll steps
• evaluate media queries and report changes
• Scroll an element into view
• Scroll to the beginning of the document
• The resize event
• The scroll event
• set up browsing context features

The following features and terms are defined in the CSS Syntax specifications: [CSSSYNTAX]¹²²²

• conformant style sheet
• parse a comma-separated list of component values
• component value
• environment encoding
• <whitespace-token>

The following terms are defined in the Selectors specification: [SELECTORS]¹²²₆

• type selector
• attribute selector
• pseudo-class

The following features are defined in the CSS Values and Units specification: [CSSVALUES]¹²²²

• <length>
• The ‘em’ unit
• The ‘ex’ unit
• The ‘vw’ unit
• The ‘vm’ unit
• The ‘px’ unit
• The ‘attr()’ function
• The math functions

The term style attribute is defined in the CSS Style Attributes specification. [CSSATTR]¹²²²

The following terms are defined in the CSS Cascading and Inheritance specification: [CSSCASCADE]¹²²²

• specified value
The CanvasRenderingContext2D object’s use of fonts depends on the features described in the CSS Fonts and Font Loading specifications, including in particular FontFace objects and the font source concept. [CSSFONTS][p1222] [CSSFONTLOAD][p1222]

The following interfaces and terms are defined in the Geometry Interfaces Module specification: [GEOMETRY][p1223]

- DOMMatrix interface, and associated m11 element, m12 element, m21 element, m22 element, m41 element, and m42 element
- DOMMatrix2DInit and DOMMatrixInit dictionaries
- The create a DOMMatrix from a dictionary and create a DOMMatrix from a 2D dictionary algorithms for DOMMatrix2DInit or DOMMatrixInit

Intersection Observer

The following term is defined in the Intersection Observer specification: [INTERSECTIONOBSERVER][p1224]

- run the update intersection observations steps

WebGL

The following interface is defined in the WebGL specification: [WEBGL][p1227]

- WebGLRenderingContext interface

WebVTT

Implementations may support WebVTT as a text track format for subtitles, captions, metadata, etc., for media resources. [WEBVTT][p1228]

The following terms, used in this specification, are defined in the WebVTT specification:

- WebVTT file
- WebVTT file using cue text
- WebVTT file using only nested cues
- WebVTT parser
- The rules for updating the display of WebVTT text tracks
- The WebVTT text track cue writing direction
- VTT Cue interface

The WebSocket protocol

The following terms are defined in the WHATWG Fetch standard: [FETCH][p1223]

- establish a WebSocket connection

The following terms are defined in the WebSocket protocol specification: [WSP][p1228]

- the WebSocket connection is established
- extensions in use
- subprotocol in use
- a WebSocket message has been received
- send a WebSocket Message
- fail the WebSocket connection
- close the WebSocket connection
- start the WebSocket closing handshake
- the WebSocket closing handshake is started
- the WebSocket connection is closed (possibly cleanly)
- the WebSocket connection close code
- the WebSocket connection close reason
- Sec-WebSocket-Protocol field

ARIA

The role attribute is defined in the ARIA specification, as are the following roles: [ARIA][p1221]

- button
- presentation

In addition, the following aria-* content attributes are defined in the ARIA specification: [ARIA][p1222]

- aria-describedby
- aria-disabled
- aria-label

Finally, the following terms are defined in the ARIA specification: [ARIA][p1221]

- accessible name
Content Security Policy

The following terms are defined in *Content Security Policy*: [CSP]\(^{1221}\)

- **Content Security Policy**
- **Content Security Policy directive**
- **CSP list**
- The **Content Security Policy syntax**
- **enforce the policy**
- The **parse a serialized Content Security Policy** algorithm
- The **Initialize a global object's CSP list** algorithm
- The **Initialize a Document's CSP list** algorithm
- The **Should element's inline behavior be blocked by Content Security Policy?** algorithm
- The **Should navigation request of type from source in target be blocked by Content Security Policy?** algorithm
- The **Should navigation response to navigation request of type from source in target be blocked by Content Security Policy?** algorithm
- The **report-uri** directive
- The **EnsureCSPDoesNotBlockStringCompilation** abstract operation
- The **frame-ancestors directive**
- The **sandbox directive**
- The **Should element be blocked a priori by Content Security Policy?** algorithm
- The **contains a header-delivered Content Security Policy** property.

Service Workers

The following terms are defined in *Service Workers*: [SW]\(^{1227}\)

- **active worker**
- **client message queue**
- **control**
- **handle fetch**
- **match service worker registration**
- **service worker**
- **service worker client**
- **ServiceWorker** interface
- **ServiceWorkerContainer** interface
- **ServiceWorkerGlobalScope** interface

Secure Contexts

The following algorithm is defined in *Secure Contexts*: [SECURE-CONTEXTS]\(^{1226}\)

- **Is environment settings object a secure context?**

Feature Policy

The following terms are defined in *Feature Policy*: [FEATUREPOLICY]\(^{1223}\)

- **feature policy**
- **container policy**
- **serialized feature policy**
- The **Initialize document's feature policy** algorithm
- The **Initialize document's feature policy from response** algorithm
- The **Is feature enabled by policy for origin** algorithm
- The **Process feature policy attributes** algorithm

Payment Request API

The following feature is defined in the *Payment Request API* specification: [PAYMENTREQUEST]\(^{1225}\)

- **PaymentRequest** interface

MathML

While support for MathML as a whole is not required by this specification (though it is encouraged, at least for Web browsers), certain features depend upon small parts of MathML being implemented. [MATHML]\(^{1224}\)

The following features are defined in the MathML specification:

- **MathML annotation-xml** element
- **MathML math** element
- **MathML merror** element
- **MathML mi** element
- **MathML mn** element
- **MathML mo** element
- **MathML ms** element
- **MathML mtext** element

SVG

While support for SVG as a whole is not required by this specification (though it is encouraged, at least for Web browsers), certain
features depend upon parts of SVG being implemented.

User agents that implement SVG must implement the SVG 2 specification, and not any earlier revisions.

The following features are defined in the SVG 2 specification: [SVG]\(^{1227}\)

- `SVGElement` interface
- `SVGImageElement` interface
- `SVGScriptElement` interface
- `SVGSVGElement` interface
- `SVG desc` element
- `SVG foreignObject` element
- `SVG image` element
- `SVG script` element
- `SVG svg` element
- `SVG title` element
- `SVG use` element

**Filter Effects**

The following feature is defined in the Filter Effects specification: [FILTERS]\(^{1223}\)

- `<filter-function-list>`

**Worklets**

The following feature is defined in the Worklets specification: [WORKLETS]\(^{1228}\)

- `WorkletGlobalScope`

**Cooperative Scheduling of Background Tasks**

The following feature is defined in the Cooperative Scheduling of Background Tasks specification: [REQUESTIDLECALLBACK]\(^{1225}\)

- `requestIdleCallback()`

This specification does not require support of any particular network protocol, style sheet language, scripting language, or any of the DOM specifications beyond those required in the list above. However, the language described by this specification is biased towards CSS as the styling language, JavaScript as the scripting language, and HTTP as the network protocol, and several features assume that those languages and protocols are in use.

A user agent that implements the HTTP protocol must implement HTTP State Management Mechanism (Cookies) as well. [HTTP]\(^{1223}\) [COOKIES]\(^{1221}\)

**Note**

This specification might have certain additional requirements on character encodings, image formats, audio formats, and video formats in the respective sections.

### 2.1.10 Extensibility \(^{5472}\)

Vendor-specific proprietary user agent extensions to this specification are strongly discouraged. Documents must not use such extensions, as doing so reduces interoperability and fragments the user base, allowing only users of specific user agents to access the content in question.

All extensions must be defined so that the use of extensions neither contradicts nor causes the non-conformance of functionality defined in the specification.

**Example**

For example, while strongly discouraged from doing so, an implementation could add a new IDL attribute "typeTime" to a control that returned the time it took the user to select the current value of a control (say). On the other hand, defining a new control that appears in a form's `elements` array would be in violation of the above requirement, as it would violate the definition of `elements` given in this specification.

When vendor-neutral extensions to this specification are needed, either this specification can be updated accordingly, or an extension...
specification can be written that overrides the requirements in this specification. When someone applying this specification to their activities decides that they will recognize the requirements of such an extension specification, it becomes an applicable specification for the purposes of conformance requirements in this specification.

Note

Someone could write a specification that defines any arbitrary byte stream as conforming, and then claim that their random junk is conforming. However, that does not mean that their random junk actually is conforming for everyone's purposes: if someone else decides that that specification does not apply to their work, then they can quite legitimately say that the aforementioned random junk is just that, junk, and not conforming at all. As far as conformance goes, what matters in a particular community is what that community agrees is applicable.

User agents must treat elements and attributes that they do not understand as semantically neutral; leaving them in the DOM (for DOM processors), and styling them according to CSS (for CSS processors), but not inferring any meaning from them.

When support for a feature is disabled (e.g. as an emergency measure to mitigate a security problem, or to aid in development, or for performance reasons), user agents must act as if they had no support for the feature whatsoever, and as if the feature was not mentioned in this specification. For example, if a particular feature is accessed via an attribute in a Web IDL interface, the attribute itself would be omitted from the objects that implement that interface — leaving the attribute on the object but making it return null or throw an exception is insufficient.

2.1.11 Interactions with XPath and XSLT

Implementations of XPath 1.0 that operate on HTML documents parsed or created in the manners described in this specification (e.g. as part of the document.evaluate() API) must act as if the following edit was applied to the XPath 1.0 specification.

First, remove this paragraph:

A QName in the node test is expanded into an expanded-name using the namespace declarations from the expression context. This is the same way expansion is done for element type names in start and end-tags except that the default namespace declared with xmlns is not used: if the QName does not have a prefix, then the namespace URI is null (this is the same way attribute names are expanded). It is an error if the QName has a prefix for which there is no namespace declaration in the expression context.

Then, insert in its place the following:

A QName in the node test is expanded into an expanded-name using the namespace declarations from the expression context. If the QName has a prefix, then there must be a namespace declaration for this prefix in the expression context, and the corresponding namespace URI is the one that is associated with this prefix. It is an error if the QName has a prefix for which there is no namespace declaration in the expression context.

If the QName has no prefix and the principal node type of the axis is element, then the default element namespace is used. Otherwise if the QName has no prefix, the namespace URI is null. The default element namespace is a member of the context for the XPath expression. The value of the default element namespace when executing an XPath expression through the DOM3 XPath API is determined in the following way:

1. If the context node is from an HTML DOM, the default element namespace is "http://www.w3.org/1999/xhtml".
2. Otherwise, the default element namespace URI is null.

Note

This is equivalent to adding the default element namespace feature of XPath 2.0 to XPath 1.0, and using the HTML namespace as the default element namespace for HTML documents. It is motivated by the desire to have implementations be compatible with legacy HTML content while still supporting the changes that this specification introduces to HTML regarding the namespace used for HTML elements, and by the desire to use XPath 1.0 rather than XPath 2.0.

Note

This change is a willful violation of the XPath 1.0 specification, motivated by desire to have implementations be compatible with legacy content while still supporting the changes that this specification introduces to HTML regarding which namespace is used for HTML elements. [XPATH10]
XSLT 1.0 processors outputting to a DOM when the output method is "html" (either explicitly or via the defaulting rule in XSLT 1.0) are affected as follows:

If the transformation program outputs an element in no namespace, the processor must, prior to constructing the corresponding DOM element node, change the namespace of the element to the HTML namespace, ASCII-lowercase the element's local name, and ASCII-lowercase the names of any non-namespaced attributes on the element.

This specification does not specify precisely how XSLT processing interacts with the HTML parser infrastructure (for example, whether an XSLT processor acts as if it puts any elements into a stack of open elements). However, XSLT processors must stop parsing if they successfully complete, and must set the current document readiness first to "interactive" and then to "complete" if they are aborted.

This specification does not specify how XSLT interacts with the navigation algorithm, how it fits in with the event loop, nor how error pages are to be handled (e.g. whether XSLT errors are to replace an incremental XSLT output, or are rendered inline, etc).

### 2.2 Case-sensitivity and string comparison

Comparing two strings in a case-sensitive manner means comparing them exactly, code point for code point.

Except where otherwise stated, string comparisons must be performed in a case-sensitive manner.

A string pattern is a prefix match for a string s when pattern is not longer than s and truncating s to pattern's length leaves the two strings as matches of each other.

### 2.3 Common microsyntaxes

There are various places in HTML that accept particular data types, such as dates or numbers. This section describes what the conformance criteria for content in those formats is, and how to parse them.

Implementors are strongly urged to carefully examine any third-party libraries they might consider using to implement the parsing of syntaxes described below. For example, date libraries are likely to implement error handling behavior that differs from what is required in this specification, since error-handling behavior is often not defined in specifications that describe date syntaxes similar to those used in this specification, and thus implementations tend to vary greatly in how they handle errors.

### 2.3.1 Common parser idioms

The White_Space characters are those that have the Unicode property "White_Space" in the Unicode PropList.txt data file. [UNICODE]

This is not to be confused with the "White_Space" value (abbreviated "WS") of the "Bidi_Class" property in the Unicode.txt data file.
Some of the micro-parsers described below follow the pattern of having an input variable that holds the string being parsed, and having a position variable pointing at the next character to parse in input.

### 2.3.2 Boolean attributes

A number of attributes are boolean attributes. The presence of a boolean attribute on an element represents the true value, and the absence of the attribute represents the false value.

If the attribute is present, its value must either be the empty string or a value that is an ASCII case-insensitive match for the attribute's canonical name, with no leading or trailing whitespace.

**Note**

The values "true" and "false" are not allowed on boolean attributes. To represent a false value, the attribute has to be omitted altogether.

**Example**

Here is an example of a checkbox that is checked and disabled. The checked and disabled attributes are the boolean attributes.

```html
<label><input type=checkbox checked name=cheese disabled> Cheese</label>
```

This could be equivalently written as this:

```html
<label><input type=checkbox checked=checked name=cheese disabled=disabled> Cheese</label>
```

You can also mix styles; the following is still equivalent:

```html
<label><input type='checkbox' checked name=cheese disabled=''> Cheese</label>
```

### 2.3.3 Keywords and enumerated attributes

Some attributes are defined as taking one of a finite set of keywords. Such attributes are called enumerated attributes. The keywords are each defined to map to a particular state (several keywords might map to the same state, in which case some of the keywords are synonyms of each other; additionally, some of the keywords can be said to be non-conforming, and are only in the specification for historical reasons). In addition, two default states can be given. The first is the invalid value default, the second is the missing value default.

If an enumerated attribute is specified, the attribute's value must be an ASCII case-insensitive match for one of the given keywords that are not said to be non-conforming, with no leading or trailing whitespace.

When the attribute is specified, if its value is an ASCII case-insensitive match for one of the given keywords then that keyword's state is the state that the attribute represents. If the attribute value matches none of the given keywords, but the attribute has an invalid value default, then the attribute represents that state. Otherwise, there is no default, and invalid values mean that there is no state represented.

When the attribute is not specified, if there is a missing value default state defined, then that is the state represented by the (missing) attribute. Otherwise, the absence of the attribute means that there is no state represented.

**Note**

The empty string can be a valid keyword.
2.3.4 Numbers

2.3.4.1 Signed integers

A string is a **valid integer** if it consists of one or more **ASCII digits**, optionally prefixed with a U+002D HYPHEN-MINUS character (-).

A **valid integer** without a U+002D HYPHEN-MINUS (-) prefix represents the number that is represented in base ten by that string of digits. A **valid integer** with a U+002D HYPHEN-MINUS (-) prefix represents the number represented in base ten by the string of digits that follows the U+002D HYPHEN-MINUS, subtracted from zero.

The **rules for parsing integers** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either an integer or an error.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *sign* have the value "positive".
4. **Skip ASCII whitespace** within *input* given *position*.
5. If *position* is past the end of *input*, return an error.
6. If the character indicated by *position* (the first character) is a U+002D HYPHEN-MINUS character (-):
   1. Let *sign* be "negative".
   2. Advance *position* to the next character.
   3. If *position* is past the end of *input*, return an error.
   Otherwise, if the character indicated by *position* (the first character) is a U+002B PLUS SIGN character (+):
      1. Advance *position* to the next character. (The "+" is ignored, but it is not conforming.)
      2. If *position* is past the end of *input*, return an error.
7. If the character indicated by *position* is not an **ASCII digit**, then return an error.
8. **Collect a sequence of code points** that are **ASCII digits** from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Let *value* be that integer.
9. If *sign* is "positive", return *value*, otherwise return the result of subtracting *value* from zero.

2.3.4.2 Non-negative integers

A string is a **valid non-negative integer** if it consists of one or more **ASCII digits**.

A **valid non-negative integer** represents the number that is represented in base ten by that string of digits.

The **rules for parsing non-negative integers** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either zero, a positive integer, or an error.

1. Let *input* be the string being parsed.
2. Let *value* be the result of parsing *input* using the **rules for parsing integers**.
3. If *value* is an error, return an error.
4. If *value* is less than zero, return an error.
5. Return *value*.

2.3.4.3 Floating-point numbers

A string is a **valid floating-point number** if it consists of:
1. Optionally, a U+002D HYPHEN-MINUS character (-).
2. One or both of the following, in the given order:
   1. A series of one or more ASCII digits.
   2. Both of the following, in the given order:
      1. A single U+002E FULL STOP character (.)
      2. A series of one or more ASCII digits.
3. Optionally:
   1. Either a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E).
   2. Optionally, a U+002D HYPHEN-MINUS character (-) or U+002B PLUS SIGN character (+).
   3. A series of one or more ASCII digits.

A valid floating-point number\(^{66}\) represents the number obtained by multiplying the significand by ten raised to the power of the exponent, where the significand is the first number, interpreted as base ten (including the decimal point and the number after the decimal point, if any, and interpreting the significand as a negative number if the whole string starts with a U+002D HYPHEN-MINUS character (-) and the number is not zero), and where the exponent is the number after the E, if any (interpreted as a negative number if there is a U+002D HYPHEN-MINUS character (-) between the E and the number and the number is not zero, or else ignoring a U+002B PLUS SIGN character (+) between the E and the number if there is one). If there is no E, then the exponent is treated as zero.

---

**Note**

The Infinity and Not-a-Number (NaN) values are not valid floating-point numbers\(^{66}\).

---

**Note**

The valid floating-point number\(^{66}\) concept is typically only used to restrict what is allowed for authors, while the user agent requirements use the rules for parsing floating-point number values\(^{67}\) below (e.g., the `max` attribute of the `progress` element). However, in some cases the user agent requirements include checking if a string is a valid floating-point number\(^{66}\) (e.g., the `value` sanitization algorithm\(^{68}\) for the `Number` state of the `input` element, or the `parse a srcset attribute`\(^{69}\) algorithm).

---

The best representation of the number \(n\) as a floating-point number is the string obtained from running `ToString(n)`. The abstract operation `ToString` is not uniquely determined. When there are multiple possible strings that could be obtained from `ToString` for a particular value, the user agent must always return the same string for that value (though it may differ from the value used by other user agents).

The rules for parsing floating-point number values are as given in the following algorithm. This algorithm must be aborted at the first step that returns something. This algorithm will return either a number or an error.

1. Let `input` be the string being parsed.
2. Let `position` be a pointer into `input`, initially pointing at the start of the string.
3. Let `value` have the value 1.
4. Let `divisor` have the value 1.
5. Let `exponent` have the value 1.
6. Skip ASCII whitespace within `input` given `position`.
7. If `position` is past the end of `input`, return an error.
8. If the character indicated by `position` is a U+002D HYPHEN-MINUS character (-):
   1. Change `value` and `divisor` to −1.
   2. Advance `position` to the next character.
   3. If `position` is past the end of `input`, return an error.

   Otherwise, if the character indicated by `position` (the first character) is a U+002B PLUS SIGN character (+):
   1. Advance `position` to the next character. (The "+" is ignored, but it is not conforming.)
   2. If `position` is past the end of `input`, return an error.
9. If the character indicated by `position` is a U+002E FULL STOP (.), and that is not the last character in `input`, and the character after the character indicated by `position` is an ASCII digit, then set `value` to zero and jump to the step labeled `fraction`.
10. If the character indicated by `position` is not an ASCII digit, then return an error.
11. Collect a sequence of code points that are ASCII digits from `input` given `position`, and interpret the resulting sequence as a base-ten integer. Multiply `value` by that integer.
12. If \( \text{position} \) is past the end of \( \text{input} \), jump to the step labeled \textit{conversion}.

13. \textit{Fraction}: If the character indicated by \( \text{position} \) is a U+002E FULL STOP (.), run these substeps:
   
   1. Advance \( \text{position} \) to the next character.
   
   2. If \( \text{position} \) is past the end of \( \text{input} \), or if the character indicated by \( \text{position} \) is not an ASCII digit, U+0065 LATIN SMALL LETTER E (e), or U+0045 LATIN CAPITAL LETTER E (E), then jump to the step labeled \textit{conversion}.
   
   3. If the character indicated by \( \text{position} \) is a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E), skip the remainder of these substeps.
   
   4. \textit{Fraction loop}: Multiply \( \text{divisor} \) by ten.
   
   5. Add the value of the character indicated by \( \text{position} \), interpreted as a base-ten digit (0..9) and divided by \( \text{divisor} \), to \( \text{value} \).
   
   6. Advance \( \text{position} \) to the next character.
   
   7. If \( \text{position} \) is past the end of \( \text{input} \), then jump to the step labeled \textit{conversion}.

   8. If the character indicated by \( \text{position} \) is an ASCII digit, jump back to the step labeled \textit{fraction loop} in these substeps.

14. If the character indicated by \( \text{position} \) is U+0065 (e) or a U+0045 (E), then:
   
   1. Advance \( \text{position} \) to the next character.
   
   2. If \( \text{position} \) is past the end of \( \text{input} \), then jump to the step labeled \textit{conversion}.

   3. If the character indicated by \( \text{position} \) is a U+002D HYPHEN-MINUS character (-):
      
      1. Change \( \text{exponent} \) to \(-1\).
      
      2. Advance \( \text{position} \) to the next character.
      
      3. If \( \text{position} \) is past the end of \( \text{input} \), then jump to the step labeled \textit{conversion}.

   Otherwise, if the character indicated by \( \text{position} \) is a U+002B PLUS SIGN character (+):
   
   1. Advance \( \text{position} \) to the next character.
   
   2. If \( \text{position} \) is past the end of \( \text{input} \), then jump to the step labeled \textit{conversion}.

   4. If the character indicated by \( \text{position} \) is not an ASCII digit, then jump to the step labeled \textit{conversion}.

   5. Collect a sequence of code points that are ASCII digits from \( \text{input} \) given \( \text{position} \), and interpret the resulting sequence as a base-ten integer. Multiply \( \text{exponent} \) by that integer.

   6. Multiply \( \text{value} \) by ten raised to the \( \text{exponent} \)th power.

15. \textit{Conversion}: Let \( S \) be the set of finite IEEE 754 double-precision floating-point values except \(-0\), but with two special values added: \( 2^{1024} \) and \(-2^{1024} \).

16. Let \( \text{rounded-value} \) be the number in \( S \) that is closest to \( \text{value} \), selecting the number with an even significand if there are two equally close values. (The two special values \( 2^{1024} \) and \(-2^{1024} \) are considered to have even significands for this purpose.)

17. If \( \text{rounded-value} \) is \( 2^{1024} \) or \(-2^{1024} \), return an error.

18. Return \( \text{rounded-value} \).

### 2.3.4.4 Percentages and lengths

The rules for parsing dimension values are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a number greater than or equal to 0.0, or an error; if a number is returned, then it is further categorized as either a percentage or a length.

1. Let \( \text{input} \) be the string being parsed.
2. Let \textit{position} be a pointer into \textit{input}, initially pointing at the start of the string.

3. \textbf{Skip ASCII whitespace} within \textit{input} given \textit{position}.

4. If \textit{position} is past the end of \textit{input}, return an error.

5. If the character indicated by \textit{position} is a U+002B PLUS SIGN character (+), advance \textit{position} to the next character.

6. If \textit{position} is past the end of \textit{input}, return an error.

7. If the character indicated by \textit{position} is not an \textbf{ASCII digit}, then return an error.

8. \textbf{Collect a sequence of code points} that are \textbf{ASCII digits} from \textit{input} given \textit{position}, and interpret the resulting sequence as a base-ten integer. Let \textit{value} be that number.

9. If \textit{position} is past the end of \textit{input}, return \textit{value} as a length.

10. If the character indicated by \textit{position} is a U+002E FULL STOP character (.):

    1. Advance \textit{position} to the next character.

    2. If \textit{position} is past the end of \textit{input}, or if the character indicated by \textit{position} is not an \textbf{ASCII digit}, then return \textit{value} as a length.

    3. Let \textit{divisor} have the value 1.

    4. \textbf{Fraction loop}: Multiply \textit{divisor} by ten.

    5. Add the value of the character indicated by \textit{position}, interpreted as a base-ten digit (0..9) and divided by \textit{divisor}, to \textit{value}.

    6. Advance \textit{position} to the next character.

    7. If \textit{position} is past the end of \textit{input}, then return \textit{value} as a length.

    8. If the character indicated by \textit{position} is an \textbf{ASCII digit}, return to the step labeled \textbf{fraction loop} in these substeps.

11. If \textit{position} is past the end of \textit{input}, return \textit{value} as a length.

12. If the character indicated by \textit{position} is a U+0025 PERCENT SIGN character (%), return \textit{value} as a percentage.

13. Return \textit{value} as a length.

\subsection*{2.3.4.5 Non-zero percentages and lengths \footnote{p69}}

The \textbf{rules for parsing nonzero dimension values} are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a number greater than 0.0, or an error; if a number is returned, then it is further categorized as either a percentage or a length.

1. Let \textit{input} be the string being parsed.

2. Let \textit{value} be the result of parsing \textit{input} using the \textbf{rules for parsing dimension values} \footnote{p68}.

3. If \textit{value} is an error, return an error.

4. If \textit{value} is zero, return an error.

5. If \textit{value} is a percentage, return \textit{value} as a percentage.

6. Return \textit{value} as a length.

\subsection*{2.3.4.6 Lists of floating-point numbers \footnote{p69}}

A \textbf{valid list of floating-point numbers} is a number of \textbf{valid floating-point numbers} \footnote{p66} separated by U+002C COMMA characters, with no other characters (e.g. no \textbf{ASCII whitespace}). In addition, there might be restrictions on the number of floating-point numbers that can be given, or on the range of values allowed.
The rules for parsing a list of floating-point numbers are as follows:

1. Let \textit{input} be the string being parsed.
2. Let \textit{position} be a pointer into \textit{input}, initially pointing at the start of the string.
3. Let \textit{numbers} be an initially empty list of floating-point numbers. This list will be the result of this algorithm.
4. Collect a sequence of code points that are ASCII whitespace, U+002C COMMA, or U+003B SEMICOLON characters from \textit{input} given \textit{position}. This skips past any leading delimiters.
5. While \textit{position} is not past the end of \textit{input}:
   1. Collect a sequence of code points that are not ASCII whitespace, U+002C COMMA, or ASCII digits, U+002E FULL STOP, or U+002D HYPHEN-MINUS characters from \textit{input} given \textit{position}. This skips past leading garbage.
   2. Collect a sequence of code points that are not ASCII whitespace, U+002C COMMA, or U+003B SEMICOLON characters from \textit{input} given \textit{position}, and let \textit{unparsed number} be the result.
   3. Let \textit{number} be the result of parsing \textit{unparsed number} using the rules for parsing floating-point number values\textsuperscript{67}. 
   4. If \textit{number} is an error, set \textit{number} to zero.
   5. Append \textit{number} to \textit{numbers}.
   6. Collect a sequence of code points that are ASCII whitespace, U+002C COMMA, or U+003B SEMICOLON characters from \textit{input} given \textit{position}. This skips past the delimiter.
6. Return \textit{numbers}.

2.3.4.7 Lists of dimensions \textsuperscript{570}

The rules for parsing a list of dimensions are as follows. These rules return a list of zero or more pairs consisting of a number and a unit, the unit being one of percentage, relative, and absolute.

1. Let \textit{raw input} be the string being parsed.
2. If the last character in \textit{raw input} is a U+002C COMMA character (,), then remove that character from \textit{raw input}.
3. Split the string \textit{raw input} on commas. Let \textit{raw tokens} be the resulting list of tokens.
4. Let \textit{result} be an empty list of number/unit pairs.
5. For each token in \textit{raw tokens}, run the following substeps:
   1. Let \textit{input} be the token.
   2. Let \textit{position} be a pointer into \textit{input}, initially pointing at the start of the string.
   3. Let \textit{value} be the number 0.
   4. Let \textit{unit} be \textit{absolute}.
   5. If \textit{position} is past the end of \textit{input}, set \textit{unit} to \textit{relative} and jump to the last substep.
   6. If the character at \textit{position} is an ASCII digit, collect a sequence of code points that are ASCII digits from \textit{input} given \textit{position}, interpret the resulting sequence as an integer in base ten, and increment \textit{value} by that integer.
   7. If the character at \textit{position} is U+002E (.), then:
      1. Collect a sequence of code points consisting of ASCII whitespace and ASCII digits from \textit{input} given \textit{position}. Let \textit{s} be the resulting sequence.
      2. Remove all ASCII whitespace in \textit{s}.
      3. If \textit{s} is not the empty string, then:
         1. Let \textit{length} be the number of characters in \textit{s} (after the spaces were removed).
2. Let $fraction$ be the result of interpreting $s$ as a base-ten integer, and then dividing that number by $10^{length}$.

3. Increment value by $fraction$.

8. **Skip ASCII whitespace** within input given position.

9. If the character at position is a U+0025 PERCENT SIGN character (%), then set unit to percentage.

   Otherwise, if the character at position is a U+002A ASTERISK character (*), then set unit to relative.

10. Add an entry to result consisting of the number given by value and the unit given by unit.

6. Return the list result.

### 2.3.5 Dates and times §71

In the algorithms below, the **number of days in month month of year year** is: 31 if month is 1, 3, 5, 7, 8, 10, or 12; 30 if month is 4, 6, 9, or 11; 29 if month is 2 and year is a number divisible by 400, or if year is a number divisible by 4 but not by 100; and 28 otherwise. This takes into account leap years in the Gregorian calendar. [GREGORIAN]\(^{1222}\)

When **ASCII digits** are used in the date and time syntaxes defined in this section, they express numbers in base ten.

#### Note

While the formats described here are intended to be subsets of the corresponding ISO8601 formats, this specification defines parsing rules in much more detail than ISO8601. Implementors are therefore encouraged to carefully examine any date parsing libraries before using them to implement the parsing rules described below; ISO8601 libraries might not parse dates and times in exactly the same manner. [ISO8601]\(^{1224}\)

Where this specification refers to the **proleptic Gregorian calendar**, it means the modern Gregorian calendar, extrapolated backwards to year 1. A date in the proleptic Gregorian calendar\(^{71}\), sometimes explicitly referred to as a **proleptic-Gregorian date**, is one that is described using that calendar even if that calendar was not in use at the time (or place) in question. [GREGORIAN]\(^{1223}\)

#### Note

The use of the Gregorian calendar as the wire format in this specification is an arbitrary choice resulting from the cultural biases of those involved in the decision. See also the section discussing date, time, and number formats\(^{469}\) in forms (for authors), implementation notes regarding localization of form controls\(^{504}\), and the time\(^{251}\) element.

### 2.3.5.1 Months §71

A **month** consists of a specific **proleptic-Gregorian date**\(^{71}\) with no time-zone information and no date information beyond a year and a month. [GREGORIAN]\(^{1223}\)

A string is a **valid month string** representing a year year and month month if it consists of the following components in the given order:

1. Four or more **ASCII digits**, representing year, where $year > 0$
2. A U+002D HYPHEN-MINUS character (-)
3. Two **ASCII digits**, representing the month $month$, in the range $1 \leq month \leq 12$

The rules to **parse a month string** are as follows. This will return either a year and month, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Let **input** be the string being parsed.
2. Let **position** be a pointer into **input**, initially pointing at the start of the string.
3. **Parse a month component**\(^{73}\) to obtain $year$ and $month$. If this returns nothing, then fail.
4. If position is not beyond the end of input, then fail.
5. Return year and month.

The rules to parse a month component, given an input string and a position, are as follows. This will return either a year and a month, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not at least four characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the year.
2. If year is not a number greater than zero, then fail.
3. If position is beyond the end of input or if the character at position is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move position forwards one character.
4. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the month.
5. If month is not a number in the range 1 \leq month \leq 12, then fail.
6. Return year and month.

2.3.5.2 Dates

A date consists of a specific proleptic-Gregorian date with no time-zone information, consisting of a year, a month, and a day.

A string is a valid date string representing a year year, month month, and day day if it consists of the following components in the given order:

1. A valid month string, representing year and month
2. A U+002D HYPHEN-MINUS character (-)
3. Two ASCII digits, representing day, in the range 1 \leq day \leq maxday where maxday is the number of days in the month month and year year

The rules to parse a date string are as follows. This will return either a date, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Let input be the string being parsed.
2. Let position be a pointer into input, initially pointing at the start of the string.
3. Parse a date component to obtain year, month, and day. If this returns nothing, then fail.
4. If position is not beyond the end of input, then fail.
5. Let date be the date with year year, month month, and day day.
6. Return date.

The rules to parse a date component, given an input string and a position, are as follows. This will return either a year, a month, and a day, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Parse a month component to obtain year and month. If this returns nothing, then fail.
2. Let maxday be the number of days in month month of year year.
3. If position is beyond the end of input or if the character at position is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move position forwards one character.
4. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the day.
5. If day is not a number in the range 1 \leq day \leq maxday, then fail.
6. Return year, month, and day.
2.3.5.3 Yearless dates

A yearless date consists of a Gregorian month and a day within that month, but with no associated year. A string is a valid yearless date string representing a month month and a day day if it consists of the following components in the given order:

1. Optionally, two U+002D HYPHEN-MINUS characters (-)
2. Two ASCII digits, representing the month month, in the range 1 ≤ month ≤ 12
3. A U+002D HYPHEN-MINUS character (-)
4. Two ASCII digits, representing day, in the range 1 ≤ day ≤ maxday where maxday is the number of days in the month month and any arbitrary leap year (e.g. 4 or 2000)

Note: In other words, if the month is "02", meaning February, then the day can be 29, as if the year was a leap year.

The rules to parse a yearless date string are as follows. This will return either a month and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let input be the string being parsed.
2. Let position be a pointer into input, initially pointing at the start of the string.
3. Parse a yearless date component to obtain month and day. If this returns nothing, then fail.
4. If position is not beyond the end of input, then fail.
5. Return month and day.

The rules to parse a yearless date component, given an input string and a position, are as follows. This will return either a month and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Collect a sequence of code points that are U+002D HYPHEN-MINUS characters (-) from input given position. If the collected sequence is not exactly zero or two characters long, then fail.
2. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the month.
3. If month is not a number in the range 1 ≤ month ≤ 12, then fail.
4. Let maxday be the number of days in month of any arbitrary leap year (e.g. 4 or 2000).
5. If position is beyond the end of input or if the character at position is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move position forwards one character.
6. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the day.
7. If day is not a number in the range 1 ≤ day ≤ maxday, then fail.
8. Return month and day.

2.3.5.4 Times

A time consists of a specific time with no time-zone information, consisting of an hour, a minute, a second, and a fraction of a second.

A string is a valid time string representing an hour hour, a minute minute, and a second second if it consists of the following components in the given order:

1. Two ASCII digits, representing hour, in the range 0 ≤ hour ≤ 23
2. A U+003A COLON character (:) 
3. Two ASCII digits, representing minute, in the range 0 ≤ minute ≤ 59
4. If second is nonzero, or optionally if second is zero:
   1. A U+003A COLON character (:)
   2. Two ASCII digits, representing the integer part of second, in the range 0 ≤ s ≤ 59
   3. If second is not an integer, or optionally if second is an integer:
      1. A U+002E FULL STOP character (.)
      2. One, two, or three ASCII digits, representing the fractional part of second

The rules to parse a time string are as follows. This will return either a time, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let input be the string being parsed.
2. Let position be a pointer into input, initially pointing at the start of the string.
3. Parse a time component to obtain hour, minute, and second. If this returns nothing, then fail.
4. If position is not beyond the end of input, then fail.
5. Let time be the time with hour hour, minute minute, and second second.
6. Return time.

The rules to parse a time component, given an input string and a position, are as follows. This will return either an hour, a minute, and a second, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the hour.
2. If hour is not a number in the range 0 ≤ hour ≤ 23, then fail.
3. If position is beyond the end of input or if the character at position is not a U+003A COLON character, then fail. Otherwise, move position forwards one character.
4. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the minute.
5. If minute is not a number in the range 0 ≤ minute ≤ 59, then fail.
6. Let second be 0.
7. If position is not beyond the end of input and the character at position is U+003A (:), then:
   1. Advance position to the next character in input.
   2. If position is beyond the end of input, or at the last character in input, or if the next two characters in input starting at position are not both ASCII digits, then fail.
   3. Collect a sequence of code points that are either ASCII digits or U+002E FULL STOP characters from input given position. If the collected sequence is three characters long, or if it is longer than three characters long and the third character is not a U+002E FULL STOP character, or if it has more than one U+002E FULL STOP character, then fail. Otherwise, interpret the resulting sequence as a base-ten number (possibly with a fractional part). Set second to that number.
   4. If second is not a number in the range 0 ≤ second < 60, then fail.
8. Return hour, minute, and second.

2.3.5.5 Local dates and times

A local date and time consists of a specific proleptic-Gregorian date, consisting of a year, a month, and a day, and a time, consisting of an hour, a minute, a second, and a fraction of a second, but expressed without a time zone.
A string is a **valid local date and time string** representing a date and time if it consists of the following components in the given order:

1. A **valid date string** representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character
3. A **valid time string** representing the time

A string is a **valid normalized local date and time string** representing a date and time if it consists of the following components in the given order:

1. A **valid date string** representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T)
3. A **valid time string** representing the time, expressed as the shortest possible string for the given time (e.g. omitting the seconds component entirely if the given time is zero seconds past the minute)

The rules to **parse a local date and time string** are as follows. This will return either a date and time, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Parse a date component to obtain *year*, *month*, and *day*. If this returns nothing, then fail.
4. If *position* is beyond the end of *input* or if the character at *position* is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then fail. Otherwise, move *position* forwards one character.
5. Parse a time component to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
6. If *position* is not beyond the end of *input*, then fail.
7. Let *date* be the date with *year*, *month*, and *day*.
8. Let *time* be the time with *hour*, *minute*, and *second*.
9. Return *date* and *time*.

### 2.3.5.6 Time zones

A **time-zone offset** consists of a signed number of hours and minutes.

A string is a **valid time-zone offset string** representing a time-zone offset if it consists of either:

- A U+005A LATIN CAPITAL LETTER Z character (Z), allowed only if the time zone is UTC
- Or, the following components, in the given order:
  1. Either a U+002B PLUS SIGN character (+) or, if the time-zone offset is not zero, a U+002D HYPHEN-MINUS character (-), representing the sign of the time-zone offset
  2. Two **ASCII digits**, representing the hours component *hour* of the time-zone offset, in the range $0 \leq *hour* \leq 23$
  3. Optionally, a U+003A COLON character (:)  
  4. Two **ASCII digits**, representing the minutes component *minute* of the time-zone offset, in the range $0 \leq *minute* \leq 59$

**Note**

This format allows for time-zone offsets from -23:59 to +23:59. Right now, in practice, the range of offsets of actual time zones is -12:00 to +14:00, and the minutes component of offsets of actual time zones is always either 00, 30, or 45. There is no guarantee that this will remain so forever, however, since time zones are used as political footballs and are thus subject to very whimsical policy decisions.
The rules to parse a time-zone offset string are as follows. This will return either a time-zone offset, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Let input be the string being parsed.
2. Let position be a pointer into input, initially pointing at the start of the string.
3. Parse a time-zone offset component to obtain timezone hours and timezone minutes. If this returns nothing, then fail.
4. If position is not beyond the end of input, then fail.
5. Return the time-zone offset that is timezone hours and timezone minutes from UTC.

The rules to parse a time-zone offset component, given an input string and a position, are as follows. This will return either time-zone hours and time-zone minutes, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. If the character at position is a U+005A LATIN CAPITAL LETTER Z character (Z), then:
   1. Let timezone hours be 0.
   2. Let timezone minutes be 0.
   3. Advance position to the next character in input.

Otherwise, if the character at position is either a U+002B PLUS SIGN (+) or a U+002D HYPHEN-MINUS (-), then:

1. If the character at position is a U+002B PLUS SIGN (+), let sign be “positive”. Otherwise, it’s a U+002D HYPHEN-MINUS (-); let sign be “negative”.
2. Advance position to the next character in input.
3. Collect a sequence of code points that are ASCII digits from input given position. Let s be the collected sequence.
4. If s is exactly two characters long, then:
   1. Interpret s as a base-ten integer. Let that number be the timezone hours.
   2. If position is beyond the end of input or if the character at position is not a U+003A COLON character, then fail. Otherwise, move position forwards one character.
   3. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the timezone minutes.

If s is exactly four characters long, then:

1. Interpret the first two characters of s as a base-ten integer. Let that number be the timezone hours.
2. Interpret the last two characters of s as a base-ten integer. Let that number be the timezone minutes.

Otherwise, fail.

5. If timezone hours is not a number in the range 0 ≤ timezone hours ≤ 23, then fail.
6. If sign is “negative”, then negate timezone hours.
7. If timezone minutes is not a number in the range 0 ≤ timezone minutes ≤ 59, then fail.
8. If sign is “negative”, then negate timezone minutes.

Otherwise, fail.

2. Return timezone hours and timezone minutes.
2.3.5.7 Global dates and times

A global date and time consists of a specific proleptic-Gregorian date, consisting of a year, a month, and a day, and a time, consisting of an hour, a minute, a second, and a fraction of a second, expressed with a time-zone offset, consisting of a signed number of hours and minutes. [GREGORIAN]

A string is a valid global date and time string representing a date, time, and a time-zone offset if it consists of the following components in the given order:

1. A valid date string representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character
3. A valid time string representing the time
4. A valid time-zone offset string representing the time-zone offset

Times in dates before the formation of UTC in the mid twentieth century must be expressed and interpreted in terms of UT1 (contemporary Earth solar time at the 0° longitude), not UTC (the approximation of UT1 that ticks in SI seconds). Time before the formation of time zones must be expressed and interpreted as UT1 times with explicit time zones that approximate the contemporary difference between the appropriate local time and the time observed at the location of Greenwich, London.

The rules to parse a global date and time string are as follows. This will return either a time in UTC, with associated time-zone offset information for round-tripping or display purposes, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Let input be the string being parsed.
2. Let position be a pointer into input, initially pointing at the start of the string.
3. **Parse a date component** to obtain *year, month, and day*. If this returns nothing, then fail.

4. If `position` is beyond the end of `input` or if the character at `position` is neither a U+0054 `LATIN CAPITAL LETTER T` character (T) nor a U+0020 `SPACE` character, then fail. Otherwise, move `position` forwards one character.

5. **Parse a time component** to obtain *hour, minute, and second*. If this returns nothing, then fail.

6. If `position` is beyond the end of `input`, then fail.

7. **Parse a time-zone offset component** to obtain `timezone` hours and `timezone` minutes. If this returns nothing, then fail.

8. If `position` is not beyond the end of `input`, then fail.

9. Let `time` be the moment in time at *year* year, *month* month, *day* day, *hour* hour, *minute* minute, and *second* second, subtracting `timezone` hours and `timezone` minutes. That moment in time is a moment in the UTC time zone.

10. Let `timezone` be `timezone` hours and `timezone` minutes from UTC.

11. Return `time` and `timezone`.

### 2.3.5.8 Weeks

*A week* consists of a week-year number and a week number representing a seven-day period starting on a Monday. Each week-year in this calendaring system has either 52 or 53 such seven-day periods, as defined below. The seven-day period starting on the Gregorian date Monday December 29th 1969 (1969-12-29) is defined as week number 1 in week-year 1970. Consecutive weeks are numbered sequentially. The week before the number 1 week in a week-year is the last week in the previous week-year, and vice versa.

**GREGORIAN**

A week-year with a number *year* has 53 weeks if it corresponds to either a year *year* in the **proleptic Gregorian calendar** that has a Thursday as its first day (January 1st), or a year *year* in the **proleptic Gregorian calendar** that has a Wednesday as its first day (January 1st) and where *year* is a number divisible by 400, or a number divisible by 4 but not by 100. All other week-years have 52 weeks.

The *week number of the last day* of a week-year with 53 weeks is 53; the week number of the last day of a week-year with 52 weeks is 52.

**Note**

The week-year number of a particular day can be different than the number of the year that contains that day in the **proleptic Gregorian calendar**. The first week in a week-year *y* is the week that contains the first Thursday of the Gregorian year *y*.

**Note**

For modern purposes, a *week* as defined here is equivalent to ISO weeks as defined in ISO 8601. ([ISO8601](https://en.wikipedia.org/wiki/ISO_8601))

A string is a **valid week string** representing a week-year *year* and week *week* if it consists of the following components in the given order:

1. Four or more `ASCII digits`, representing `year`, where `year` > 0
2. A U+002D `HYPHEN-MINUS` character (-)
3. A U+0057 `LATIN CAPITAL LETTER W` character (W)
4. Two `ASCII digits`, representing the week *week*, in the range 1 ≤ *week* ≤ maxweek, where maxweek is the *week number of the last day* of week-year *year*.

The rules to **parse a week string** are as follows. This will return either a week-year number and week number, or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Let `input` be the string being parsed.
2. Let `position` be a pointer into `input`, initially pointing at the start of the string.
3. **Collect a sequence of code points** that are `ASCII digits` from `input` given `position`. If the collected sequence is not at least four characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *year*.
4. If *year* is not a number greater than zero, then fail.
5. If position is beyond the end of input or if the character at position is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move position forwards one character.

6. If position is beyond the end of input or if the character at position is not a U+0057 LATIN CAPITAL LETTER W character (W), then fail. Otherwise, move position forwards one character.

7. Collect a sequence of code points that are ASCII digits from input given position. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the week.

8. Let maxweek be the week number of the last day of year.

9. If week is not a number in the range 1 ≤ week ≤ maxweek, then fail.

10. If position is not beyond the end of input, then fail.

11. Return the week-year number year and the week number week.

### 2.3.5.9 Durations

A duration consists of a number of seconds.

**Note**

*Since months and seconds are not comparable (a month is not a precise number of seconds, but is instead a period whose exact length depends on the precise day from which it is measured) a duration as defined in this specification cannot include months (or years, which are equivalent to twelve months). Only durations that describe a specific number of seconds can be described.*

A string is a valid duration string representing a duration if it consists of either of the following:

- A literal U+0050 LATIN CAPITAL LETTER P character followed by one or more of the following subcomponents, in the order given, where the number of days, hours, minutes, and seconds corresponds to the same number of seconds as in t:
  1. One or more ASCII digits followed by a U+0044 LATIN CAPITAL LETTER D character, representing a number of days.
  2. A U+0054 LATIN CAPITAL LETTER T character followed by one or more of the following subcomponents, in the order given:
    1. One or more ASCII digits followed by a U+0048 LATIN CAPITAL LETTER H character, representing a number of hours.
    2. One or more ASCII digits followed by a U+004D LATIN CAPITAL LETTER M character, representing a number of minutes.
    3. The following components:
      1. One or more ASCII digits, representing a number of seconds.
      2. Optionally, a U+002E FULL STOP character (.) followed by one, two, or three ASCII digits, representing a fraction of a second.
      3. A U+0053 LATIN CAPITAL LETTER S character.

  **Note**

  *This, as with a number of other date- and time-related microsyntaxes defined in this specification, is based on one of the formats defined in ISO 8601. ISO8601*

- One or more duration time components, each with a different duration time component scale, in any order; the sum of the represented seconds being equal to the number of seconds in t.

A duration time component is a string consisting of the following components:

1. Zero or more ASCII whitespace.

2. One or more ASCII digits, representing a number of time units, scaled by the duration time component scale specified (see below) to represent a number of seconds.

3. If the duration time component scale specified is 1 (i.e. the units are seconds), then, optionally, a U+002E FULL STOP character (.) followed by one, two, or three ASCII digits, representing a fraction of a second.
4. Zero or more ASCII whitespace.

5. One of the following characters, representing the duration time component scale of the time unit used in the numeric part of the duration:

- U+0057 LATIN CAPITAL LETTER W character
- U+0077 LATIN SMALL LETTER W character
  Weeks. The scale is 604800.

- U+0044 LATIN CAPITAL LETTER D character
- U+0064 LATIN SMALL LETTER D character
  Days. The scale is 86400.

- U+0048 LATIN CAPITAL LETTER H character
- U+0068 LATIN SMALL LETTER H character
  Hours. The scale is 3600.

- U+004D LATIN CAPITAL LETTER M character
- U+006D LATIN SMALL LETTER M character
  Minutes. The scale is 60.

- U+0053 LATIN CAPITAL LETTER S character
- U+0073 LATIN SMALL LETTER S character
  Seconds. The scale is 1.

6. Zero or more ASCII whitespace.

---

Note

This is not based on any of the formats in ISO 8601. It is intended to be a more human-readable alternative to the ISO 8601 duration format.

The rules to parse a duration string are as follows. This will return either a duration or nothing. If at any point the algorithm says that it “fails”, this means that it is aborted at that point and returns nothing.

1. Let input be the string being parsed.

2. Let position be a pointer into input, initially pointing at the start of the string.

3. Let months, seconds, and component count all be zero.

4. Let M-disambiguator be minutes.

Note

This flag’s other value is months. It is used to disambiguate the "M" unit in ISO8601 durations, which use the same unit for months and minutes. Months are not allowed, but are parsed for future compatibility and to avoid misinterpreting ISO8601 durations that would be valid in other contexts.

5. Skip ASCII whitespace within input given position.

6. If position is past the end of input, then fail.

7. If the character in input pointed to by position is a U+0050 LATIN CAPITAL LETTER P character, then advance position to the next character, set M-disambiguator to months, and skip ASCII whitespace within input given position.

8. While true:

   1. Let units be undefined. It will be assigned one of the following values: years, months, weeks, days, hours, minutes, and seconds.

   2. Let next character be undefined. It is used to process characters from the input.

   3. If position is past the end of input, then break.

   4. If the character in input pointed to by position is a U+0054 LATIN CAPITAL LETTER T character, then advance position to the next character, set M-disambiguator to minutes, skip ASCII whitespace within input given position, and continue.
5. Set next character to the character in input pointed to by position.

6. If next character is a U+002E FULL STOP character (.), then let $N$ equal zero. (Do not advance position. That is taken care of below.)

   Otherwise, if next character is an ASCII digit, then collect a sequence of code points that are ASCII digits from input given position, interpret the resulting sequence as a base-ten integer, and let $N$ be that number.

   Otherwise next character is not part of a number; fail.

7. If position is past the end of input, then fail.

8. Set next character to the character in input pointed to by position, and this time advance position to the next character. (If next character was a U+002E FULL STOP character (.) before, it will still be that character this time.)

9. If next character is U+002E (.), then:

   1. Collect a sequence of code points that are ASCII digits from input given position. Let $s$ be the resulting sequence.
   2. If $s$ is the empty string, then fail.
   3. Let length be the number of characters in $s$.
   4. Let fraction be the result of interpreting $s$ as a base-ten integer, and then dividing that number by $10^{\text{length}}$.
   5. Increment $N$ by fraction.
   6. Skip ASCII whitespace within input given position.
   7. If position is past the end of input, then fail.
   8. Set next character to the character in input pointed to by position, and advance position to the next character.
   9. If next character is neither a U+0053 LATIN CAPITAL LETTER S character nor a U+0073 LATIN SMALL LETTER S character, then fail.
   10. Set units to seconds.

Otherwise:

   1. If next character is ASCII whitespace, then skip ASCII whitespace within input given position, set next character to the character in input pointed to by position, and advance position to the next character.
   2. If next character is a U+0059 LATIN CAPITAL LETTER Y character, or a U+0079 LATIN SMALL LETTER Y character, set units to years and set $M$-disambiguator to months.

      If next character is a U+004D LATIN CAPITAL LETTER M character or a U+006D LATIN SMALL LETTER M character, and $M$-disambiguator is months, then set units to months.

      If next character is a U+0057 LATIN CAPITAL LETTER W character or a U+0077 LATIN SMALL LETTER W character, set units to weeks and set $M$-disambiguator to minutes.

      If next character is a U+0044 LATIN CAPITAL LETTER D character or a U+0064 LATIN SMALL LETTER D character, set units to days and set $M$-disambiguator to minutes.

      If next character is a U+0048 LATIN CAPITAL LETTER H character or a U+0068 LATIN SMALL LETTER H character, set units to hours and set $M$-disambiguator to minutes.

      If next character is a U+004D LATIN CAPITAL LETTER M character or a U+006D LATIN SMALL LETTER M character, and $M$-disambiguator is minutes, then set units to minutes.

      If next character is a U+0053 LATIN CAPITAL LETTER S character or a U+0073 LATIN SMALL LETTER S character, set units to seconds and set $M$-disambiguator to minutes.

      Otherwise if next character is none of the above characters, then fail.

10. Increment component count.
11. Let \( \text{multiplier} \) be 1.

12. If \( \text{units} \) is years, multiply \( \text{multiplier} \) by 12 and set \( \text{units} \) to months.

13. If \( \text{units} \) is months, add the product of \( N \) and \( \text{multiplier} \) to months.

Otherwise:

1. If \( \text{units} \) is weeks, multiply \( \text{multiplier} \) by 7 and set \( \text{units} \) to days.

2. If \( \text{units} \) is days, multiply \( \text{multiplier} \) by 24 and set \( \text{units} \) to hours.

3. If \( \text{units} \) is hours, multiply \( \text{multiplier} \) by 60 and set \( \text{units} \) to minutes.

4. If \( \text{units} \) is minutes, multiply \( \text{multiplier} \) by 60 and set \( \text{units} \) to seconds.

5. Forcibly, \( \text{units} \) is now seconds. Add the product of \( N \) and \( \text{multiplier} \) to seconds.

14. Skip ASCII whitespace within \text{input} given position.

9. If \text{component count} \ is zero, fail.

10. If \text{months} \ is not zero, fail.

11. Return the \text{duration} consisting of \text{seconds} seconds.

### 2.3.5.10 Vaguer moments in time

A string is a \text{valid date string with optional time} if it is also one of the following:

- A \text{valid date string}

- A \text{valid global date and time string}

The rules to \text{parse a date or time string} are as follows. The algorithm will return either a \text{date}, a \text{time}, a \text{global date and time}, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let \text{input} be the string being parsed.

2. Let \text{position} be a pointer into \text{input}, initially pointing at the start of the string.

3. Set \text{start position} to the same position as \text{position}.

4. Set the \text{date present} and \text{time present} flags to true.

5. \text{Parse a date component} to obtain \text{year}, \text{month}, and \text{day}. If this fails, then set the \text{date present} flag to false.

6. If \text{date present} is true, and \text{position} is not beyond the end of \text{input}, and the character at \text{position} is either a U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character, then advance \text{position} to the next character in \text{input}.

   Otherwise, if \text{date present} is true, and either \text{position} is beyond the end of \text{input} or the character at \text{position} is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then set \text{time present} to false.

   Otherwise, if \text{date present} is false, set \text{position} back to the same position as \text{start position}.

7. If the \text{time present} flag is true, then \text{parse a time component} to obtain \text{hour}, \text{minute}, and \text{second}. If this returns nothing, then fail.

8. If the \text{date present} and \text{time present} flags are both true, but \text{position} is beyond the end of \text{input}, then fail.

9. If the \text{date present} and \text{time present} flags are both true, \text{parse a time-zone offset component} to obtain \text{timezone hours} and \text{timezone minutes}. If this returns nothing, then fail.

10. If \text{position} is not beyond the end of \text{input}, then fail.

11. If the \text{date present} flag is true and the \text{time present} flag is false, then let \text{date} be the date with \text{year} \text{year}, \text{month} \text{month}, and \text{day} \text{day}, and return \text{date}. 

   \text{82}
Otherwise, if the *time* present flag is true and the *date* present flag is false, then let *time* be the time with hour *hour*, minute *minute*, and second *second*, and return *time*.

Otherwise, let *time* be the moment in time at year *year*, month *month*, day *day*, hours *hour*, minute *minute*, second *second*, subtracting *timezone* hours and *timezone* minutes minutes, that moment in time being a moment in the UTC time zone; let *timezone* be *timezone* hours and *timezone* minutes minutes from UTC; and return *time* and *timezone*.

### 2.3.6 Colors

A simple color consists of three 8-bit numbers in the range 0..255, representing the red, green, and blue components of the color respectively, in the sRGB color space. [SRGB]

A string is a valid simple color if it is exactly seven characters long, and the first character is a U+0023 NUMBER SIGN character (#), and the remaining six characters are all ASCII hex digits, with the first two digits representing the red component, the middle two digits representing the green component, and the last two digits representing the blue component, in hexadecimal.

A string is a valid lowercase simple color if it is a valid simple color and doesn't use any characters in the range U+0041 LATIN CAPITAL LETTER A to U+0046 LATIN CAPITAL LETTER F.

The rules for parsing simple color values are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a simple color or an error.

1. Let *input* be the string being parsed.
2. If *input* is not exactly seven characters long, then return an error.
3. If the first character in *input* is not a U+0023 NUMBER SIGN character (#), then return an error.
4. If the last six characters of *input* are not all ASCII hex digits, then return an error.
5. Let *result* be a simple color.
6. Interpret the second and third characters as a hexadecimal number and let the result be the red component of *result*.
7. Interpret the fourth and fifth characters as a hexadecimal number and let the result be the green component of *result*.
8. Interpret the sixth and seventh characters as a hexadecimal number and let the result be the blue component of *result*.
9. Return *result*.

The rules for serializing simple color values given a simple color are as given in the following algorithm:

1. Let *result* be a string consisting of a single U+0023 NUMBER SIGN character (#).
2. Convert the red, green, and blue components in turn to two-digit hexadecimal numbers using ASCII lower hex digits, zero-padding if necessary, and append these numbers to *result*, in the order red, green, blue.
3. Return *result*, which will be a valid lowercase simple color.

Some obsolete legacy attributes parse colors in a more complicated manner, using the rules for parsing a legacy color value, which are given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a simple color or an error.

1. Let *input* be the string being parsed.
2. If *input* is the empty string, then return an error.
3. Strip leading and trailing ASCII whitespace from *input*.
4. If *input* is an ASCII case-insensitive match for the string "transparent", then return an error.
5. If *input* is an ASCII case-insensitive match for one of the named colors, then return the simple color corresponding to that keyword. [CSSCOLOR]
6. If input is four characters long, and the first character in input is U+0023 (#), and the last three characters of input are all ASCII hex digits, then:

1. Let result be a simple color.

2. Interpret the second character of input as a hexadecimal digit; let the red component of result be the resulting number multiplied by 17.

3. Interpret the third character of input as a hexadecimal digit; let the green component of result be the resulting number multiplied by 17.

4. Interpret the fourth character of input as a hexadecimal digit; let the blue component of result be the resulting number multiplied by 17.

5. Return result.

7. Replace any characters in input that have a code point greater than U+FFFF (i.e., any characters that are not in the basic multilingual plane) with the two-character string "00".

8. If input is longer than 128 characters, truncate input, leaving only the first 128 characters.

9. If the first character in input is a U+0023 NUMBER SIGN character (#), remove it.

10. Replace any character in input that is not an ASCII hex digit with the character U+0030 DIGIT ZERO (0).

11. While input's length is zero or not a multiple of three, append a U+0030 DIGIT ZERO (0) character to input.

12. Split input into three strings of equal length, to obtain three components. Let length be the length of those components (one third the length of input).

13. If length is greater than 8, then remove the leading length-8 characters in each component, and let length be 8.

14. While length is greater than two and the first character in each component is a U+0030 DIGIT ZERO (0) character, remove that character and reduce length by one.

15. If length is still greater than two, truncate each component, leaving only the first two characters in each.

16. Let result be a simple color.

17. Interpret the first component as a hexadecimal number; let the red component of result be the resulting number.

18. Interpret the second component as a hexadecimal number; let the green component of result be the resulting number.

19. Interpret the third component as a hexadecimal number; let the blue component of result be the resulting number.

20. Return result.

**Note**

CSS2 System Colors are not recognized.

---

2.3.7 Space-separated tokens

A set of space-separated tokens is a string containing zero or more words (known as tokens) separated by one or more ASCII whitespace, where words consist of any string of one or more characters, none of which are ASCII whitespace.

A string containing a set of space-separated tokens may have leading or trailing ASCII whitespace.

An unordered set of unique space-separated tokens is a set of space-separated tokens where none of the tokens are duplicated.

An ordered set of unique space-separated tokens is a set of space-separated tokens where none of the tokens are duplicated but where the order of the tokens is meaningful.
Sets of space-separated tokens\(^{84}\) sometimes have a defined set of allowed values. When a set of allowed values is defined, the tokens must all be from that list of allowed values; other values are non-conforming. If no such set of allowed values is provided, then all values are conforming.

**Note**
How tokens in a set of space-separated tokens\(^{84}\) are to be compared (e.g. case-sensitively or not) is defined on a per-set basis.

### 2.3.8 Comma-separated tokens  

A set of comma-separated tokens is a string containing zero or more tokens each separated from the next by a single U+002C COMMA character (,), where tokens consist of any string of zero or more characters, neither beginning nor ending with ASCII whitespace, nor containing any U+002C COMMA characters (,), and optionally surrounded by ASCII whitespace.

**Example**
For instance, the string "a, b, , d" consists of four tokens: "a", "b", the empty string, and "d". Leading and trailing whitespace around each token doesn't count as part of the token, and the empty string can be a token.

Sets of comma-separated tokens\(^{85}\) sometimes have further restrictions on what consists a valid token. When such restrictions are defined, the tokens must all fit within those restrictions; other values are non-conforming. If no such restrictions are specified, then all values are conforming.

### 2.3.9 References  

A valid hash-name reference to an element of type type is a string consisting of a U+0023 NUMBER SIGN character (#) followed by a string which exactly matches the value of the name attribute of an element with type type in the same tree.

The rules for parsing a hash-name reference to an element of type type, given a context node scope, are as follows:

1. If the string being parsed does not contain a U+0023 NUMBER SIGN character, or if the first such character in the string is the last character in the string, then return null.
2. Let s be the string from the character immediately after the first U+0023 NUMBER SIGN character in the string being parsed up to the end of that string.
3. Return the first element of type type in scope's tree, in tree order, that has an id\(^{133}\) or name attribute whose value is s, or null if there is no such element.

**Note**
Although id\(^{133}\) attributes are accounted for when parsing, they are not used in determining whether a value is a valid hash-name reference\(^{85}\). That is, a hash-name reference that refers to an element based on id\(^{133}\) is a conformance error (unless that element also has a name attribute with the same value).

### 2.3.10 Media queries  

A string is a valid media query list if it matches the &lt;media-query-list&gt; production of the Media Queries specification. [MQ]\(^{125}\)

A string matches the environment of the user if it is the empty string, a string consisting of only ASCII whitespace, or is a media query list that matches the user's environment according to the definitions given in the Media Queries specification. [MQ]\(^{125}\)

### 2.4 URLs  

#### 2.4.1 Terminology  

A string is a valid non-empty URL if it is a valid URL string but it is not the empty string.
A string is a **valid URL potentially surrounded by spaces** if, after stripping leading and trailing ASCII whitespace from it, it is a **valid URL string**.

A string is a **valid non-empty URL potentially surrounded by spaces** if, after stripping leading and trailing ASCII whitespace from it, it is a **valid non-empty URL**.

This specification defines the URL `about:legacy-compat` as a reserved, though unresolvable, `about:` URL, for use in `DOCTYPE`'s in **HTML documents** when needed for compatibility with XML tools. [ABOUT]

This specification defines the URL `about:html-kind` as a reserved, though unresolvable, `about:` URL, that is used as an identifier for kinds of media tracks. [ABOUT]

This specification defines the URL `about:srcdoc` as a reserved, though unresolvable, `about:` URL, that is used as the URL of `iframe srcdoc` documents. [ABOUT]

The **fallback base URL** of a `Document` object `document` is the **URL record** obtained by running these steps:

1. If `document` is an `iframe srcdoc` document, then return the `document base URL` of `document`'s `browsing context`'s `node document`.
2. If `document`'s `URL` is `about:blank`, and `document`'s `browsing context` has a `creator browsing context`, then return the `creator base URL`.

The **document base URL** of a `Document` object `document` is the **absolute URL** obtained by running these steps:

1. If there is no `base` element that has an `href` attribute in the `Document`, then return the `Document`'s `fallback base URL`.
2. Otherwise, return the `frozen base URL` of the first `base` element in the `Document` that has an `href` attribute, in tree order.

### 2.4.2 Parsing URLs

Parsing a URL is the process of taking a string and obtaining the **URL record** that it represents. While this process is defined in the WHATWG URL standard, the HTML standard defines a wrapper for convenience. [URL]

**Note**

This wrapper is only useful when the character encoding for the URL parser has to match that of the document or environment settings object for legacy reasons. When that is not the case the **URL parser** can be used directly.

To **parse a URL** `url`, relative to either a `document` or environment settings object, the user agent must use the following steps. Parsing a URL either results in failure or a **resulting URL string** and **resulting URL record**.

1. Let `encoding` be `document`'s character encoding, if `document` was given, and environment settings object's API URL character encoding, otherwise.
2. Let `baseUrl` be `document`'s `base URL`, if `document` was given, and environment settings object's API base URL otherwise.
3. Let `urlRecord` be the result of applying the **URL parser** to `url`, with `baseUrl` and `encoding`.
4. If `urlRecord` is failure, then return failure.
5. Let `urlString` be the result of applying the **URL serializer** to `urlRecord`.
6. Return `urlString` as the **resulting URL string** and `urlRecord` as the **resulting URL record**.

### 2.4.3 Dynamic changes to base URLs

When a document's **document base URL** changes, all elements in that document are **affected by a base URL change**.
The following are base URL change steps, which run when an element is affected by a base URL change (as defined by the DOM specification):

- **If the element creates a hyperlink**
  
  If the URL identified by the hyperlink is being shown to the user, or if any data derived from that URL is affecting the display, then the href attribute should be reparsed relative to the element's node document and the UI updated appropriately.

  **Example**
  
  For example, the CSS :link/:visited pseudo-classes might have been affected.

  If the hyperlink has a ping attribute and its URL(s) are being shown to the user, then the ping attribute's tokens should be reparsed relative to the element's node document and the UI updated appropriately.

- **If the element is a q, blockquote, ins, or del element with a cite attribute**
  
  If the URL identified by the cite attribute is being shown to the user, or if any data derived from that URL is affecting the display, then the URL should be reparsed relative to the element's node document and the UI updated appropriately.

- **Otherwise**
  
  The element is not directly affected.

  **Example**
  
  For instance, changing the base URL doesn't affect the image displayed by img elements, although subsequent accesses of the src IDL attribute from script will return a new absolute URL that might no longer correspond to the image being shown.

### 2.5 Fetching resources

#### 2.5.1 Terminology

A response whose type is "basic", "cors", or "default" is CORS-same-origin. [FETCH]

A response whose type is "opaque" or "opaqueredirect" is CORS-cross-origin.

A response's unsafe response is its internal response if it has one, and the response itself otherwise.

To create a potential-CORS request, given a url, destination, corsAttributeState, and an optional same-origin fallback flag, run these steps:

1. Let mode be "no-cors" if corsAttributeState is No CORS, and "cors" otherwise.
2. If same-origin fallback flag is set and mode is "no-cors", set mode to "same-origin".
3. Let credentialsMode be "include".
4. If corsAttributeState is Anonymous, set credentialsMode to "same-origin".
5. Let request be a new request whose url is url, destination is destination, mode is mode, credentials mode is credentialsMode, and whose use-URL-credentials flag is set.

#### 2.5.2 Determining the type of a resource

The Content-Type metadata of a resource must be obtained and interpreted in a manner consistent with the requirements of the WHATWG MIME Sniffing standard. [MIMESNIFF]

The computed MIME type of a resource must be found in a manner consistent with the requirements given in the WHATWG MIME Sniffing standard. [MIMESNIFF]

The rules for sniffing images specifically, the rules for distinguishing if a resource is text or binary, and the rules for sniffing audio and video specifically are also defined in the WHATWG MIME Sniffing standard. These rules return a MIME type as
their result. [MIMESNIFF]

⚠Warning! It is imperative that the rules in the WHATWG MIME Sniffing standard be followed exactly. When a user agent uses different heuristics for content type detection than the server expects, security problems can occur. For more details, see the WHATWG MIME Sniffing standard. [MIMESNIFF]

2.5.3 Extracting character encodings from meta elements

The algorithm for extracting a character encoding from a meta element, given a string s, is as follows. It either returns a character encoding or nothing.

1. Let position be a pointer into s, initially pointing at the start of the string.
2. Loop: Find the first seven characters in s after position that are an ASCII case-insensitive match for the word "charset". If no such match is found, return nothing.
3. Skip any ASCII whitespace that immediately follow the word "charset" (there might not be any).
4. If the next character is not a U+003D EQUALS SIGN (=), then move position to point just before that next character, and jump back to the step labeled loop.
5. Skip any ASCII whitespace that immediately follow the equals sign (there might not be any).
6. Process the next character as follows:
   - If it is a U+0022 QUOTATION MARK character (") and there is a later U+0022 QUOTATION MARK character (") in s
   - If it is a U+0027 APOSTROPHE character ('') and there is a later U+0027 APOSTROPHE character ('') in s
     Return the result of getting an encoding from the substring that is between this character and the next earliest occurrence of this character.
   - If it is an unmatched U+0022 QUOTATION MARK character (")
   - If it is an unmatched U+0027 APOSTROPHE character ('')
   - If there is no next character
     Return nothing.
   - Otherwise
     Return the result of getting an encoding from the substring that consists of this character up to but not including the first ASCII whitespace or U+003B SEMICOLON character (;), or the end of s, whichever comes first.

Note

This algorithm is distinct from those in the HTTP specification (for example, HTTP doesn’t allow the use of single quotes and requires supporting a backslash-escape mechanism that is not supported by this algorithm). While the algorithm is used in contexts that, historically, were related to HTTP, the syntax as supported by implementations diverged some time ago. [HTTP]

2.5.4 CORS settings attributes

A CORS settings attribute is an enumerated attribute. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
<th>Brief description</th>
</tr>

</table>

The empty string is also a valid keyword, and maps to the Anonymous state. The attribute’s invalid value default is the Anonymous state. For the purposes of reflection, the canonical case for the Anonymous state is the anonymous keyword. The missing value default, used when the attribute is omitted, is the No CORS state.

The majority of fetches governed by CORS settings attributes will be done via the create a potential-CORS request algorithm.
For module scripts\(^{868}\), certain CORS settings attributes\(^{868}\) have been repurposed to have a slightly different meaning, wherein they only impact the request's credentials mode (since the mode is always "cors"). To perform this translation, we define the module script credentials mode for a given CORS settings attribute\(^{88}\) to be determined by switching on the attribute's state:

- **No CORS**\(^{88}\)
  "omitted"
- **Anonymous**\(^{88}\)
  "same-origin"
- **Use Credentials**\(^{88}\)
  "include"

### 2.5.5 Referrer policy attributes \(^{89}\)

A referer policy attribute is an enumerated attribute\(^{665}\). Each referer policy, including the empty string, is a keyword for this attribute, mapping to a state of the same name.

The attribute’s invalid value default\(^{665}\) and missing value default\(^{665}\) are both the empty string state.

The impact of these states on the processing model of various fetches is defined in more detail throughout this specification, in the WHATWG Fetch standard, and in Referrer Policy. [FETCH]\(^{1223}\) [REFERRERPOLICY]\(^{1225}\)

**Note**

Several signals can contribute to which processing model is used for a given fetch; a referer policy attribute\(^{89}\) is only one of them. In general, the order in which these signals are processed are:

1. First, the presence of a noscript\(^{292}\) link type;
2. Then, the value of a referer policy attribute\(^{89}\);
3. Then, the presence of any meta\(^{158}\) element with name\(^{159}\) attribute set to referer\(^{215}\);
4. Finally, the 'Referrer-Policy' HTTP header.

### 2.5.6 Nonce attributes \(^{89}\)

A nonce content attribute represents a cryptographic nonce ("number used once") which can be used by Content Security Policy to determine whether or not a given fetch will be allowed to proceed. The value is text. [CSP]\(^{91221}\)

Elements that have a nonce\(^{89}\) content attribute ensure that the cryptographic nonce is only exposed to script (and not to side-channels like CSS attribute selectors) by extracting the value from the content attribute, moving it into an internal slot named [CryptographicNonce]\(^{89}\), and exposing it to script via the HTMLOrSVGEElement\(^{121}\) interface mixin. Unless otherwise specified, the slot’s value is the empty string.

For web developers (non-normative)

```
  element . nonce
  Returns the value of the element's [CryptographicNonce]\(^{89}\) internal slot.
  Can be set, to update that slot's value.
```

The nonce IDL attribute must, on getting, return the value of this element's [CryptographicNonce]\(^{89}\); and on setting, set this element's [CryptographicNonce]\(^{89}\) to the given value.

**Note**

*Note how the setter for the nonce\(^{89}\) IDL attribute does not update the corresponding content attribute. This, as well as the below
Whenever an element including `HTMLOrSVGElement` has its `nonce` attribute is set or changed, set this element's `[[CryptographicNonce]]` to the given value.

Whenever an element including `HTMLOrSVGElement` becomes browsing-context connected, the user agent must execute the following steps on the `element`:

1. Let `CSP list` be `element`'s `shadow-including root`'s `CSP list`.
2. If `CSP list` contains a `header-delivered Content Security Policy`, and `element` has a `nonce` content attribute `attr` whose value is not the empty string, then:
   1. Set an attribute value for `element` using "nonce" and the empty string.

Note: As each `Document`'s `CSP list` is append-only, user agents can optimize away the `contains a header-delivered Content Security Policy` check by, for example, holding a flag on the `Document`, set during `Document` initialization.

The cloning steps for elements that include `HTMLOrSVGElement` must set the `[[CryptographicNonce]]` slot on the copy to the value of the slot on the element being cloned.

### 2.6 Common DOM interfaces

#### 2.6.1 Reflecting content attributes in IDL attributes

Some IDL attributes are defined to reflect a particular content attribute. This means that on getting, the IDL attribute returns the current value of the content attribute, and on setting, the IDL attribute changes the value of the content attribute to the given value.

In general, on getting, if the content attribute is not present, the IDL attribute must act as if the content attribute's value is the empty string; and on setting, if the content attribute is not present, it must first be added.

If a reflecting IDL attribute is a `DOMString` attribute whose content attribute is defined to contain a `URL`, then on getting, if the content attribute is absent, the IDL attribute must return the empty string. Otherwise, the IDL attribute must `parse` the value of the content attribute relative to the element's `node document`, and if that is successful, return the `resulting URL string`. If parsing fails, then the value of the content attribute must be returned instead, converted to a `USVString`. On setting, the content attribute must be set to the specified new value.

If a reflecting IDL attribute is a `DOMString` attribute whose content attribute is an `enumerated attribute`, and the IDL attribute is limited to only known values, then, on getting, the IDL attribute must return the conforming value associated with the state the attribute is in (in its canonical case), if any, or the empty string if the attribute is in a state that has no associated keyword value or if the attribute is not in a defined state (e.g. the attribute is missing and there is no missing value default). On setting, the content attribute must be set to the specified new value.

If a reflecting IDL attribute is a nullable `DOMString` attribute whose content attribute is an `enumerated attribute`, then, on getting, if the corresponding content attribute is in its missing value default then the IDL attribute must return null, otherwise, the IDL attribute must return the conforming value associated with the state the attribute is in (in its canonical case). On setting, if the new value is null, the content attribute must be removed, and otherwise, the content attribute must be set to the specified new value.

If a reflecting IDL attribute is a `DOMString` or `USVString` attribute but doesn't fall into any of the above categories, then the getting and setting must be done in a transparent, case-preserving manner.

If a reflecting IDL attribute is a `boolean` attribute, then on getting the IDL attribute must return true if the content attribute is set, and false if it is absent. On setting, the content attribute must be removed if the IDL attribute is set to false, and must be set to the empty string if the IDL attribute is set to true. (This corresponds to the rules for `boolean content attributes`.)

If a reflecting IDL attribute has a signed integer type (`long`) then, on getting, the content attribute must be parsed according to the rules for parsing signed integers, and if that is successful, and the value is in the range of the IDL attribute's type, the resulting setting of the `nonce` content attribute to the empty string when an element becomes browsing-context connected, is meant to prevent exfiltration of the nonce value through mechanisms that can easily read content attributes, such as selectors. Learn more in issue #2369, where this behavior was introduced.
value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, then the default value must be returned instead, or 0 if there is no default value. On setting, the given value must be converted to the shortest possible string representing the number as a valid non-negative integer and then that string must be used as the new content attribute value.

If a reflecting IDL attribute has a signed integer type (long) that is limited to only non-negative numbers then, on getting, the content attribute must be parsed according to the rules for parsing non-negative integers, and if that is successful, and the value is in the range of the IDL attribute’s type, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or −1 if there is no default value. On setting, if the value is negative, the user agent must throw an "IndexSizeError" DOMException. Otherwise, the given value must be converted to the shortest possible string representing the number as a valid non-negative integer and then that string must be used as the new content attribute value.

If a reflecting IDL attribute has an unsigned integer type (unsigned long) that is limited to only non-negative numbers greater than zero, then the behavior is similar to the previous case, but zero is not allowed. On getting, the content attribute must first be parsed according to the rules for parsing non-negative integers, and if that is successful, and the value is in the range 0 to 2147483647 inclusive, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or 0 if there is no default value. On setting, first, if the new value is in the range 0 to 2147483647, then let \( n \) be the new value, otherwise let \( n \) be the default value, or 0 if there is no default value; then, \( n \) must be converted to the shortest possible string representing the number as a valid non-negative integer and that string must be used as the new content attribute value.

If a reflecting IDL attribute has an unsigned integer type (unsigned long) that is limited to only non-negative numbers greater than zero with fallback, then the behavior is similar to the previous case, but disallowed values are converted to the default value. On getting, the content attribute must first be parsed according to the rules for parsing non-negative integers, and if that is successful, and the value is in the range 1 to 2147483647 inclusive, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or 1 if there is no default value. On setting, if the value is zero, the user agent must throw an "IndexSizeError" DOMException. Otherwise, first, if the new value is in the range 1 to 2147483647, then let \( n \) be the new value, otherwise let \( n \) be the default value, or 1 if there is no default value; then, \( n \) must be converted to the shortest possible string representing the number as a valid non-negative integer and that string must be used as the new content attribute value.

If a reflecting IDL attribute has an unsigned integer type (unsigned long) that is clamped to the range \([min, max]\), then on getting, the content attribute must first be parsed according to the rules for parsing non-negative integers, and if that is successful, and the value is between \( min \) and \( max \) inclusive, the resulting value must be returned. If it fails, the default value must be returned. If it succeeds but the value is less than \( min \), \( min \) must be returned. If it succeeds but the value is greater than \( max \), \( max \) must be returned. On setting, it behaves the same as setting a regular reflected unsigned integer.

If a reflecting IDL attribute has a floating-point number type (double or unrestricted double), then, on getting, the content attribute must be parsed according to the rules for parsing floating-point number values, and if that is successful, the resulting value must be returned. If, on the other hand, it fails, or if the attribute is absent, the default value must be returned instead, or 0.0 if there is no default value. On setting, the given value must be converted to the best representation of the number as a floating-point number and then that string must be used as the new content attribute value.

If a reflecting IDL attribute has a floating-point number type (double or unrestricted double) that is limited to numbers greater than zero, then the behavior is similar to the previous case, but zero and negative values are not allowed. On getting, the content attribute must be parsed according to the rules for parsing floating-point number values, and if that is successful and the value is greater than 0.0, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or 0.0 if there is no default value. On setting, if the value is less than or equal to zero, the value must be ignored. Otherwise, the given value must be converted to the best representation of the number as a floating-point number and then that string must be used as the new content attribute value.

---

The values Infinity and Not-a-Number (NaN) values throw an exception on setting, as defined in the Web IDL specification. [WEBIDL] [2227]

If a reflecting IDL attribute has the type DOMTokenList, then on getting it must return a DOMTokenList object whose associated
element is the element in question and whose associated attribute's local name is the name of the attribute in question.

2.6.2 Collections §p92

The HTMLFormControlsCollection\(^{p94}\) and HTMLOptionsCollection\(^{p95}\) interfaces are collections derived from the HTMLCollection interface. The HTMLAllCollection\(^{p92}\) interface is a collection, but is not so derived.

2.6.2.1 The HTMLAllCollection\(^{p92}\) interface §p92

The HTMLAllCollection\(^{p92}\) interface is used for the legacy document.all\(^{p1187}\) attribute. It operates similarly to HTMLCollection; the main differences are that it allows a staggering variety of different (ab)uses of its methods to all end up returning something, and that it can be called as a function as an alternative to property access.

All HTMLAllCollection\(^{p92}\) objects are rooted at a Document\(^{p116}\) and have a filter that matches all elements, so the elements represented by the collection of an HTMLAllCollection\(^{p92}\) object consist of all the descendant elements of the root Document\(^{p116}\).

Objects that implement the HTMLAllCollection\(^{p92}\) interface are legacy platform objects with an additional [[Call]] internal method described in the section below\(^{p96}\). They also have an [[IsHTMLDDA]] internal slot.

Objects that implement the HTMLAllCollection\(^{p92}\) interface have several unusual behaviors, due to the fact that they have an [[IsHTMLDDA]] internal slot:

- The ToBoolean abstract operation in JavaScript returns false when given objects implementing the HTMLAllCollection\(^{p92}\) interface.
- The Abstract Equality Comparison algorithm, when given objects implementing the HTMLAllCollection\(^{p92}\) interface, returns true when compared to the undefined and null values. (Comparisons using the Strict Equality Comparison algorithm, and Abstract Equality comparisons to other values such as strings or objects, are unaffected.)
- The typeof operator in JavaScript returns the string “undefined” when applied to objects implementing the HTMLAllCollection\(^{p92}\) interface.

These special behaviors are motivated by a desire for compatibility with two classes of legacy content: one that uses the presence of document.all\(^{p1187}\) as a way to detect legacy user agents, and one that only supports those legacy user agents and uses the document.all\(^{p1187}\) object without testing for its presence first. [JAVASCRIPT]\(^{p1224}\)

```idl
[Exposed=Window, LegacyUnenumerableNamedProperties]
interface HTMLAllCollection {
    readonly attribute unsigned long length;
    getter Element (unsigned long index);
    getter (HTMLCollection or Element)? namedItem(DOMString name);
    (HTMLCollection or Element)? item(optional DOMString nameOrIndex);

    // Note: HTMLAllCollection objects have a custom [[Call]] internal method and an [[IsHTMLDDA]] internal slot.
};
```

For web developers (non-normative)

```
collection . length\(^{p93}\)
```

Returns the number of elements in the collection.
element = collection.item(index)

Returns the item with index index from the collection (determined by tree order).

element = collection.item(name)

collection = collection.item(name)

Returns the item with ID or name name from the collection.

If there are multiple matching items, then an HTMLCollection object containing all those elements is returned.

Only button, form, iframe, input, map, object, select, and textarea elements can have a name for the purpose of this method; their name is given by the value of their name attribute.

The object's supported property indices are as defined for HTMLCollection objects.

The supported property names consist of the non-empty values of all the id attributes of all the elements represented by the collection, and the non-empty values of all the name attributes of all the "all"-named elements represented by the collection, in tree order, ignoring later duplicates, with the id of an element preceding its name if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

On getting, the length attribute must return the number of nodes represented by the collection.

The indexed property getter must return the result of getting the "all"-indexed element from this HTMLAllCollection given the passed index.

The namedItem(name) method must return the result of getting the "all"-named element(s) from this HTMLAllCollection given name.

The item(nameOrIndex) method must perform the following steps:

1. If nameOrIndex was not provided, return null.
2. Return the result of getting the "all"-indexed or named element(s) from this HTMLAllCollection, given nameOrIndex.

The following elements are "all"-named elements: button, form, iframe, input, map, object, select, and textarea.

To get the "all"-indexed element from an HTMLAllCollection collection given an index index, return the indexth element in collection, or null if there is no such indexth element.

To get the "all"-named element(s) from an HTMLAllCollection collection given a name name, perform the following steps:

1. If name is the empty string, return null.
2. Let subCollection be an HTMLCollection object rooted at the same Document as collection, whose filter matches only elements that are either:
   - "all"-named elements with a name attribute equal to name, or,
   - elements with an ID equal to name.
3. If there is exactly one element in subCollection, then return that element.
4. Otherwise, if subCollection is empty, return null.
To get the "all"-indexed or named element(s) from an HTMLAllCollection\(^\text{p93}\) collection given nameOrIndex:

1. If nameOrIndex, converted to a JavaScript String value, is an array index property name, return the result of getting the "all"-indexed element\(^\text{p93}\) from this HTMLAllCollection\(^\text{p92}\) given the number represented by nameOrIndex.

2. Return the result of getting the "all"-named element(s)\(^\text{p93}\) from this HTMLAllCollection\(^\text{p92}\) given nameOrIndex.

2.6.2.1 [[Call]] (thisArgument, argumentsList) \(^\text{p94}\)

1. If argumentsList's size is zero, or if argumentsList[0] is undefined, return null.

2. Let nameOrIndex be the result of converting argumentsList[0] to a DOMString.

3. Let result be the result of getting the "all"-indexed or named element(s)\(^\text{p94}\) from this HTMLAllCollection\(^\text{p92}\) given nameOrIndex.

4. Return the result of converting result to an ECMAScript value.

**Note**

The thisArgument is ignored, and thus code such as `Function.prototype.call.call(document.all, null, "x")` will still search for elements. (document.all.call does not exist, since document.all does not inherit from Function.prototype.)

2.6.2.2 The HTMLFormControlsCollection\(^\text{p94}\) interface \(^\text{p94}\)

The HTMLFormControlsCollection\(^\text{p94}\) interface is used for collections of listed elements\(^\text{p470}\) in form\(^\text{p470}\) elements.

```idl
[Exposed=Window]
interface HTMLFormControlsCollection : HTMLCollection {
  // inherits length and item()
  getter (RadioNodeList or Element)? namedItem(DOMString name); // shadows inherited namedItem()
};

[Exposed=Window]
interface RadioNodeList : NodeList {
  attribute DOMString value;
};
```

**For web developers (non-normative)**

- `collection.length`
  - Returns the number of elements in the collection.

- `element = collection.item(index)`

- `element = collection[index]`
  - Returns the item with index index from the collection. The items are sorted in tree order.

- `element = collection.namedItem(name)`

- `radioNodeList = collection.namedItem(name)`

- `element = collection[name]`
  - Returns the item with ID or name name from the collection.
  
  If there are multiple matching items, then a RadioNodeList\(^\text{p94}\) object containing all those elements is returned.

- `radioNodeList.value [ = value ]`
  - Returns the value of the first checked radio button represented by the object.
The object’s supported property indices are as defined for HTMLCollection objects.

The supported property names consist of the non-empty values of all the id\(^{133}\) and name\(^{549}\) attributes of all the elements represented by the collection, in tree order, ignoring later duplicates, with the id\(^{133}\) of an element preceding its name\(^{549}\) if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

The namedItem(name) method must act according to the following algorithm:

1. If name is the empty string, return null and stop the algorithm.
2. If, at the time the method is called, there is exactly one node in the collection that has either an id\(^{133}\) attribute or a name\(^{549}\) attribute equal to name\(^{549}\), then return that node and stop the algorithm.
3. Otherwise, if there are no nodes in the collection that have either an id\(^{133}\) attribute or a name\(^{549}\) attribute equal to name\(^{549}\), then return null and stop the algorithm.
4. Otherwise, create a new RadioNodeList\(^{94}\) object representing a live view of the HTMLFormControlsCollection\(^{94}\) object, further filtered so that the only nodes in the RadioNodeList\(^{94}\) object are those that have either an id\(^{133}\) attribute or a name\(^{549}\) attribute equal to name\(^{549}\). The nodes in the RadioNodeList\(^{94}\) object must be sorted in tree order.
5. Return that RadioNodeList\(^{94}\) object.

Members of the RadioNodeList\(^{94}\) interface inherited from the NodeList interface must behave as they would on a NodeList object.

The value IDL attribute on the RadioNodeList\(^{94}\) object, on getting, must return the value returned by running the following steps:

1. Let element be the first element in tree order represented by the RadioNodeList\(^{94}\) object that is an input\(^{476}\) element whose type\(^{478}\) attribute is in the Radio Button\(^{497}\) state and whose checkedness\(^{547}\) is true. Otherwise, let it be null.
2. If element is null, return the empty string.
3. If element is an element with no value\(^{480}\) attribute, return the string "on".
4. Otherwise, return the value of element’s value\(^{480}\) attribute.

On setting, the value\(^{95}\) IDL attribute must run the following steps:

1. If the new value is the string "on": let element be the first element in tree order represented by the RadioNodeList\(^{94}\) object that is an input\(^{476}\) element whose type\(^{478}\) attribute is in the Radio Button\(^{497}\) state and whose value\(^{480}\) content attribute is either absent, or present and equal to the new value, if any. If no such element exists, then instead let element be null.
   
   Otherwise: let element be the first element in tree order represented by the RadioNodeList\(^{94}\) object that is an input\(^{476}\) element whose type\(^{478}\) attribute is in the Radio Button\(^{497}\) state and whose value\(^{480}\) content attribute is present and equal to the new value, if any. If no such element exists, then instead let element be null.

2. If element is not null, then set its checkedness\(^{547}\) to true.

2.6.2.3 The HTMLOptionsCollection\(^{95}\) interface

The HTMLOptionsCollection\(^{95}\) interface is used for collections of option\(^{528}\) elements. It is always rooted on a select\(^{520}\) element and has attributes and methods that manipulate that element’s descendants.

[IDL]
```idl
[Exposed=Window]
interface HTMLOptionsCollection : HTMLCollection {
  // inherits item(), namedItem()
  [CEReactions] attribute unsigned long length; // shadows inherited length
  [CEReactions] setter void (unsigned long index, HTMLOptionElement? option);
  [CEReactions] void add((HTMLOptionElement or HTMLOptGroupElement) element, optional (HTMLElement or
```
The object's supported property indices are as defined for HTMLCollection objects.

On getting, the length attribute must return the number of nodes represented by the collection.

On setting, the behavior depends on whether the new value is equal to, greater than, or less than the number of nodes represented by the collection at that time. If the number is the same, then setting the attribute must do nothing. If the new value is greater, then new option elements with no attributes and no child nodes must be appended to the select element on which the HTMLOptionsCollection is rooted, where \( n \) is the difference between the two numbers (new value minus old value). Mutation events must be fired as if a DocumentFragment containing the new option elements had been inserted. If the new value is lower, then the last \( n \) nodes in the collection must be removed from their parent nodes, where \( n \) is the difference between the two numbers (old value minus new value).

Setting length never removes or adds any optgroup elements, and never adds new children to existing optgroup elements (though it can remove children from them).
The supported property names consist of the non-empty values of all the `id` and `name` attributes of all the elements represented by the collection, in tree order, ignoring later duplicates, with the `id` of an element preceding its `name` if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

When the user agent is to set the value of a new indexed property or set the value of an existing indexed property for a given property index to a new value, it must run the following algorithm:

1. If `value` is null, invoke the steps for the `remove` method with `index` as the argument, and return.
2. Let `length` be the number of nodes represented by the collection.
3. Let `n` be `index` minus `length`.
4. If `n` is greater than zero, then append a `DocumentFragment` consisting of `n-1` new `option` elements with no attributes and no child nodes to the `select` element on which the `HTMLSelectElement` is rooted.
5. If `n` is greater than or equal to zero, append `value` to the `select` element. Otherwise, replace the indexth element in the collection by `value`.

The `add(element, before)` method must act according to the following algorithm:

1. If `element` is an ancestor of the `select` element on which the `HTMLSelectElement` is rooted, then throw a "HierarchyRequestError" DOMException.
2. If `before` is an element, but that element isn't a descendant of the `select` element on which the `HTMLSelectElement` is rooted, then throw a "NotFoundError" DOMException.
3. If `element` and `before` are the same element, then return.
4. If `before` is a node, then let `reference` be that node. Otherwise, if `before` is an integer, and there is a `before`th node in the collection, let `reference` be that node. Otherwise, let `reference` be null.
5. If `reference` is not null, let `parent` be the parent node of `reference`. Otherwise, let `parent` be the `select` element on which the `HTMLSelectElement` is rooted.
6. Pre-insert `element` into `parent` node before `reference`.

The `remove(index)` method must act according to the following algorithm:

1. If the number of nodes represented by the collection is zero, return.
2. If `index` is not a number greater than or equal to 0 and less than the number of nodes represented by the collection, return.
3. Let `element` be the `index`th element in the collection.
4. Remove `element` from its parent node.

The `selectedIndex` IDL attribute must act like the identically named attribute on the `select` element on which the `HTMLSelectElement` is rooted.

2.6.3 The `DOMStringList` interface

The `DOMStringList` interface is a non-fashionable retro way of representing a list of strings.

```idl
[Exposed=(Window,Worker)]
interface DOMStringList {
  readonly attribute unsigned long length;
  getter DOMString? item(unsigned long index);
  boolean contains(DOMString string);
};
```

⚠️ Warning!

New APIs must use `sequence<DOMString>` or equivalent rather than `DOMStringList`.

97
For web developers (non-normative)

strings . length[^98]

Returns the number of strings in strings.

strings[index]

strings . item[^98](index)

Returns the string with index index from strings.

strings . contains[^98](string)

Returns true if strings contains string, and false otherwise.

Each DOMStringList[^97] object has an associated list.

The supported property indices for a DOMStringList[^97] object are the numbers zero to the associated list's size minus one. If its associated list is empty, it has no supported property indices.

The length attribute's getter must return this DOMStringList[^97] object's associated list's size.

The item(index) method, when invoked, must return the indexth item in this DOMStringList[^97] object's associated list, or null if index plus one is greater than this DOMStringList[^97] object's associated list's size.

The contains(string) method, when invoked, must return true if this DOMStringList[^97] object's associated list contains string, and false otherwise.

2.6.4 Garbage collection  §[^98]

There is an implied strong reference from any IDL attribute that returns a pre-existing object to that object.

Example

For example, the window.document[^793] attribute means that there is a strong reference from a Window[^791] object to its Document[^110] object. Similarly, there is always a strong reference from a Document[^110] to any descendant nodes, and from any node to its node document.

2.7 Safe passing of structured data  §[^98]

This section uses the terminology and typographic conventions from the JavaScript specification. [JAVA SCRIPT][^1224]

2.7.1 Serializable objects  §[^98]

Serializable objects[^98] support being serialized, and later deserialized, in a way that is independent of any given JavaScript Realm. This allows them to be stored on disk and later restored, or cloned across document and worker boundaries (including across documents of different origins[^803] or in different event loops[^803]).

Not all objects are serializable objects[^98], and not all aspects of objects that are serializable objects[^98] are necessarily preserved when they are serialized.

Platform objects can be serializable objects[^98] if they implement only interfaces decorated with the [Serializable] IDL extended attribute. Such interfaces must also define the following algorithms:

serialization steps, taking a platform object value, a Record serialized, and a boolean forStorage

A set of steps that serializes the data in value into fields of serialized. The resulting data serialized into serialized must be independent of any JavaScript Realm.
These steps may throw an exception if serialization is not possible.

These steps may perform a sub-serialization\(^{103}\) to serialize nested data structures. They should not call StructuredSerialize\(^{104}\) directly, as doing so will omit the important memory argument.

The introduction of these steps should omit mention of the forStorage argument if it is not relevant to the algorithm.

**deserialization steps, taking a Record serialized and a platform object value**

A set of steps that deserializes the data in serialized, using it to set up value as appropriate. value will be a newly-created instance of the platform object type in question, with none of its internal data set up; setting that up is the job of these steps.

These steps may throw an exception if deserialization is not possible.

These steps may perform a sub-deserialization\(^{106}\) to deserialize nested data structures. They should not call StructuredDeserialize\(^{104}\) directly, as doing so will omit the important targetRealm and memory arguments.

It is up to the definition of individual platform objects to determine what data is serialized and deserialized by these steps. Typically the steps are very symmetric.

The [Serializable]\(^{98}\) extended attribute must take no arguments, and must not appear on anything other than an interface. It must appear only once on an interface. It must not be used on a callback interface. If it appears on a partial interface or an interface that is really a mixin, then it must also appear on the original or mixed-in-to interface, and any supplied serialization steps\(^{98}\) and deserialization steps\(^{99}\) for the partial interface or mixin should be understood as being appended to those of the original or mixed-in-to interface.

---

**Example**

Let's say we were defining a platform object Person, which had associated with it two pieces of associated data:

- a name value, which is a string;
- and a best friend value, which is either another Person instance or null

We could then define Person instances to be serializable objects\(^{98}\) by annotating the Person interface with the [Serializable]\(^{98}\) extended attribute, and defining the following accompanying algorithms:

### serialization steps\(^{98}\)

1. Set serialized.[[Name]] to value's associated name value.
2. Let serializedBestFriend be the sub-serialization\(^{103}\) of value's associated best friend value.

### deserialization steps\(^{99}\)

1. Set value's associated name value to serialized.[[Name]].
2. Let deserializedBestFriend be the sub-deserialization\(^{106}\) of serialized.[[BestFriend]].
3. Set value's associated best friend value to deserializedBestFriend.

Objects defined in the JavaScript specification are handled by the StructuredSerialize\(^{104}\) abstract operation directly.

---

**Note**

Originally, this specification defined the concept of “cloneable objects”, which could be cloned from one JavaScript Realm to another. However, to better specify the behavior of certain more complex situations, the model was updated to make the serialization and deserialization explicit.

---

### 2.7.2 Transferable objects\(^{99}\)

Transferable objects\(^{99}\) support being transferred across event loops\(^{893}\). Transferring is effectively recreating the object while sharing a reference to the underlying data and then detaching the object being transferred. This is useful to transfer ownership of expensive resources. Not all objects are transferable objects\(^{99}\) and not all aspects of objects that are transferable objects\(^{99}\) are necessarily
preserved when transferred.

Platform objects can be transferable objects if they implement only interfaces decorated with the [Transferable] IDL extended attribute. Such interfaces must also define the following algorithms:

**transfer steps, taking a platform object value and a Record dataHolder**

A set of steps that transfers the data in value into fields of dataHolder. The resulting data held in dataHolder must be independent of any JavaScript Realm.

These steps may throw an exception if transferral is not possible.

**transfer-receiving steps, taking a Record dataHolder and a platform object value**

A set of steps that receives the data in dataHolder, using it to set up value as appropriate. value will be a newly-created instance of the platform object type in question, with none of its internal data set up; setting that up is the job of these steps.

These steps may throw an exception if it is not possible to receive the transfer.

It is up to the definition of individual platform objects to determine what data is transferred by these steps. Typically the steps are very symmetric.

The [Transferable] extended attribute must take no arguments, and must not appear on anything other than an interface. It must appear only once on an interface. It must not be used on a callback interface. If it appears on a partial interface or an interface that is really a mixin, then it must also appear on the original or mixed-in-to interface, and any supplied serialization steps and deserialization steps for the partial interface or mixin should be understood as being appended to those of the original or mixed-into interface.

Platform objects that are transferable objects have a [[Detached]] internal slot. This is used to ensure that once a platform object has been transferred, it cannot be transferred again.

Objects defined in the JavaScript specification are handled by the StructuredSerializeWithTransfer abstract operation directly.

### 2.7.3 StructuredSerializeInternal (value, forStorage [ , memory ] )

The StructuredSerializeInternal abstract operation takes as input a JavaScript value value and serializes it to a Realm-independent form, represented here as a Record. This serialized form has all the information necessary to later deserialize into a new JavaScript value in a different Realm.

This process can throw an exception, for example when trying to serialize un-serializable objects.

1. If memory was not supplied, let memory be an empty map.

   **Note**

   The purpose of the memory map is to avoid serializing objects twice. This ends up preserving cycles and the identity of duplicate objects in graphs.

2. If memory[value] exists, then return memory[value].

3. Let deep be false.

4. If Type(value) is Undefined, Null, Boolean, Number, BigInt, or String, then return { [[Type]]: "primitive", [[Value]]: value }.

5. If Type(value) is Symbol, then throw a "DataCloneError" DOMException.

6. Let serialized be an uninitialized value.

7. If value has a [[BooleanData]] internal slot, then set serialized to { [[Type]]: "Boolean", [[BooleanData]]: value.[[BooleanData]] }.
8. Otherwise, if `value` has a `[[NumberData]]` internal slot, then set `serialized` to `{ [[Type]]: "Number", [[NumberData]]: value.[[NumberData]] }.

9. Otherwise, if `value` has a `[[BigIntData]]` internal slot, then set `serialized` to `{ [[Type]]: "BigInt", [[BigIntData]]: value.[[BigIntData]] }.

10. Otherwise, if `value` has a `[[StringData]]` internal slot, then set `serialized` to `{ [[Type]]: "String", [[StringData]]: value.[[StringData]] }.

11. Otherwise, if `value` has a `[[DateValue]]` internal slot, then set `serialized` to `{ [[Type]]: "Date", [[DateValue]]: value.[[DateValue]] }.

12. Otherwise, if `value` has a `[[RegExpMatcher]]` internal slot, then set `serialized` to `{ [[Type]]: "RegExp", [[RegExpMatcher]]: value.[[RegExpMatcher]], [[OriginalSource]]: value.[[OriginalSource]], [[OriginalFlags]]: value.[[OriginalFlags]] }.

13. Otherwise, if `value` has an `[[ArrayBufferData]]` internal slot, then:
   1. Let `size` be `value.[[ArrayBufferByteLength]].
   2. If `IsSharedArrayBuffer(value)` is true, then:
      1. If `forStorage` is true, then throw a "DataCloneError" DOMException.
      2. Set `serialized` to `{ [[Type]]: "SharedArrayBuffer", [[ArrayBufferData]]: value.[[ArrayBufferData]], [[ArrayBufferByteLength]]: size, [[AgentCluster]]: the current Realm Record’s corresponding agent cluster }.
   3. Otherwise:
      1. If `IsDetachedBuffer(value)` is true, then throw a "DataCloneError" DOMException.
      2. Let `dataCopy` be `CreateByteDataBlock(size).`
      3. Perform `CopyDataBlockBytes(dataCopy, 0, value.[[ArrayBufferData]], 0, size).
      4. Set `serialized` to `{ [[Type]]: "ArrayBuffer", [[ArrayBufferData]]: dataCopy, [[ArrayBufferByteLength]]: size }.

14. Otherwise, if `value` has a `[[ViewedArrayBuffer]]` internal slot, then:
   1. Let `buffer` be the value of `value`’s `[[ViewedArrayBuffer]]` internal slot.
   2. Let `bufferSerialized` be `StructuredSerializeInternal(buffer, forStorage, memory).
   3. Assert: `bufferSerialized.[[Type]]` is "ArrayBuffer".
   4. If `value` has a `[[DataView]]` internal slot, then set `serialized` to `{ [[Type]]: "ArrayBufferView", [[Constructor]]: "DataView", [[ArrayBufferDataSerialized]]: bufferSerialized, [[ByteLength]]: value.[[ByteLength]], [[ByteOffset]]: value.[[ByteOffset]] }.
   5. Otherwise:
      1. Assert: `value` has a `[[TypedArrayName]]` internal slot.
      2. Set `serialized` to `{ [[Type]]: "ArrayBufferView", [[Constructor]]: value.[[TypedArrayName]], [[ArrayBufferDataSerialized]]: bufferSerialized, [[ByteLength]]: value.[[ByteLength]], [[ByteOffset]]: value.[[ByteOffset]], [[ArrayLength]]: value.[[ArrayLength]] }.

15. Otherwise, if `value` has `[[MapData]]` internal slot, then:
   1. Set `serialized` to `{ [[Type]]: "Map", [[MapData]]: a new empty List }.
   2. Set `deep` to true.

16. Otherwise, if `value` has `[[SetData]]` internal slot, then:
   1. Set `serialized` to `{ [[Type]]: "Set", [[SetData]]: a new empty List }.
2. Set `deep` to true.

17. Otherwise, if `value` is an Array exotic object, then:
   1. Let `valueLenDescriptor` be `? OrdinaryGetOwnProperty(value, "length")`.
   2. Let `valueLen` be `valueLenDescriptor.[[Value]].`
   3. Set `serialized` to `{ [[Type]]: "Array", [[Length]]: valueLen, [[Properties]]: a new empty List }`.
   4. Set `deep` to true.

18. Otherwise, if `value` is a platform object that is a serializable object:
   1. If `value` has a `[[Detached]]` internal slot whose value is true, then throw a "DataCloneError" DOMException.
   2. Let `typeString` be the identifier of the primary interface of `value`.
   3. Set `serialized` to `{ [[Type]]: typeString }`.
   4. Set `deep` to true.

19. Otherwise, if `value` is a platform object, then throw a "DataCloneError" DOMException.

20. Otherwise, if `IsCallable(value)` is true, then throw a "DataCloneError" DOMException.

21. Otherwise, if `value` has any internal slot other than `[[Prototype]]` or `[[Extensible]]`, then throw a "DataCloneError" DOMException.

Example
For instance, a `[[PromiseState]]` or `[[WeakMapData]]` internal slot.

22. Otherwise, if `value` is an exotic object, then throw a "DataCloneError" DOMException.

Example
For instance, a proxy object.

23. Otherwise:
   1. Set `serialized` to `{ [[Type]]: "Object", [[Properties]]: a new empty List }`.
   2. Set `deep` to true.

25. If `deep` is true, then:
   1. If `value` has a `[[MapData]]` internal slot, then:
      1. Let `copiedList` be a new empty List.
      2. For each `Record` `{{Key]}, [[Value]} } entry of value.{{MapData]]`:
         1. Let `copiedEntry` be a new `Record` `{{Key]}, [[Value]}: entry.{{Value]} }`.
         2. If `copiedEntry.{{Key]} is not the special value empty`, append `copiedEntry` to `copiedList`.
      3. For each `Record` `{{Key]}, [[Value]} } entry of copiedList`:
         1. Let `serializedKey` be `StructuredSerializeInternal(entry.{{Key]}, forStorage, memory)`
         2. Let `serializedValue` be `StructuredSerializeInternal(entry.{{Value]}, forStorage, memory)`
         3. Append `{{Key]}: serializedKey, [[Value]}: serializedValue } to `serialized.{{MapData]}.
   2. Otherwise, if `value` has a `[[SetData]]` internal slot, then:
      1. Let `copiedList` be a new empty List.
      2. For each `entry` of `value.{{SetData}}`:
         1. If `entry` is not the special value empty`, append `entry` to `copiedList`.
3. **For each** entry of copiedList:
   1. **Let** `serializedEntry` **be** \( \text{StructuredSerializeInternal} \)\(^{100}\)(entry, forStorage, memory).
   2. **Append** `serializedEntry` **to** `serialized`\([\text{[SetData]}]\).

3. Otherwise, if `value` is a **platform object** that is a **serializable object**\(^{98}\), then perform the appropriate **serialization steps**\(^{98}\) given value, `serialized`, and `forStorage`.

   The **serialization steps**\(^{98}\) may need to perform a **sub-serialization**. This is an operation which takes as input a value `subValue`, and returns \( \text{StructuredSerializeInternal} \)\(^{110}\)(`subValue`, `forStorage`, memory). (In other words, a **sub-serialization**\(^{110}\) is a specialization of \( \text{StructuredSerializeInternal} \)\(^{110}\) to be consistent within this invocation.)

4. Otherwise:
   1. **Let** `enumerableKeys` **be** a new empty **List**.
   2. **For each** key in `value`\([\text{OwnPropertyKeys]}\)()::
      1. If `Type(key)` is String, then:
         1. **Let** `valueDesc` be `value`\([\text{GetOwnProperty]}\)(key).
         2. If `valueDesc`.\([\text{Enumerable]}\) is true, then **append** key to `enumerableKeys`.
      3. **For each** key in `enumerableKeys`:
         1. If `HasOwnProperty`(`value`, key) is true, then:
            1. **Let** `inputValue` be `value`\([\text{Get]}\)(key, `value`).
            2. **Let** `outputValue` be \( \text{StructuredSerializeInternal} \)\(^{100}\)(`inputValue`, `forStorage`, memory).
            3. **Append** \{ [[Key]]: key, [[Value]]: `outputValue` \} **to** `serialized`\([\text{[Properties]}]\).

**Note**

The key collection performed above is very similar to the JavaScript specification's `EnumerableOwnProperty` operation, but crucially it uses the deterministic ordering provided by the `OwnPropertyKeys` internal method, instead of reordering the keys in an unspecified manner as `EnumerableOwnProperty` does. \([\text{JAVASCRIPT}}^{1124}\]

**Example**

It's important to realize that the **Records** produced by `StructuredSerializeInternal`\(^{110}\) might contain "pointers" to other records that create circular references. For example, when we pass the following JavaScript object into `StructuredSerializeInternal`\(^{110}\):

```javascript
const o = {};
o.myself = o;
```

it produces the following result:

```javascript
{
[[Type]]: "Object",
[[Properties]]: «
  {[[Key]]: "myself",
   [[Value]]: <a pointer to this whole structure>
  }
»
}
```
2.7.4 `StructuredSerialize ( value )`  
1. Return `StructuredSerializeInternal(value, false)`.

2.7.5 `StructuredSerializeForStorage ( value )`  
1. Return `StructuredSerializeInternal(value, true)`.

2.7.6 `StructuredDeserialize ( serialized, targetRealm [ , memory ] )`  

The `StructuredDeserialize` abstract operation takes as input a `Record` `serialized`, which was previously produced by `StructuredSerialize` or `StructuredSerializeForStorage`, and deserializes it into a new JavaScript value, created in `targetRealm`.

This process can throw an exception, for example when trying to allocate memory for the new objects (especially `ArrayBuffer` objects).

1. If `memory` was not supplied, let `memory` be an empty `map`.
   
   **Note:** The purpose of the memory map is to avoid deserializing objects twice. This ends up preserving cycles and the identity of duplicate objects in graphs.

2. If `memory[serialized]` exists, then return `memory[serialized]`.
3. Let `deep` be false.
4. Let `value` be an uninitialized value.
5. If `serialized.[Type]` is "primitive", then set `value` to `serialized.[Value]`.
6. Otherwise, if `serialized.[Type]` is "Boolean", then set `value` to a new Boolean object in `targetRealm` whose `[[BooleanData]]` internal slot value is `serialized.[BooleanData]`.
7. Otherwise, if `serialized.[Type]` is "Number", then set `value` to a new Number object in `targetRealm` whose `[[NumberData]]` internal slot value is `serialized.[NumberData]`.
8. Otherwise, if `serialized.[Type]` is "BigInt", then set `value` to a new BigInt object in `targetRealm` whose `[[BigIntData]]` internal slot value is `serialized.[BigIntData]`.
9. Otherwise, if `serialized.[Type]` is "String", then set `value` to a new String object in `targetRealm` whose `[[StringData]]` internal slot value is `serialized.[StringData]`.
10. Otherwise, if `serialized.[Type]` is "Date", then set `value` to a new Date object in `targetRealm` whose `[[DateValue]]` internal slot value is `serialized.[DateValue]`.
11. Otherwise, if `serialized.[Type]` is "RegExp", then set `value` to a new RegExp object in `targetRealm` whose `[[RegExpMatcher]]` internal slot value is `serialized.[RegExpMatcher]`, whose `[[OriginalSource]]` internal slot value is `serialized.[OriginalSource]`, and whose `[[OriginalFlags]]` internal slot value is `serialized.[OriginalFlags]`.
12. Otherwise, if `serialized.[Type]` is "SharedArrayBuffer", then:
    
    1. If `targetRealm`'s corresponding `agent cluster` is not `serialized.[AgentCluster]`, then throw a "DataCloneError" `DOMException`.
    2. Otherwise, set `value` to a new SharedArrayBuffer object in `targetRealm` whose `[[ArrayBufferData]]` internal slot value is `serialized.[ArrayBufferData]` and whose `[[ArrayBufferByteLength]]` internal slot value is `serialized.[ArrayBufferByteLength]`.
13. Otherwise, if `serialized.[Type]` is "ArrayBuffer", then set `value` to a new ArrayBuffer object in `targetRealm` whose `[[ArrayBufferData]]` internal slot value is `serialized.[ArrayBufferData]`, and whose `[[ArrayBufferByteLength]]` internal slot value is `serialized.[ArrayBufferByteLength]`.

If this throws an exception, catch it, and then throw a "DataCloneError" `DOMException`. 

104
14. Otherwise, if `serialized.[[Type]]` is "ArrayBufferView", then:
   1. Let `deserializedArrayBuffer` be `StructuredDeserialize(serialized.[[ArrayBufferSerialized]], targetRealm, memory).
   2. If `serialized.[[Constructor]]` is "DataView", then set `value` to a new DataView object in `targetRealm` whose `[[ViewedArrayBuffer]]` internal slot value is `deserializedArrayBuffer`, whose `[[ByteLength]]` internal slot value is `serialized.[[ByteLength]]`, and whose `[[ByteOffset]]` internal slot value is `serialized.[[ByteOffset]]`.
   3. Otherwise, set `value` to a new typed array object in `targetRealm`, using the constructor given by `serialized.[[Constructor]]`, whose `[[ViewedArrayBuffer]]` internal slot value is `deserializedArrayBuffer`, whose `[[TypedArrayName]]` internal slot value is `serialized.[[Constructor]]`, whose `[[ByteLength]]` internal slot value is `serialized.[[ByteLength]]`, whose `[[ByteOffset]]` internal slot value is `serialized.[[ByteOffset]]`, and whose `[[ArrayLength]]` internal slot value is `serialized.[[ArrayLength]]`.

15. Otherwise, if `serialized.[[Type]]` is "Map", then:
   1. Set `value` to a new Map object in `targetRealm` whose `[[MapData]]` internal slot value is a new empty `List`.
   2. Set `deep` to true.

16. Otherwise, if `serialized.[[Type]]` is "Set", then:
   1. Set `value` to a new Set object in `targetRealm` whose `[[SetData]]` internal slot value is a new empty `List`.
   2. Set `deep` to true.

17. Otherwise, if `serialized.[[Type]]` is "Array", then:
   1. Let `outputProto` be the `%ArrayPrototype%` intrinsic object in `targetRealm`.
   2. Set `value` to `ArrayCreate(serialized.[[Length]], outputProto)`.
   3. Set `deep` to true.

18. Otherwise, if `serialized.[[Type]]` is "Object", then:
   1. Set `value` to a new Object in `targetRealm`.
   2. Set `deep` to true.

19. Otherwise:
   1. Let `interfaceName` be `serialized.[[Type]]`.
   2. If the interface identified by `interfaceName` is not exposed in `targetRealm`, then throw a "DataCloneError" `DOMException`.
   3. Set `value` to a new instance of the interface identified by `interfaceName`, created in `targetRealm`.
   4. Set `deep` to true.

20. Set `memory[serialized]` to `value`.

21. If `deep` is true, then:
   1. If `serialized.[[Type]]` is "Map", then:
      1. For each `Record` { [[Key]], [[Value]] } entry of `serialized.[[MapData]]`:
         1. Let `deserializedKey` be `StructuredDeserialize(serialized.[[ArrayBufferSerialized]], targetRealm, memory)`.
         2. Let `deserializedValue` be `StructuredDeserialize(serialized.[[ArrayBufferSerialized]], targetRealm, memory)`.
         3. Append { [[Key]]: `deserializedKey`, [[Value]]: `deserializedValue` } to `value.[[MapData]]`.
   2. Otherwise, if `serialized.[[Type]]` is "Set", then:
      1. For each entry of `serialized.[[SetData]]`: 

---

Note: This step might throw an exception if there is not enough memory available to create such an `ArrayBuffer` object.
Let deserializedEntry be ? StructuredDeserialize\(^{p104}\)(entry, targetRealm, memory).

Append deserializedEntry to value.\([\text{SetData}]\).

3. Otherwise, if serialized.\([\text{Type}]\) is "Array" or "Object", then:
   1. For each Record \{ [[Key]], [[Value]] \} entry of serialized.\([\text{Properties}]\):
      1. Let deserializedValue be ? StructuredDeserialize\(^{p104}\)(entry.\([\text{Value}]\), targetRealm, memory).
      2. Let result be ! CreateDataProperty\(value\), entry.\([\text{Key}]\), deserializedValue).
      3. Assert: result is true.
   4. Otherwise:
      1. Perform the appropriate deserialization steps\(^{p99}\) for the interface identified by serialized.\([\text{Type}]\), given serialized and value.

The deserialization steps\(^{p99}\) may need to perform a sub-deserialization. This is an operation which takes as input a previously-serialized Record subSerialized, and returns StructuredDeserialize\(^{p104}\)(subSerialized, targetRealm, memory). (In other words, a sub-deserialization\(^{p106}\) is a specialization of StructuredDeserialize\(^{p104}\) to be consistent within this invocation.)

22. Return value.

2.7.7 StructuredSerializeWithTransfer ( value, transferList ) \(^{5p10}\)

1. Let memory be an empty map.

   In addition to how it is used normally by StructuredSerializeInternal\(^{p100}\), in this algorithm memory is also used to ensure that StructuredSerializeInternal\(^{p100}\) ignores items in transferList, and let us do our own handling instead.

2. For each transferable of transferList:
   1. If transferable has neither an [[ArrayBufferData]] internal slot nor a [[Detached]]\(^{p106}\) internal slot, then throw a "DataCloneError" DOMException.
   2. If transferable has an [[ArrayBufferData]] internal slot and ! IsSharedArrayBuffer\(\text{\(\text{transferable}\)}\) is true, then throw a "DataCloneError" DOMException.
   3. If memory[transferable] exists, then throw a "DataCloneError" DOMException.
   4. Set memory[transferable] to \{ [[Type]]: an uninitialized value \}.

   Note transferable is not transferred yet as transferring has side effects and StructuredSerializeInternal\(^{p100}\) needs to be able to throw first.

3. Let serialized be ? StructuredSerializeInternal\(^{p100}\)(value, false, memory).

4. Let transferDataHolders be a new empty List.

5. For each transferable of transferList:
   1. If transferable has an [[ArrayBufferData]] internal slot and ! IsDetachedBuffer\(\text{\(\text{transferable}\)}\) is true, then throw a "DataCloneError" DOMException.
   2. If transferable has a [[Detached]]\(^{p106}\) internal slot and transferable.\([\text{[Detached]]}\)\(^{p106}\) is true, then throw a "DataCloneError" DOMException.
   3. Let dataHolder be memory[transferable].
   4. If transferable has an [[ArrayBufferData]] internal slot, then:
1. Set `dataHolder.[[Type]]` to "ArrayBuffer".

2. Set `dataHolder.[[ArrayBufferData]]` to `transferable.[[ArrayBufferData]]`.

3. Set `dataHolder.[[ArrayBufferByteLength]]` to `transferable.[[ArrayBufferByteLength]]`.

4. Perform `! DetachArrayBuffer(transferable)`.

5. Otherwise:
   1. Assert: `transferable` is a platform object that is a transferable object

   2. Let `interfaceName` be the identifier of the primary interface of `transferable`.

   3. Set `dataHolder.[[Type]]` to `interfaceName`.

   4. Perform the appropriate transfer steps for the interface identified by `interfaceName`, given `transferable` and `dataHolder`.

   5. Set `transferable.[[Detached]]` to true.

6. Append `dataHolder` to `transferDataHolders`.

6. Return `{ [[Serialized]]: serialized, [[TransferDataHolders]]: transferDataHolders }`.

2.7.8 `StructuredDeserializeWithTransfer ( serializeWithTransferResult, targetRealm )` 

1. Let `memory` be an empty map.

   **Note**
   Analogous to `StructuredSerializeWithTransfer`, in addition to how it is used normally by `StructuredDeserialize`, in this algorithm `memory` is also used to ensure that `StructuredDeserialize` ignores items in `serializeWithTransferResult.[[TransferDataHolders]]`, and let us do our own handling instead.

2. Let `transferredValues` be a new empty List.

3. For each `transferDataHolder` of `serializeWithTransferResult.[[TransferDataHolders]]`:
   1. Let `value` be an uninitialized value.

   2. If `transferDataHolder.[[Type]]` is "ArrayBuffer", then set `value` to a new ArrayBuffer object in `targetRealm` whose `[[ArrayBufferData]]` internal slot value is `transferDataHolder.[[ArrayBufferData]]`, and whose `[[ArrayBufferByteLength]]` internal slot value is `transferDataHolder.[[ArrayBufferByteLength]]`.

   **Note**
   In cases where the original memory occupied by `[[ArrayBufferData]]` is accessible during the deserialization, this step is unlikely to throw an exception, as no new memory needs to be allocated: the memory occupied by `[[ArrayBufferData]]` is instead just getting transferred into the new ArrayBuffer. This could be true, for example, when both the source and target Realms are in the same process.

3. Otherwise:
   1. Let `interfaceName` be `transferDataHolder.[[Type]]`.

   2. If the interface identified by `interfaceName` is not exposed in `targetRealm`, then throw a "DataCloneError" DOMException.

   3. Set `value` to a new instance of the interface identified by `interfaceName`, created in `targetRealm`.

   4. Perform the appropriate transfer-receiving steps for the interface identified by `interfaceName` given `transferDataHolder` and `value`.

   5. Set `memory[transferDataHolder]` to `value`.

6. Append `value` to `transferredValues`.

107
4. Let deserialized be ?StructuredDeserialize\(^{104}\)(serializeWithTransferResult.[[Serialized]], targetRealm, memory).

5. Return \{ [[Deserialized]]: deserialized, [[TransferredValues]]: transferredValues \}.

### 2.7.9 Performing serialization and transferring from other specifications

Other specifications may use the abstract operations defined here. The following provides some guidance on when each abstract operation is typically useful, with examples.

**StructuredSerializeWithTransfer\(^{106}\)**

**StructuredDeserializeWithTransfer\(^{107}\)**

Cloning a value to another JavaScript Realm, with a transfer list, but where the target Realm is not known ahead of time. In this case the serialization step can be performed immediately, with the deserialization step delayed until the target Realm becomes known.

**Example**

```javascript
messagePort.postMessage() \(^{967}\) uses this pair of abstract operations, as the destination Realm is not known until the MessagePort \(^{965}\) has been shipped\(^{966}\).
```

**StructuredSerialize\(^{104}\)**

**StructuredSerializeForStorage\(^{104}\)**

**StructuredDeserialize\(^{104}\)**

Creating a JavaScript Realm-independent snapshot of a given value which can be saved for an indefinite amount of time, and then reified back into a JavaScript value later, possibly multiple times.

**StructuredSerializeForStorage\(^{104}\)** can be used for situations where the serialization is anticipated to be stored in a persistent manner, instead of passed between Realms. It throws when attempting to serialize `SharedArrayBuffer` objects, since storing shared memory does not make sense. Similarly, it can throw or possibly have different behavior when given a platform object with custom serialization steps\(^98\) when the forStorage argument is true.

**Example**

```javascript
history.pushState() \(^{813}\) and history.replaceState() \(^{813}\) use StructuredSerializeForStorage\(^{104}\) on author-supplied state objects, storing them as `serialized state`\(^{810}\) in the appropriate session history entry\(^{809}\). Then, StructuredDeserialize\(^{104}\) is used so that the `history.state`\(^{812}\) property can return a clone of the originally-supplied state object.
```

**Example**

```javascript
broadcastChannel.postMessage() \(^{969}\) uses StructuredSerialize\(^{104}\) on its input, then uses StructuredDeserialize\(^{104}\) multiple times on the result to produce a fresh clone for each destination being broadcast to. Note that transferring does not make sense in multi-destination situations.
```

**Example**

Any API for persisting JavaScript values to the filesystem would also use StructuredSerializeForStorage\(^{104}\) on its input and StructuredDeserialize\(^{104}\) on its output.

In general, call sites may pass in Web IDL values instead of JavaScript values; this is to be understood to perform an implicit conversion to the JavaScript value before invoking these algorithms.

**Note**

This specification used to define a "structured clone" algorithm, and more recently a StructuredClone abstract operation. However, in practice all known uses of it were better served by separate serialization and deserialization steps, so it was removed.

Call sites that are not invoked as a result of author code synchronously calling into a user agent method must take care to properly prepare to run script\(^{987}\) and prepare to run a callback\(^{981}\) before invoking StructuredSerialize\(^{104}\), StructuredSerializeForStorage\(^{104}\), or StructuredSerializeWithTransfer\(^{106}\) abstract operations, if they are being performed on arbitrary objects. This is necessary because the serialization process can invoke author-defined accessors as part of its final deep-serialization steps, and these accessors could call into operations that rely on the entry\(^{979}\) and incumbent\(^{979}\) concepts being properly set up.

**Example**

```javascript
window.postMessage() \(^{961}\) performs StructuredSerializeWithTransfer\(^{106}\) on its arguments, but is careful to do so immediately,
```
inside the synchronous portion of its algorithm. Thus it is able to use the algorithms without needing to prepare to run script and prepare to run a callback.

Example

In contrast, a hypothetical API that used StructuredSerialize to serialize some author-supplied object periodically, directly from a task on the event loop, would need to ensure it performs the appropriate preparations beforehand. As of this time, we know of no such APIs on the platform; usually it is simpler to perform the serialization ahead of time, as a synchronous consequence of author code.
3 Semantics, structure, and APIs of HTML documents

3.1 Documents

Every XML and HTML document in an HTML UA is represented by a `Document` object. [DOM]

The `Document` object’s URL is defined in the WHATWG DOM standard. It is initially set when the `Document` object is created, but can change during the lifetime of the `Document` object; for example, it changes when the user navigates to a fragment on the page and when the `pushState()` method is called with a new URL. [DOM]

⚠ Warning! Interactive user agents typically expose the `Document` object’s URL in their user interface. This is the primary mechanism by which a user can tell if a site is attempting to impersonate another.

When a `Document` is created by a script using the `createDocument()` or `createHTMLDocument()` the `Document` is both ready for post-load tasks and completely loaded immediately.

The document’s referrer is a string (representing a URL) that can be set when the `Document` is created. If it is not explicitly set, then its value is the empty string.

Each `Document` object has a reload override flag that is originally unset. The flag is set by the `document.open(type, replace)` and `document.write()` methods in certain situations. When the flag is set, the `Document` also has a reload override buffer which is a Unicode string that is used as the source of the document when it is reloaded.

When the user agent is to perform an overridden reload, given a source browsing context, it must act as follows:

1. Let source be the value of the browsing context's active document's reload override buffer.
2. Let address be the browsing context’s active document’s URL.
3. Let HTTPS state be the HTTPS state of the browsing context’s active document.
4. Let referrer policy be the referrer policy of the browsing context’s active document.
5. Let CSP list be the CSP list of the browsing context’s active document.
6. Navigate the browsing context to a new response whose body is source, header list is `"Referer-Policy"`/referrer policy, CSP list is CSP list and HTTPS state is HTTPS state, with the exceptions enabled set and replacement enabled. The source browsing context is that given to the overridden reload algorithm. When the navigate algorithm creates a `Document` object for this purpose, set that `Document`’s reload override flag and set its reload override buffer to source. Rethrow any exceptions.

When it comes time to set the document’s address in the navigation algorithm, use address as the override URL.

3.1.1 The `Document` object

The WHATWG DOM standard defines a `Document` interface, which this specification extends significantly.

```
enum DocumentReadyState { "loading", "interactive", "complete" };
typedef (HTMLScriptElement or SVGScriptElement) HTMLOrSVGScriptElement;

[OverrideBuiltins]
partial interface Document {  // resource metadata management
  [PutForwards=href, Unforgeable] readonly attribute Location? location;
  attribute USVString domain;
  readonly attribute USVString referrer;
  attribute USVString cookie;
```

```
```
The `Document` has an HTTPS state (an HTTPS state value), initially "none", which represents the security properties of the network channel used to deliver the `Document`'s data.

The `Document` has a referrer policy (a referrer policy), initially the empty string, which represents the default referrer policy used by fetches initiated by the `Document`.

The `Document` has a CSP list, which is a CSP list containing all of the Content Security Policy objects active for the document. The list is empty unless otherwise specified.

The `Document` has a feature policy, which is a feature policy, which is initially empty.

The `Document` has a module map, which is a module map, initially empty.
The referrer attribute must return the document’s referrer.

The referrer attribute must return the document’s referrer.

For web developers (non-normative)

document. referrer

Returns the URL of the Document from which the user navigated to this one, unless it was blocked or there was no such document, in which case it returns the empty string.

The noreferrer link type can be used to block the referrer.

For web developers (non-normative)

document. cookie [ = value ]

Returns the HTTP cookies that apply to the Document. If there are no cookies or cookies can’t be applied to this resource, the empty string will be returned.

Can be set, to add a new cookie to the element’s set of HTTP cookies.

If the contents are sandboxed into a unique origin (e.g. in an iframe with the sandbox attribute), a “SecurityError” DOMException will be thrown on getting and setting.

The cookie attribute represents the cookies of the resource identified by the document’s URL.

A Document object that falls into one of the following conditions is a cookie-averse Document object:

- A Document that has no browsing context.
- A Document whose URL’s scheme is not a network scheme.

On getting, if the document is a cookie-averse Document object, then the user agent must return the empty string. Otherwise, if the Document’s origin is an opaque origin, the user agent must throw a “SecurityError” DOMException. Otherwise, the user agent must return the cookie-string for the document’s URL for a “non-HTTP” API, decoded using UTF-8 decode without BOM.

On setting, if the document is a cookie-averse Document object, then the user agent must do nothing. Otherwise, if the Document’s origin is an opaque origin, the user agent must throw a “SecurityError” DOMException. Otherwise, the user agent must act as it would when receiving a set-cookie-string for the document’s URL via a “non-HTTP” API, consisting of the new value encoded as UTF-8.

Note

Since the cookie attribute is accessible across frames, the path restrictions on cookies are only a tool to help manage which cookies are sent to which parts of the site, and are not in any way a security feature.

⚠ Warning!

The cookie attribute’s getter and setter synchronously access shared state. Since there is no locking mechanism, other browsing contexts in a multiprocess user agent can modify cookies while scripts are running. A site could, for instance, try to read a cookie, increment its value, then write it back out, using the new value of the cookie as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same “unique” identifier for both sessions, with potentially disastrous effects.

For web developers (non-normative)

document. lastModified

Returns the date of the last modification to the document, as reported by the server, in the form "MM/DD/YYYY hh:mm:ss", in the user’s local time zone.

If the last modification date is not known, the current time is returned instead.

The lastModified attribute, on getting, must return the date and time of the document’s source file’s last modification, in the...
user's local time zone, in the following format:

1. The month component of the date.
2. A U+002F SOLIDUS character (/).
3. The day component of the date.
4. A U+002F SOLIDUS character (/).
5. The year component of the date.
6. A U+0020 SPACE character.
7. The hours component of the time.
8. A U+003A COLON character (:).
9. The minutes component of the time.
10. A U+003A COLON character (:).
11. The seconds component of the time.

All the numeric components above, other than the year, must be given as two ASCII digits representing the number in base ten, zero-padded if necessary. The year must be given as the shortest possible string of four or more ASCII digits representing the number in base ten, zero-padded if necessary.

The Document source file's last modification date and time must be derived from relevant features of the networking protocols used, e.g. from the value of the HTTP `Last-Modified` header of the document, or from metadata in the file system for local files. If the last modification date and time are not known, the attribute must return the current date and time in the above format.

---

For web developers (non-normative)

```javascript
document.readyState
```

Returns "loading" while the Document is loading, "interactive" once it is finished parsing but still loading subresources, and "complete" once it has loaded.

The `readystatechange` event fires on the Document object when this value changes.

The `DOMContentLoaded` event fires after the transition to "interactive" but before the transition to "complete", at the point where all subresources apart from async script elements have loaded.

Each document has a current document readiness. When a Document object is created, it must have its current document readiness set to the string "loading" if the document is associated with an HTML parser, an XML parser, or an XSLT processor, and to the string "complete" otherwise. Various algorithms during page loading affect this value. When the value is set, the user agent must fire an event named `readystatechange` at the Document object.

A Document is said to have an active parser if it is associated with an HTML parser, or an XML parser, that has not yet been stopped or aborted.

The `readyState` IDL attribute must, on getting, return the current document readiness.

---

3.1.3 DOM tree accessors

The `html` element of a document is its `document element`, if it's an `html` element, and null otherwise.

---

For web developers (non-normative)

```javascript
document.head
```

Returns the head element.
The **head element** of a document is the first head element that is a child of the html element, if there is one, or null otherwise.

The **head** attribute, on getting, must return the head element of the document (a head element or null).

For web developers (non-normative)

`document . title` [ = value ]

Returns the document's title, as given by the title element for HTML and as given by the SVG title element for SVG. Can be set, to update the document's title. If there is no appropriate element to update, the new value is ignored.

The **title element** of a document is the first title element in the document (in tree order), if there is one, or null otherwise.

The title attribute must, on getting, run the following algorithm:

1. If the document element is an SVG svg element, then let value be the child text content of the first SVG title element that is a child of the document element.
2. Otherwise, let value be the child text content of the title element, or the empty string if the title element is null.
3. Strip and collapse ASCII whitespace in value.
4. Return value.

On setting, the steps corresponding to the first matching condition in the following list must be run:

↪ If the document element is an SVG svg element

1. If there is an SVG title element that is a child of the document element, let element be the first such element.
2. Otherwise:
   1. Let element be the result of creating an element given the document element's node document, title, and the SVG namespace.
   2. Insert element as the first child of the document element.
3. Act as if the textContent IDL attribute of element was set to the new value being assigned.

↪ If the document element is in the HTML namespace

1. If the title element is null and the head element is null, then return.
2. If the title element is non-null, let element be the title element.
3. Otherwise:
   1. Let element be the result of creating an element given the document element's node document, title, and the HTML namespace.
   2. Append element to the head element.
4. Act as if the textContent IDL attribute of element was set to the new value being assigned.

↪ Otherwise

Do nothing.

For web developers (non-normative)

`document . body` [ = value ]

Returns the body element.

Can be set, to replace the body element.

If the new value is not a body or frameset element, this will throw a "HierarchyRequestError" DOMException.
The body element of a document is the first of \html_element\’s children that is either a \body\ element or a frameset element, or null if there is no such element.

The body attribute, on getting, must return the body element of the document (either a \body\ element, a frameset element, or null). On setting, the following algorithm must be run:

1. If the new value is not a \body\ or frameset element, then throw a "HierarchyRequestError" DOMException.
2. Otherwise, if the new value is the same as the body element, return.
3. Otherwise, if the body element is not null, then replace the body element with the new value within the body element’s parent and return.
4. Otherwise, if there is no document element, throw a "HierarchyRequestError" DOMException.
5. Otherwise, the body element is null, but there’s a document element. Append the new value to the document element.

The images attribute must return an HTMLCollection rooted at the Document node, whose filter matches only img elements.

The embeds attribute must return an HTMLCollection rooted at the Document node, whose filter matches only embed elements.

The plugins attribute must return the same object as that returned by the embeds attribute.

The links attribute must return an HTMLCollection of the a and area elements with href attributes.

The forms attribute must return an HTMLCollection of the form elements.

For web developers (non-normative)

example

In this example, the setter successfully inserts a body element (though this is non-conforming since SVG does not allow a body as child of SVG). However the getter will return null because the document element is not html.

Note

The value returned by the body getter is not always the one passed to the setter.
The `scripts` attribute must return an `HTMLCollection` rooted at the `Document` node, whose filter matches only `script` elements.

For web developers (non-normative)

\[
\text{collection} = \text{document}\cdot\text{getElementsByTagName}(\text{name})
\]

Returns a `NodeList` of elements in the `Document` that have a `name` attribute with the value `name`.

The `getElementsByTagName(name)` method takes a string `name`, and must return a `live` `NodeList` containing all the `HTML elements` in that document that have a `name` attribute whose value is equal to the `name` argument (in a `case-sensitive` manner), in `tree order`. When the method is invoked on a `Document` object again with the same argument, the user agent may return the same as the object returned by the earlier call. In other cases, a new `NodeList` object must be returned.

For web developers (non-normative)

\[
\text{document}\cdot\text{currentScript}
\]

Returns the `script` element, or the `SVG script` element, that is currently executing, as long as the element represents a `classic script`. In the case of reentrant script execution, returns the one that most recently started executing amongst those that have not yet finished executing.

Returns null if the `Document` is not currently executing a `script` or `SVG script` element (e.g., because the running script is an event handler, or a timeout), or if the currently executing `script` or `SVG script` element represents a `module script`.

The `currentScript` attribute, on getting, must return the value to which it was most recently set. When the `Document` is created, the `currentScript` must be initialized to null.

Note

This API has fallen out of favor in the implementer and standards community, as it globally exposes `script` or `SVG script` elements. As such, it is not available in newer contexts, such as when running `module scripts` or when running scripts in a `shadow tree`. We are looking into creating a new solution for identifying the running script in such contexts, which does not make it globally available: see issue #1013.

The `Document` interface supports named properties. The supported property names of a `Document` object `document` at any moment consist of the following, in `tree order` according to the element that contributed them, ignoring later duplicates, and with values from `id` attributes coming before values from `name` attributes when the same element contributes both:

- the value of the `name` content attribute for all `exposed embed`, `form`, `iframe`, `img`, and `exposed` `object` elements that have a non-empty `name` content attribute and are in a document tree with `document` as their root;
- the value of the `id` content attribute for all `exposed`, `object` elements that have a non-empty `id` content attribute and are in a document tree with `document` as their root; and
- the value of the `id` content attribute for all `img` elements that have both a non-empty `id` content attribute and a non-empty `name` content attribute, and are in a document tree with `document` as their root.

To determine the value of a named property `name` for a `Document`, the user agent must return the value obtained using the following steps:

1. Let `elements` be the list of `named elements` with the name `name` that are in a document tree with the `Document` as their root.

   Note

   There will be at least one such element, by definition.

2. If `elements` has only one element, and that element is an `iframe` element, and that `iframe` element's `nested browsing context` is not null, then return the `WindowProxy` object of the element's `nested browsing context`.

3. Otherwise, if `elements` has only one element, return that element.
4. Otherwise return an HTMLCollection rooted at the Document node, whose filter matches only named elements with the name name.

Named elements with the name name, for the purposes of the above algorithm, are those that are either:

- Exposed embed, form, iframe, img, or exposed object elements that have a name content attribute whose value is name, or
- Exposed object elements that have an id content attribute whose value is name, or
- img elements that have an id content attribute whose value is name, and that have a non-empty name content attribute present also.

An embed or object element is said to be exposed if it has no exposed object ancestor, and, for object elements, is additionally either not showing its fallback content or has no object or embed descendants.

Note
The dir attribute on the Document interface is defined along with the dir content attribute.

3.2 Elements

3.2.1 Semantics

Elements, attributes, and attribute values in HTML are defined (by this specification) to have certain meanings (semantics). For example, the ol element represents an ordered list, and the lang attribute represents the language of the content.

These definitions allow HTML processors, such as Web browsers or search engines, to present and use documents and applications in a wide variety of contexts that the author might not have considered.

Example

As a simple example, consider a Web page written by an author who only considered desktop computer Web browsers:

```html
<!DOCTYPE HTML>
<html lang="en">
  <head>
    <title>My Page</title>
  </head>
  <body>
    <h1>Welcome to my page</h1>
    <p>I like cars and lorries and have a big Jeep!</p>
    <h2>Where I live</h2>
    <p>I live in a small hut on a mountain!</p>
  </body>
</html>
```

Because HTML conveys meaning, rather than presentation, the same page can also be used by a small browser on a mobile phone, without any change to the page. Instead of headings being in large letters as on the desktop, for example, the browser on the mobile phone might use the same size text for the whole page, but with the headings in bold.

But it goes further than just differences in screen size: the same page could equally be used by a blind user using a browser based around speech synthesis, which instead of displaying the page on a screen, reads the page to the user, e.g. using headphones. Instead of large text for the headings, the speech browser might use a different volume or a slower voice.

That's not all, either. Since the browsers know which parts of the page are the headings, they can create a document outline that the user can use to quickly navigate around the document, using keys for "jump to next heading" or "jump to previous heading". Such features are especially common with speech browsers, where users would otherwise find quickly navigating a page quite difficult.
Even beyond browsers, software can make use of this information. Search engines can use the headings to more effectively index a page, or to provide quick links to subsections of the page from their results. Tools can use the headings to create a table of contents (that is in fact how this very specification's table of contents is generated).

This example has focused on headings, but the same principle applies to all of the semantics in HTML.

Authors must not use elements, attributes, or attribute values for purposes other than their appropriate intended semantic purpose, as doing so prevents software from correctly processing the page.

For example, the following snippet, intended to represent the heading of a corporate site, is non-conforming because the second line is not intended to be a heading of a subsection, but merely a subheading or subtitle (a subordinate heading for the same section).

```html
<body>
<h1>ACME Corporation</h1>
<h2>The leaders in arbitrary fast delivery since 1920</h2>
...
</body>
```

The `hgroup` element is intended for these kinds of situations:

```html
<body>
<hgroup>
<h1>ACME Corporation</h1>
<h2>The leaders in arbitrary fast delivery since 1920</h2>
</hgroup>
...
</body>
```

The document in this next example is similarly non-conforming, despite being syntactically correct, because the data placed in the cells is clearly not tabular data, and the `cite` element mis-used:

```html
<!DOCTYPE HTML>
<html lang="en-GB">
<head> <title> Demonstration </title> </head>
<body>
<table>
<tr> <td> My favourite animal is the cat. </td> </tr>
<tr> <td> --<a href="https://example.org/~ernest/">Ernest</a>, in an essay from 1992 </td> </tr>
</table>
</body>
</html>
```

This would make software that relies on these semantics fail: for example, a speech browser that allowed a blind user to navigate tables in the document would report the quote above as a table, confusing the user; similarly, a tool that extracted titles of works from pages would extract “Ernest” as the title of a work, even though it’s actually a person’s name, not a title.

A corrected version of this document might be:

```html
<!DOCTYPE HTML>
```
Authors must not use elements, attributes, or attribute values that are not permitted by this specification or other applicable specifications, as doing so makes it significantly harder for the language to be extended in the future.

Examples

In the next example, there is a non-conforming attribute value (“carpet”) and a non-conforming attribute (“texture”), which is not permitted by this specification:

```html
<label>Carpet: <input type="carpet" name="c" texture="deep pile"></label>
```

Here would be an alternative and correct way to mark this up:

```html
<label>Carpet: <input type="text" class="carpet" name="c" data-texture="deep pile"></label>
```

DOM nodes whose node document does not have a browsing context are exempt from all document conformance requirements other than the HTML syntax requirements and XML syntax requirements.

Examples

In particular, the template element's template contents node document does not have a browsing context. For example, the content model's requirements and attribute value microsyntax requirements do not apply to a template element's template contents. In this example an img element has attribute values that are placeholders that would be invalid outside a template element.

```html
<template>
  <article>
    <img src="{{src}}" alt="{{alt}}">
    <h1></h1>
  </article>
</template>
```

However, if the above markup were to omit the end tag, that would be a violation of the HTML syntax, and would thus be flagged as an error by conformance checkers.

Through scripting and using other mechanisms, the values of attributes, text, and indeed the entire structure of the document may change dynamically while a user agent is processing it. The semantics of a document at an instant in time are those represented by the state of the document at that instant in time, and the semantics of a document can therefore change over time. User agents must update their presentation of the document as this occurs.

Examples

HTML has a progress element that describes a progress bar. If its "value" attribute is dynamically updated by a script, the UA would update the rendering to show the progress changing.
The nodes representing HTML elements in the DOM must implement, and expose to scripts, the interfaces listed for them in the relevant sections of this specification. This includes HTML elements in XML documents, even when those documents are in another context (e.g. inside an XSLT transform).

Elements in the DOM represent things; that is, they have intrinsic meaning, also known as semantics.

For example, an ol element represents an ordered list.

Elements can be referenced (referred to) in some way, either explicitly or implicitly. One way that an element in the DOM can be explicitly referenced is by giving an id attribute to the element, and then creating a hyperlink with that id attribute's value as the fragment for the hyperlink's href attribute value. Hyperlinks are not necessary for a reference, however; any manner of referring to the element in question will suffice.

Consider the following figure element, which is given an id attribute:

```html
<figure id="module-script-graph">
  <img src="module-script-graph.svg" alt="Module A depends on module B, which depends on modules C and D.">
  <figcaption>Figure 27: a simple module graph</figcaption>
</figure>
```

A hyperlink-based reference could be created using the a element, like so:

```html
As we can see in <a href="#module-script-graph">figure 27</a>, ...
```

However, there are many other ways of referencing the figure element, such as:

- "As depicted in the figure of modules A, B, C, and D..."
- "In Figure 27..." (without a hyperlink)
- "From the contents of the 'simple module graph' figure..."
- "In the figure below..." (but this is discouraged)

The basic interface, from which all the HTML elements interfaces inherit, and which must be used by elements that have no additional requirements, is the HTMLElement interface.

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLElement : Element {
  // metadata attributes
  [CEReactions] attribute DOMString title;
  [CEReactions] attribute DOMString lang;
  [CEReactions] attribute boolean translate;
  [CEReactions] attribute DOMString dir;

  // user interaction
  [CEReactions] attribute boolean hidden;
  void click();
  [CEReactions] attribute DOMString accessKey;
  readonly attribute DOMString accessKeyLabel;
  [CEReactions] attribute boolean draggable;
  [CEReactions] attribute boolean spellcheck;
  [CEReactions] attribute DOMString autocapitalize;
}
```
The `HTMLUnknownElement` interface holds methods and attributes related to a number of disparate features, and the members of this interface are therefore described in various different sections of this specification.

The `element interface` for an element with name `name` in the `HTML namespace` is determined as follows:

1. If `name` is `applet`, `bgsound`, `blink`, `isindex`, `keygen`, `multicol`, `nextid`, or `spacer`, then return `HTMLUnknownElement`.
2. If `name` is `acronym`, `basefont`, `big`, `center`, `nobr`, `noembed`, `noframes`, `plaintext`, `rb`, `rtc`, `strike`, or `tt`, then return `HTMLElement`.
3. If `name` is `listing` or `xmp`, then return `HTMLPreElement`.
4. Otherwise, if this specification defines an interface appropriate for the `element type` corresponding to the local name `name`, then return that interface.
5. If other applicable specifications define an appropriate interface for `name`, then return the interface they define.
6. If `name` is a `valid custom element name`, then return `HTMLElement`.
7. Return `HTMLUnknownElement`.

Features shared between HTML and SVG elements use the `HTMLOrSVGElemet` interface mixin:

```idl
interface mixin HTMLOrSVGElemet {
    [SameObject] readonly attribute DOMStringMap dataset;
    attribute DOMString nonce; // intentionally no [CEReactions]

    [CEReactions] attribute long tabindex;
    void focus(optional FocusOptions options);
    void blur();
};
```

### 3.2.3 HTML element constructors

To support the `custom elements` feature, all HTML elements have special constructor behavior. This is indicated via the `[HTMLConstructor]` IDL `extended attribute`. It indicates that the interface object for the given interface will have a specific behavior when called, as defined in detail below.

The `[HTMLConstructor]` `extended attribute` must take no arguments, and must not appear on anything other than an interface. It must appear only once on an interface, and the interface must not be annotated with the `[Constructor]` or `[NoInterfaceObject]` `extended attributes`. (However, the interface may be annotated with `[NamedConstructor]; there is no conflict there.) It must not be
used on a callback interface.

**Interface objects** for interfaces annotated with the **[HTMLConstructor]** extended attribute must run the following steps as the function body behavior for both [[Call]] and [[Construct]] invocations of the corresponding JavaScript function object. When invoked with [[Call]], the NewTarget value is undefined, and so the algorithm below will immediately throw. When invoked with [[Construct]], the [[Construct]] `newTarget` parameter provides the NewTarget value.

1. Let `registry` be the current global object's `CustomElementRegistry` object.

2. If NewTarget is equal to the active function object, then throw a `TypeError`.

Example

This can occur when a custom element is defined using an element interface as its constructor:

```javascript
customElements.define("bad-1", HTMLButtonElement);
new HTMLButtonElement(); // (1)
document.createElement("bad-1"); // (2)
```

In this case, during the execution of `HTMLButtonElement` (either explicitly, as in (1), or implicitly, as in (2)), both the active function object and NewTarget are `HTMLButtonElement`. If this check was not present, it would be possible to create an instance of `HTMLButtonElement` whose local name was `bad-1`.

3. Let `definition` be the entry in `registry` with `constructor` equal to NewTarget. If there is no such definition, then throw a `TypeError`.

Note

*Since there can be no entry in registry with a `constructor` of undefined, this step also prevents HTML element constructors from being called as functions (since in that case NewTarget will be undefined).*

4. Let `is value` be null.

5. If `definition’s local name` is equal to `definition’s name` (i.e., `definition` is for an autonomous custom element), then:

   1. If the active function object is not `HTMLElement`, then throw a `TypeError`.

Example

This can occur when a custom element is defined to not extend any local names, but inherits from a non-`HTMLElement` class:

```javascript
customElements.define("bad-2", class Bad2 extends HTMLParagraphElement {});
```

In this case, during the (implicit) `super()` call that occurs when constructing an instance of `Bad2`, the active function object is `HTMLParagraphElement`, not `HTMLElement`.

6. Otherwise (i.e., if `definition` is for a customized built-in element):

   1. Let `valid local names` be the list of local names for elements defined in this specification or in other applicable specifications that use the active function object as their element interface.

Example

This can occur when a custom element is defined to extend a given local name but inherits from the wrong class:

```javascript
customElements.define("bad-3", class Bad3 extends HTMLQuoteElement {}, { extends: "p" });
```
In this case, during the (implicit) super() call that occurs when constructing an instance of Bad3, valid local names is the list containing q and blockquote, but definition's local name is p, which is not in that list.

3. Set is value to definition's name.

7. Let prototype be Get(NewTarget, "prototype"). Rethrow any exceptions.

8. If Type(prototype) is not Object, then:
   1. Let realm be GetFunctionRealm(NewTarget).
   2. Set prototype to the interface prototype object of realm whose interface is the same as the interface of the active function object.

Note
The realm of the active function object might not be realm, so we are using the more general concept of "the same interface" across realms; we are not looking for equality of interface objects. This fallback behavior, including using the realm of NewTarget and looking up the appropriate prototype there, is designed to match analogous behavior for the JavaScript built-ins.

9. If definition's construction stack is empty, then:
   1. Let element be a new element that implements the interface to which the active function object corresponds, with no attributes, namespace set to the HTML namespace, local name set to definition's local name, and node document set to the current global object's associated Document.
   3. Set element's custom element state to "custom".
   4. Set element's custom element definition to definition.
   5. Set element's is value to is value.
   6. Return element.

Note
This occurs when author script constructs a new custom element directly, e.g. via new MyCustomElement().

10. Let element be the last entry in definition's construction stack.

11. If element is an already constructed marker, then throw an "InvalidStateError" DOMException.

Example
This can occur when the author code inside the custom element constructor, non-conformantly, creates another instance of the class being constructed, before calling super():

```javascript
let doSillyThing = false;

class DontDoThis extends HTMLElement {
  constructor() {
    if (doSillyThing) {
      doSillyThing = false;
      new DontDoThis();
      // Now the construction stack will contain an already constructed marker.
    }
  }
  // This will then fail with an "InvalidStateError" DOMException:
  super();
}
```

13. Replace the last entry in `definition`'s `construction stack` with an `already constructed marker`.

**Note**

This step is normally reached when upgrading a custom element; the existing element is returned, so that the `super()` call inside the custom element constructor assigns that existing element to `this`.

In addition to the constructor behavior implied by `[HTMLConstructor]`, some elements also have named constructors (which are really factory functions with a modified `prototype` property).

**Example**

Named constructors for HTML elements can also be used in an `extends` clause when defining a custom element constructor:

```javascript
class AutoEmbiggenedImage extends Image {
  constructor(width, height) {
    super(width * 10, height * 10);
  }
}
customElements.define("auto-embiggened", AutoEmbiggenedImage, { extends: "img" });
const image = new AutoEmbiggenedImage(15, 20);
console.assert(image.width === 150);
console.assert(image.height === 200);
```

### 3.2.4 Element definitions

Each element in this specification has a definition that includes the following information:

**Categories**

A list of `categories` to which the element belongs. These are used when defining the `content models` for each element.
**Contexts in which this element can be used**

A non-normative description of where the element can be used. This information is redundant with the content models of elements that allow this one as a child, and is provided only as a convenience.

**Note**

For simplicity, only the most specific expectations are listed. For example, an element that is both flow content and phrasing content can be used anywhere that either flow content or phrasing content is expected, but since anywhere that flow content is expected, phrasing content is also expected (since all phrasing content is flow content), only "where phrasing content is expected" will be listed.

**Content model**

A normative description of what content must be included as children and descendants of the element.

**Tag omission in text/html**

A non-normative description of whether, in the text/html syntax, the start and end tags can be omitted. This information is redundant with the normative requirements given in the optional tags section, and is provided in the element definitions only as a convenience.

**Content attributes**

A normative list of attributes that may be specified on the element (except where otherwise disallowed), along with non-normative descriptions of those attributes. (The content to the left of the dash is normative, the content to the right of the dash is not.)

**DOM interface**

A normative definition of a DOM interface that such elements must implement.

This is then followed by a description of what the element represents, along with any additional normative conformance criteria that may apply to authors and implementations. Examples are sometimes also included.

### 3.2.4.1 Attributes

An attribute value is a string. Except where otherwise specified, attribute values on HTML elements may be any string value, including the empty string, and there is no restriction on what text can be specified in such attribute values.

### 3.2.5 Content models

Each element defined in this specification has a content model: a description of the element's expected contents. An HTML element must have contents that match the requirements described in the element's content model. The contents of an element are its children in the DOM.

ASCII whitespace is always allowed between elements. User agents represent these characters between elements in the source markup as Text nodes in the DOM. Empty Text nodes and Text nodes consisting of just sequences of those characters are considered inter-element whitespace.

Inter-element whitespace, comment nodes, and processing instruction nodes must be ignored when establishing whether an element's contents match the element's content model or not, and must be ignored when following algorithms that define document and element semantics.

**Note**

Thus, an element A is said to be preceded or followed by a second element B if A and B have the same parent node and there are no other element nodes or Text nodes (other than inter-element whitespace) between them. Similarly, a node is the only child of an element if that element contains no other nodes other than inter-element whitespace, comment nodes, and processing instruction nodes.

Authors must not use HTML elements anywhere except where they are explicitly allowed, as defined for each element, or as explicitly required by other specifications. For XML compound documents, these contexts could be inside elements from other namespaces, if those elements are defined as providing the relevant contexts.

**Example**
For example, the Atom specification defines a content element. When its type attribute has the value xhtml, the Atom specification requires that it contain a single HTML div element. Thus, a div element is allowed in that context, even though this is not explicitly normatively stated by this specification. [ATOM]

In addition, HTML elements may be orphan nodes (i.e. without a parent node).

Example

For example, creating a td element and storing it in a global variable in a script is conforming, even though td elements are otherwise only supposed to be used inside tr elements.

```javascript
var data = {
    name: "Banana",
    cell: document.createElement('td'),
};
```

3.2.5.1 The "nothing" content model

When an element’s content model is nothing, the element must contain no Text nodes (other than inter-element whitespace) and no element nodes.

Note

Most HTML elements whose content model is "nothing" are also, for convenience, void elements (elements that have no end tag in the HTML syntax). However, these are entirely separate concepts.

3.2.5.2 Kinds of content

Each element in HTML falls into zero or more categories that group elements with similar characteristics together. The following broad categories are used in this specification:

- Metadata content
- Flow content
- Sectioning content
- Heading content
- Phrasing content
- Embedded content
- Interactive content

Note

Some elements also fall into other categories, which are defined in other parts of this specification.

These categories are related as follows:
Sectioning content, heading content, phrasing content, embedded content, and interactive content are all types of flow content. Metadata is sometimes flow content. Metadata and interactive content are sometimes phrasing content. Embedded content is also a type of phrasing content, and sometimes is interactive content.

Other categories are also used for specific purposes, e.g. form controls are specified using a number of categories to define common requirements. Some elements have unique requirements and do not fit into any particular category.

### 3.2.5.2.1 Metadata content

**Metadata content** is content that sets up the presentation or behavior of the rest of the content, or that sets up the relationship of the document with other documents, or that conveys other "out of band" information.

- base
- link
- meta
- noscript
- script
- style
- template
- title

Elements from other namespaces whose semantics are primarily metadata-related (e.g. RDF) are also metadata content.

---

Thus, in the XML serialization, one can use RDF, like this:

```xml
<html xmlns="http://www.w3.org/1999/xhtml"
     xmlns:r="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
     xml:lang="en">
  <head>
    <title>Hedral's Home Page</title>
    <r:RDF>
      <Person xmlns="http://www.w3.org/2000/10/swap/pim/contact#"
               r:about="https://hedral.example.com/#">
        <fullName>Cat Hedral</fullName>
        <mailbox r:resource="mailto:hedral@damowmow.com"/>
        <personalTitle>Sir</personalTitle>
      </Person>
    </r:RDF>
  </head>
  <body>
    <h1>My home page</h1>
    <p>I like playing with string, I guess. Sister says squirrels are fun too so sometimes I follow her to play with them.</p>
  </body>
</html>
```

This isn't possible in the HTML serialization, however.
3.2.5.2.2 Flow content

Most elements that are used in the body of documents and applications are categorized as flow content.

```plaintext
<area> <abbr> <address> <article> <audio> <b> <bdi> <bdo> <br> <button> <canvas> <cite> <code> <data> <datalist> <details> <dfn> <dialog> <div> <dl> <dt> <em> <embed> <fieldset> <figure> <footer> <form> <h1> <h2> <h3> <h4> <h5> <h6> <header> <hr> <html> <i> <iframe> <iframe> <input> <ins> <kbd> <label> <legend> <li> <link> <main> <map> <mark> <meta> <meter> <nav> <object> <ol> <p> <pre> <progress> <q> <rb> <r> <ruby> <s> <samp> <script> <select> <small> <source> <span> <strong> <style> <sub> <summary> <sup> <table> <tbody> <td> <template> <textarea> <tfoot> <th> <thead> <time> <tt> <u> <ul> <var> <video> <wbr> <picture> <ruby> <ruby> <ruby> <ruby> <ruby>
```

3.2.5.2.3 Sectioning content

Sectioning content is content that defines the scope of headings and footers. Each sectioning content element potentially has a heading and an outline. See the section on headings and sections for further details.

**Note**

There are also certain elements that are sectioning roots. These are distinct from sectioning content, but they can also have an outline.

3.2.5.2.4 Heading content

Heading content defines the header of a section (whether explicitly marked up using sectioning content elements, or implied by the heading content itself).

```plaintext
<h1> <h2> <h3> <h4> <h5> <h6> <header> <hr> <html> `<i> <iframe> <iframe> <input> <ins> <kbd> <label> <legend> <li> <link> <main> <map> <mark> <meta> <meter> <nav> <object> <ol> <p> <pre> <progress> <q> <rb> <r> <ruby> <s> <samp> <script> <select> <small> <source> <span> <strong> <style> <sub> <summary> <sup> <table> <tbody> <td> <template> <textarea> <tfoot> <th> <thead> <time> <tt> <u> <ul> <var> <video> <wbr> <picture> <ruby> <ruby> <ruby> <ruby> <ruby>```

3.2.5.2.5 Phrasing content

Phrasing content is the text of the document, as well as elements that mark up that text at the intra-paragraph level. Runs of phrasing content form paragraphs.

```plaintext
<area> <abbr> <address> <article> <audio> <b> <bdi> <bdo> <br> <button> <canvas> <cite> <code> <data> <datalist> <details> <dfn> <dialog> <div> <dl> <dt> <em> <embed> <fieldset> <figure> <footer> <form> <h1> <h2> <h3> <h4> <h5> <h6> <header> <hr> <html> `<i> <iframe> <iframe> <input> <ins> <kbd> <label> <legend> <li> <link> <main> <map> <mark> <meta> <meter> <nav> <object> <ol> <p> <pre> <progress> <q> <rb> <r> <ruby> <s> <samp> <script> <select> <small> <source> <span> <strong> <style> <sub> <summary> <sup> <table> <tbody> <td> <template> <textarea> <tfoot> <th> <thead> <time> <tt> <u> <ul> <var> <video> <wbr> <picture> <ruby> <ruby> <ruby> <ruby> <ruby>```

**Note**

Most elements that are categorized as phrasing content can only contain elements that are themselves categorized as phrasing content, not any flow content.

Text, in the context of content models, means either nothing, or Text nodes. Text is sometimes used as a content model on its own, but is also phrasing content, and can be inter-element whitespace, if the Text nodes are empty or contain just ASCII whitespace.

Text nodes and attribute values must consist of scalar values, excluding noncharacters, and controls other than ASCII whitespace. This specification includes extra constraints on the exact value of Text nodes and attribute values depending on their precise context.
3.2.5.6 Embedded content

**Embedded content** is content that imports another resource into the document, or content from another vocabulary that is inserted into the document.

\[\text{audio}^{368}, \text{canvas}^{614}, \text{embed}^{354}, \text{iframe}^{347}, \text{img}^{357}, \text{MathML math}, \text{object}^{350}, \text{picture}^{303}, \text{SVG svg}, \text{video}^{365}\]

Elements that are from namespaces other than the [HTML namespace](https://www.w3.org/html) and that convey content but not metadata, are **embedded content** for the purposes of the content models defined in this specification. (For example, MathML, or SVG.)

Some embedded content elements can have **fallback content**: content that is to be used when the external resource cannot be used (e.g. because it is of an unsupported format). The element definitions state what the fallback is, if any.

3.2.5.7 Interactive content

**Interactive content** is content that is specifically intended for user interaction.

\[\text{a}^{328} \text{(if the href}^{327} \text{attribute is present), audio}^{368} \text{(if the controls}^{342} \text{attribute is present), button}^{318}, \text{details}^{584}, \text{embed}^{354}, \text{iframe}^{347}, \text{img}^{357} \text{(if the usemap}^{340} \text{attribute is present), input}^{475} \text{(if the type}^{474} \text{attribute is not in the Hidden state), label}^{474}, \text{object}^{358} \text{(if the usemap}^{340} \text{attribute is present), select}^{520}, \text{textarea}^{356}, \text{video}^{365} \text{(if the controls}^{342} \text{attribute is present)}\]

The `tabindex` attribute can also make any element into **interactive content**.

3.2.5.8 Palpable content

As a general rule, elements whose content model allows any **flow content** or **phrasing content** should have at least one node in its **contents** that is **palpable content** and that does not have the `hidden` attribute specified.

**Note**

Palpable content makes an element non-empty by providing either some descendant non-empty text, or else something users can hear (audio elements) or view (video elements) or otherwise interact with (for example, interactive form controls).

This requirement is not a hard requirement, however, as there are many cases where an element can be empty legitimately, for example when it is used as a placeholder which will later be filled in by a script, or when the element is part of a template and would on most pages be filled in but on some pages is not relevant.

Conformance checkers are encouraged to provide a mechanism for authors to find elements that fail to fulfill this requirement, as an authoring aid.

The following elements are palpable content:

\[\text{a}^{328}, \text{abbr}^{204}, \text{address}^{206}, \text{article}^{217}, \text{aside}^{201}, \text{audio}^{368} \text{(if the controls}^{342} \text{attribute is present), b}^{328}, \text{bd}^{269}, \text{bdo}^{269}, \text{blockquote}^{210}, \text{button}^{518}, \text{canvas}^{614}, \text{cite}^{237}, \text{code}^{258}, \text{data}^{259}, \text{details}^{584}, \text{dfn}^{248}, \text{div}^{229}, \text{dl}^{218} \text{(if the element's children include at least one name-value group), em}^{233}, \text{embed}^{354}, \text{fieldset}^{544}, \text{figure}^{224}, \text{footer}^{188}, \text{form}^{479}, \text{h1}^{218}, \text{h2}^{218}, \text{h3}^{218}, \text{h4}^{218}, \text{h5}^{218}, \text{h6}^{218}, \text{header}^{218}, \text{hr}^{218}, \text{i}^{263}, \text{iframe}^{347}, \text{img}^{357}, \text{input}^{475} \text{(if the type}^{478} \text{attribute is not in the Hidden state), ins}^{208}, \text{kbd}^{203}, \text{label}^{234}, \text{main}^{228}, \text{map}^{226}, \text{mark}^{226}, \text{MathML math}, \text{menu}^{216} \text{(if the element's children include at least one li}^{212} \text{element), meter}^{239}, \text{nav}^{218}, \text{object}^{358}, \text{ol}^{213} \text{(if the element's children include at least one li}^{212} \text{element), output}^{235}, \text{p}^{269}, \text{pre}^{229}, \text{progress}^{537}, \text{n}^{229}, \text{ruby}^{242}, \text{s}^{227}, \text{samp}^{269}, \text{section}^{217}, \text{select}^{356}, \text{small}^{236}, \text{span}^{278}, \text{strong}^{234}, \text{sub}^{262}, \text{sup}^{262}, \text{SVG svg}, \text{table}^{435}, \text{textarea}^{358}, \text{time}^{251}, \text{u}^{265}, \text{ul}^{215} \text{(if the element's children include at least one li}^{212} \text{element), var}^{259}, \text{video}^{365}, \text{autonomous custom elements}^{468}, \text{textarea}^{358} \text{that is not inter-element whitespace}^{225}\]

3.2.5.9 Script-supporting elements

**Script-supporting elements** are those that do not `represent` anything themselves (i.e. they are not rendered), but are used to support scripts, e.g. to provide functionality for the user.
The following elements are script-supporting elements:

⇒ `script`, `template`.

### 3.2.5.3 Transparent content models

Some elements are described as **transparent**; they have "transparent" in the description of their content model. The content model of a transparent element is derived from the content model of its parent element: the elements required in the part of the content model that is "transparent" are the same elements as required in the part of the content model of the parent of the transparent element in which the transparent element finds itself.

**Example**

For instance, an `ins` element inside a `ruby` element cannot contain an `rt` element, because the part of the `ruby` element's content model that allows `ins` elements is the part that allows **phrasing content**, and the `rt` element is not **phrasing content**.

**Note**

In some cases, where transparent elements are nested in each other, the process has to be applied iteratively.

**Example**

Consider the following markup fragment:

```html
<p><object><param><ins><map><a href="/">Apples</a></map></ins></object></p>
```

To check whether "Apples" is allowed inside the `a` element, the content models are examined. The `a` element's content model is transparent, as is the `map` element's, as is the `ins` element's, as is the `object` element's in which the `ins` element is found. The `object` element is found in the `p` element, whose content model is **phrasing content**. Thus, "Apples" is allowed, as text is phrasing content.

When a transparent element has no parent, then the part of its content model that is "transparent" must instead be treated as accepting any **flow content**.

### 3.2.5.4 Paragraphs

The term **paragraph** as defined in this section is used for more than just the definition of the `p` element. The concept defined here is used to describe how to interpret documents. The `p` element is merely one of several ways of marking up a **paragraph**.

A paragraph is typically a run of **phrasing content** that forms a block of text with one or more sentences that discuss a particular topic, as in typography, but can also be used for more general thematic grouping. For instance, an address is also a paragraph, as is a part of a form, a byline, or a stanza in a poem.

**Example**

In the following example, there are two paragraphs in a section. There is also a heading, which contains phrasing content that is not a paragraph. Note how the comments and **inter-element whitespace** do not form paragraphs.

```html
<section>
  <h1>Example of paragraphs</h1>
  This is the `<em>`first`</em>` paragraph in this example.
  <p>This is the second.</p>
  <!-- This is not a paragraph. -->
</section>
```
Paragraphs in flow content are defined relative to what the document looks like without the a, ins, del, and map elements complicating matters, since those elements, with their hybrid content models, can straddle paragraph boundaries, as shown in the first two examples below.

**Note**

Generally, having elements straddle paragraph boundaries is best avoided. Maintaining such markup can be difficult.

**Example**

The following example takes the markup from the earlier example and puts ins and del elements around some of the markup to show that the text was changed (though in this case, the changes admittedly don’t make much sense). Notice how this example has exactly the same paragraphs as the previous one, despite the ins and del elements — the ins element straddles the heading and the first paragraph, and the del element straddles the boundary between the two paragraphs.

```html
<section>
  <ins><h1>Example of paragraphs</h1></ins>
  This is the <em>first</em> paragraph in this example<del>.
  <p>This is the second.</p><del>
  <!-- This is not a paragraph. -->
</section>
```

Let view be a view of the DOM that replaces all a, ins, del, and map elements in the document with their contents. Then, in view, for each run of sibling phrasing content, nodes uninterrupted by other types of content, in an element that accepts content other than phrasing content, as well as phrasing content, let first be the first node of the run, and let last be the last node of the run. For each such run that consists of at least one node that is neither embedded content nor inter-element whitespace, a paragraph exists in the original DOM from immediately before first to immediately after last. (Paragraphs can thus span across a, ins, del, and map elements.)

Conformance checkers may warn authors of cases where they have paragraphs that overlap each other (this can happen with object, video, audio, and canvas elements, and indirectly through elements in other namespaces that allow HTML to be further embedded therein, like SVG or MathML).

A paragraph is also formed explicitly by p elements.

**Note**

The p element can be used to wrap individual paragraphs when there would otherwise not be any content other than phrasing content to separate the paragraphs from each other.

**Example**

In the following example, the link spans half of the first paragraph, all of the heading separating the two paragraphs, and half of the second paragraph. It straddles the paragraphs and the heading.

```html
<header>
  Welcome!
  <a href="about.html">This is home of...</a>
  <h1>The Falcons!</h1>
  The Lockheed Martin multirole jet fighter aircraft!
</header>

This page discusses the F-16 Fighting Falcon's innermost secrets.
```

Here is another way of marking this up, this time showing the paragraphs explicitly, and splitting the one link element into three:

```html
<header>
  <p>Welcome! <a href="about.html">This is home of...</a></p>
  <h1><a href="about.html">The Falcons!</a></h1>
  <p><a href="about.html">The Lockheed Martin multirole jet fighter aircraft!</a> This page discusses the F-16 Fighting</p>
</header>
```
Falcon's innermost secrets.</p>
</header>

Example

It is possible for paragraphs to overlap when using certain elements that define fallback content. For example, in the following section:

```html
<section>
<h1>My Cats</h1>
You can play with my cat simulator.
<object data="cats.sim">
To see the cat simulator, use one of the following links:
<ul>
<li><a href="cats.sim">Download simulator file</a>
<li><a href="https://sims.example.com/watch?v=LYds5xY4INU">Use online simulator</a>
</ul>
Alternatively, upgrade to the Mellblom Browser.
</object>
I'm quite proud of it.
</section>
```

There are five paragraphs:

1. The paragraph that says "You can play with my cat simulator." where `object` is the `object` element.
2. The paragraph that says "To see the cat simulator, use one of the following links:"
3. The paragraph that says "Download simulator file".
4. The paragraph that says "Use online simulator".
5. The paragraph that says "Alternatively, upgrade to the Mellblom Browser."

The first paragraph is overlapped by the other four. A user agent that supports the "cats.sim" resource will only show the first one, but a user agent that shows the fallback will confusingly show the first sentence of the first paragraph as if it was in the same paragraph as the second one, and will show the last paragraph as if it was at the start of the second sentence of the first paragraph.

To avoid this confusion, explicit `p` elements can be used. For example:

```html
<section>
<h1>My Cats</h1>
<p>You can play with my cat simulator.</p>
<object data="cats.sim">
<p>To see the cat simulator, use one of the following links:</p>
<ul>
<li><a href="cats.sim">Download simulator file</a></li>
<li><a href="https://sims.example.com/watch?v=LYds5xY4INU">Use online simulator</a></li>
</ul>
<p>Alternatively, upgrade to the Mellblom Browser.</p>
</object>
<p>I'm quite proud of it.</p>
</section>
```

3.2.6 Global attributes

The following attributes are common to and may be specified on all HTML elements (even those not defined in this specification):

- `accesskey`
- `autocapitalize`
- `contenteditable`
These attributes are only defined by this specification as attributes for HTML elements. When this specification refers to elements having these attributes, elements from namespaces that are not defined as having these attributes must not be considered as being elements with these attributes.

Example

For example, in the following XML fragment, the "bogus" element does not have a \texttt{dir} attribute as defined in this specification, despite having an attribute with the literal name "dir". Thus, the directionality of the inner-most \texttt{span} element is 'rtl', inherited from the \texttt{div} element indirectly through the "bogus" element.

\begin{verbatim}
<\div xmlns="http://www.w3.org/1999/xhtml" dir="rtl">
  <bogus xmlns="https://example.net/ns" dir="ltr">
    <span xmlns="http://www.w3.org/1999/xhtml">
    </span>
  </bogus>
</\div>
\end{verbatim}

The WHATWG DOM standard defines the user agent requirements for the \texttt{class}, \texttt{id}, and \texttt{slot} attributes for any element in any namespace. [DOM]

The \texttt{class}, \texttt{id}, and \texttt{slot} attributes may be specified on all HTML elements.

When specified on HTML elements, the \texttt{class} attribute must have a value that is a \texttt{set of space-separated tokens} representing the various classes that the element belongs to.

Note

Assigning classes to an element affects class matching in selectors in CSS, the \texttt{getElementsByClassName()} method in the DOM, and other such features.

There are no additional restrictions on the tokens authors can use in the \texttt{class} attribute, but authors are encouraged to use values that describe the nature of the content, rather than values that describe the desired presentation of the content.

When specified on HTML elements, the \texttt{id} attribute value must be unique amongst all the IDs in the element's tree and must contain at least one character. The value must not contain any ASCII whitespace.

Note

The \texttt{id} attribute specifies its element's unique identifier (ID).

There are no other restrictions on what form an ID can take; in particular, IDs can consist of just digits, start with a digit, start with an underscore, consist of just punctuation, etc.

An element's unique identifier can be used for a variety of purposes, most notably as a way to link to specific parts of a document.
Identifiers are opaque strings. Particular meanings should not be derived from the value of the id attribute.

There are no conformance requirements for the slot attribute specific to HTML elements.

To enable assistive technology products to expose a more fine-grained interface than is otherwise possible with HTML elements and attributes, a set of annotations for assistive technology products can be specified (the ARIA role and aria-* attributes).

The following event handler content attributes may be specified on any HTML element:

- onabort
- onauxclick
- onblur
- oncancel
- oncanplay
- oncanplaythrough
- onchange
- onclick
- oncontextmenu
- oncuechange
- ondblclick
- ondrag
- ondragend
- ondragenter
- ondragexit
- ondragleave
- ondragover
- ondragstart
- ondrop
- ondurationchange
- onemptied
- onended
- onerror
- onfocus
- oninput
- oninvalid
- onkeydown
- onkeypress
- onkeyup
- onload
- onloadeddata
- onloadedmetadata
- onloadend
- onloadstart
- onmousedown
- onmouseenter
- onmouseleave
- onmousemove
- onmouseout
- onmouseover
- onmouseup
- onwheel
- onpause
- onplay
- onplaying
- onprogress
- onratechange
- onreset

Note: The slot attribute is used to assign a slot to an element: an element with a slot attribute is assigned to the slot created by the slot element whose name attribute's value matches that slot attribute's value — but only if that slot element finds itself in the shadow tree whose root's host has the corresponding slot attribute value.
Custom data attributes\(^{(44)}\) (e.g. data-foldername or data-msgid) can be specified on any HTML element\(^{(44)}\), to store custom data, state, annotations, and similar, specific to the page.

In HTML documents\(^{(5)}\), elements in the HTML namespace may have an xmlns attribute specified, if, and only if, it has the exact value "http://www.w3.org/1999/xhtml". This does not apply to XML documents.

The XML specification also allows the use of the xml:space\(^{(49)}\) attribute in the XML namespace on any element in an XML document\(^{(128)}\). This attribute has no effect on HTML elements\(^{(44)}\), as the default behavior in HTML is to preserve whitespace.

### Note

In HTML, the xmlns attribute has absolutely no effect. It is basically a talisman. It is allowed merely to make migration to and from XML mildly easier. When parsed by an HTML parser\(^{(122)}\), the attribute ends up in no namespace, not the "http://www.w3.org/2000/xmlns/" namespace like namespace declaration attributes in XML do.

In XML, an xmlns attribute is part of the namespace declaration mechanism, and an element cannot actually have an xmlns attribute in no namespace specified.

There is no way to serialize the xml:space\(^{(49)}\) attribute on HTML elements\(^{(44)}\) in the text/html\(^{(128)}\) syntax.

#### 3.2.6.1 The title\(^{(128)}\) attribute \(^{(5)}\)

The title attribute represents\(^{(120)}\) advisory information for the element, such as would be appropriate for a tooltip. On a link, this could be the title or a description of the target resource; on an image, it could be the image credit or a description of the image; on a paragraph, it could be a footnote or commentary on the text; on a citation, it could be further information about the source; on interactive content\(^{(129)}\), it could be a label for, or instructions for, use of the element; and so forth. The value is text.

Relying on the title\(^{(128)}\) attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g., requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

If this attribute is omitted from an element, then it implies that the title\(^{(128)}\) attribute of the nearest ancestor HTML element\(^{(44)}\) with a title\(^{(128)}\) attribute set is also relevant to this element. Setting the attribute overrides this, explicitly stating that the advisory information of any ancestors is not relevant to this element. Setting the attribute to the empty string indicates that the element has no
If the `title` attribute's value contains U+000A LINE FEED (LF) characters, the content is split into multiple lines. Each U+000A LINE FEED (LF) character represents a line break.

**Example**

Caution is advised with respect to the use of newlines in `title` attributes.

For instance, the following snippet actually defines an abbreviation's expansion with a line break in it:

```html
<p>My logs show that there was some interest in <abbr title="Hypertext Transport Protocol">HTTP</abbr> today.</p>
```

Some elements, such as `link`, `abbr`, and `input`, define additional semantics for the `title` attribute beyond the semantics described above.

The **advisory information** of an element is the value that the following algorithm returns, with the algorithm being aborted once a value is returned. When the algorithm returns the empty string, then there is no advisory information.

1. If the element has a `title` attribute, then return its value.
2. If the element has a parent element, then return the parent element's advisory information.
3. Return the empty string.

User agents should inform the user when elements have advisory information, otherwise the information would not be discoverable.

The `title` IDL attribute must reflect the `title` content attribute.

### 3.2.6.2 The `lang` and `xml:lang` attributes

The `lang` attribute (in no namespace) specifies the primary language for the element's contents and for any of the element's attributes that contain text. Its value must be a valid BCP 47 language tag, or the empty string. Setting the attribute to the empty string indicates that the primary language is unknown. [BCP47]

The `lang` attribute in the **XML namespace** is defined in XML. [XML]

If these attributes are omitted from an element, then the language of this element is the same as the language of its parent element, if any.

The `lang` attribute in no namespace may be used on any **HTML element**.

The `lang` attribute in the **XML namespace** may be used on **HTML elements** in XML documents, as well as elements in other namespaces if the relevant specifications allow it (in particular, MathML and SVG allow `lang` attributes in the **XML namespace** to be specified on their elements). If both the `lang` attribute in no namespace and the `lang` attribute in the **XML namespace** are specified on the same element, they must have exactly the same value when compared in an ASCII case-insensitive manner.

Authors must not use the `lang` attribute in the **XML namespace** on **HTML elements** in **HTML documents**, To ease migration to and from XML, authors may specify an attribute in no namespace with no prefix and with the literal localname "xml:lang" on **HTML elements** in **HTML documents**, but such attributes must only be specified if a `lang` attribute in no namespace is also specified, and both attributes must have the same value when compared in an ASCII case-insensitive manner.

**Note**

The attribute in no namespace with no prefix and with the literal localname "xml:lang" has no effect on language processing.

To determine the **language** of a node, user agents must look at the nearest ancestor element (including the element itself if the node is an element) that has a `lang` attribute in the **XML namespace** set or is an **HTML element** and has a `lang` in no namespace attribute set. That attribute specifies the language of the node (regardless of its value).
If both the `lang` attribute in no namespace and the `lang` attribute in the XML namespace\(^{1136}\) are set on an element, user agents must use the `lang` attribute in the XML namespace\(^{1136}\), and the `lang`\(^{1136}\) attribute in no namespace must be ignored\(^{1136}\) for the purposes of determining the element's language.

If node's inclusive ancestors do not have either attribute set, but there is a pragma-set default language\(^{1164}\) set, then that is the language of the node. If there is no pragma-set default language\(^{1164}\) set, then language information from a higher-level protocol (such as HTTP), if any, must be used as the final fallback language instead. In the absence of any such language information, and in cases where the higher-level protocol reports multiple languages, the language of the node is unknown, and the corresponding language tag is the empty string.

If the resulting value is not a recognized language tag, then it must be treated as an unknown language having the given language tag, distinct from all other languages. For the purposes of round-tripping or communicating with other services that expect language tags, user agents should pass unknown language tags through unmodified, and tagged as being BCP 47 language tags, so that subsequent services do not interpret the data as another type of language description. [BCP47]\(^{1137}\).

**Example**

Thus, for instance, an element with `lang`="xyzzy" would be matched by the selector `:lang(xyzzy)` (e.g. in CSS), but it would not be matched by `:lang(abcd)`, even though both are equally invalid. Similarly, if a Web browser and screen reader working in unison communicated about the language of the element, the browser would tell the screen reader that the language was “xyzzy”, even if it knew it was invalid, just in case the screen reader actually supported a language with that tag after all. Even if the screen reader supported both BCP 47 and another syntax for encoding language names, and in that other syntax the string “xyzzy” was a way to denote the Belarusian language, it would be incorrect for the screen reader to then start treating text as Belarusian, because “xyzzy” is not how Belarusian is described in BCP 47 codes (BCP 47 uses the code “be” for Belarusian).

If the resulting value is the empty string, then it must be interpreted as meaning that the language of the node is explicitly unknown.

User agents may use the element's language to determine proper processing or rendering (e.g. in the selection of appropriate fonts or pronunciations, for dictionary selection, or for the user interfaces of form controls such as date pickers).

The `lang` IDL attribute must `reflect`\(^{190}\) the `lang`\(^{1136}\) content attribute in no namespace.

### 3.2.6.3 The `translate`\(^{1137}\) attribute \(^{911}\)

The `translate` attribute is an enumerated attribute\(^{665}\) that is used to specify whether an element's attribute values and the values of its `Text` node children are to be translated when the page is localized, or whether to leave them unchanged.

The attribute's keywords are the empty string, yes, and no. The empty string and the yes keyword map to the yes state. The no keyword maps to the no state. In addition, there is a third state, the inherit state, which is the `missing value default`\(^{666}\) and the invalid value default\(^{665}\).

Each element (even non-HTML elements) has a translation mode, which is in either the `translate-enabled`\(^{1137}\) state or the `no-translate`\(^{613}\) state. If an HTML element\(^{644}\)'s `translate`\(^{1137}\) attribute is in the yes state, then the element's `translation mode`\(^{613}\) is in the `translate-enabled`\(^{1137}\) state; otherwise, if the element's `translate`\(^{1137}\) attribute is in the no state, then the element's `translation mode`\(^{1137}\) is in the `no-translate`\(^{613}\) state. Otherwise, either the element's `translate`\(^{1137}\) attribute is in the inherit state, or the element is not an HTML element\(^{644}\) and thus does not have a `translate`\(^{1137}\) attribute; in either case, the element's `translation mode`\(^{613}\) is in the same state as its parent element's, if any, or in the `translate-enabled`\(^{1137}\) state, if the element is a `document element`.

When an element is in the `translate-enabled` state, the element's `translatable attributes`\(^{613}\) and the values of its `Text` node children are to be translated when the page is localized.

When an element is in the `no-translate` state, the element's attribute values and the values of its `Text` node children are to be left as-is when the page is localized, e.g. because the element contains a person's name or a name of a computer program.

The following attributes are translatable attributes:

- `abbr`\(^{655}\) on the `tt`\(^{651}\) elements
- `alt` on the `area`\(^{629}\), `img`\(^{590}\), and `input`\(^{693}\) elements
- `content`\(^{519}\) on the `meta`\(^{319}\) elements, if the `name`\(^{319}\) attribute specifies a metadata name whose value is known to be translatable
- `download`\(^{525}\) on the `a`\(^{528}\) and `area`\(^{428}\) elements
- `label` on the `optgroup`\(^{527}\), `option`\(^{527}\), and `track`\(^{471}\) elements
• lang on HTML elements, must be "translated" to match the language used in the translation
• placeholder on input and textarea elements
• srcdoc on iframe elements; must be parsed and recursively processed
• style on HTML elements; must be parsed and recursively processed (e.g. for the values of 'content' properties)
• title on all HTML elements
• value on input elements with a type attribute in the Button state or the Reset Button state

Other specifications may define other attributes that are also translatable attributes. For example, ARIA would define the aria-label attribute as translatable.

The translate IDL attribute must, on getting, return true if the element's translation mode is translate-enabled, and false otherwise. On setting, it must set the content attribute's value to "yes" if the new value is true, and set the content attribute's value to "no" otherwise.

Example

In this example, everything in the document is to be translated when the page is localized, except the sample keyboard input and sample program output:

```html
<!DOCTYPE HTML>
<html lang=en> <!-- default on the document element is translate=yes -->
<head>
  <title>The Bee Game</title> <!-- implied translate=yes inherited from ancestors -->
</head>
<body>
<p>The Bee Game is a text adventure game in English.</p>
<p>When the game launches, the first thing you should do is type <kbd>eat honey</kbd>. The game will respond with: Yum yum! That was some good honey!</p>
<pre><samp>Yum yum! That was some good honey!</samp></pre>
</body>
</html>
```

3.2.6.4 The dir attribute

The dir attribute specifies the element's text directionality. The attribute is an enumerated attribute, with the following keywords and states:

The ltr keyword, which maps to the ltr state

Indicates that the contents of the element are explicitly directionally isolated left-to-right text.

The rtl keyword, which maps to the rtl state

Indicates that the contents of the element are explicitly directionally isolated right-to-left text.

The auto keyword, which maps to the auto state

Indicates that the contents of the element are explicitly directionally isolated text, but that the direction is to be determined programmatically using the contents of the element (as described below).

Note

The heuristic used by this state is very crude (it just looks at the first character with a strong directionality, in a manner analogous to the Paragraph Level determination in the bidirectional algorithm). Authors are urged to only use this value as a last resort when the direction of the text is truly unknown and no better server-side heuristic can be applied.

Note

For textarea and pre elements, the heuristic is applied on a per-paragraph level.

The attribute has no invalid value default and no missing value default.

The directionality of an element (any element, not just an HTML element) is either 'ltr' or 'rtl', and is determined as per the first
appropriate set of steps from the following list:

↪ If the element’s `dir` attribute is in the `ltr` state

↪ If the element is a `document element` and the `dir` attribute is not in a defined state (i.e. it is not present or has an invalid value)

↪ If the element is an `input` element whose `type` attribute is in the `Telephone` state, and the `dir` attribute is not in a defined state (i.e. it is not present or has an invalid value)

The `directionality` of the element is `ltr`.

↪ If the element’s `dir` attribute is in the `rtl` state

↪ If the element is an `input` element whose `type` attribute is in the `Telephone`, `URL`, or `E-mail` state, and the `dir` attribute is in the `auto` state

If the element’s `value` contains a character of bidirectional character type AL or R, and there is no character of bidirectional character type L anywhere before it in the element’s `value`, then the `directionality` of the element is `rtl`. [BIDI]

Otherwise, the `directionality` of the element is the same as the element’s parent element’s `directionality`.

Otherwise, the `directionality` of the element is the same as the element’s parent element’s `directionality`.

↪ If the element is a `textarea` element and the `dir` attribute is in the `auto` state

If the element has a parent element and the `dir` attribute is not in a defined state (i.e. it is not present or has an invalid value)

The `directionality` of the element is the same as the element’s parent element’s `directionality`.

Note: Since the `dir` attribute is only defined for `HTML elements`, it cannot be present on elements from other namespaces. Thus, elements from other namespaces always just inherit their `directionality` from their parent element, or, if they don’t have one, default to `ltr`.

Note: This attribute `has rendering requirements involving the bidirectional algorithm`.

The `directionality` of an attribute of an `HTML element`, which is used when the text of that attribute is to be included in the rendering in some manner, is determined as per the first appropriate set of steps from the following list:
If the attribute is a directionality-capable attribute and the element's `dir` attribute is in the `auto` state, find the first character (in logical order) of the attribute's value that is of bidirectional character type L, AL, or R. Otherwise, the directionality of the attribute is 'rtl'.

Otherwise, the directionality of the attribute is 'ltr'.

The following attributes are directionality-capable attributes:

- `abbr` on `th` elements
- `alt` on `area`, `img`, and `input` elements
- `content` on `meta` elements, if the `name` attribute specifies a metadata name whose value is primarily intended to be human-readable rather than machine-readable
- `label` on `optgroup`, `option`, and `track` elements
- `placeholder` on `input` and `textarea` elements
- `title` on all HTML elements

The `dir` IDL attribute on an element must reflect the `dir` content attribute of that element, limited to only known values.

The `dir` IDL attribute on `Document` objects must reflect the `dir` content attribute of the `html`'s `dir` attribute, if any, limited to only known values. If there is no such element, then the attribute must return the empty string and do nothing on setting.

For web developers (non-normative)

```html
document . dir [ = value ]
```

Returns the `html` element's `dir` attribute's value, if any.

Can be set, to either "ltr", "rtl", or "auto" to replace the `html` element's `dir` attribute's value.

If there is no `html` element, returns the empty string and ignores new values.

Authors are strongly encouraged to use the `dir` attribute to indicate text direction rather than using CSS, since that way their documents will continue to render correctly even in the absence of CSS (e.g. as interpreted by search engines).

Example

This markup fragment is of an IM conversation.

```html
<p dir="auto" class="u1">Student</bdi>:</p>

How do you write "What's your name?" in Arabic?

<p dir="auto" class="u2">Teacher</bdi>:</p>

ما اسمك؟

<p dir="auto" class="u1">Student</bdi>:</p>

Thanks.

<p dir="auto" class="u2">Teacher</bdi>:</p>

شكوراً.

<p dir="auto" class="u2">Teacher</bdi>:</p>

That's written "شكراً".

<p dir="auto" class="u2">Teacher</bdi>:</p>

Do you know how to write "Please"?

<p dir="auto" class="u1">Student</bdi>:</p>

من فضلك, right?
```

Given a suitable style sheet and the default alignment styles for the `p` element, namely to align the text to the start edge of the paragraph, the resulting rendering could be as follows:
As noted earlier, the `auto` value is not a panacea. The final paragraph in this example is misinterpreted as being right-to-left text, since it begins with an Arabic character, which causes the "right?" to be to the left of the Arabic text.

### 3.2.6.5 The `style` attribute

All HTML elements may have the `style` content attribute set. This is a style attribute as defined by the CSS Style Attributes specification. [CSSATTR]

In user agents that support CSS, the attribute's value must be parsed when the attribute is added or has its value changed, according to the rules given for style attributes. [CSSATTR]

However, if the Should element's inline behavior be blocked by Content Security Policy? algorithm returns "Blocked" when executed upon the attribute's element, "style attribute", and the attribute's value, then the style rules defined in the attribute's value must not be applied to the element. [CSP]

Documents that use `style` attributes on any of their elements must still be comprehensible and usable if those attributes were removed.

**Note**

In particular, using the `style` attribute to hide and show content, or to convey meaning that is otherwise not included in the document, is non-conforming. (To hide and show content, use the `hidden` attribute.)

---

### For web developers (non-normative)

**element.style**

Returns a `CSSStyleDeclaration` object for the element's `style` attribute.

---

The `style` IDL attribute is defined in the CSS Object Model (CSSOM) specification. [CSSOM]

---

### Example

In the following example, the words that refer to colors are marked up using the `span` element and the `style` attribute to make those words show up in the relevant colors in visual media.

```html
<p>My sweat suit is <span style="color: green; background: transparent">green</span> and my eyes are <span style="color: blue; background: transparent">blue</span>.</p>
```

---

### 3.2.6.6 Embedding custom non-visible data with the `data-*` attributes

A custom data attribute is an attribute in no namespace whose name starts with the string "data-", has at least one character after the hyphen, is XML-compatible, and contains no ASCII upper alphas.
Custom data attributes[^141] are intended to store custom data, state, annotations, and similar, private to the page or application, for which there are no more appropriate attributes or elements.

These attributes are not intended for use by software that is not known to the administrators of the site that uses the attributes. For generic extensions that are to be used by multiple independent tools, either this specification should be extended to provide the feature explicitly, or a technology like microdata[^1095] should be used (with a standardized vocabulary).

---

**Example**

For instance, a site about music could annotate list items representing tracks in an album with custom data attributes containing the length of each track. This information could then be used by the site itself to allow the user to sort the list by track length, or to filter the list for tracks of certain lengths.

```html
<ol>
  <li data-length="2m11s">Beyond The Sea</li>
  ...
</ol>
```

It would be inappropriate, however, for the user to use generic software not associated with that music site to search for tracks of a certain length by looking at this data.

This is because these attributes are intended for use by the site's own scripts, and are not a generic extension mechanism for publicly-usable metadata.

---

**Example**

Similarly, a page author could write markup that provides information for a translation tool that they are intending to use:

```html
<p>The third <span data-mytrans-de="Anspruch">claim</span> covers the case of <span translate="no">HTML</span> markup.</p>
```

In this example, the "data-mytrans-de" attribute gives specific text for the MyTrans product to use when translating the phrase "claim" to German. However, the standard `translate` attribute is used to tell it that in all languages, "HTML" is to remain unchanged. When a standard attribute is available, there is no need for a custom data attribute[^141] to be used.

---

**Example**

In this example, custom data attributes are used to store the result of a feature detection for `PaymentRequest`, which could be used in CSS to style a checkout page differently.

```html
<script>
  if ('PaymentRequest' in window) {
    document.documentElement.dataset.hasPaymentRequest = '';
  }
</script>
```

Here, the `data-has-payment-request` attribute is effectively being used as a boolean attribute[^65]; it is enough to check the presence of the attribute. However, if the author so wishes, it could later be populated with some value, maybe to indicate limited functionality of the feature.

Every HTML element[^644] may have any number of custom data attributes[^141] specified, with any value.

Authors should carefully design such extensions so that when the attributes are ignored and any associated CSS dropped, the page is still usable.
User agents must not derive any implementation behavior from these attributes or values. Specifications intended for user agents
must not define these attributes to have any meaningful values.

JavaScript libraries may use the custom data attributes, as they are considered to be part of the page on which they are used.
Authors of libraries that are reused by many authors are encouraged to include their name in the attribute names, to reduce the risk of
clashes. Where it makes sense, library authors are also encouraged to make the exact name used in the attribute names customizable,
so that libraries whose authors unknowingly picked the same name can be used on the same page, and so that multiple versions of a
particular library can be used on the same page even when those versions are not mutually compatible.

For example, a library called "DoQuery" could use attribute names like data-doquery-range, and a library called "jJo" could use
attributes names like data-jjo-range. The jJo library could also provide an API to set which prefix to use (e.g. J.setDataPrefix('j2'),
making the attributes have names like data-j2-range).

For web developers (non-normative)

```html
<element . dataset>
Returns a DOMStringMap object for the element's data-* attributes.

Hyphenated names become camel-cased. For example, data-foo-bar="" becomes element.dataset.foobar.
```

The dataset IDL attribute provides convenient accessors for all the data-* attributes on an element. On getting, the dataset IDL attribute
must return a DOMStringMap, whose associated element is this element.

The DOMStringMap interface is used for the dataset attribute. Each DOMStringMap has an associated element.

```
IDL [Exposed=Window, OverrideBuiltins]
interface DOMStringMap {
    getter DOMString (DOMString name);
    [CEReactions] setter void (DOMString name, DOMString value);
    [CEReactions] deleter void (DOMString name);
};
```

To get a DOMStringMap's name-value pairs, run the following algorithm:

1. Let list be an empty list of name-value pairs.
2. For each content attribute on the DOMStringMap's associated element whose first five characters are the string "data-" and whose remaining characters (if any) do not include any ASCII upper alphas, in the order that those attributes are listed in the element's attribute list, add a name-value pair to list whose name is the attribute's name with the first five characters removed and whose value is the attribute's value.
3. For each name in list, for each U+002D HYPHEN-MINUS character (-) in the name that is followed by an ASCII lower alpha, remove the U+002D HYPHEN-MINUS character (-) and replace the character that followed it by the same character converted to ASCII uppercase.
4. Return list.

The supported property names on a DOMStringMap object at any instant are the names of each pair returned from getting the
DOMStringMap's name-value pairs at that instant, in the order returned.

To determine the value of a named property name for a DOMStringMap, return the value component of the name-value pair whose
name component is name in the list returned from getting the DOMStringMap's name-value pairs.

To set the value of a new named property or set the value of an existing named property for a DOMStringMap, given a property
name name and a new value value, run the following steps:

1. If name contains a U+002D HYPHEN-MINUS character (-) followed by an ASCII lower alpha, then throw a "SyntaxError"
DOMException.
2. For each ASCII upper alpha in name, insert a U+002D HYPHEN-MINUS character (-) before the character and replace the character with the same character converted to ASCII lowercase.

3. Insert the string data- at the front of name.

4. If name does not match the XML Name production, throw an "InvalidCharacterError" DOMException.

5. Set an attribute value for the DOMStringMap's associated element using name and value.

To delete an existing named property name for a DOMStringMap, run the following steps:

1. For each ASCII upper alpha in name, insert a U+002D HYPHEN-MINUS character (-) before the character and replace the character with the same character converted to ASCII lowercase.

2. Insert the string data- at the front of name.

3. Remove an attribute by name given name and the DOMStringMap's associated element.

Note
This algorithm will only get invoked by the Web IDL specification for names that are given by the earlier algorithm for getting the DOMStringMap's name-value pairs. [WEBIDL]

Example
If a Web page wanted an element to represent a space ship, e.g. as part of a game, it would have to use the class attribute along with data-* attributes:

```html
<div class="spaceship" data-ship-id="92432"
    data-weapons="laser 2" data-shields="50%"
    data-x="30" data-y="10" data-z="90">
  <button class="fire"
    onclick="spaceships[this.parentNode.dataset.shipId].fire()">
    Fire
  </button>
</div>
```

Notice how the hyphenated attribute name becomes camel-cased in the API.

Example
Given the following fragment and elements with similar constructions:

```html
<img class="tower" id="tower5" data-x="12" data-y="5"
    data-ai="robotarget" data-hp="46" data-ability="flames"
    src="towers/rocket.png" alt="Rocket Tower">

...one could imagine a function splashDamage() that takes some arguments, the first of which is the element to process:

```javascript
function splashDamage(node, x, y, damage) {
  if (node.classList.contains('tower') && // checking the 'class' attribute
      node.dataset.x == x && // reading the 'data-x' attribute
      node.dataset.y == y) { // reading the 'data-y' attribute
    var hp = parseInt(node.dataset.hp); // reading the 'data-hp' attribute
    hp = hp - damage;
    if (hp < 0) {
      hp = 0;
      node.dataset.ai = 'dead'; // setting the 'data-ai' attribute
      delete node.dataset.ability; // removing the 'data-ability' attribute
    }
    node.dataset.hp = hp; // setting the 'data-hp' attribute
  }
}
```
On getting, the `innerText` attribute must follow these steps:

1. If this element is not `being rendered`, or if the user agent is a non-CSS user agent, then return the same value as the `textContent` IDL attribute on this element.
   
   **Note**
   
   This step can produce surprising results, as when the `innerText` attribute is accessed on an element not `being rendered`, its text contents are returned, but when accessed on an element that is `being rendered`, all of its children that are not `being rendered` have their text contents ignored.

2. Let `results` be the list resulting in running the `inner text collection steps` with this element. Each item in `results` will either be a JavaScript string or a positive integer (a required line break count).
   
   **Note**
   
   Intuitively, a required line break count item means that a certain number of line breaks appear at that point, but they can be collapsed with the line breaks induced by adjacent required line break count items, reminiscent to CSS margin-collapsing.

3. **Remove** any items from `results` that are the empty string.

4. **Remove** any runs of consecutive `required line break count` items at the start or end of `results`.

5. **Replace** each remaining run of consecutive `required line break count` items with a string consisting of as many U+000A LINE FEED (LF) characters as the maximum of the values in the `required line break count` items.

6. Return the concatenation of the string items in `results`.

The `inner text collection steps`, given a `node` `node`, are as follows:

1. Let `items` be the result of running the `inner text collection steps` with each child node of `node` in `tree order`, and then concatenating the results to a single list.

2. If `node`'s computed value of `visibility` is not `visible`, then return `items`.

3. If `node` is not `being rendered`, then return `items`. For the purpose of this step, the following elements must act as described if the computed value of the `display` property is not `none`:

   ○ `select` elements have an associated non-replaced inline CSS box whose child boxes include only those of `optgroup` and `option` element child nodes;
   
     ○ `optgroup` elements have an associated non-replaced block-level CSS box whose child boxes include only those of `option` element child nodes; and
   
     ○ `option` element have an associated non-replaced block-level CSS box whose child boxes are as normal for non-replaced block-level CSS boxes.

   **Note**
   
   Items can be non-empty due to `display:contents`.

4. If `node` is a `Text` node, then for each CSS text box produced by `node`, in content order, compute the text of the box after application of the CSS `white-space` processing rules and `text-transform` rules, set `items` to the list of the resulting strings, and return `items`. The CSS `white-space` processing rules are slightly modified: collapsible spaces at the end of lines are always collapsed, but they are only removed if the line is the last line of the block, or it ends with a `br` element. Soft hyphens should be preserved. ([CSS2])

5. If `node` is a `br` element, then append a string containing a single U+000A LINE FEED (LF) character to `items`.

6. If `node`'s computed value of `display` is `table-cell`, and `node`'s CSS box is not the last `table-cell` box of its enclosing `table-row` box, then append a string containing a single U+0009 CHARACTER TABULATION (tab) character to `items`.
7. If node's computed value of 'display' is 'table-row', and node's CSS box is not the last 'table-row' box of the nearest ancestor 'table' box, then append a string containing a single U+000A LINE FEED (LF) character to items.

8. If node is a p element, then append 2 (a required line break count) at the beginning and end of items.

9. If node's used value of 'display' is block-level or 'table-caption', then append 1 (a required line break count) at the beginning and end of items. [CSSDISPLAY]

10. Return items.

Note
Floats and absolutely-positioned elements fall into this category.

Note
This algorithm is amenable to being generalized to work on ranges. Then we can use it as the basis for Selection's stringifier and maybe expose it directly on ranges. See Bugzilla bug 10583.

On setting, the InnerText attribute must follow these steps:

1. Let document be this element's node document.

2. Let fragment be a new DocumentFragment object whose node document is document.

3. Let input be the given value.

4. Let position be a pointer into input, initially pointing at the start of the string.

5. Let text be the empty string.

6. While position is not past the end of input:

   1. Collect a sequence of code points that are not U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters from input given position. Set text to the collected characters.

   2. If text is not the empty string, then append a new Text node whose data is text and node document is document to fragment.

   3. While position is not past the end of input, and the character at position is either a U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) character:

      1. If the character at position is a U+000D CARRIAGE RETURN (CR) character and the next character is a U+000A LINE FEED (LF) character, then advance position to the next character in input.

      2. Advance position to the next character in input.

      3. Append the result of creating an element given document, br, and the HTML namespace to fragment.

   7. Replace all with fragment within this element.

3.2.8 Requirements relating to the bidirectional algorithm

3.2.8.1 Authoring conformance criteria for bidirectional-algorithm formatting characters

Text content in HTML elements with Text nodes in their contents, and text in attributes of HTML elements that allow free-form text, may contain characters in the ranges U+202A to U+202E and U+2066 to U+2069 (the bidirectional-algorithm formatting characters). [BIDI]

Note
Authors are encouraged to use the dir attribute, the bdo element, and the bdi element, rather than maintaining the bidirectional-algorithm formatting characters manually. The bidirectional-algorithm formatting characters interact poorly with CSS.
3.2.8.2 User agent conformance criteria

User agents must implement the Unicode bidirectional algorithm to determine the proper ordering of characters when rendering documents and parts of documents. [BIDI]

The mapping of HTML to the Unicode bidirectional algorithm must be done in one of three ways. Either the user agent must implement CSS, including in particular the CSS `unicode-bidi`, `direction`, and `content` properties, and must have, in its user agent style sheet, the rules using those properties given in this specification's rendering section, or, alternatively, the user agent must act as if it implemented just the aforementioned properties and had a user agent style sheet that included all the aforementioned rules, but without letting style sheets specified in documents override them, or, alternatively, the user agent must implement another styling language with equivalent semantics. [CSSGC]

The following elements and attributes have requirements defined by the rendering section that, due to the requirements in this section, are requirements on all user agents (not just those that support the suggested default rendering):

- `dir` attribute
- `bdi` element
- `bdo` element
- `br` element
- `pre` element
- `textarea` element
- `wbr` element

3.2.9 Requirements related to ARIA and to platform accessibility APIs

User agent requirements for implementing Accessibility API semantics on HTML elements are defined in HTML Accessibility API Mappings. [HTMLAAM]

Conformance checker requirements for checking use of ARIA `role` and `aria-*` attributes on HTML elements are defined in ARIA in HTML. [ARIAHTML]
4 The elements of HTML

4.1 The document element

4.1.1 The html element

Categories:
None.

Contexts in which this element can be used:
As document's document element.
Wherever a subdocument fragment is allowed in a compound document.

Content model:
A head element followed by a body element.

Tag omission in text/html:
An html element's start tag can be omitted if the first thing inside the html element is not a comment.
An html element's end tag can be omitted if the html element is not immediately followed by a comment.

Content attributes:
Global attributes:
manifest — Application cache manifest

DOM interface:

```
IDL [Exposed=Window, HTMLConstructor]
interface HTMLHtmlElement : HTMLElement {};
```

The html element represents the root of an HTML document.

Authors are encouraged to specify a lang attribute on the root html element, giving the document's language. This aids speech synthesis tools to determine what pronunciations to use, translation tools to determine what rules to use, and so forth.

The manifest attribute gives the address of the document's application cache manifest, if there is one. If the attribute is present, the attribute's value must be a valid non-empty URL potentially surrounded by spaces.

The manifest attribute is part of the legacy "offline Web applications" feature, which is in the process of being removed from the Web platform. (This is a long process that takes many years.) Using the manifest attribute at this time is highly discouraged. Use service workers instead. [SW]  

The manifest attribute only has an effect during the early stages of document load. Changing the attribute dynamically thus has no effect (and thus, no DOM API is provided for this attribute).

Note:
For the purposes of application cache selection, later base elements cannot affect the parsing of URLs in manifest attributes, as the attributes are processed before those elements are seen.

Note:
The window.applicationCache IDL attribute provides scripted access to the offline application cache mechanism.

Example:
The html element in the following example declares that the document's language is English.

```
<!DOCTYPE html>
<html lang="en">
```

4
<head>
<title>Swapping Songs</title>
</head>
<body>
<h1>Swapping Songs</h1>
<p>Tonight I swapped some of the songs I wrote with some friends, who gave me some of the songs they wrote. I love sharing my music.</p>
</body>
</html>

4.2 Document metadata

4.2.1 The head element

Categories:
None.

Contexts in which this element can be used:
As the first element in an html element.

Content model:
If the document is an iframe srcdoc document or if title information is available from a higher-level protocol: Zero or more elements of metadata content, of which no more than one is a title element and no more than one is a base element. Otherwise: One or more elements of metadata content, of which exactly one is a title element and no more than one is a base element.

Tag omission in text/html:
A head element's start tag can be omitted if the element is empty, or if the first thing inside the head element is an element.
A head element's end tag can be omitted if the head element is not immediately followed by ASCII whitespace or a comment.

Content attributes:
Global attributes

DOM interface:

```
[Exposed=Window, HTMLConstructor]
interface HTMLHeadElement : HTMLElement {
};
```

The head element represents a collection of metadata for the Document.

Example

The collection of metadata in a head element can be large or small. Here is an example of a very short one:

```
<!doctype html>
<html lang=en>
<head>
<title>A document with a short head</title>
</head>
<body>
...
```

Here is an example of a longer one:
The `title` element is a required child in most situations, but when a higher-level protocol provides title information, e.g. in the Subject line of an e-mail when HTML is used as an e-mail authoring format, the `title` element can be omitted.

4.2.2 The `title` element

Categories:
- Metadata content

Contexts in which this element can be used:
In a `head` element containing no other `title` elements.

Content model:
- `Text` that is not `inter-element whitespace`.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:

[IDL]
```idl
[Exposed=Window,
  HTMLConstructor]
interface HTMLTitleElement : HTMLElement {
  [CFReactions] attribute DOMString text;
};
```

The `title` element represents the document's title or name. Authors should use titles that identify their documents even when they are used out of context, for example in a user's history or bookmarks, or in search results. The document's title is often different from its first heading, since the first heading does not have to stand alone when taken out of context.

There must be no more than one `title` element per document.

**Note**

If it's reasonable for the `Document` to have no title, then the `title` element is probably not required. See the `head` element's content model for a description of when the element is required.

**For web developers (non-normative)**

`title . text[ = value ]`

Returns the child text content of the element.
The IDL attribute text must return the child text content of the title element. On setting, it must act the same way as the textContent IDL attribute.

**Example**

Here are some examples of appropriate titles, contrasted with the top-level headings that might be used on those same pages.

```html
<title>Introduction to The Mating Rituals of Bees</title>  
...  
<h1>Introduction</h1>  
<p>This companion guide to the highly successful <cite>Introduction to Medieval Bee-Keeping</cite> book is...</p>
```

The next page might be a part of the same site. Note how the title describes the subject matter unambiguously, while the first heading assumes the reader knows what the context is and therefore won't wonder if the dances are Salsa or Waltz:

```html
<title>Dances used during bee mating rituals</title>  
...  
<h1>The Dances</h1>
```

The string to use as the document's title is given by the document.title IDL attribute.

User agents should use the document's title when referring to the document in their user interface. When the contents of a title element are used in this way, the directionality of that title element should be used to set the directionality of the document's title in the user interface.

### 4.2.3 The base element

**Categories**: Metadata content.

**Contexts in which this element can be used**: In a head element containing no other base elements.

**Content model**: Nothing.

**Tag omission in text/html**: No end tag.

**Content attributes**: Global attributes:

- href
- target

**DOM interface**: 

```javascript
IDL [Exposed=Window, HTMLConstructor]
interface HTMLBaseElement : HTMLElement {
    [CFReactions] attribute USVString href;
    [CFReactions] attribute DOMString target;
};
```

The base element allows authors to specify the document base URL for the purposes of parsing URLs, and the name of the default browsing context for the purposes of following hyperlinks. The element does not represent any content beyond this...
There must be no more than one `base` element per document. A `base` element must have either an `href` attribute, a `target` attribute, or both.

The `href` content attribute, if specified, must contain a valid URL potentially surrounded by spaces.

A `base` element, if it has an `href` attribute, must come before any other elements in the tree that have attributes defined as taking URLs, except the `html` element (its `manifest` attribute isn't affected by `base` elements).

The `target` attribute, if specified, must contain a valid browsing context name or keyword, which specifies which browsing context is to be used as the default when hyperlinks and forms in the Document cause navigation.

A `base` element, if it has a `target` attribute, must come before any elements in the tree that represent hyperlinks.

To get an element's target, given an `a`, `area`, or `form` element, run these steps:

1. If the element has a `target` attribute, then return that attribute's value.
2. If the element's node document contains a `base` element with a `target` attribute, then return the value of the `target` attribute of the first such `base` element.
3. Return the empty string.

A `base` element that is the first `base` element with an `href` content attribute in a document tree has a frozen base URL. The frozen base URL must be immediately set for an element whenever any of the following situations occur:

- The `base` element becomes the first `base` element in tree order with an `href` content attribute in its Document.
- The `base` element is the first `base` element in tree order with an `href` content attribute in its Document, and its `href` content attribute is changed.

To set the frozen base URL for an element:

1. Let `document` be element's node document.
2. Let `urlRecord` be the result of parsing the value of element's `href` content attribute with `document`'s fallback base URL, and `document`'s character encoding. (Thus, the `base` element isn't affected by itself.)
3. Set element's `frozen base URL` to `document`'s fallback base URL, if `urlRecord` is failure or running `Is base allowed for Document?` on the resulting URL record and `document` returns "Blocked", and to `urlRecord` otherwise.

The `href` IDL attribute, on getting, must return the result of running the following algorithm:

1. Let `document` be element's node document.
2. Let `url` be the value of the `href` attribute of this element, if it has one, and the empty string otherwise.
3. Let `urlRecord` be the result of parsing `url` with `document`'s fallback base URL, and `document`'s character encoding. (Thus, the `base` element isn't affected by other `base` elements or itself.)
4. If `urlRecord` is failure, return `url`.
5. Return the serialization of `urlRecord`.

The `href` IDL attribute, on setting, must set the `href` content attribute to the given new value.

The `target` IDL attribute must reflect the content attribute of the same name.
In this example, a `<base>` element is used to set the document base URL:

```html
<!DOCTYPE html>
<html lang="en">
  <head>
    <title>This is an example for the <base> element</title>
    <base href="https://www.example.com/news/index.html">
  </head>
  <body>
    <p>Visit the <a href="archives.html">archives</a>.</p>
  </body>
</html>
```

The link in the above example would be a link to "https://www.example.com/news/archives.html".

### 4.2.4 The `<link>` element

Categories:

- **Metadata content**: If the element is allowed in the body, phrasing content.
- If the element is allowed in the body:

**Contexts in which this element can be used**:

- Where metadata content is expected.
- In a `noscript` element that is a child of a `head` element.
- If the element is allowed in the body, where phrasing content is expected.

**Content model**:

Nothing.

**Tag omission in text/html**:

No end tag.

**Content attributes**:

- **Global attributes**:
  - `href` — Address of the hyperlink.
  - `crossorigin` — How the element handles crossorigin requests.
  - `rel` — Relationship between the document containing the hyperlink and the destination resource.
  - `media` — Applicable media.
  - `integrity` — Integrity metadata used in Subresource Integrity checks [SRI]
  - `hreflang` — Language of the linked resource.
  - `type` — Hint for the type of the referenced resource.
  - `referrerpolicy` — Referrer policy for fetches initiated by the element.
  - `sizes` — Sizes of the icons (for `rel`="icon").
  - `as` — Potential destination for a preload request (for `rel`="preload" and `rel`="modulepreload").
  - `color` — Color to use when customizing a site's icon (for `rel`="mask-icon").

Also, the `title` attribute has special semantics on this element: Title of the link; CSS style sheet set name.

**DOM interface**:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLLinkElement : HTMLElement {
  [CEReactions] attribute USVString href;
  [CEReactions] attribute DOMString? crossorigin;
  [CEReactions] attribute DOMString rel;
  [CEReactions] attribute DOMString as; // (default ")
  [SameObject, PutForwards=value] readonly attribute DOMTokenList relList;
}
```
The `link` element allows authors to link their document to other resources.

The destination of the link(s) is given by the `href` attribute, which must be present and must contain a valid non-empty URL potentially surrounded by spaces[86]. If the `href` attribute is absent, then the element does not define a link.

The `crossorigin` attribute is a CORS settings attribute[88]. It is intended for use with external resource links[273].

The types of link indicated (the relationships) are given by the value of the `rel` attribute, which, if present, must have a value that is a set of space-separated tokens[86]. The allowed keywords and their meanings[86] are defined in a later section. If the `rel` attribute is absent, has no keywords, or if none of the keywords used are allowed according to the definitions in this specification, then the element does not create any links.

The `rel` attribute's supported tokens are the keywords defined in HTML link types[273], which are allowed on `link` elements, impact the processing model, and are supported by the user agent. The possible supported tokens are `alternate`, `dns-prefetch`, `icon`, `modulepreload`, `next`, `pingback`, `preconnect`, `prefetch`, `preload`, `prerender`, `search`, and `stylesheet`. The `rel` attribute's supported tokens must only include the tokens from this list that the user agent implements the processing model for.

Note: Theoretically a user agent could support the processing model for the `canonical` keyword — if it were a search engine that executed JavaScript. But in practice that’s quite unlikely. So in most cases, `canonical` ought not be included in `rel`'s supported tokens.

A `link` element must have either a `rel` attribute or an `itemprop` attribute, but not both.

If a `link` element has an `itemprop` attribute, or has a `rel` attribute that contains only keywords that are `body-ok`, then the element is said to be allowed in the body. This means that the element can be used where phrasing content is expected.

Note: If the `rel` attribute is used, the element can only sometimes be used in the `body` of the page. When used with the `itemprop` attribute, the element can be used both in the `head` element and in the `body` of the page, subject to the constraints of the microdata model.

Two categories of links can be created using the `link` element: links to external resources[273] and hyperlinks[273]. The link types section[273] defines whether a particular link type is an external resource or a hyperlink. One `link` element can create multiple links (of which some might be external resource links[273] and some might be hyperlinks[273]), exactly which and how many links are created depends on the keywords given in the `rel` attribute. User agents must process the links on a per-link basis, not a per-element basis.

Note: Each link created for a `link` element is handled separately. For instance, if there are two `link` elements with `rel="stylesheet"`, they each count as a separate external resource, and each is affected by its own attributes independently. Similarly, if a single `link` element has a `rel` attribute with the value `next` `stylesheet`, it creates both a `hyperlink` (for the `next` keyword) and an external resource link (for the `stylesheet` keyword), and they are affected by other attributes (such as `media` or `title`) differently.

Example: For example, the following `link` element creates two hyperlinks (to the same page):

```html
<link rel="author license" href="/about"/>
```
The two links created by this element are one whose semantic is that the target page has information about the current page's author, and one whose semantic is that the target page has information regarding the license under which the current page is provided.

**Note**

Hyperlinks created with the `link` element and its `rel` attribute apply to the whole document. This contrasts with the `rel` attribute of `a` and `area` elements, which indicates the type of a link whose context is given by the link's location within the document.

The exact behavior for links to external resources depends on the exact relationship, as defined for the relevant `link`.

The `media` attribute says which media the resource applies to. The value must be a valid media query list.

The `integrity` attribute represents the integrity metadata for requests which this element is responsible for. The value is text. The attribute must not be specified on `link` elements that do not have a `rel` attribute that contains the `stylesheet` keyword.

The `hreflang` attribute on the `link` element has the same semantics as the `hreflang` attribute on the `a` element.

The `type` attribute gives the MIME type of the linked resource. It is purely advisory. The value must be a valid MIME type string.

For external resource links, the `type` attribute is used as a hint to user agents so that they can avoid fetching resources they do not support.

The `referrerpolicy` attribute is a referrer policy attribute. It is intended for use with external resource links, where it helps set the referrer policy used when obtaining the external resource.

The `title` attribute gives the title of the link. With one exception, it is purely advisory. The value is text. The exception is for style sheet links that are in a document tree, for which the `title` attribute defines CSS style sheet sets.

**Note**

The `title` attribute on `link` elements differs from the global `title` attribute of most other elements in that a link without a title does not inherit the title of the parent element: it merely has no title.

The `sizes` attribute gives the sizes of icons for visual media. Its value, if present, is merely advisory. User agents may use the value to decide which icon(s) to use if multiple icons are available. If specified, the attribute must have a value that is an unordered set of unique space-separated tokens, which are ASCII case-insensitive. Each value must be either an ASCII case-insensitive match for the string "any", or a value that consists of two valid non-negative integers that do not have a leading U+0030 DIGIT ZERO (0) character and that are separated by a single U+0078 LATIN SMALL LETTER X or U+0058 LATIN CAPITAL LETTER X character. The attribute must not be specified on `link` elements that do not have a `rel` attribute that specifies the `icon` keyword or the `apple-touch-icon` keyword.

**Note**

The `apple-touch-icon` keyword is a registered extension to the predefined set of link types, but user agents are not required to support it in any way.

The `as` attribute specifies the potential destination for a preload request for the resource given by the `href` attribute. It is an enumerated attribute. Each potential destination is a keyword for this attribute, mapping to a state of the same name. The attribute must be specified on `link` elements that have a `rel` attribute that contains the `preload` keyword. It may be specified on `link` elements that have a `rel` attribute that contains the `modulepreload` keyword; in such cases it must have a value which is a script-like destination. For other `link` elements, it must not be specified.

The processing model for how the `as` attribute is used is given in the steps to obtain the resource, for for preload links and for modulepreload links, respectively.

**Note**

The attribute does not have a missing value default or invalid value default, meaning that invalid or missing values for the...
The `color` attribute is used with the `mask-icon` link type. The attribute must not be specified on `link` elements that do not have a `rel` attribute that contains the `mask-icon` keyword. The value must be a string that matches the CSS `<color>` production, defining a suggested color that user agents can use to customize the display of the icon that the user sees when they pin your site.

Note

This specification does not have any user agent requirements for the `color` attribute.

Note

The `mask-icon` keyword is a registered extension to the predefined set of link types, but user agents are not required to support it in any way.

The IDL attributes `href`, `hreflang`, `integrity`, `media`, `rel`, `sizes`, and `type` each must reflect the respective content attributes of the same name.

Note

There is no reflecting IDL attribute for the `color` attribute, but this might be added later.

The `as` IDL attribute must reflect the `as` content attribute, limited to only known values.

The `crossOrigin` IDL attribute must reflect the `crossorigin` content attribute, limited to only known values.

The `referrerPolicy` IDL attribute must reflect the `referrerpolicy` content attribute, limited to only known values.

The `relList` IDL attribute must reflect the `rel` content attribute.

### 4.2.4.1 Processing the `media` attribute

If the link is a hyperlink, then the `media` attribute is purely advisory, and describes for which media the document in question was designed.

However, if the link is an external resource link, then the `media` attribute is prescriptive. The user agent must apply the external resource when the `media` attribute’s value matches the environment and the other relevant conditions apply, and must not apply it otherwise.

The default, if the `media` attribute is omitted, is "all", meaning that by default links apply to all media.

Note

The external resource might have further restrictions defined within that limit its applicability. For example, a CSS style sheet might have some `@media` blocks. This specification does not override such further restrictions or requirements.

### 4.2.4.2 Processing the `type` attribute

If the `type` attribute is present, then the user agent must assume that the resource is of the given type (even if that is not a valid MIME type string, e.g. the empty string). If the attribute is omitted, but the external resource link type has a default type defined, then the user agent must assume that the resource is of that type. If the UA does not support the given MIME type for the given link relationship, then the UA should not obtain the resource; if the UA does support the given MIME type for the given link relationship, then the UA should obtain the resource at the appropriate time as specified for the external resource link’s particular type. If the attribute is omitted, and the external resource link type does not have a default type defined, but the user agent would obtain the resource if the type was known and supported, then the user agent should obtain the resource under the assumption that it will be supported.

User agents must not consider the `type` attribute authoritative — upon fetching the resource, user agents must not use the `type` attribute to map to no state. This is accounted for in the processing model. For `preload` links, both conditions are an error; for `modulepreload` links, a missing value will be treated as "script".
attribute to determine its actual type. Only the actual type (as defined in the next paragraph) is used to determine whether to apply the resource, not the aforementioned assumed type.

If the external resource link type defines rules for processing the resource's Content-Type metadata, then those rules apply. Otherwise, if the resource is expected to be an image, user agents may apply the image sniffing rules, with the official type being the type determined from the resource's Content-Type metadata, and use the resulting computed type of the resource as if it was the actual type. Otherwise, if neither of these conditions apply or if the user agent opts not to apply the image sniffing rules, then the user agent must use the resource's Content-Type metadata to determine the type of the resource. If there is no type metadata, but the external resource link type has a default type defined, then the user agent must assume that the resource is of that type.

Once the user agent has established the type of the resource, the user agent must apply the resource if it is of a supported type and the other relevant conditions apply, and must ignore the resource otherwise.

For external resources that are represented in the DOM (for example, style sheets), the DOM representation must be made available (modulo cross-origin restrictions) even if the resource is not applied. To obtain the resource, the user agent must run the following steps:

1. If the href attribute's value is the empty string, then return.
2. Parse the URL given by the href attribute, relative to the element's node document. If that fails, then return. Otherwise, let url be the resulting URL record.
3. Let corsAttributeState be the current state of the element's crossorigin content attribute.
4. Let request's client be the result of creating a potential-CORS request given url, the empty string, and corsAttributeState.
5. Set request's client to the Link element's node document's Window object's environment settings object.
6. Set request's cryptographic nonce metadata to the current value of the Link element's [[CryptographicNonce]] internal slot.
7. Set request's integrity metadata to the current value of the Link element's integrity content attribute.
8. Set request's referrer policy to the current state of the Link element's referrerpolicy attribute.
9. If the rel attribute contains the preload keyword, then:
   1. Let as be the current state of the as attribute.
   2. If as is no state, then return.

4.2.4.3 Obtaining a resource from a Link element

For external resources that are represented in the DOM (for example, style sheets), the DOM representation must be made available (modulo cross-origin restrictions) even if the resource is not applied. To obtain the resource, the user agent must run the following steps:

1. If the href attribute's value is the empty string, then return.
2. Parse the URL given by the href attribute, relative to the element's node document. If that fails, then return. Otherwise, let url be the resulting URL record.
3. Let corsAttributeState be the current state of the element's crossorigin content attribute.
4. Let request be the result of creating a potential-CORS request given url, the empty string, and corsAttributeState.
5. Set request's client to the Link element's node document's Window object's environment settings object.
6. Set request's cryptographic nonce metadata to the current value of the Link element's [[CryptographicNonce]] internal slot.
7. Set request's integrity metadata to the current value of the Link element's integrity content attribute.
8. Set request's referrer policy to the current state of the Link element's referrerpolicy attribute.
9. If the rel attribute contains the preload keyword, then:
   1. Let as be the current state of the as attribute.
   2. If as is no state, then return.
3. Set request's destination to the result of translating as.

10. Fetch request.

User agents may opt to only try to obtain such resources when they are needed, instead of pro-actively fetching all the external resources that are not applied.

The semantics of the protocol used (e.g. HTTP) must be followed when fetching external resources. (For example, redirects will be followed and 404 responses will cause the external resource to not be applied.)

Once the attempts to obtain the resource and its critical subresources are complete, the user agent must, if the loads were successful, queue a task to fire an event named load at the link element, or, if the resource or one of its critical subresources failed to completely load for any reason (e.g. DNS error, HTTP 404 response, a connection being prematurely closed, unsupported Content-Type), queue a task to fire an event named error at the link element. Non-network errors in processing the resource or its subresources (e.g. CSS parse errors, PNG decoding errors) are not failures for the purposes of this paragraph.

The task source for these tasks is the DOM manipulation task source.

Unless otherwise specified for a given rel keyword, the element must delay the load event of the element's node document until all the attempts to obtain the resource and its critical subresources are complete. (Resources that the user agent has not yet attempted to obtain, e.g. because it is waiting for the resource to be needed, do not delay the load event.)

### 4.2.4.4 Processing `Link` headers

HTTP `Link` headers, if supported, must be assumed to come before any links in the document, in the order that they were given in the HTTP message. These headers are to be processed according to the rules given in the relevant specifications. [HTTP][1223]

**Note**

Registration of relation types in HTTP `Link` headers is distinct from HTML link types, and thus their semantics can be different from same-named HTML types.

### 4.2.4.5 Providing users with a means to follow hyperlinks created using the `link` element

Interactive user agents may provide users with a means to follow the hyperlinks created using the `link` element, somewhere within their user interface. The exact interface is not defined by this specification, but it could include the following information (obtained from the element's attributes, again as defined below), in some form or another (possibly simplified), for each hyperlink created with each `link` element in the document:

- The relationship between this document and the resource (given by the `rel` attribute)
- The title of the resource (given by the `title` attribute).
- The address of the resource (given by the `href` attribute).
- The language of the resource (given by the `hreflang` attribute).
- The optimum media for the resource (given by the `media` attribute).

User agents could also include other information, such as the type of the resource (as given by the `type` attribute).

The activation behavior of `link` elements that create hyperlinks is to follow the hyperlink created by the `link` element.

### 4.2.5 The `meta` element

**Categories**: Metadata content

If the `itemprop` attribute is present: flow content.
If the `itemprop` attribute is present: phrasing content.

**Contexts in which this element can be used**:

- If the `charset` attribute is present, or if the element’s `http-equiv` attribute is in the Encoding declaration state; in a `head` element.
- If the `http-equiv` attribute is present but not in the Encoding declaration state: in a `head` element.
- If the `http-equiv` attribute is present but not in the Encoding declaration state: in a `noscript` element that is a child of a `head` element.
- If the `name` attribute is present: where metadata content is expected.
- If the `itemprop` attribute is present: where metadata content is expected.
- If the `itemprop` attribute is present: where phrasing content is expected.

**Content model**:

Nothing.

**Tag omission in text/html**:

No end tag.

**Content attributes**:

- **Global attributes**
  - `name` — Metadata name
  - `http-equiv` —Pragma directive
  - `content` — Value of the element
  - `charset` — Character encoding declaration

**DOM interface**:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLMetaElement : HTMLElement {
    [CF] attribute DOMString name;
    [CF] attribute DOMString httpEquiv;
    [CF] attribute DOMString content;
};
```

The `meta` element represents various kinds of metadata that cannot be expressed using the `title`, `base`, `link`, `style`, and `script` elements.

The `meta` element can represent document-level metadata with the `name` attribute, pragma directives with the `http-equiv` attribute, and the file’s character encoding declaration, when an HTML document is serialized to string form (e.g. for transmission over the network or for disk storage) with the `charset` attribute.

Exactly one of the `name`, `http-equiv`, `charset`, and `itemprop` attributes must be specified.

If either `name`, `http-equiv`, or `itemprop` is specified, then the `content` attribute must also be specified. Otherwise, it must be omitted.

The `charset` attribute specifies the character encoding used by the document. This is a character encoding declaration. If the attribute is present, its value must be an ASCII case-insensitive match for the string "utf-8".

---

The `charset` attribute on the `meta` element has no effect in XML documents, but is allowed in XML documents in order to facilitate migration to and from XML.

There must not be more than one `meta` element with a `charset` attribute per document.

The `content` attribute gives the value of the document metadata or pragma directive when the element is used for those purposes. The allowed values depend on the exact context, as described in subsequent sections of this specification.

If a `meta` element has a `name` attribute, it sets document metadata. Document metadata is expressed in terms of name-value pairs, the `name` attribute on the `meta` element giving the name, and the `content` attribute on the same element giving the value. The name specifies what aspect of metadata is being set; valid names and the meaning of their values are described in the following sections. If a `meta` element has no `content` attribute, then the value part of the metadata name-value pair is the empty string.
The **name** and **content** IDL attributes must reflect the respective content attributes of the same name. The IDL attribute **httpEquiv** must reflect the content attribute **http-equiv**.

### 4.2.5.1 Standard metadata names

This specification defines a few names for the **name** attribute of the **meta** element.

Names are case-insensitive, and must be compared in an ASCII case-insensitive manner.

#### application-name

The value must be a short free-form string giving the name of the Web application that the page represents. If the page is not a Web application, the **application-name** metadata name must not be used. Translations of the Web application’s name may be given, using the **lang** attribute to specify the language of each name.

There must not be more than one **meta** element with a given **language** and where the **name** attribute value is an ASCII case-insensitive match for **application-name** per document.

User agents may use the application name in UI in preference to the page’s **title**, since the title might include status messages and the like relevant to the status of the page at a particular moment in time instead of just being the name of the application.

To find the application name to use given an ordered list of languages (e.g. British English, American English, and English), user agents must run the following steps:

1. Let **languages** be the list of languages.
2. Let **default language** be the **language** of the **Document**’s **document element**, if any, and if that language is not unknown.
3. If there is a default language, and if it is not the same language as any of the languages in **languages**, append it to **languages**.
4. Let **winning language** be the first language in **languages** for which there is a **meta** element in the **Document** where the **name** attribute value is an ASCII case-insensitive match for **application-name** and whose **language** is the language in question.
   
   If none of the languages have such a **meta** element, then return; there’s no given application name.
5. Return the value of the **content** attribute of the first **meta** element in the **Document** in tree order where the **name** attribute value is an ASCII case-insensitive match for **application-name** and whose **language** is **winning language**.

**Note**

This algorithm would be used by a browser when it needs a name for the page, for instance, to label a bookmark. The languages it would provide to the algorithm would be the user’s preferred languages.

#### author

The value must be a free-form string giving the name of one of the page's authors.

#### description

The value must be a free-form string that describes the page. The value must be appropriate for use in a directory of pages, e.g. in a search engine. There must not be more than one **meta** element where the **name** attribute value is an ASCII case-insensitive match for **description** per document.

#### generator

The value must be a free-form string that identifies one of the software packages used to generate the document. This value must not be used on pages whose markup is not generated by software, e.g. pages whose markup was written by a user in a text editor.

**Example**

Here is what a tool called "Frontweaver" could include in its output, in the page's **head** element, to identify itself as the tool used to generate the page:
keywords

The value must be a set of comma-separated tokens, each of which is a keyword relevant to the page.

Example

This page about typefaces on British motorways uses a meta element to specify some keywords that users might use to look for the page:

```html
<!DOCTYPE HTML>
<html lang="en-GB">
<head>
  <title>Typefaces on UK motorways</title>
  <meta name="keywords" content="british,type face,font,fonts,highway,highways">
</head>
<body>
...
```

Note

Many search engines do not consider such keywords, because this feature has historically been used unreliably and even misleadingly as a way to spam search engine results in a way that is not helpful for users.

To obtain the list of keywords that the author has specified as applicable to the page, the user agent must run the following steps:

1. Let keywords be an empty list.
2. For each meta element with a name attribute and a content attribute and where the name attribute value is an ASCII case-insensitive match for keywords:
   1. Split the value of the element's content attribute on commas.
   2. Add the resulting tokens, if any, to keywords.
3. Remove any duplicates from keywords.
4. Return keywords. This is the list of keywords that the author has specified as applicable to the page.

User agents should not use this information when there is insufficient confidence in the reliability of the value.

Example

For instance, it would be reasonable for a content management system to use the keyword information of pages within the system to populate the index of a site-specific search engine, but a large-scale content aggregator that used this information would likely find that certain users would try to game its ranking mechanism through the use of inappropriate keywords.

referrer

The value must be a referrer policy, which defines the default referrer policy for the Document. [REFERERPOLICY]

If any meta elements are inserted into the document or removed from the document, or existing meta elements have their name or content attributes changed, user agents must run the following algorithm:

1. Let candidate elements be the list of all meta elements that meet the following criteria, in tree order:
   - The element is in a document tree
   - The element has a name attribute, whose value is an ASCII case-insensitive match for referrer
   - The element has a content attribute, whose value is not the empty string
   - The element is a child of the head element of the document
2. For each element in candidate elements:
   1. Let value be the value of element's content attribute, converted to ASCII lowercase.
   2. If value is one of the values given in the first column of the following table, then set value to the value given in the second column:
### Legacy value

<table>
<thead>
<tr>
<th>Legacy value</th>
<th>Referrer policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>never</td>
<td>no-referrer</td>
</tr>
<tr>
<td>default</td>
<td>no-referrer-when-downgrade</td>
</tr>
<tr>
<td>always</td>
<td>unsafe-url</td>
</tr>
<tr>
<td>origin-when-crossorigin</td>
<td>origin-when-cross-origin</td>
</tr>
</tbody>
</table>

3. If value is a referrer policy, then set element’s node document’s referrer policy\(^{111}\) to policy.

#### Note

The fact that these steps are applied for each element enables deployment of fallback values for older user agents. [REFERRERPOLICY]\(^{1225}\)

### theme-color

The value must be a string that matches the CSS `<color>` production, defining a suggested color that user agents should use to customize the display of the page or of the surrounding user interface. For example, a browser might color the page’s title bar with the specified value, or use it as a color highlight in a tab bar or task switcher.

There must not be more than one `meta` element with its `name` attribute value set to an ASCII case-insensitive match for `theme-color`\(^{148}\) per document.

#### Example

This standard itself uses "WHATWG green" as its theme color:

```html
<!DOCTYPE HTML>
<title>HTML Standard</title>
<meta name="theme-color" content="#3c790a">
...
```

To obtain a page’s theme color, user agents must run the following steps:

1. Let candidate elements be the list of all `meta` elements that meet the following criteria, in tree order:
   - The element is in a document tree
   - The element has a `name` attribute, whose value is an ASCII case-insensitive match for `theme-color`\(^{148}\)
   - The element has a `content` attribute

2. For each element in candidate elements:
   1. Let value be the result of stripping leading and trailing ASCII whitespace from the value of element’s `content` attribute.
   2. Let color be the result of parsing\(^{57}\) value.
   3. If color is not failure, then return color.

3. Return nothing (the page has no theme color).

If any `meta` elements are inserted into the document\(^{44}\) or removed from the document\(^{44}\) or existing `meta` elements have their `name` or `content` attributes changed, user agents must re-run the above algorithm and apply the result to any affected UI.

When using the theme color in UI, user agents may adjust it in implementation-specific ways to make it more suitable for the UI in question. For example, if a user agent intends to use the theme color as a background and display white text over it, it might use a darker variant of the theme color in that part of the UI, to ensure adequate contrast.

#### 4.2.5.2 Other metadata names

Anyone can create and use their own extensions to the predefined set of metadata names. There is no requirement to register such extensions.

However, a new metadata name should not be created in any of the following cases:

- If either the name is a URL, or the value of its accompanying `content` attribute is a URL; in those cases, registering it as an extension to the predefined set of link types\(^{297}\) is encouraged (rather than creating a new metadata name).
• If the name is for something expected to have processing requirements in user agents; in that case it ought to be standardized.

Also, before creating and using a new metadata name, consulting the WHATWG Wiki MetaExtensions page is encouraged — to avoid choosing a metadata name that's already in use, and to avoid duplicating the purpose of any metadata names that are already in use, and to avoid new standardized names clashing with your chosen name. [WHATWGWiki]

Anyone is free to edit the WHATWG Wiki MetaExtensions page at any time to add a metadata name. New metadata names can be specified with the following information:

**Keyword**

The actual name being defined. The name should not be confusingly similar to any other defined name (e.g. differing only in case).

**Brief description**

A short non-normative description of what the metadata name's meaning is, including the format the value is required to be in.

**Specification**

A link to a more detailed description of the metadata name's semantics and requirements. It could be another page on the Wiki, or a link to an external page.

**Synonyms**

A list of other names that have exactly the same processing requirements. Authors should not use the names defined to be synonyms (they are only intended to allow user agents to support legacy content). Anyone may remove synonyms that are not used in practice; only names that need to be processed as synonyms for compatibility with legacy content are to be registered in this way.

**Status**

One of the following:

- **Proposed**
  The name has not received wide peer review and approval. Someone has proposed it and is, or soon will be, using it.

- **Ratified**
  The name has received wide peer review and approval. It has a specification that unambiguously defines how to handle pages that use the name, including when they use it in incorrect ways.

- **Discontinued**
  The metadata name has received wide peer review and it has been found wanting. Existing pages are using this metadata name, but new pages should avoid it. The “brief description” and “specification” entries will give details of what authors should use instead, if anything.

If a metadata name is found to be redundant with existing values, it should be removed and listed as a synonym for the existing value.

If a metadata name is added in the “proposed” state for a period of a month or more without being used or specified, then it may be removed from the WHATWG Wiki MetaExtensions page.

If a metadata name is added with the “proposed” status and found to be redundant with existing values, it should be removed and listed as a synonym for the existing value. If a metadata name is added with the “proposed” status and found to be harmful, then it should be changed to “discontinued” status.

Anyone can change the status at any time, but should only do so in accordance with the definitions above.

### 4.2.5.3 Pragma directives

When the `http-equiv` attribute is specified on a `meta` element, the element is a pragma directive.

The `http-equiv` attribute is an enumerated attribute. The following table lists the keywords defined for this attribute. The states given in the first cell of the rows with keywords give the states to which those keywords map. Some of the keywords are non-conforming, as noted in the last column.

<table>
<thead>
<tr>
<th>State</th>
<th>Keyword</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content Language</td>
<td>content-language</td>
<td>Non-conforming</td>
</tr>
<tr>
<td>Encoding declaration</td>
<td>content-type</td>
<td></td>
</tr>
</tbody>
</table>
When a `meta` element is inserted into the document, if its `http-equiv` attribute is present and represents one of the above states, then the user agent must run the algorithm appropriate for that state, as described in the following list:

**Content language state** ([http-equiv="content-language"])

This pragma sets the **pragma-set default language**. Until such a pragma is successfully processed, there is no **pragma-set default language**.

1. If the `meta` element has no `content` attribute, then return.
2. If the element's `content` attribute contains a U+002C COMMA character (,) then return.
3. Let `input` be the value of the element's `content` attribute.
4. Let `position` point at the first character of `input`.
5. **Skip ASCII whitespace** within `input` given `position`.
6. **Collect a sequence of code points** that are not **ASCII whitespace** from `input` given `position`.
7. Let `candidate` be the string that resulted from the previous step.
8. If `candidate` is the empty string, return.
9. Set the **pragma-set default language** to `candidate`.

**Note**
If the value consists of multiple space-separated tokens, tokens after the first are ignored.

**Encoding declaration state** ([http-equiv="content-type"])

The **Encoding declaration state** is just an alternative form of setting the `charset` attribute: it is a **character encoding declaration**. This state's user agent requirements are all handled by the parsing section of the specification.

For `meta` elements with an `http-equiv` attribute in the **Encoding declaration state**, the `content` attribute must have a value that is an **ASCII case-insensitive** match for a string that consists of: the literal string "text/html;", optionally followed by any number of **ASCII whitespace**, followed by the literal string "charset=utf-8".

A document must not contain both a `meta` element with an `http-equiv` attribute in the **Encoding declaration state** and a `meta` element with the `charset` attribute present.

The **Encoding declaration state** may be used in **HTML documents**, but elements with an `http-equiv` attribute in that state must not be used in **XML documents**.

**Default style state** ([http-equiv="default-style"])

This pragma sets the **name** of the default **CSS style sheet set**.

1. If the `meta` element has no `content` attribute, or if that attribute's value is the empty string, then return.
2. **Change the preferred CSS style sheet set name** with the name being the value of the element's `content` attribute.

**Refresh state** ([http-equiv="refresh"])

This pragma acts as timed redirect.
A Document object has an associated will declaratively refresh (a boolean). It is initially false.

1. If the meta element has no content attribute, or if that attribute’s value is the empty string, then return.
2. Let input be the value of the element’s content attribute.
3. Run the shared declarative refresh steps with the meta element’s node document, input, and the meta element.

The shared declarative refresh steps, given a Document object document, string input, and optionally a meta element meta, are as follows:

1. If document’s will declaratively refresh is true, then return.
2. Let position point at the first code point of input.
3. Skip ASCII whitespace within input given position.
4. Let time be 0.
5. Collect a sequence of code points that are ASCII digits from input given position, and let the result be timeString.
6. If timeString is the empty string, then:
   1. If the code point in input pointed to by position is not U+002E (.), then return.
7. Otherwise, set time to the result of parsing timeString using the rules for parsing non-negative integers.
8. Collect a sequence of code points that are ASCII digits and U+002E FULL STOP characters (.) from input given position. Ignore any collected characters.
9. Let urlRecord be document’s URL.
10. If position is not past the end of input, then:
    1. If the code point in input pointed to by position is not U+003B (;), U+002C (,), or ASCII whitespace, then return.
    2. Skip ASCII whitespace within input given position.
    3. If the code point in input pointed to by position is U+003B (;) or U+002C (,), then advance position to the next code point.
    4. Skip ASCII whitespace within input given position.
11. If position is not past the end of input, then:
    1. Let urlString be the substring of input from the code point at position to the end of the string.
    2. If the code point in input pointed to by position is U+0055 (U) or U+0075 (u), then advance position to the next code point. Otherwise, jump to the step labeled skip quotes.
    3. If the code point in input pointed to by position is U+0052 (R) or U+0072 (r), then advance position to the next code point. Otherwise, jump to the step labeled parse.
    4. If the code point in input pointed to by position is U+004C (L) or U+006C (l), then advance position to the next code point. Otherwise, jump to the step labeled parse.
    5. Skip ASCII whitespace within input given position.
    6. If the code point in input pointed to by position is U+003D (=), then advance position to the next code point. Otherwise, jump to the step labeled parse.
    7. Skip ASCII whitespace within input given position.
    8. Skip quotes: If the code point in input pointed to by position is U+0027 (’), U+0022 (“), or ASCII whitespace, then let quote be that code point, and advance position to the next code point. Otherwise, let quote be the empty string.
    9. Set urlString to the substring of input from the code point at position to the end of the string.
10. If quote is not the empty string, and there is a code point in urlString equal to quote, then truncate urlString at that code point, so that it and all subsequent code points are removed.
11. Parse: Parse urlString relative to document. If that fails, return. Otherwise, set urlRecord to the resulting URL.
12. Set document's will declaratively refresh\textsuperscript{165} to true.

13. Perform one or more of the following steps:
   
   \begin{itemize}
   \item After the refresh has come due (as defined below), if the user has not canceled the redirect and, if meta is given, document's active sandboxing flag\textsuperscript{168} does not have the sandboxed automatic features browsing context flag\textsuperscript{167} set, then navigate\textsuperscript{182} document's browsing context\textsuperscript{170} to urlRecord, with replacement enabled\textsuperscript{193}, and with document's browsing context\textsuperscript{178} as the source browsing context\textsuperscript{182}.
   
   For the purposes of the previous paragraph, a refresh is said to have come due as soon as the later of the following two conditions occurs:
   \begin{itemize}
   \item At least time seconds have elapsed since document has completely loaded\textsuperscript{1107}, adjusted to take into account user or user agent preferences.
   \item If meta is given, at least time seconds have elapsed since meta was inserted into the document\textsuperscript{544} document, adjusted to take into account user or user agent preferences.
   \end{itemize}
   
   Note: It is important to use document here, and not meta's node document, as that might have changed between the initial set of steps and the refresh coming due and meta is not always given (in case of the HTTP Refresh\textsuperscript{1196} header).
   \end{itemize}
   
   \begin{itemize}
   \item Provide the user with an interface that, when selected, navigates\textsuperscript{486} a browsing context\textsuperscript{178} to urlRecord, with document's browsing context\textsuperscript{170} as the source browsing context\textsuperscript{182}.
   \item Do nothing.
   \end{itemize}
   
   In addition, the user agent may, as with anything, inform the user of any and all aspects of its operation, including the state of any timers, the destinations of any timed redirects, and so forth.

For meta\textsuperscript{113} elements with an http-equiv\textsuperscript{163} attribute in the Refresh state\textsuperscript{164}, the content\textsuperscript{159} attribute must have a value consisting either of:

\begin{itemize}
\item just a valid non-negative integer\textsuperscript{66}, or
\item a valid non-negative integer\textsuperscript{66}, followed by a U+003B SEMICOLON character (;), followed by one or more ASCII whitespace, followed by a substring that is an ASCII case-insensitive match for the string "URL", followed by a U+003D EQUALS SIGN character (=), followed by a valid URL string that does not start with a literal U+0027 APOSTROPHE (’) or U+0022 QUOTATION MARK ("”) character.
\end{itemize}

In the former case, the integer represents a number of seconds before the page is to be reloaded; in the latter case the integer represents a number of seconds before the page is to be replaced by the page at the given URL.

**Example**

A news organization's front page could include the following markup in the page's head\textsuperscript{149} element, to ensure that the page automatically reloads from the server every five minutes:

\[
\text{<meta http-equiv="Refresh" content="300">}
\]

**Example**

A sequence of pages could be used as an automated slide show by making each page refresh to the next page in the sequence, using markup such as the following:

\[
\text{<meta http-equiv="Refresh" content="20; URL=page4.html">}
\]

**Set-Cookie state** (http-equiv="\texttt{set-cookie}\textsuperscript{161}")

This pragma is non-conforming and has no effect.

User agents are required to ignore this pragma.
X-UA-Compatible state (http-equiv="x-ua-compatible")

In practice, this pragma encourages Internet Explorer to more closely follow the specifications.

For `meta` elements with an `http-equiv` attribute in the X-UA-Compatible state, the `content` attribute must have a value that is an ASCII case-insensitive match for the string "IE=edge".

User agents are required to ignore this pragma.

Content security policy state (http-equiv="content-security-policy")

This pragma enforces a Content Security Policy on a Document. [CSP]

1. If the `meta` element is not a child of a `head` element, return.
2. If the `meta` element has no `content` attribute, or if that attribute's value is the empty string, then return.
3. Let `policy` be the result of executing Content Security Policy's parse a serialized Content Security Policy algorithm on the `meta` element's `content` attribute's value, with a source of "meta", and a disposition of "enforce".
4. Remove all occurrences of the report-uri, frame-ancestors, and sandbox directives from policy.
5. Enforce the policy `policy`.

For `meta` elements with an `http-equiv` attribute in the Content security policy state, the `content` attribute must have a value consisting of a valid Content Security Policy, but must not contain any report-uri, frame-ancestors, or sandbox directives. The Content Security Policy given in the `content` attribute will be enforced upon the current document. [CSP]

Example

A page might choose to mitigate the risk of cross-site scripting attacks by preventing the execution of inline JavaScript, as well as blocking all plugin content, using a policy such as the following:

```html
<meta http-equiv="Content-Security-Policy" content="script-src 'self'; object-src 'none'">
```

There must not be more than one `meta` element with any particular state in the document at a time.

4.2.5.4 Specifying the document’s character encoding

A character encoding declaration is a mechanism by which the character encoding used to store or transmit a document is specified.

The Encoding standard requires use of the UTF-8 character encoding and requires use of the "utf-8" encoding label to identify it. Those requirements necessitate that the document's character encoding declaration, if it exists, specifies an encoding label using an ASCII case-insensitive match for "utf-8". Regardless of whether a character encoding declaration is present or not, the actual character encoding used to encode the document must be UTF-8. [ENCODING]

To enforce the above rules, authoring tools must default to using UTF-8 for newly-created documents.

The following restrictions also apply:

- The character encoding declaration must be serialized without the use of character references or character escapes of any kind.
- The element containing the character encoding declaration must be serialized completely within the first 1024 bytes of the document.

In addition, due to a number of restrictions on `meta` elements, there can only be one `meta`-based character encoding declaration per document.

If an HTML document does not start with a BOM, and its encoding is not explicitly given by Content-Type metadata, and the document is not an iframe srcdoc document, then the encoding must be specified using a `meta` element with a charset attribute or a `meta` element with an `http-equiv` attribute in the Encoding declaration state.

Note
A character encoding declaration is required (either in the Content-Type metadata or explicitly in the file) even when all characters are in the ASCII range, because a character encoding is needed to process non-ASCII characters entered by the user in forms, in URLs generated by scripts, and so forth.

Using non-UTF-8 encodings can have unexpected results on form submission and URL encodings, which use the document's character encoding by default.

If the document is an iframe srcdoc document, the document must not have a character encoding declaration. (In this case, the source is already decoded, since it is part of the document that contained the iframe.)

In XML, the XML declaration should be used for inline character encoding information, if necessary.

Example

In HTML, to declare that the character encoding is UTF-8, the author could include the following markup near the top of the document (in the head element):

```html
<meta charset="utf-8">
```

In XML, the XML declaration would be used instead, at the very top of the markup:

```
<?xml version="1.0" encoding="utf-8"?>
```

4.2.6 The style element

Categories:

Metadata content.

Contexts in which this element can be used:

Where metadata content is expected.

In a noscript element that is a child of a head element.

Content model:

Text that gives a conformant style sheet.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes:

media — Applicable media

Also, the title attribute has special semantics on this element: CSS style sheet set name.

DOM interface:

```
[Exposed=Window, HTMLConstructor]
interface HTMLStyleElement : HTMLElement {
    [CEReactions] attribute DOMString media;
};
```

The style element allows authors to embed CSS style sheets in their documents. The style element is one of several inputs to the styling processing model. The element does not represent content for the user.

The media attribute says which media the styles apply to. The value must be a valid media query list. The user agent must apply the styles when the media attribute's value matches the environment and the other relevant conditions apply, and must not apply them otherwise.
The default, if the `media` attribute is omitted, is "all", meaning that by default styles apply to all media.

The `title` attribute on `style` elements defines CSS style sheet sets. If the `style` element has no `title` attribute, then it has no title; the `title` attribute of ancestors does not apply to the `style` element. If the `style` element is not in a document tree, then the `title` attribute is ignored. [CSSOM]

The `title` attribute on `style` elements, like the `title` attribute on `link` elements, differs from the global `title` attribute in that a `style` block without a title does not inherit the title of the parent element: it merely has no title.

The `child text content` of a `style` element must be that of a conformant style sheet.

The user agent must run the update a style block algorithm whenever one of the following conditions occur:

- The element is popped off the stack of open elements of an HTML parser or XML parser.
- The element is not on the stack of open elements of an HTML parser or XML parser, and it becomes connected or disconnected.
- The element's child text content change steps run.

The update a style block algorithm is as follows:

1. Let `element` be the `style` element.
2. If `element` has an associated CSS style sheet, remove the CSS style sheet in question.
3. If `element`'s root is neither a shadow root nor a document, then return.
4. If `element`'s `type` attribute is present and its value is neither the empty string nor an ASCII case-insensitive match for "text/css", then return.
5. If the Should element's inline behavior be blocked by Content Security Policy? algorithm returns "Blocked" when executed upon the `style` element, "style", and the `style` element's child text content, then return. [CSP]
6. Create a CSS style sheet with the following properties:

   - `type` text/css
   - `owner node` `element`
   - `media` The `media` attribute of `element`.
   - `title` The `title` attribute of `element`, if `element` is in a document tree, or the empty string otherwise.

Note

In particular, a `type` value with parameters, such as "text/css; charset=utf-8", will cause this algorithm to return early.

Note

This is a reference to the (possibly absent at this time) attribute, rather than a copy of the attribute's current value. The CSSOM specification defines what happens when the attribute is dynamically set, changed, or removed.

Note

Again, this is a reference to the attribute.
alternate flag
Unset.

origin-clean flag
Set.

location
parent CSS style sheet
owner CSS rule
null

disabled flag
Left at its default value.

CSS rules
Left uninitialized.

This doesn't seem right. Presumably we should be using the element's child text content? Tracked as issue #2997.

Once the attempts to obtain the style sheet's critical subresources\(^{544}\), if any, are complete, or, if the style sheet has no critical subresources\(^{544}\), once the style sheet has been parsed and processed, the user agent must, if the loads were successful or there were none, queue a task\(^{5993}\) to fire an event named load\(^{5121}\) at the style\(^{5166}\) element, or, if one of the style sheet’s critical subresources\(^{544}\) failed to completely load for any reason (e.g. DNS error, HTTP 404 response, a connection being prematurely closed, unsupported Content-Type), queue a task\(^{5993}\) to fire an event named error\(^{5121}\) at the style\(^{5166}\) element. Non-network errors in processing the style sheet or its subresources (e.g. CSS parse errors, PNG decoding errors) are not failures for the purposes of this paragraph.

The task source\(^{5993}\) for these tasks\(^{5993}\) is the DOM manipulation task source\(^{5997}\).

The element must delay the load event\(^{51107}\) of the element’s node document until all the attempts to obtain the style sheet's critical subresources\(^{544}\), if any, are complete.

Note
This specification does not specify a style system, but CSS is expected to be supported by most Web browsers. [CSS]\(^{1221}\)

The media IDL attribute must reflect\(^{599}\) the content attribute of the same name.

The LinkStyle interface is also implemented by this element. [CSSOM]\(^{1222}\)

Example
The following document has its stress emphasis styled as bright red text rather than italics text, while leaving titles of works and Latin words in their default italics. It shows how using appropriate elements enables easier restyling of documents.

```html
<!DOCTYPE html>
<html lang="en-US">
<head>
<title>My favorite book</title>
<style>
  body { color: black; background: white; }
  em { font-style: normal; color: red; }
</style>
</head>
<body>
<p>My <em>favorite</em> book of all time has <em>got</em> to be <cite>A Cat's Life</cite>. It is a book by P. Rahmel that talks about the <i lang="la">Felis Catus</i> in modern human society.</p>
</body>
</html>
```
4.2.7 Interactions of styling and scripting

Style sheets, whether added by a link element, a style element, an "<?xml-stylesheet?>" PI, an HTTP "Link" header, or some other mechanism, have a style sheet ready flag, which is initially unset.

When a style sheet is ready to be applied, its style sheet ready flag must be set. If the style sheet referenced no other resources (e.g. it was an internal style sheet given by a style element with no @import rules), then the style rules must be immediately made available to script; otherwise, the style rules must only be made available to script once the event loop reaches its update the rendering step.

A style sheet in the context of the Document of an HTML parser or XML parser is said to be a style sheet that is blocking scripts if all of the following conditions occur:

- The element was created by that Document's parser.
- The element is either a style element or a link element that was an external resource link that contributes to the styling processing model when the element was created by the parser.
- If the element is a link element, it's media attribute's value matches the environment.
- The element's style sheet was enabled when the element was created by the parser.
- The element's style sheet ready flag is not yet set.
- The last time the event loop reached step 1, the element's root was that Document.
- The user agent hasn't given up on that particular style sheet yet. A user agent may give up on a style sheet at any time.

Note: Giving up on a style sheet before the style sheet loads, if the style sheet eventually does still load, means that the script might end up operating with incorrect information. For example, if a style sheet sets the color of an element to green, but a script that inspects the resulting style is executed before the sheet is loaded, the script will find that the element is black (or whatever the default color is), and might thus make poor choices (e.g. deciding to use black as the color elsewhere on the page, instead of green). Implementors have to balance the likelihood of a script using incorrect information with the performance impact of doing nothing while waiting for a slow network request to finish.

A Document has a style sheet that is blocking scripts if there is either a style sheet that is blocking scripts, in the context of that Document, or if that Document has a browsing context that has a parent browsing context, and the active document of that parent browsing context itself has a style sheet that is blocking scripts.

A Document has no style sheet that is blocking scripts if it does not have a style sheet that is blocking scripts as defined in the previous paragraph.

4.3 Sections

4.3.1 The body element

Categories:
- Sectioning root

Contexts in which this element can be used:
- As the second element in an html element.

Content model:
- Flow content.

Tag omission in text/html:
- A body element's start tag can be omitted if the element is empty, or if the first thing inside the body element is not ASCII whitespace or a comment, except if the first thing inside the body element is a meta, link, script, style, or template element.
- A body element's end tag can be omitted if the body element is not immediately followed by a comment.

Content attributes:
- Global attributes
The body element represents the contents of the document.

In conforming documents, there is only one body element. The document.body IDL attribute provides scripts with easy access to a document's body element.

**Note**

Some DOM operations (for example, parts of the drag and drop model) are defined in terms of "the body element". This refers to a particular element in the DOM, as per the definition of the term, and not any arbitrary body element.

The body element exposes as event handler content attributes a number of the event handlers of the Window object. It also mirrors their event handler IDL attributes.

The event handlers of the Window object named by the Window reflecting body element event handler set, exposed on the body element, replace the generic event handlers with the same names normally supported by HTML elements.

**Example**

Thus, for example, a bubbling error event dispatched on a child of the body element of a Document would first trigger the onerror event handler content attribute of that element, then that of the root html element, and only then would it trigger the onerror event handler content attribute on the body element. This is because the event would bubble from the target, to the body, to the html, to the Document, to the Window, and the event handler on the body is watching the Window, not the body. A regular event listener attached to the body using addEventListener(), however, would run when the event bubbled through the body and not when it reaches the Window object.

**Example**

This page updates an indicator to show whether or not the user is online:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>Online or offline?</title>
  <script>
    function update(online) {
      document.getElementById('status').textContent = online ? 'Online' : 'Offline';
    }
  </script>
</head>
```
4.3.2 The article element

Categories:
- Flow content
- Sectioning content
- Palpable content

Contexts in which this element can be used:
- Where flow content is expected.

Content model:
- Flow content

Tag omission in text/html:
- Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:
- Uses HTMLElement

The article element represents a complete, or self-contained, composition in a document, page, application, or site and that is, in principle, independently distributable or reusable, e.g. in syndication. This could be a forum post, a magazine or newspaper article, a blog entry, a user-submitted comment, an interactive widget or gadget, or any other independent item of content.

When article elements are nested, the inner article elements represent articles that are in principle related to the contents of the outer article. For instance, a blog entry on a site that accepts user-submitted comments could represent the comments as article elements nested within the article element for the blog entry.

Author information associated with an article element (q.v. the address element) does not apply to nested article elements.

Note
- When used specifically with content to be redistributed in syndication, the article element is similar in purpose to the entry element in Atom. [ATOM]

Note
- The schema.org microdata vocabulary can be used to provide the publication date for an article element, using one of the CreativeWork subtypes.

When the main content of the page (i.e. excluding footers, headers, navigation blocks, and sidebars) is all one single self-contained composition, that content may be marked with an article element, but it is technically redundant in that case (since it's self-evident that the page is a single composition, as it is a single document).

Example
- This example shows a blog post using the article element, with some schema.org annotations:
The Very First Rule of Life

If there's a microphone anywhere near you, assume it's hot and sending whatever you're saying to the world. Seriously.

Here is that same blog post, but showing some of the comments:

Here is that same blog post, but showing some of the comments:

If there's a microphone anywhere near you, assume it's hot and sending whatever you're saying to the world. Seriously.

... Yeah! Especially when talking about your lobbyist friends!

Hey, you have the same first name as me.

Notice the use of footer to give the information for each comment (such as who wrote it and when): the footer element can appear at the start of its section when appropriate, such as in this case. (Using header in this case wouldn't be wrong either; it's mostly a matter of authoring preference.)

In this example, article elements are used to host widgets on a portal page. The widgets are implemented as customized built-in elements in order to get specific styling and scripted behavior.
4.3.3 The `section` element

Categories:
- Flow content
- Sectioning content
- Palpable content

Contexts in which this element can be used:
Where flow content is expected.

Content model:
- Flow content

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:
Uses `HTMLElement`.

The `section` element represents a generic section of a document or application. A section, in this context, is a thematic grouping of content, typically with a heading.

Example
Examples of sections would be chapters, the various tabbed pages in a tabbed dialog box, or the numbered sections of a thesis. A Web site’s home page could be split into sections for an introduction, news items, and contact information.

Note
Authors are encouraged to use the `article` element instead of the `section` element when it would make sense to syndicate the contents of the element.
The `section` element is not a generic container element. When an element is needed only for styling purposes or as a convenience for scripting, authors are encouraged to use the `div` element instead. A general rule is that the `section` element is appropriate only if the element’s contents would be listed explicitly in the document’s `outline`.

Example

In the following example, we see an article (part of a larger Web page) about apples, containing two short sections.

```html
<article>
  <hgroup>
    <h1>Apples</h1>
    <h2>Tasty, delicious fruit!</h2>
  </hgroup>
  <p>The apple is the pomaceous fruit of the apple tree.</p>
  <section>
    <h1>Red Delicious</h1>
    <p>These bright red apples are the most common found in many supermarkets.</p>
  </section>
  <section>
    <h1>Granny Smith</h1>
    <p>These juicy, green apples make a great filling for apple pies.</p>
  </section>
</article>
```

Notice how the use of `section` means that the author can use `h1` elements throughout, without having to worry about whether a particular section is at the top level, the second level, the third level, and so on.

Example

Here is a graduation programme with two sections, one for the list of people graduating, and one for the description of the ceremony. (The markup in this example features an uncommon style sometimes used to minimize the amount of `inter-element whitespace`.)

```html
<!DOCTYPE Html>
<html lang=en>
  <head>
    <title>Graduation Ceremony Summer 2022</title>
  </head>
  <body>
    <h1>Graduation</h1>
    <section>
      <h1>Ceremony</h1>
      <p>Opening Procession</p>
      <p>Speech by Validactorian</p>
      <p>Speech by Class President</p>
      <p>Presentation of Diplomas</p>
      <p>Closing Speech by Headmaster</p>
    </section>
  </body>
</html>
```
In this example, a book author has marked up some sections as chapters and some as appendices, and uses CSS to style the headers in these two classes of section differently.

```html
<example>
  In this example, a book author has marked up some sections as chapters and some as appendices, and uses CSS to style the headers in these two classes of section differently.

  <style>
    section {
      border: double medium; margin: 2em;
    }
    section.chapter h1 {
      font: 2em Roboto, Helvetica Neue, sans-serif;
    }
    section.appendix h1 {
      font: small-caps 2em Roboto, Helvetica Neue, sans-serif;
    }
  </style>

  <header>
    <hgroup>
      <h1>My Book</h1>
      <h2>A sample with not much content</h2>
    </hgroup>
    <p>Published by Dummy Publicorp Ltd.</p>
  </header>

  <section class="chapter">
    <h1>My First Chapter</h1>
    <p>This is the first of my chapters. It doesn't say much.</p>
    <p>But it has two paragraphs!</p>
  </section>

  <section class="chapter">
    <h1>It Continues: The Second Chapter</h1>
    <p>Bla dee bla, dee bla dee bla. Boom.</p>
  </section>

  <section class="chapter">
    <h1>Chapter Three: A Further Example</h1>
    <p>It's not like a battle between brightness and earthtones would go unnoticed.</p>
    <p>But it might ruin my story.</p>
  </section>

  <section class="appendix">
    <h1>Appendix A: Overview of Examples</h1>
    <p>These are demonstrations.</p>
  </section>

  <section class="appendix">
    <h1>Appendix B: Some Closing Remarks</h1>
    <p>Hopefully this long example shows that you can style</p>
  </section>
</example>
```
sections, so long as they are used to indicate actual sections.</p>
</section>

4.3.4 The nav element

Categories:
- Flow content
- Sectioning content
- Palpable content

Contexts in which this element can be used:
Where flow content is expected.

Content model:
Flow content.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:
Uses HTMLElement.

The nav element represents a section of a page that links to other pages or to parts within the page: a section with navigation links.

Note
Not all groups of links on a page need to be in a nav element — the element is primarily intended for sections that consist of major navigation blocks. In particular, it is common for footers to have a short list of links to various pages of a site, such as the terms of service, the home page, and a copyright page. The footer element alone is sufficient for such cases; while a nav element can be used in such cases, it is usually unnecessary.

Note
User agents (such as screen readers) that are targeted at users who can benefit from navigation information being omitted in the initial rendering, or who can benefit from navigation information being immediately available, can use this element as a way to determine what content on the page to initially skip or provide on request (or both).

Example
In the following example, there are two nav elements, one for primary navigation around the site, and one for secondary navigation around the page itself.

```html
<body>
  <h1>The Wiki Center Of Exampland</h1>
  <nav>
    <ul>
      <li><a href="/">Home</a></li>
      <li><a href="/events">Current Events</a></li>
      ...more...
    </ul>
  </nav>
  <article>
    <header>
      <h1>Demos in Exampland</h1>
      <p>Written by A. N. Other.</p>
    </header>
```
In the following example, the page has several places where links are present, but only one of those places is considered a navigation section.

```html
<body itemscope itemtype="http://schema.org/Blog">
  <header>
    <h1>Wake up sheeple!</h1>
    <p>
      <a href="news.html">News</a> -
      <a href="blog.html">Blog</a> -
      <a href="forums.html">Forums</a>
    </p>
    <p>Last Modified: <span itemprop="dateModified">2009-04-01</span></p>
  </header>
  <nav>
    <ul>
      <li><a href="articles.html">Index of all articles</a></li>
      <li><a href="today.html">Things sheeple need to wake up for today</a></li>
      <li><a href="successes.html">Sheeple we have managed to wake</a></li>
    </ul>
  </nav>
  <main>
    <article itemscope itemtype="http://schema.org/BlogPosting">
      <header>
        <h1 itemprop="headline">My Day at the Beach</h1>
      </header>
      <div itemprop="articleBody">
        <p>Today I went to the beach and had a lot of fun.</p>
        ...more content...
      </div>
      <footer>
        Posted <time itemprop="datePublished" datetime="2009-10-10">Thursday</time>.</footer>
    </article>
  </main>
</body>
```
Example

A `<nav>` element doesn't have to contain a list, it can contain other kinds of content as well. In this navigation block, links are provided in prose:

```html
<nav>
  <h1>Navigation</h1>
  <p>You are on my home page. To the north lies <a href="/blog">my blog</a>, from whence the sounds of battle can be heard. To the east you can see a large mountain, upon which many <a href="/school">school papers</a> are littered. Far up thus mountain you can spy a little figure who appears to be me, desperately scribbling a <a href="/school/thesis">thesis</a>.</p>
  <p>To the west are several exits. One fun-looking exit is labeled <a href="https://games.example.com/">"games"</a>. Another more boring-looking exit is labeled <a href="https://isp.example.net/">"ISP"</a>.</p>
  <p>To the south lies a dark and dank <a href="/about">contacts page</a>. Cobwebs cover its disused entrance, and at one point you see a rat run quickly out of the page.</p>
</nav>
```

Example

In this example, `<nav>` is used in an e-mail application, to let the user switch folders:

```html
<p><input type=button value="Compose" onclick="compose()"></p>
<nav>
  <h1>Folders</h1>
  <ul>
    <li><a href="/inbox" onclick="return openFolder(this.href)">Inbox</a> <span class=count></span></li>
    <li><a href="/sent" onclick="return openFolder(this.href)">Sent</a></li>
    <li><a href="/drafts" onclick="return openFolder(this.href)">Drafts</a></li>
    <li><a href="/trash" onclick="return openFolder(this.href)">Trash</a></li>
    <li><a href="/customers" onclick="return openFolder(this.href)">Customers</a></li>
  </ul>
</nav>
```

You can also see microdata annotations in the above example that use the schema.org vocabulary to provide the publication date and other metadata about the blog post.
4.3.5 The aside element

Categories:
- Flow content
- Sectioning content
- Palpable content

Contexts in which this element can be used:
- Where flow content is expected.

Content model:
- Flow content

Tag omission in text/html:
- Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:
- Uses HTMLElement.

The aside element represents a section of a page that consists of content that is tangentially related to the content around the aside element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography.

The element can be used for typographical effects like pull quotes or sidebars, for advertising, for groups of nav elements, and for other content that is considered separate from the main content of the page.

**Note**

*It's not appropriate to use the aside element just for parentheticals, since those are part of the main flow of the document.*

**Example**

The following example shows how an aside is used to mark up background material on Switzerland in a much longer news story on Europe.

```html
<aside>
  <h1>Switzerland</h1>
  <p>Switzerland, a land-locked country in the middle of geographic Europe, has not joined the geopolitical European Union, though it is a signatory to a number of European treaties.</p>
</aside>
```

**Example**

The following example shows how an aside is used to mark up a pull quote in a longer article.

```html
...<p>He later joined a large company, continuing on the same work.
  <q>I love my job. People ask me what I do for fun when I'm not at work. But I'm paid to do my hobby, so I never know what to answer. Some people wonder what they would do if they didn't have to work... but I know what I would do, because I was unemployed for a year, and I filled that time doing exactly what I do now.</q></p>

<aside>
  <q>People ask me what I do for fun when I'm not at work. But I'm paid to do my hobby, so I never know what to answer.</q>
</aside>
```
Of course his work – or should that be hobby? – isn't his only passion. He also enjoys other pleasures.

---

The following extract shows how aside can be used for blogrolls and other side content on a blog:

```html
<body>
<header>
<h1>My wonderful blog</h1>
<p>My tagline</p>
</header>
<aside>
<!-- this aside contains two sections that are tangentially related to the page, namely, links to other blogs, and links to blog posts from this blog -->
<nav>
<h1>My blogroll</h1>
<ul>
<li><a href="https://blog.example.com/">Example Blog</a>
</li>
</ul>
</nav>
<nav>
<h1>Archives</h1>
<ol reversed>
<li><a href="/last-post">My last post</a>
</li>
<li><a href="/first-post">My first post</a>
</li>
</ol>
</nav>
</aside>
<aside>
<!-- this aside is tangentially related to the page also, it contains twitter messages from the blog author -->
<h1>Twitter Feed</h1>
<blockquote cite="https://twitter.example.net/t31351234">I'm on vacation, writing my blog.</blockquote>
<blockquote cite="https://twitter.example.net/t31219752">I'm going to go on vacation soon.</blockquote>
</aside>
<article>
<!-- this is a blog post -->
<h1>My last post</h1>
<p>This is my last post.</p>
<footer>
<p><a href="/last-post" rel=bookmark>Permalink</a></p>
</footer>
</article>
<article>
<!-- this is also a blog post -->
<h1>My first post</h1>
<p>This is my first post.</p>
<footer>
</footer>
</article>
```

---

Example

The following extract shows how aside can be used for blogrolls and other side content on a blog:

```html
<body>
<header>
<h1>My wonderful blog</h1>
<p>My tagline</p>
</header>
<aside>
<!-- this aside contains two sections that are tangentially related to the page, namely, links to other blogs, and links to blog posts from this blog -->
<nav>
<h1>My blogroll</h1>
<ul>
<li><a href="https://blog.example.com/">Example Blog</a>
</li>
</ul>
</nav>
<nav>
<h1>Archives</h1>
<ol reversed>
<li><a href="/last-post">My last post</a>
</li>
<li><a href="/first-post">My first post</a>
</li>
</ol>
</nav>
</aside>
<aside>
<!-- this aside is tangentially related to the page also, it contains twitter messages from the blog author -->
<h1>Twitter Feed</h1>
<blockquote cite="https://twitter.example.net/t31351234">I'm on vacation, writing my blog.</blockquote>
<blockquote cite="https://twitter.example.net/t31219752">I'm going to go on vacation soon.</blockquote>
</aside>
<article>
<!-- this is a blog post -->
<h1>My last post</h1>
<p>This is my last post.</p>
<footer>
<p><a href="/last-post" rel=bookmark>Permalink</a></p>
</footer>
</article>
<article>
<!-- this is also a blog post -->
<h1>My first post</h1>
<p>This is my first post.</p>
<footer>
</footer>
</article>
```
4.3.6 The h1, h2, h3, h4, h5, and h6 elements

These elements represent headings for their sections.

The semantics and meaning of these elements are defined in the section on headings and sections.

These elements have a rank given by the number in their name. The h1 element is said to have the highest rank, the h6 element has the lowest rank, and two elements with the same name have equal rank.

Example

As far as their respective document outlines (their heading and section structures) are concerned, these two snippets are semantically equivalent:

```html
<body>
  <h1>Let's call it a drawing surface</h1>
</body>
```
Authors might prefer the former style for its terseness, or the latter style for its convenience in the face of heavy editing; which is best is purely an issue of preferred authoring style.

The two styles can be combined, for compatibility with legacy tools while still future-proofing for when that compatibility is no longer needed. This third snippet again has the same outline as the previous two:

```html
<body>
<h1>Let's call it a draw(ing surface)</h1>
<section>
<h2>Diving in</h2>
</section>
<section>
<h2>Simple shapes</h2>
</section>
<section>
<h2>Canvas coordinates</h2>
<section>
<h3>Canvas coordinates diagram</h3>
</section>
</section>
<section>
<h2>Paths</h2>
</section>
</body>
```
Contexts in which this element can be used:
Where flow content is expected.

Content model:
One or more \( h1, h2, h3, h4, h5, h6 \) elements, optionally intermixed with script-supporting elements.

Tag omission in `text/html`:
Neither tag is omissible.

Content attributes:
Global attributes

DOM interface:
Uses `HTMLElement`.

The `hgroup` element represents the heading of a section, which consists of all the \( h1 - h6 \) element children of the `hgroup` element. The element is used to group a set of \( h1 - h6 \) elements when the heading has multiple levels, such as subheadings, alternative titles, or taglines.

The `rank` of an `hgroup` element is the rank of the highest-ranked \( h1 - h6 \) element descendant of the `hgroup` element, if there are any such elements, or otherwise the same as for an `h1` element (the highest rank). Other `h1 - h6` elements of heading content in the `hgroup` element indicate subheadings or subtitles or (secondary) alternative titles.

The section on headings and sections defines how `hgroup` elements are assigned to individual sections.

Here are some examples of valid headings.

```html
<hgroup>
  <h1>The reality dysfunction</h1>
  <h2>Space is not the only void</h2>
</hgroup>

<hgroup>
  <h1>Dr. Strangelove</h1>
  <h2>Or: How I Learned to Stop Worrying and Love the Bomb</h2>
</hgroup>
```

The point of using `hgroup` in these examples is to prevent the `h2` element (which acts as a secondary title) from creating a separate section of its own in any outline and to instead cause the contents of the `h2` to be shown in rendered output from the outline algorithm in some way to indicate that it is not the title of a separate section but instead just a secondary title in a group of titles.

How a user agent exposes such multi-level headings in user interfaces (e.g. in tables of contents or search results) is left open to implementers, as it is a user interface issue. The first example above could be rendered as:

```
The reality dysfunction: Space is not the only void
```

Alternatively, it could look like this:

```
The reality dysfunction (Space is not the only void)
```

In interfaces where a title can be rendered on multiple lines, it could be rendered as follows, maybe with the first line in a bigger font size:

```
The reality dysfunction
Space is not the only void
```
The following two examples show ways in which two <h1> headings could be used within an <hgroup> element to group the US and UK names for the same movie.

```html
<hgroup>
  <h1>The Avengers</h1>
  <h1>Avengers Assemble</h1>
</hgroup>

<hgroup>
  <h1>Avengers Assemble</h1>
  <h1>The Avengers</h1>
</hgroup>
```

The first example above shows how the movie names might be grouped in a publication in the US, with the US name The Avengers as the (primary) title, and the UK name Avengers Assemble as the (secondary) alternative title. The second example above shows how the movie names might be grouped in a publication in the UK, with the UK name as the (primary) title, and the US name as the (secondary) alternative title.

In both cases it is important to note the use of the <hgroup> element to group the two titles indicates that the titles are not equivalent; instead the first <h1> gives the (primary) title while the second gives the (secondary) alternative title. Even though both the title and alternative title are marked up with <h1> elements, in a rendered view of output from the outline algorithm, the second <h1> in the <hgroup> will be shown in some way that clearly indicates it is secondary; for example:

In a US publication:

The Avengers (Avengers Assemble)

In a UK publication:

Avengers Assemble (The Avengers)

Example

In the following example, an <hgroup> element is used to mark up a two-level heading in a wizard-style dialog box:

```html
<dialog onclose="walletSetup.continue(this.returnValue)"
  <hgroup>
    <h1>Wallet Setup</h1>
    <h2>Configure your Wallet funding source</h2>
  </hgroup>
  <p>Your Wallet can be used to buy wands at the merchant in town, to buy potions from travelling salesmen you may find in the dungeons, and to pay for mercenaries.</p>
  <p>We support two payment sources:</p>
  <form method="dialog">
    <fieldset oninput="this.getElementsByTagName('input')[0].checked = true">
      <legend><label><input type=radio name=payment-type value=cc> Credit Card</label></legend>
      <p>Name on card: <input name=cc1 autocomplete="section-cc cc-name" placeholder="Y. Name"/></p>
      <p>Card number: <input name=cc2 inputmode=numeric autocomplete="section-cc cc-number" placeholder="6331 1019 9999 0016"></p>
      <p>Expiry Date: <input name=cc3 type=month autocomplete="section-cc cc-exp" placeholder="2020-02"></p>
      <p>Security Code: <input name=cc4 inputmode=numeric autocomplete="section-cc cc-csc" placeholder="246"></p>
    </fieldset>
    <fieldset oninput="this.getElementsByTagName('input')[0].checked = true">
      <legend><label><input type=radio name=payment-type value=bank> Checking Account</label></legend>
      <p>Name on account: <input name=bank1 autocomplete="section-bank cc-name"></p>
    </fieldset>
  </form>
</dialog>
```
4.3.8 The `header` element

**Categories**: Flow content, Palpable content.

**Contexts in which this element can be used**: Where `flow content` is expected.

**Content model**: Flow content, but with no `header` or `footer` element descendants.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**: Global attributes

**DOM interface**: Uses `HTMLElement`.

The `header` element represents, a group of introductory or navigational aids.

A `header` element is intended to usually contain the section's heading (an `h1`–`h6` element or an `hgroup` element), but this is not required. The `header` element can also be used to wrap a section's table of contents, a search form, or any relevant logos.

**Example**

Here are some sample headers. This first one is for a game:

```html
<header>
  <p>Welcome to...</p>
  <h1>Voidwars!</h1>
</header>
```

The following snippet shows how the element can be used to mark up a specification's header:

```html
<header>
  <hgroup>
    <h1>Fullscreen API</h1>
    <h2>Living Standard — Last Updated 19 October 2015</h2>
  </hgroup>
  <dl>
    <dt>Participate:</dt>
    <dd><a href="https://github.com/whatwg/fullscreen">GitHub whatwg/fullscreen</a></dd>
    <dt>Commits:</dt>
    <dd><a href="https://github.com/whatwg/fullscreen/commits">GitHub whatwg/fullscreen/commits</a></dd>
  </dl>
</header>
```
4.3.9 The `footer` element

Categories:
- Flow content
- Palpable content

Contexts in which this element can be used:
Where flow content is expected.

Content model:
- Flow content, but with no `header` or `footer` element descendants.

Tag omission in `text/html`:
Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:
Uses `HTMLElement`.

The `footer` element represents, for its nearest ancestor sectioning content or sectioning root element. A footer typically contains information about its section such as who wrote it, links to related documents, copyright data, and the like.

When the `footer` element contains entire sections, they represent appendices, indexes, long colophons, verbose license agreements, and other such content.
Footers don’t necessarily have to appear at the end of a section, though they usually do.

When the nearest ancestor sectioning content or sectioning root element is the body element, then it applies to the whole page.

The footer element is not sectioning content; it doesn’t introduce a new section.

Contact information for the author or editor of a section belongs in an address element, possibly inside a footer. Bylines and other information that could be suitable for both a header or a footer can be placed in either (or neither). The primary purpose of these elements is merely to help the author write self-explanatory markup that is easy to maintain and style; they are not intended to impose specific structures on authors.

Example

Here is a page with two footers, one at the top and one at the bottom, with the same content:

```html
<body>
<footer><a href="../">Back to index... </a></footer>
<hgroup>
<h1>Lorem ipsum</h1>
<h2>The ipsum of all lorems</h2>
</hgroup>
<p>A dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat. Duis aute irure dolor in reprehenderit in voluptate velit esse cillum dolore eu fugiat nulla pariatur. Excepteur sint occaecat cupidatat non proident, sunt in culpa qui officia deserunt mollit anim id est laborum.</p>
<footer><a href="../">Back to index... </a></footer>
</body>
```

Example

Here is an example which shows the footer element being used both for a site-wide footer and for a section footer.

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
<title>The Ramblings of a Scientist</title>
<body>
<h1>The Ramblings of a Scientist</h1>
<article>
<h1>Episode 15</h1>
<video src="/fm/015.ogv" controls preload>
<p><a href="/fm/015.ogv">Download video</a>.</p>
</video>
<footer>!-- footer for article -->
<p>Published <time datetime="2009-10-21T18:26:00-07:00">on 2009/10/21 at 6:26pm</time></p>
</footer>
</article>
<article>
<h1>My Favorite Trains</h1>
<p>I love my trains. My favorite train of all time is a Köf.</p>
<p>It is fun to see them pull some coal cars because they look so dwarfed in comparison.</p>
<footer>!-- footer for article -->
<p>Published <time datetime="2009-09-15T14:54:07-07:00">on 2009/09/15 at 2:54pm</time></p>
</footer>
</article>
</body>
</html>
```
Some site designs have what is sometimes referred to as “fat footers” — footers that contain a lot of material, including images, links to other articles, links to pages for sending feedback, special offers... in some ways, a whole “front page” in the footer.

This fragment shows the bottom of a page on a site with a “fat footer”:

```html
...<footer><nav><section><h1>Articles</h1><p><img src="images/somersaults.jpeg" alt=""> Go to the gym with our somersaults class! Our teacher Jim takes you through the paces in this two-part article. <a href="articles/somersaults/1">Part 1</a> · <a href="articles/somersaults/2">Part 2</a></p><p><img src="images/kindplus.jpeg"> Tired of walking on the edge of a cliff? Our guest writer Lara shows you how to bumble your way through the bars. <a href="articles/kindplus/1">Read more</a></p><p><img src="images/crisps.jpeg"> The chips are down, now all that’s left is a potato. What can you do with it? <a href="articles/crisps/1">Read more</a></p></section><ul><li><a href="/about">About us...</a></li><li><a href="/feedback">Send feedback!</a></li><li><a href="/sitemap">Sitemap</a></li></ul></nav><p>Copyright © 2015 The Snacker — <a href="/tos">Terms of Service</a></p></footer></body></html>
```

4.3.10 The *address* element

Categories:
- Flow content
- Palpable content

Contexts in which this element can be used:
- Where flow content is expected.

Content model:
- Flow content, but with no heading content descendants, no sectioning content descendants, and no header.
The `address` element represents the contact information for its nearest `article` or `body` element ancestor. If that is the body element, then the contact information applies to the document as a whole.

For example, a page at the W3C Web site related to HTML might include the following contact information:

```html
<Address>
  <A href="../People/Raggett/">Dave Raggett</A>,
  <A href="../People/Arnaud/">Arnaud Le Hors</A>,
  contact persons for the <A href="Activity">W3C HTML Activity</A>
</Address>
```

The `address` element must not be used to represent arbitrary addresses (e.g. postal addresses), unless those addresses are in fact the relevant contact information. (The `p` element is the appropriate element for marking up postal addresses in general.)

The `address` element must not contain information other than contact information.

For example, the following is non-conforming use of the `address` element:

```html
<Address>Last Modified: 1999/12/24 23:37:50</Address>
```

Typically, the `address` element would be included along with other information in a `footer` element.

The contact information for a node `node` is a collection of `address` elements defined by the first applicable entry from the following list:

- If `node` is an `article` element
- If `node` is a `body` element
  - The contact information consists of all the `address` elements that have `node` as an ancestor and do not have another `body` or `article` element ancestor that is a descendant of `node`.
- If `node` has an ancestor element that is an `article` element
- If `node` has an ancestor element that is a `body` element
  - The contact information of `node` is the same as the contact information of the nearest `article` or `body` element ancestor, whichever is nearest.
- If `node`'s `node document` has a `body` element
  - The contact information of `node` is the same as the contact information of the `body` element of the `Document`.
- Otherwise
  - There is no contact information for `node`.

User agents may expose the contact information of a node to the user, or use it for other purposes, such as indexing sections based on the sections' contact information.
In this example the footer contains contact information and a copyright notice.

```html
<footer>
    <address>
        For more details, contact
        <a href="mailto:js@example.com">John Smith</a>.
    </address>
    <p>&copy; copyright 2038 Example Corp.</p>
</footer>
```

### 4.3.11 Headings and sections

The `h1`–`h6` elements and the `hgroup` element are headings.

The first element of `heading content` in an element of `sectioning content` represents the heading for that section. Subsequent headings of equal or higher `rank` start new (implied) sections, headings of lower `rank` start implied subsections that are part of the previous one. In both cases, the element represents the heading of the implied section.

Certain elements are said to be *sectioning roots*, including `blockquote`, `body`, `details`, `dialog`, `fieldset`, `figure`, `td`, etc. These elements can have their own outlines, but the sections and headings inside these elements do not contribute to the outlines of their ancestors.

Sectioning content elements are always considered subsections of their nearest ancestor sectioning root or their nearest ancestor element of sectioning content, whichever is nearest, regardless of what implied sections other headings may have created.

**Example**

For the following fragment:

```html
<body>
    <h1>Foo</h1>
    <h2>Bar</h2>
    <blockquote>
        <h3>Bla</h3>
    </blockquote>
    <p>Baz</p>
    <h2>Quux</h2>
    <section>
        <h3>Thud</h3>
    </section>
    <p>Grunt</p>
</body>
```

...the structure would be:

1. Foo (heading of explicit `body` section, containing the "Grunt" paragraph)
   1. Bar (heading starting implied section, containing a block quote and the "Baz" paragraph)
   2. Quux (heading starting implied section with no content other than the heading itself)
   3. Thud (heading of explicit `section` section)

Notice how the `section` ends the earlier implicit section so that a later paragraph ("Grunt") is back at the top level.

Sections may contain headings of any `rank`, but authors are strongly encouraged to either use only `h1` elements, or to use elements of the appropriate `rank` for the section’s nesting level.
Authors are also encouraged to explicitly wrap sections in elements of `sectioning content`, instead of relying on the implicit sections generated by having multiple headings in one element of `sectioning content`.

**Example**

For example, the following is correct:

```html
<body>
  <h4>Apples</h4>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>They taste lovely.</p>
    <h6>Sweet</h6>
    <p>Red apples are sweeter than green ones.</p>
  </section>
  <h1>Color</h1>
  <p>Apples come in various colors.</p>
</section>
</body>
```

However, the same document would be more clearly expressed as:

```html
<body>
  <h1>Apples</h1>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>They taste lovely.</p>
  </section>
  <section>
    <h3>Sweet</h3>
    <p>Red apples are sweeter than green ones.</p>
  </section>
  <section>
    <h2>Color</h2>
    <p>Apples come in various colors.</p>
  </section>
</body>
```

Both of the documents above are semantically identical and would produce the same outline in compliant user agents.

This third example is also semantically identical, and might be easier to maintain (e.g. if sections are often moved around in editing):

```html
<body>
  <h1>Apples</h1>
  <p>Apples are fruit.</p>
  <section>
    <h1>Taste</h1>
    <p>They taste lovely.</p>
  </section>
  <section>
    <h1>Sweet</h1>
    <p>Red apples are sweeter than green ones.</p>
  </section>
  <section>
    <h1>Color</h1>
    <p>Apples come in various colors.</p>
  </section>
</body>
```
This section defines an algorithm for creating an outline for a sectioning content element or a sectioning root element. It is defined in terms of a walk over the nodes of a DOM tree, in tree order, with each node being visited when it is entered and when it is exited during the walk.

The outline for a sectioning content element or a sectioning root element consists of a list of one or more potentially nested sections. The element for which an outline is created is said to be the outline's owner.

A section is a container that corresponds to some nodes in the original DOM tree. Each section can have one heading associated with it, and can contain any number of further nested sections. The algorithm for the outline also associates each node in the DOM tree with a particular section and potentially a heading. (The sections in the outline aren't section elements, though some may correspond to such elements — they are merely conceptual sections.)

The following example would need explicit style rules to be rendered well in legacy browsers. Legacy browsers without CSS support would render all the headings as top-level headings.

### 4.3.11.1 Creating an outline

This section defines an algorithm for creating an outline for a sectioning content element or a sectioning root element. It is defined in terms of a walk over the nodes of a DOM tree, in tree order, with each node being visited when it is entered and when it is exited during the walk.

The outline for a sectioning content element or a sectioning root element consists of a list of one or more potentially nested sections. The element for which an outline is created is said to be the outline's owner.

A section is a container that corresponds to some nodes in the original DOM tree. Each section can have one heading associated with it, and can contain any number of further nested sections. The algorithm for the outline also associates each node in the DOM tree with a particular section and potentially a heading. (The sections in the outline aren't section elements, though some may correspond to such elements — they are merely conceptual sections.)

The following markup fragment:

```html
<body>
  <hgroup id="document-title">
    <h1>HTML</h1>
    <h2>Living Standard — Last Updated 12 August 2016</h2>
  </hgroup>
  <p>Some intro to the document.</p>
  <h2>Table of contents</h2>
  <ol id="toc">
    ...
  </ol>
  <h2>First section</h2>
  <p>Some intro to the first section.</p>
</body>
```

...results in the following outline being created for the body node (and thus the entire document):

1. **Section created for body node.**
   Associated with heading `<hgroup id="document-title">...` consisting of primary heading `<h1>HTML</h1>` and secondary heading `<h2>Living Standard — Last Updated 12 August 2016</h2>.
   Also associated with the paragraph `<p>Some intro to the document.</p>` (though it likely would not be shown in a rendered view of the outline).
   Nested sections:
   1. **Section implied for first h2 element.**
      Associated with heading `<h2>Table of contents</h2>.
      Also associated with the ordered list `<ol id="toc">
      ...
      </ol>` (though it likely would not be shown in a rendered view of the outline).
      No nested sections.
   2. **Section implied for second h2 element.**
      Associated with heading `<h2>First section</h2>.
      Also associated with the paragraph `<p>Some intro to the first section.</p>` (though it likely would not be shown in a rendered view of the outline).
      No nested sections.

The following image shows what a rendered view of the outline might look like.
The algorithm that must be followed during a walk of a DOM subtree rooted at a sectioning content element or a sectioning root element to determine that element's outline is as follows:

1. Let current outline target be null. (It holds the element whose outline is being created.)
2. Let current section be null. (It holds a pointer to a section, so that elements in the DOM can all be associated with a section.)
3. Create a stack to hold elements, which is used to handle nesting. Initialize this stack to empty.
4. Walk over the DOM in tree order, starting with the sectioning content element or sectioning root element at the root of the subtree for which an outline is to be created, and trigger the first relevant step below for each element as the walk enters and exits it.

When exiting an element, if that element is the element at the top of the stack

When exiting an element, if the stack is not empty

When entering an element with a hidden attribute

When entering a sectioning content element

When exiting a sectioning content element, if the stack is not empty
3. Let current section be the last section in the outline of the current outline target element.

4. Append the outline of the sectioning content element being exited to the current section. (This does not change which section is the last section in the outline.)

When entering a sectioning root element
Run these steps:

1. If current outline target is not null, push current outline target onto the stack.
2. Let current outline target be the element that is being entered.
3. Let current outline target’s parent section be current section.
4. Let current section be a newly created section for the current outline target element.
5. Let there be a new outline for the new current outline target, initialized with just the new current section as the only section in the outline.

When exiting a sectioning root element, if the stack is not empty
Run these steps:

1. If the current section has no heading, create an implied heading and let that be the heading for the current section.
2. Let current section be current outline target’s parent section.
3. Pop the top element from the stack, and let the current outline target be that element.

When exiting a sectioning content element or a sectioning root element (when the stack is empty)
If the current section has no heading, create an implied heading and let that be the heading for the current section.

When entering a heading content element
If the current section has no heading, let the element being entered be the heading for the current section.

Otherwise, if the element being entered has a rank equal to or higher than the heading of the last section of the outline of the current outline target, or if the heading of the last section of the outline of the current outline target is an implied heading, then create a new section and append it to the outline of the current outline target element, so that this new section is the new last section of that outline. Let current section be that new section. Let the element being entered be the new heading for the current section.

Otherwise, run these substeps:

1. Let candidate section be current section.
2. Heading loop: If the element being entered has a rank lower than the rank of the heading of the candidate section, then create a new section, and append it to candidate section. (This does not change which section is the last section in the outline.) Let current section be this new section. Let the element being entered be the new heading for the current section. Abort these substeps.
3. Let new candidate section be the section that contains candidate section in the outline of current outline target.
4. Let candidate section be new candidate section.
5. Return to the step labeled heading loop.

Push the element being entered onto the stack. (This causes the algorithm to skip any descendants of the element.)

Note: Recall that h1 has the highest rank, and h6 has the lowest rank.

Otherwise

Do nothing.

In addition, whenever the walk exits a node, after doing the steps above, if the node is not associated with a section yet, associate the node with the current section.

5. Associate all non-element nodes that are in the subtree for which an outline is being created with the section with which their parent element is associated.

6. Associate all nodes in the subtree with the heading of the section with which they are associated, if any.

The tree of sections created by the algorithm above, or a proper subset thereof, must be used when generating document outlines, for example when generating tables of contents.

The outline created for the body of a Document is the outline of the entire document.

When creating an interactive table of contents, entries should jump the user to the relevant sectioning content, if the section was created for a real element in the original document, or to the relevant heading content, if the section in the tree was generated for a heading in the above process.

Note: Selecting the first section of the document therefore always takes the user to the top of the document, regardless of where the first heading in the body is to be found.

The outline depth of a heading content element associated with a section, section is the number of sections that are ancestors of section in the outermost outline that section finds itself in when the outlines of its Document's elements are created, plus 1. The outline depth of a heading content element not associated with a section is 1.

User agents should provide default headings for sections that do not have explicit section headings.

Example

Consider the following snippet:

```html
<body>
  <nav>
    <p><a href="/">Home</a></p>
  </nav>
  <p>Hello world.</p>
  <aside>
    <p>My cat is cute.</p>
  </aside>
</body>
```

Although it contains no headings, this snippet has three sections: a document (the body) with two subsections (a nav and an aside). A user agent could present the outline as follows:

1. Untitled document
   1. Navigation
   2. Sidebar

These default headings ("Untitled document", "Navigation", "Sidebar") are not specified by this specification, and might vary with the user's language, the page's language, the user's preferences, the user agent implementer's preferences, etc.
The following JavaScript function shows how the tree walk could be implemented. The root argument is the root of the tree to walk (either a sectioning content element or a sectioning root element), and the enter and exit arguments are callbacks that are called with the nodes as they are entered and exited. (JavaScript)

```javascript
function (root, enter, exit) {
    var node = root;
    start: while (node) {
        enter(node);
        if (node.firstChild) {
            node = node.firstChild;
            continue start;
        }
        while (node) {
            exit(node);
            if (node == root) {
                node = null;
            } else if (node.nextSibling) {
                node = node.nextSibling;
                continue start;
            } else {
                node = node.parentNode;
            }
        }
    }
}
```

4.3.11.2 Sample outlines

This section is non-normative.

Example

The following document shows a straight-forward application of the outline algorithm. First, here is the document, which is a book with very short chapters and subsections:

```html
<!DOCTYPE HTML>
<html lang=en>
<title>The Tax Book (all in one page)</title>
<h1>The Tax Book</h1>
<h2>Earning money</h2>
<p>Earning money is good.</p>
<h3>Getting a job</h3>
<p>To earn money you typically need a job.</p>
<h2>Spending money</h2>
<p>Spending is what money is mainly used for.</p>
<h3>Cheap things</h3>
<p>Buying cheap things often not cost-effective.</p>
<h3>Expensive things</h3>
<p>The most expensive thing is often not the most cost-effective either.</p>
<h2>Investing money</h2>
<p>You can lend your money to other people.</p>
<h2>Losing money</h2>
<p>If you spend money or invest money, sooner or later you will lose money.</p>
<h3>Poor judgement</h3>
<p>Usually if you lose money it's because you made a mistake.</p>
```

This book would form the following outline:
1. The Tax Book
   1. Earning money
      1. Getting a job
   2. Spending money
      1. Cheap things
      2. Expensive things
   3. Investing money
   4. Losing money
      1. Poor judgement

Notice that the title element does not participate in the outline.

Example

Here is a similar document, but this time using section elements to get the same effect:

```html
<!DOCTYPE HTML>
<html lang=en>
<title>The Tax Book (all in one page)</title>
<h1>The Tax Book</h1>
<section>
  <h1>Earning money</h1>
  <p>Earning money is good.</p>
</section>
<section>
  <h1>Getting a job</h1>
  <p>To earn money you typically need a job.</p>
</section>
<section>
  <h1>Spending money</h1>
  <p>Spending is what money is mainly used for.</p>
  <section>
    <h1>Cheap things</h1>
    <p>Buying cheap things often not cost-effective.</p>
  </section>
  <section>
    <h1>Expensive things</h1>
    <p>The most expensive thing is often not the most cost-effective either.</p>
  </section>
</section>
<section>
  <h1>Investing money</h1>
  <p>You can lend your money to other people.</p>
</section>
<section>
  <h1>Losing money</h1>
  <p>If you spend money or invest money, sooner or later you will lose money.
  <section>
    <h1>Poor judgement</h1>
    <p>Usually if you lose money it's because you made a mistake.</p>
  </section>
</section>
```

This book would form the same outline:

1. The Tax Book
   1. Earning money
      1. Getting a job
   2. Spending money
      1. Cheap things
      2. Expensive things
   3. Investing money
   4. Losing money
1. Poor judgement

Example

A document can contain multiple top-level headings:

<!DOCTYPE HTML>
<html lang=en>
<title>Alphabetic Fruit</title>
<h1>Apples</h1>
<p>Pomaceous.</p>
<h1>Bananas</h1>
<p>Edible.</p>
<h1>Carambola</h1>
<p>Star.</p>
</example>

This would form the following simple outline consisting of three top-level sections:

1. Apples
2. Bananas
3. Carambola

Effectively, the <code>body</code> element is split into three.

Example

Mixing both the <code>h1-h6</code> model and the <code>section/h1</code> model can lead to some unintuitive results.

Consider for example the following, which is just the previous example but with the contents of the (implied) <code>body</code> wrapped in a <code>section</code>:

<example>

<!DOCTYPE HTML>
<html lang=en>
<title>Alphabetic Fruit</title>
<section>
<h1>Apples</h1>
<p>Pomaceous.</p>
<h1>Bananas</h1>
<p>Edible.</p>
<h1>Carambola</h1>
<p>Star.</p>
</section>
</example>

The resulting outline would be:

1. (untitled page)
   1. Apples
   2. Bananas
   3. Carambola

This result is described as unintuitive because it results in three subsections even though there's only one <code>section</code> element. Effectively, the <code>section</code> is split into three, just like the implied <code>body</code> element in the previous example.

(In this example, "(untitled page)" is the implied heading for the <code>body</code> element, since it has no explicit heading.)

Example

Headings never rise above other sections. Thus, in the following example, the first <code>h1</code> does not actually describe the page header; it describes the header for the second half of the page:
A plea from our caretakers

Please, we beg of you, send help! We're stuck in the server room!

Feathers

Epidermal growths.

The resulting outline would be:

1. (untitled page)
   1. A plea from our caretakers
   2. Feathers

Example

Thus, when an article element starts with a nav block and only later has its heading, the result is that the nav block is not part of the same section as the rest of the article in the outline. For instance, take this document:

Example

The resulting outline would be:

1. Ray's blog
   1. Untitled article
      1. Untitled navigation section
   2. We're adopting a child!

Also worthy of note in this example is that the header element has no effect whatsoever on the document outline.

Example

The hgroup element can be used for subheadings. For example:
We sleep.

The afternoon
12:00 to 18:00

We study.

Additional Commentary
Because not all this is necessarily true
Ok it's almost certainly not true

Yeah we probably play, rather than study.

The evening
18:00 to 00:00

We play.

The night
00:00 to 06:00

We play some more.

The resulting outline would be:

1. The morning 06:00 to 12:00
2. The afternoon 12:00 to 18:00
3. The evening 18:00 to 00:00
4. The night 00:00 to 06:00

Exactly how this is represented by user agents, as most interface issues, is left as a matter of implementation preference, but the key part is that the `<hgroup>`'s descendant `<h1>`, `<h2>`, `<h3>`, `<h6>` elements are what form the element's heading. Thus, the following would be equally valid:

1. The morning — 06:00 to 12:00
2. The afternoon — 12:00 to 18:00
   1. Additional Commentary — Because not all this is necessarily true — Ok it's almost certainly not true
3. The evening — 18:00 to 00:00
4. The night — 00:00 to 06:00

But so would the following:

1. The morning
2. The afternoon
   1. Additional Commentary
3. The evening
4. The night

The following would also be valid, though maybe less practical in most contexts:

1. The morning
   06:00 to 12:00
2. The afternoon
   12:00 to 18:00
   1. Additional Commentary
      Because not all this is necessarily true
      Ok it's almost certainly not true
3. The evening
   18:00 to 00:00
4. The night
   00:00 to 06:00
### 4.3.11.3 Exposing outlines to users

User agents are encouraged to expose page outlines to users to aid in navigation. This is especially true for non-visual media, e.g. screen readers.

However, to mitigate the difficulties that arise from authors misusing sectioning content, user agents are also encouraged to offer a mode that navigates the page using heading content alone.

For instance, a user agent could map the arrow keys as follows:

**Shift+← Left**
- Go to previous section, including subsections of previous sections

**Shift+→ Right**
- Go to next section, including subsections of the current section

**Shift+↑ Up**
- Go to parent section of the current section

**Shift+↓ Down**
- Go to next section, skipping subsections of the current section

Plus in addition, the user agent could map the \( j \) and \( k \) keys to navigating to the previous or next element of heading content, regardless of the section’s outline depth and ignoring sections with no headings.

### 4.3.12 Usage summary

This section is non-normative.

<table>
<thead>
<tr>
<th>Element</th>
<th>Purpose</th>
<th>Example</th>
</tr>
</thead>
</table>
| body[171] | The contents of the document. | `<!DOCTYPE HTML>
<html lang="en">
<head> <title>Steve Hill's Home Page</title> </head>
<body> <p>Hard Trance is My Life.</p> </body>
</html>` |
| article[171] | A complete, or self-contained, composition in a document, page, application, or site and that is, in principle, independently distributable or reusable, e.g. in syndication. This could be a forum post, a magazine or newspaper article, a blog entry, a user-submitted comment, an interactive widget or gadget, or any other independent item of content. | `<article>
  <img src="/tumblr_masqy2s5yn1rzfqbpo1_500.jpg" alt="Yellow smiley face with the caption 'masif'">
  <p>My fave Masif tee so far!</p>
  <footer>Posted 2 days ago</footer>
</article>` |
| section[171] | A generic section of a document or application. A section, in this context, is a thematic grouping of content, typically with a heading. | `<h1>Biography</h1>
  <section>
    <h1>The facts</h1>
    <p>1500+ shows, 14+ countries</p>
  </section>
  <section>
    <h1>2010/2011 figures per year</h1>
    <p>100+ shows, 8+ countries</p>
  </section>` |
4.3.12.1 Article or section? §420

This section is non-normative.

A section forms part of something else. An article is its own thing. But how does one know which is which? Mostly the real
answer is "it depends on author intent".

For example, one could imagine a book with a "Granny Smith" chapter that just said “These juicy, green apples make a great filling for apple pies.”; that would be a section because there'd be lots of other chapters on (maybe) other kinds of apples.

On the other hand, one could imagine a tweet or reddit comment or tumblr post or newspaper classified ad that just said "Granny Smith. These juicy, green apples make a great filling for apple pies."; it would then be article because that was the whole thing.

A comment on an article is not part of the article on which it is commenting, therefore it is its own article.

4.4 Grouping content

4.4.1 The p element

Categories:
Flow content
Palpable content

Contexts in which this element can be used:
Where flow content is expected.

Content model:
Phrasing content

Tag omission in text/html:
A p element's end tag can be omitted if the p element is immediately followed by an address, article, aside, blockquote, details, div, dl, fieldset, figcaption, figure, footer, form, h1, h2, h3, h4, h5, h6, header, hgroup, hr, main, menu, nav, ol, p, pre, section, table, or ul element, or if there is no more content in the parent element and the parent element is an HTML element that is not an a, audio, del, ins, map, noscript, or video element, or an autonomous custom element.

Content attributes:
Global attributes

DOM interface:

IDL

```
interface HTMLParagraphElement : HTMLElement {};
```

The p element represents a paragraph.

Note
While paragraphs are usually represented in visual media by blocks of text that are physically separated from adjacent blocks through blank lines, a style sheet or user agent would be equally justified in presenting paragraph breaks in a different manner, for instance using inline pilcrows (¶).

Example

The following examples are conforming HTML fragments:

```
<p>The little kitten gently seated herself on a piece of carpet. Later in her life, this would be referred to as the time the cat sat on the mat.</p>

<fieldset>
<legend>Personal information</legend>
<p>
<label>Name: <input name="n"></label>
```
The `p` element should not be used when a more specific element is more appropriate.

Example

The following example is technically correct:

```html
<section>
<!-- ... -->
<p>Last modified: 2001-04-23</p>
<p>Author: fred@example.com</p>
</section>
```

However, it would be better marked-up as:

```html
<section>
<!-- ... -->
<footer>Last modified: 2001-04-23</footer>
<address>Author: fred@example.com</address>
</section>
```

Or:

```html
<section>
<!-- ... -->
<footer>
<p>Last modified: 2001-04-23</p>
<address>Author: fred@example.com</address>
</footer>
</section>
```

Note

List elements (in particular, `ol` and `ul` elements) cannot be children of `p` elements. When a sentence contains a bulleted list, therefore, one might wonder how it should be marked up.

Example

For instance, this fantastic sentence has bullets relating to

- wizards,
- faster-than-light travel, and
- telepathy,

and is further discussed below.
The solution is to realize that a paragraph in HTML terms, is not a logical concept, but a structural one. In the fantastic example above, there are actually five paragraphs as defined by this specification: one before the list, one for each bullet, and one after the list.

**Example**

The markup for the above example could therefore be:

```html
<p>For instance, this fantastic sentence has bullets relating to</p>
<ul>
  <li>wizards, </li>
  <li>faster-than-light travel, and </li>
  <li>telepathy, </li>
</ul>
<p>and is further discussed below.</p>
```

Authors wishing to conveniently style such "logical" paragraphs consisting of multiple "structural" paragraphs can use the `div` element instead of the `p` element.

**Example**

Thus for instance the above example could become the following:

```html
<div>
  For instance, this fantastic sentence has bullets relating to
  <ul>
    <li>wizards, </li>
    <li>faster-than-light travel, and </li>
    <li>telepathy, </li>
  </ul>
  and is further discussed below.
</div>
```

This example still has five structural paragraphs, but now the author can style just the `div` instead of having to consider each part of the example separately.

### 4.4.2 The `hr` element

**Categories**: Flow content.

**Contexts in which this element can be used**: Where flow content is expected.

**Content model**: Nothing.

**Tag omission in text/html**: No end tag.

**Content attributes**: Global attributes.

**DOM interface**:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLHRElement : HTMLElement {};
```
The `hr` element represents a paragraph-level thematic break, e.g. a scene change in a story, or a transition to another topic within a section of a reference book.

**Example**

The following fictional extract from a project manual shows two sections that use the `hr` element to separate topics within the section.

```xml
<section>
  <h1>Communication</h1>
  <p>There are various methods of communication. This section covers a few of the important ones used by the project.</p>
  <hr>
  <p>Communication stones seem to come in pairs and have mysterious properties:</p>
  <ul>
    <li>They can transfer thoughts in two directions once activated if used alone.</li>
    <li>If used with another device, they can transfer one's consciousness to another body.</li>
    <li>If both stones are used with another device, the consciousnesses switch bodies.</li>
  </ul>
  <hr>
  <p>Radios use the electromagnetic spectrum in the meter range and longer.</p>
  <hr>
  <p>Signal flares use the electromagnetic spectrum in the nanometer range.</p>
</section>

<section>
  <h1>Food</h1>
  <p>All food at the project is rationed:</p>
  <dl>
    <dt>Potatoes</dt>
    <dd>Two per day</dd>
    <dt>Soup</dt>
    <dd>One bowl per day</dd>
  </dl>
  <hr>
  <p>Cooking is done by the chefs on a set rotation.</p>
</section>
```

There is no need for an `hr` element between the sections themselves, since the `section` elements and the `h1` elements imply thematic changes themselves.

**Example**

The following extract from *Pandora's Star* by Peter F. Hamilton shows two paragraphs that precede a scene change and the paragraph that follows it. The scene change, represented in the printed book by a gap containing a solitary centered star between the second and third paragraphs, is here represented using the `hr` element.

```
<p>Dudley was ninety-two, in his second life, and fast approaching time for another rejuvenation. Despite his body having the physical age of a standard fifty-year-old, the prospect of a long degrading campaign within academia was one he regarded with dread. For a supposedly advanced civilization, the Intersolar Commonwealth could be appallingly backward at times, not to mention cruel.</p>
<p><i>Maybe it won’t be that bad</i>, he told himself. The lie was comforting enough to get him through the rest of the night’s</p>
```
The pre element represents a block of preformatted text, in which structure is represented by typographic conventions rather than by elements.

Some examples of cases where the pre element could be used:

- Including an e-mail, with paragraphs indicated by blank lines, lists indicated by lines prefixed with a bullet, and so on.
- Including fragments of computer code, with structure indicated according to the conventions of that language.
- Displaying ASCII art.

Authors are encouraged to consider how preformatted text will be experienced when the formatting is lost, as will be the case for users of speech synthesizers, braille displays, and the like. For cases like ASCII art, it is likely that an alternative presentation, such as a textual description, would be more universally accessible to the readers of the document.

To represent a block of computer code, the pre element can be used with a code element; to represent a block of computer output the pre element can be used with a samp element. Similarly, the kbd element can be used within a pre element to shift.

<hr>

The Carlton AllLander drove Dudley home just after dawn. Like the astronomer, the vehicle was old and worn, but perfectly capable of doing its job. It had a cheap diesel engine, common enough on a semi-frontier world like Gralmond, although its drive array was a thoroughly modern photoneural processor. With its high suspension and deep-tread tyres it could plough along the dirt track to the observatory in all weather and seasons, including the metre-deep snow of Gralmond's winters.
**Note**

This element has rendering requirements involving the bidirectional algorithm.

**Example**

In the following snippet, a sample of computer code is presented.

```
<p> This is the <code>Panel</code> constructor: </p>
<pre>
function Panel(element, canClose, closeHandler) {
  this.element = element;
  this.canClose = canClose;
  this.closeHandler = function () { if (closeHandler) closeHandler() };
}</pre>

**Example**

In the following snippet, <samp> and <kbd> elements are mixed in the contents of a <pre> element to show a session of Zork I.

```
<pre>
<samp>You are in an open field west of a big white house with a boarded front door.
There is a small mailbox here.
</samp>
<kbd>open mailbox</kbd>
<samp>Opening the mailbox reveals:
A leaflet.
</samp>
</pre>
```

**Example**

The following shows a contemporary poem that uses the <pre> element to preserve its unusual formatting, which forms an intrinsic part of the poem itself.

```
<pre>
maxling
it is with a heart heavy
that i admit loss of a feline so loved
a friend lost to the unknown (night)
~cdr 11dec07</pre>
```

4.4.4 The **blockquote** element

Categories:

- Flow content
- Sectioning root
- Palpable content
Contexts in which this element can be used:

Where flow content is expected.

Content model:

Flow content.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

- Global attributes:
  - cite — Link to the source of the quotation or more information about the edit

DOM interface:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLQuoteElement : HTMLElement {
  [CFReactions] attribute USVString cite;
};
```

The `HTMLQuoteElement` interface is also used by the `q` element.

The **blockquote** element represents a section that is quoted from another source.

Content inside a **blockquote** must be quoted from another source, whose address, if it has one, may be cited in the `cite` attribute.

If the `cite` attribute is present, it must be a valid URL potentially surrounded by spaces. To obtain the corresponding citation link, the value of the attribute must be parsed relative to the element's node document. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g., by server-side scripts collecting statistics about a site's use of quotations), not for readers.

The content of a **blockquote** may be abbreviated or may have context added in the conventional manner for the text's language.

**Example**

For example, in English this is traditionally done using square brackets. Consider a page with the sentence "Jane ate the cracker. She then said she liked apples and fish."; it could be quoted as follows:

```html
<blockquote>
  <p>[Jane] then said she liked [...] fish.</p>
</blockquote>
```

Attribution for the quotation, if any, must be placed outside the **blockquote** element.

**Example**

For example, here the attribution is given in a paragraph after the quote:

```html
<blockquote>
  <p>I contend that we are both atheists. I just believe in one fewer god than you do. When you understand why you dismiss all the other possible gods, you will understand why I dismiss yours.</p>
</blockquote>
<p>-- Stephen Roberts</p>
```

The other examples below show other ways of showing attribution.
The **cite** IDL attribute must **reflect** the element’s **cite** content attribute.

**Example**

Here a **blockquote** element is used in conjunction with a **figure** element and its **figcaption** to clearly relate a quote to its attribution (which is not part of the quote and therefore doesn't belong inside the **blockquote** itself):

```html
<figure>
  <blockquote>
    <p>The truth may be puzzling. It may take some work to grapple with. It may be counterintuitive. It may contradict deeply held prejudices. It may not be consonant with what we desperately want to be true. But our preferences do not determine what's true. We have a method, and that method helps us to reach not absolute truth, only asymptotic approaches to the truth — never there, just closer and closer, always finding vast new oceans of undiscovered possibilities. Cleverly designed experiments are the key.</p>
  </blockquote>
  <figcaption>Carl Sagan, in "**cite** Wonder and Skepticism"**, from the **cite** Skeptical Inquirer** Volume 19, Issue 1 (January-February 1995)**</figcaption>
</figure>
```

**Example**

This next example shows the use of **cite** alongside **blockquote**:

```html
<p>His next piece was the aptly named **cite** Sonnet 130**:p</p>
<blockquote cite="https://quotes.example.org/s/sonnet130.html">
  <p><br>
    Coral is far more red, than her lips red, </p>
  ...</blockquote>
```

**Example**

This example shows how a forum post could use **blockquote** to show what post a user is replying to. The **article** element is used for each post, to mark up the threading.

```html
<article>
  <h1><a href="https://bacon.example.com/?blog=109431">Bacon on a crowbar</a></h1>
</article>
<article><strong>t3yw</strong> 12 points 1 hour ago</article>
<article><p>I bet a narwhal would love that.</p><p>My mistress' eyes are nothing like the sun, <br>
Coral is far more red, than her lips red, <br>
...<br>
</article>
<article><strong>greg</strong> 8 points 1 hour ago</article>
<article><blockquote>
  <p>I bet a narwhal would love that.</p>
  <p>Dude narwhals don't eat bacon.</p>
</blockquote></article>
<article><p>Next thing you'll be saying they don't get capes and wizard hats either!<p><p>
</article>
<article><strong>t3yw</strong> 15 points 1 hour ago</article>
<article><blockquote><p>I bet a narwhal would love that.<br>
Dude narwhals don't eat bacon.</p>
</blockquote></article>
<article><p>Next thing you'll be saying they don't get capes and wizard hats either!</p></article>
```
4.4.5 The ol element

Categories:
- Flow content
  - If the element’s children include at least one li element: Palpable

Contexts in which this element can be used:
- Where flow content is expected.

Content model:
- Zero or more li and script-supporting elements.

Tag omission in text/html:
- Neither tag is omissible.

Content attributes:
- Global attributes
  - reversed — Number the list backwards
  - start — Starting value of the list
  - type — Kind of list marker

Example

This example shows the use of a blockquote for short snippets, demonstrating that one does not have to use p elements inside blockquote elements:

<p>He began his list of "lessons" with the following:</p>
<blockquote>One should never assume that his side of the issue will be recognized, let alone that it will be conceded to have merits.</blockquote>
<p>He continued with a number of similar points, ending with:</p>
<blockquote>Finally, one should be prepared for the threat of breakdown in negotiations at any given moment and not be cowed by the possibility.</blockquote>
<p>We shall now discuss these points...</p>

Note

Examples of how to represent a conversation are shown in a later section; it is not appropriate to use the cite and blockquote elements for this purpose.
DOM interface:\(^{125}\):

```javascript
[Exposed=Window, HTMLConstructor]
interface HTMLOLListElement : HTMLElement {
  [CEReactions] attribute boolean reversed;
  [CEReactions] attribute long start;
  [CEReactions] attribute DOMString type;
};
```

The `ol` element represents a list of items, where the items have been intentionally ordered, such that changing the order would change the meaning of the document.

The items of the list are the `li` element child nodes of the `ol` element, in tree order.

The `reversed` attribute is a boolean attribute. If present, it indicates that the list is a descending list (..., 3, 2, 1). If the attribute is omitted, the list is an ascending list (1, 2, 3, ...).

The `start` attribute, if present, must be a valid integer. It is used to determine the starting value of the list.

An `ol` element has a starting value, which is an integer determined as follows:

1. If the `ol` element has a `start` attribute, then:
   1. Let `parsed` be the result of parsing the value of the attribute as an integer.
   2. If `parsed` is not an error, then return `parsed`.

2. If the `ol` element has a `reversed` attribute, then return the number of owned `li` elements.

The `type` attribute can be used to specify the kind of marker to use in the list, in the cases where that matters (e.g. because items are to be referenced by their number/letter). The attribute, if specified, must have a value that is a case-sensitive match for one of the characters given in the first cell of one of the rows of the following table. The `type` attribute represents the state given in the cell in the second column of the row whose first cell matches the attribute's value; if none of the cells match, or if the attribute is omitted, then the attribute represents the decimal state.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
<th>Description</th>
<th>Examples for values 1-3 and 3999-4001</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (U+0031)</td>
<td>decimal</td>
<td>Decimal numbers</td>
<td>1. 2. 3. ... 3999. 4000. 4001. ...</td>
</tr>
<tr>
<td>a (U+0061)</td>
<td>lower-alpha</td>
<td>Lowercase latin alphabet</td>
<td>a. b. c. ... eww. eww. eww. ...</td>
</tr>
<tr>
<td>A (U+0041)</td>
<td>upper-alpha</td>
<td>Uppercase latin alphabet</td>
<td>A. B. C. ... EWJ. EWJ. EWJ. ...</td>
</tr>
<tr>
<td>1 (U+0069)</td>
<td>lower-roman</td>
<td>Lowercase roman numerals</td>
<td>I. II. III. ... mmcmxcix. iv. ivl. ...</td>
</tr>
<tr>
<td>I (U+0049)</td>
<td>upper-roman</td>
<td>Uppercase roman numerals</td>
<td>I. II. III. ... MCMCMXIX. IV. IVL. ...</td>
</tr>
</tbody>
</table>

User agents should render the items of the list in a manner consistent with the state of the `type` attribute of the `ol` element. Numbers less than or equal to zero should always use the decimal system regardless of the `type` attribute.

Note

For CSS user agents, a mapping for this attribute to the `list-style-type` CSS property is given in the rendering section (the mapping is straightforward: the states above have the same names as their corresponding CSS values).

Note

It is possible to redefine the default CSS list styles used to implement this attribute in CSS user agents; doing so will affect how list items are rendered.

The `reversed` and `type IDL attributes must reflect the respective content attributes of the same name.

The `start IDL attribute must reflect the content attribute of the same name, with a default value of 1.
This means that the `start` IDL attribute does not necessarily match the list's `starting value`, in cases where the `start` content attribute is omitted and the `reversed` content attribute is specified.

---

**Example**

The following markup shows a list where the order matters, and where the `ol` element is therefore appropriate. Compare this list to the equivalent list in the `ul` section to see an example of the same items using the `ul` element.

```html
<p>I have lived in the following countries (given in the order of when I first lived there):</p>
<ol>
  <li>Switzerland</li>
  <li>United Kingdom</li>
  <li>United States</li>
  <li>Norway</li>
</ol>
```

Note how changing the order of the list changes the meaning of the document. In the following example, changing the relative order of the first two items has changed the birthplace of the author:

```html
<p>I have lived in the following countries (given in the order of when I first lived there):</p>
<ol>
  <li>United Kingdom</li>
  <li>Switzerland</li>
  <li>United States</li>
  <li>Norway</li>
</ol>
```

---

### 4.4.6 The `ul` element

**Categories**: Flow content.

If the element’s children include at least one `li` element: Palpable content.

**Contexts in which this element can be used**: Where flow content is expected.

**Content model**: Zero or more `li` and script-supporting elements.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**: Global attributes.

**DOM interface**:

```javascript
interface HTMLListElement : HTMLElement {};
```

The `ul` element represents a list of items, where the order of the items is not important — that is, where changing the order would not materially change the meaning of the document.

The items of the list are the `li` element child nodes of the `ul` element.
The following markup shows a list where the order does not matter, and where the `<ul>` element is therefore appropriate. Compare this list to the equivalent list in the `<ol>` section to see an example of the same items using the `<ol>` element.

```html
<p>I have lived in the following countries:</p>
<ul>
  <li>Norway</li>
  <li>Switzerland</li>
  <li>United Kingdom</li>
  <li>United States</li>
</ul>
```

Note that changing the order of the list does not change the meaning of the document. The items in the snippet above are given in alphabetical order, but in the snippet below they are given in order of the size of their current account balance in 2007, without changing the meaning of the document whatsoever:

```html
<p>I have lived in the following countries:</p>
<ul>
  <li>Switzerland</li>
  <li>Norway</li>
  <li>United Kingdom</li>
  <li>United States</li>
</ul>
```

4.4.7 The `<menu>` element

**Categories**: Flow content

If the element's children include at least one `<li>` element: Palpable content.

**Contexts in which this element can be used**: Where flow content is expected.

**Content model**: Zero or more `<li>` and script-supporting elements.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**: Global attributes

**DOM interface**:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLMenuElement : HTMLElement {
}
```

The `<menu>` element represents a toolbar consisting of its contents, in the form of an unordered list of items (represented by `<li>` elements), each of which represents a command that the user can perform or activate.

**Note**

The `<menu>` element is simply a semantic alternative to `<ul>` to express an unordered list of commands (a "toolbar").

**Example**

In this example, a text-editing application uses a `<menu>` element to provide a series of editing commands:
4.4.8 The **li** element

**Categories:**
None.

**Contexts in which this element can be used:**
- Inside **ol** elements.
- Inside **ul** elements.
- Inside **menu** elements.

**Content model:**
Flow content.

**Tag omission in text/html:**
An **li** element’s end tag can be omitted if the **li** element is immediately followed by another **li** element or if there is no more content in the parent element.

**Content attributes:**
- **Global attributes**
  - If the element is not a child of an **ul** or **menu** element: `value` — Ordinal value of the list item.

**DOM interface:**

```javascript
IDL
[Exposed=Window,
  HTMLConstructor]
interface HTMLLIElement : HTMLElement {
  [CEReactions] attribute long value;
};
```

The **li** element represents a list item. If its parent element is an **ol**, **ul**, or **menu** element, then the element is an item of the parent element’s list, as defined for those elements. Otherwise, the list item has no defined list-related relationship to any other **li** element.

The `value` attribute, if present, must be a valid integer. It is used to determine the **ordinal value** of the list item, when the **li**’s **list owner** is an **ol** element.

Any element whose computed value of ‘display’ is ‘list-item’ has a **list owner**, which is determined as follows:

1. If the element is not being rendered, return null; the element has no **list owner**.
2. Let `ancestor` be the element’s parent.
3. If the element has an **ol**, **ul**, or **menu** ancestor, set `ancestor` to the closest such ancestor element.
4. Return the closest inclusive ancestor of `ancestor` that produces a CSS box.

**Note:** Such an element will always exist, as at the very least the document element will always produce a CSS box.

To determine the **ordinal value** of each element owned by a given **list owner** owner, perform the following steps:
1. Let $i$ be 1.

2. If owner is an ol element, let numbering be owner's starting value. Otherwise, let numbering be 1.

3. Loop: If $i$ is greater than the number of list items that owner owns, then return; all of owner's owned list items have been assigned ordinal values.

4. Let item be the $i$th of owner's owned list items, in tree order.

5. If item is an li element that has a value attribute, then:
   1. Let parsed be the result of parsing the value of the attribute as an integer.
   2. If parsed is not an error, then set numbering to parsed.

6. The ordinal value of item is numbering.

7. If owner is an ol element, and owner has a reversed attribute, decrement numbering by 1; otherwise, increment numbering by 1.

8. Increment $i$ by 1.

9. Go to the step labeled loop.

The value IDL attribute must reflect the value of the value content attribute.

Example

The element's value IDL attribute does not directly correspond to its ordinal value; it simply reflects the content attribute. For example, given this list:

```
<ol>
  <li>Item 1</li>
  <li value="3">Item 3</li>
  <li>Item 4</li>
</ol>
```

The ordinal values are 1, 3, and 4, whereas the value IDL attributes return 0, 3, 0 on getting.

Example

The following example, the top ten movies are listed (in reverse order). Note the way the list is given a title by using a figure element and its figcaption element.

```
<figure>
  <figcaption>The top 10 movies of all time</figcaption>
  <ol>
    <li value="10"><cite>Josie and the Pussycats</cite>, 2001</li>
    <li value="9"><cite>Црна мачка, бели мачор</cite>, 1998</li>
    <li value="8"><cite>A Bug's Life</cite>, 1998</li>
    <li value="7"><cite>Toy Story</cite>, 1995</li>
    <li value="6"><cite>Monsters, Inc</cite>, 2001</li>
    <li value="5"><cite>Cars</cite>, 2006</li>
    <li value="4"><cite>Toy Story 2</cite>, 1999</li>
    <li value="3"><cite>Finding Nemo</cite>, 2003</li>
    <li value="2"><cite>The Incredibles</cite>, 2004</li>
    <li value="1"><cite>Ratatouille</cite>, 2007</li>
  </ol>
</figure>
```

The markup could also be written as follows, using the reversed attribute on the ol element:
The top 10 movies of all time:

1. *Josie and the Pussycats*, 2001
2. *Црна мачка, бели мачор*, 1998
7. *Toy Story 2*, 1999

**Note:** While it is conforming to include heading elements (e.g. `<h1>` inside `<li>` elements, it likely does not convey the semantics that the author intended. A heading starts a new section, so a heading in a list implicitly splits the list into spanning multiple sections.

### 4.4.9 The `dl` element

**Categories:**

- Flow content
- Palpable content

If the element’s children include at least one name-value group: Palpable content.

**Contexts in which this element can be used:** Where flow content is expected.

**Content model:**

Either: Zero or more groups each consisting of one or more `dt` elements followed by one or more `dd` elements, optionally intermixed with script-supporting elements.

Or: One or more `div` elements, optionally intermixed with script-supporting elements.

**Tag omission in text/html:** Neither tag is omissible.

**Content attributes:**

- Global attributes

**DOM interface:**

```
[Exposed=Window, HTMLConstructor]
interface HTMLDListElement : HTMLElement {};
```

The `dt` element represents an association list consisting of zero or more name-value groups (a description list). A name-value group consists of one or more names (`dt` elements, possibly as children of a `div` element child) followed by one or more values (`dd` elements, possibly as children of a `div` element child), ignoring any nodes other than `dt` and `dd` element children, and `dt` and `dd` elements that are children of `div` element children. Within a single `dt` element, there should not be more than one `dt` element for each name.

Name-value groups may be terms and definitions, metadata topics and values, questions and answers, or any other groups of name-value data.

The values within a group are alternatives; multiple paragraphs forming part of the same value must all be given within the same `dd` element.

The order of the list of groups, and of the names and values within each group, may be significant.
In order to annotate groups with microdata\(^{705}\) attributes, or other global attributes\(^{9132}\) that apply to whole groups, or just for styling purposes, each group in a \(\text{dl}\) element can be wrapped in a \(\text{div}\) element. This does not change the semantics of the \(\text{dl}\) element.

The name-value groups of a \(\text{dl}\) element are determined using the following algorithm. A name-value group has a name (a list of \(\text{dt}\) elements, initially empty) and a value (a list of \(\text{dd}\) elements, initially empty).

1. Let \(\text{groups}\) be an empty list of name-value groups.
2. Let \(\text{current}\) be a new name-value group.
3. Let \(\text{seenDd}\) be false.
4. Let \(\text{child}\) be \(\text{dl}\)'s first child.
5. Let \(\text{grandchild}\) be null.
6. While \(\text{child}\) is not null:
   1. If \(\text{child}\) is a \(\text{div}\) element, then:
      1. Let \(\text{grandchild}\) be \(\text{child}\)'s first child.
      2. While \(\text{grandchild}\) is not null:
         1. Process \(\text{dt}\) or \(\text{dd}\) for \(\text{grandchild}\).
         2. Set \(\text{grandchild}\) to \(\text{grandchild}\)'s next sibling.
   2. Otherwise, process \(\text{dt}\) or \(\text{dd}\) for \(\text{child}\).
   3. Set \(\text{child}\) to \(\text{child}\)'s next sibling.
7. If \(\text{current}\) is not empty, then append \(\text{current}\) to \(\text{groups}\).
8. Return \(\text{groups}\).

To process \(\text{dt}\) or \(\text{dd}\) for a node \(\text{node}\) means to follow these steps:

1. Let \(\text{groups}\), \(\text{current}\), and \(\text{seenDd}\) be the same variables as those of the same name in the algorithm that invoked these steps.
2. If \(\text{node}\) is a \(\text{dt}\) element, then:
   1. If \(\text{seenDd}\) is true, then append \(\text{current}\) to \(\text{groups}\), set \(\text{current}\) to a new name-value group, and set \(\text{seenDd}\) to false.
   2. Append \(\text{node}\) to \(\text{current}\)'s name.
3. Otherwise, if \(\text{node}\) is a \(\text{dd}\) element, then append \(\text{node}\) to \(\text{current}\)'s value and set \(\text{seenDd}\) to true.

**Note**

When a name-value group has an empty list as name or value, it is often due to accidentally using \(\text{dd}\) elements in the place of \(\text{dt}\) elements and vice versa. Conformance checkers can spot such mistakes and might be able to advise authors how to correctly use the markup.

**Example**

In the following example, one entry ("Authors") is linked to two values ("John" and "Luke").

\[
<\text{dl}>
<\text{dt}> Authors
<\text{dd}> John
<\text{dd}> Luke
<\text{dt}> Editor
<\text{dd}> Frank
</\text{dl}>
\]
In the following example, one definition is linked to two terms.

```html
<dl>
  <dt lang="en-US">color</dt>
  <dd>A sensation which (in humans) derives from the ability of the fine structure of the eye to distinguish three differently filtered analyses of a view.</dd>
  <dt lang="en-GB">colour</dt>
</dl>
```

The following example illustrates the use of the `dl` element to mark up metadata of sorts. At the end of the example, one group has two metadata labels ("Authors" and "Editors") and two values ("Robert Rothman" and "Daniel Jackson"). This example also uses the `div` element around the groups of `dt` and `dd` element, to aid with styling.

```html
<dl>
  <div>
    <dt>Last modified time</dt>
    <dd>2004-12-23T23:33Z</dd>
  </div>
  <div>
    <dt>Recommended update interval</dt>
    <dd>60s</dd>
  </div>
  <div>
    <dt>Authors</dt>
    <dd>Robert Rothman</dd>
    <dt>Editors</dt>
    <dd>Daniel Jackson</dd>
  </div>
</dl>
```

The following example shows the `dl` element used to give a set of instructions. The order of the instructions here is important (in the other examples, the order of the blocks was not important).

```html
<p>Determine the victory points as follows (use the first matching case):</p>
<dl>
  <dt>If you have exactly five gold coins</dt>
  <dd>You get five victory points</dd>
  <dt>If you have one or more gold coins, and you have one or more silver coins</dt>
  <dd>You get two victory points</dd>
  <dt>If you have one or more silver coins</dt>
  <dd>You get one victory point</dd>
  <dt>Otherwise</dt>
  <dd>You get no victory points</dd>
</dl>
```

The following snippet shows a `dl` element being used as a glossary. Note the use of `dfn` to indicate the word being defined.

```html
<dl>
  <dt><dfn>Apart</dfn>ment</dt>
</dl>
```
An execution context grouping one or more threads with one or more COM objects.

**Flat**, n.

A deflated tire.

The user's login directory.

This example uses microdata\(^{705}\) attributes in a **dl** element, together with the **div** element, to annotate the ice cream desserts at a French restaurant.

**Example**

This example uses microdata\(^{705}\) attributes in a **dl** element, together with the **div** element, to annotate the ice cream desserts at a French restaurant.

Without the **div** element the markup would need to use the **itemref** attribute to link the data in the **dd** elements with the item, as follows.

**Note**

The **dl** element is inappropriate for marking up dialogue. See some examples of how to mark up dialogue\(^{665}\).
4.4.10 The dt element

Categories: None.

Contexts in which this element can be used:
Before dd or dt elements inside dl elements.
Before dd or dt elements inside div elements that are children of a dl element.

Content model:
Flow content, but with no header, footer, sectioning content, or heading content descendants.

Tag omission in text/html:
A dt element's end tag can be omitted if the dt element is immediately followed by another dt element or a dd element.

Content attributes:
Global attributes

DOM interface:
Uses HTMLElement.

The dt element represents the term, or name, part of a term-description group in a description list (dl element).

Note
The dt element itself, when used in a dl element, does not indicate that its contents are a term being defined, but this can be indicated using the dfn element.

Example
This example shows a list of frequently asked questions (a FAQ) marked up using the dt element for questions and the dd element for answers.

```html
<article>
  <h1>FAQ</h1>
  <dl>
    <dt>What do we want?</dt>
    <dd>Our data.</dd>
    <dt>When do we want it?</dt>
    <dd>Now.</dd>
    <dt>Where is it?</dt>
    <dd>We are not sure.</dd>
  </dl>
</article>
```

4.4.11 The dd element

Categories: None.

Contexts in which this element can be used:
After dt or dd elements inside dl elements.
After dt or dd elements inside div elements that are children of a dl element.

Content model:
Flow content

Tag omission in text/html:
A dd element's end tag can be omitted if the dd element is immediately followed by another dd element or a dt element, or if there is no more content in the parent element.
The **dd** element represents the description, definition, or value, part of a term-description group in a description list (**dl** element).

**Example**

A **dl** can be used to define a vocabulary list, like in a dictionary. In the following example, each entry, given by a **dt** with a **dfn**, has several **dd**, showing the various parts of the definition.

```html
<dl>
  <dt>happiness</dt>
  <dd class="pronunciation">/'hæ p. nes/</dd>
  <dd class="part-of-speech"><i><abbr>n.</abbr></i></dd>
  <dd>The state of being happy.</dd>
  <dd>Good fortune; success. <q>Oh <b>happiness</b>! It worked!</q></dd>
  <dt>rejoice</dt>
  <dd class="pronunciation">/ri jois'/</dd>
  <dd><i><abbr>v.intr.</abbr></i> To be delighted oneself.</dd>
  <dd><i><abbr>v.tr.</abbr></i> To cause one to be delighted.</dd>
</dl>
```

### 4.4.12 The **figure** element

**Categories**: Flow content, Sectioning root, Palpable content.

**Contexts in which this element can be used**: Where flow content is expected.

**Content model**: Either: one **figcaption** element followed by flow content. Or: flow content followed by one **figcaption** element. Or: flow content.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**: Global attributes

**DOM interface**: Uses HTML Element.

The **figure** element represents some flow content, optionally with a caption, that is self-contained (like a complete sentence) and is typically referenced as a single unit from the main flow of the document.

**Note**

"Self-contained" in this context does not necessarily mean independent. For example, each sentence in a paragraph is self-contained; an image that is part of a sentence would be inappropriate for **figure**, but an entire sentence made of images would be fitting.

The element can thus be used to annotate illustrations, diagrams, photos, code listings, etc.
When a `figure` element is referred to from the main content of the document by identifying it by its caption (e.g., by figure number), it enables such content to be easily moved away from that primary content, e.g., to the side of the page, to dedicated pages, or to an appendix, without affecting the flow of the document.

If a `figure` element is referenced by its relative position, e.g., "in the photograph above" or "as the next figure shows", then moving the figure would disrupt the page's meaning. Authors are encouraged to consider using labels to refer to figures, rather than using such relative references, so that the page can easily be restyled without affecting the page's meaning.

The first `figcaption` element child of the element, if any, represents the caption of the `figure` element's contents. If there is no child `figcaption` element, then there is no caption.

A `figure` element's contents are part of the surrounding flow. If the purpose of the page is to display the figure, for example a photograph on an image sharing site, the `figure` and `figcaption` elements can be used to explicitly provide a caption for that figure. For content that is only tangentially related, or that serves a separate purpose than the surrounding flow, the `aside` element should be used (and can itself wrap a `figure`). For example, a pull quote that repeats content from an `article` would be more appropriate in an `aside` than in a `figure`, because it isn't part of the content, it's a repetition of the content for the purposes of enticing readers or highlighting key topics.

Example

This example shows the `figure` element to mark up a code listing.

```xml
<p>In <a href="#l4">listing 4</a> we see the primary core interface API declaration.</p>
<figure id="l4">
  <figcaption>Listing 4. The primary core interface API declaration.</figcaption>
  <pre>
  interface PrimaryCore {
    boolean verifyDataLine();
    void sendData(in sequence<byte> data);
    void initSelfDestruct();
  }
  </pre>
</figure>
<p>The API is designed to use UTF-8.</p>
```

Example

Here we see a `figure` element to mark up a photo that is the main content of the page (as in a gallery).

```html
<!DOCTYPE HTML>
<html lang="en">
<title>Bubbles at work — My Gallery™</title>
<figure>
  <img src="bubbles-work.jpeg" alt="Bubbles, sitting in his office chair, works on his latest project intently."/>
  <figcaption>Bubbles at work</figcaption>
</figure>
<nav><a href="19414.html">Prev</a> — <a href="19416.html">Next</a></nav>
```

Example

In this example, we see an image that is not a figure, as well as an image and a video that are. The first image is literally part of the example's second sentence, so it's not a self-contained unit, and thus `figure` would be inappropriate.

```html
<h2>Malinko's comics</h2>
<p>This case centered on some sort of "intellectual property"
```
infringement related to a comic (see Exhibit A). The suit started after a trailer ending with these words:

<blockquote>
<img src="promblem-packed-action.png" alt="ROUGH COPY! Promblem-Packed Action!"/>
</blockquote>

<p>...was aired. A lawyer, armed with a Bigger Notebook, launched a preemptive strike using snowballs. A complete copy of the trailer is included with Exhibit B.</p>

<figure>
<img src="ex-a.png" alt="Two squiggles on a dirty piece of paper."/>
<figcaption>Exhibit A. The alleged <cite>rough copy</cite> comic.</figcaption>
</figure>

<figure>
<video src="ex-b.mov"></video>
<figcaption>Exhibit B. The <cite>Rough Copy</cite> trailer.</figcaption>
</figure>

<p>The case was resolved out of court.</p>

Example

Here, a part of a poem is marked up using <cite>Jabberwocky</cite>.

<p>'Twas brillig, and the slithy toves<br>
Did gyre and gimble in the wabe;<br>
All mimsy were the borogoves,<br>
And the mome raths outgrabe.</p>

<figcaption><cite>Jabberwocky</cite> (first verse). Lewis Carroll, 1832-98</figcaption>

Example

In this example, which could be part of a much larger work discussing a castle, nested <cite>Jabberwocky</cite> elements are used to provide both a group caption and individual captions for each figure in the group:

<figure>
<figcaption>The castle through the ages: 1423, 1858, and 1999 respectively.</figcaption>
</figure>

<figure>
<figcaption>Etching. Anonymous, ca. 1423.</figcaption>
<img src="castle1423.jpeg" alt="The castle has one tower, and a tall wall around it."/>
</figure>

<figure>
<figcaption>Oil-based paint on canvas. Maria Towle, 1858.</figcaption>
<img src="castle1858.jpeg" alt="The castle now has two towers and two walls."/>
</figure>

<figure>
<figcaption>Film photograph. Peter Jankle, 1999.</figcaption>
<img src="castle1999.jpeg" alt="The castle lies in ruins, the original tower all that remains in one piece."/>
</figure>
The previous example could also be more succinctly written as follows (using `title` attributes in place of the nested `figure`/`figcaption` pairs):

```html
<figure>
  <img src="castle1423.jpeg" title="Etching. Anonymous, ca. 1423." alt="The castle has one tower, and a tall wall around it.">
  <img src="castle1858.jpeg" title="Oil-based paint on canvas. Maria Towle, 1858." alt="The castle now has two towers and two walls.">
  <img src="castle1999.jpeg" title="Film photograph. Peter Jankle, 1999." alt="The castle lies in ruins, the original tower all that remains in one piece.">
  <figcaption>The castle through the ages: 1423, 1858, and 1999 respectively.</figcaption>
</figure>
```

The figure is sometimes referenced only implicitly from the content:

```html
<article>
  <h1>Fiscal negotiations stumble in Congress as deadline nears</h1>
  <figure>
    <img src="obama-reid.jpeg" alt="Obama and Reid sit together smiling in the Oval Office.">
    <figcaption>Barack Obama and Harry Reid. White House press photograph.</figcaption>
  </figure>
  <p>Negotiations in Congress to end the fiscal impasse sputtered on Tuesday, leaving both chambers grasping for a way to reopen the government and raise the country's borrowing authority with a Thursday deadline drawing near.</p>
  ...
</article>

### 4.4.13 The `figcaption` element

**Categories**:

None.

**Contexts in which this element can be used**:

As the first or last child of a `figure` element.

**Content model**:

Flow content.

**Tag omission in text/html**:

Neither tag is omissible.

**Content attributes**:

Global attributes.

**DOM interface**:

Uses `HTMLElement`.

The `figcaption` element represents a caption or legend for the rest of the contents of the `figcaption` element's parent `figure` element, if any.

The element can contain additional information about the source:

```html
<figcaption>
```

4.4.14 The **main** element

**Categories**: Flow content, Palpable content.

**Contexts in which this element can be used**: Where flow content is expected, but only if it is a hierarchically correct main element.

**Content model**: Flow content.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**: Global attributes.

**DOM interface**: Uses `HTMLElement`.

The **main** element represents the dominant contents of the document.

A document must not have more than one **main** element that does not have the `hidden` attribute specified.

A **hierarchically correct main element** is one whose ancestor elements are limited to html, body, div, form without an accessible name, and autonomous custom elements. Each **main** element must be a hierarchically correct main element.

**Example**

In this example, the author has used a presentation where each component of the page is rendered in a box. To wrap the main content of the page (as opposed to the header, the footer, the navigation bar, and a sidebar), the **main** element is used.

```html
<!DOCTYPE html>
<html lang="en">
<title>RPG System 17</title>
<style>
header, nav, aside, main, footer {
  margin: 0.5em; border: thin solid; padding: 0.5em;
  background: #eff; color: black; box-shadow: 0 0 0.25em #033;
}

h1, h2, p {
  margin: 0;
}

nav, main {
  float: left;
}

aside {
  float: right;
}

footer {
  clear: both;
}
</style>
<header>
<h1>System Eighteen</h1>
</header>
<nav>
<p>A duck.</p>
</nav>
</body>
</html>
```
In the following example, multiple main elements are used and script is used to make navigation work without a server roundtrip and to set the hidden attribute on those that are not current:

```html
<!doctype html>
<html lang=en-CA>
<head>
  <meta charset=utf-8>
  <title>…</title>
  <link rel=stylesheet href=spa.css>
  <script src=spa.js async></script>
</head>
<body>
  <nav>
    <a href=/>Home</a>
    <a href=/about> About</a>
    <a href=/contact> Contact</a>
  </nav>
  <main>
    <h1>Home</h1>
    …
  </main>
  <main hidden>
    <h1> About</h1>
    …
  </main>
  <main hidden>
    <h1> Contact</h1>
    …
  </main>
  <footer>Made with ❤️ by <a href=https://example.com/>Example 💀</a>.</footer>
</body>
</html>
```

### 4.4.15 The div element

**Categories:**
- Flow content
- Palpable content

**Contexts in which this element can be used:**
Where flow content is expected.
As a child of a dl element.

**Content model:**
If the element is a child of a dl element: one or more dt elements followed by one or more dd elements, optionally
intermixed with script-supporting elements. If the element is not a child of a `<dl>` element: flow content.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**: Global attributes

**DOM interface**:

```
[Exposed=Window,
  HTMLConstructor]
interface HTMLDivElement : HTMLElement {};
```

The `<div>` element has no special meaning at all. It represents its children. It can be used with the `class`, `lang`, and `title` attributes to mark up semantics common to a group of consecutive elements. It can also be used in a `<dl>` element, wrapping groups of `<dt>` and `<dd>` elements.

**Note**

Authors are strongly encouraged to view the `<div>` element as an element of last resort, for when no other element is suitable. Use of more appropriate elements instead of the `<div>` element leads to better accessibility for readers and easier maintainability for authors.

**Example**

For example, a blog post would be marked up using `<article>`, a chapter using `<section>`, a page's navigation aids using `<nav>`, and a group of form controls using `<fieldset>`.

On the other hand, `<div>` elements can be useful for stylistic purposes or to wrap multiple paragraphs within a section that are all to be annotated in a similar way. In the following example, we see `<div>` elements used as a way to set the language of two paragraphs at once, instead of setting the language on the two paragraph elements separately:

```html
<article lang="en-US">
  <h1>My use of language and my cats</h1>
  <p>My cat's behavior hasn't changed much since her absence, except that she plays her new physique to the neighbors regularly, in an attempt to get pets.</p>
  <div lang="en-GB">
    <p>My other cat, coloured black and white, is a sweetie. He followed us to the pool today, walking down the pavement with us. Yesterday he apparently visited our neighbours. I wonder if he recognises that their flat is a mirror image of ours.</p>
    <p>Hm, I just noticed that in the last paragraph I used British English. But I'm supposed to write in American English. So I shouldn't say "pavement" or "flat" or "colour"...</p>
  </div>
  <p>I should say "sidewalk" and "apartment" and "color"!</p>
</article>
```

4.5 Text-level semantics

4.5.1 The `<a>` element

**Categories**: Flow content, Phrasing content

If the element has an `<href>` attribute: Interactive content.
Contexts in which this element can be used:

Where phrasing content is expected.

Content model:

Transparent, but there must be no interactive content or a element descendants.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes:

- href — Address of the hyperlink
- target — Browsing context for hyperlink navigation
- download — Whether to download the resource instead of navigating to it, and its file name if so
- ping — URLs to ping
- rel — Relationship between the location in the document containing the hyperlink and the destination resource
- hreflang — Language of the linked resource
- type — Hint for the type of the referenced resource
- referrerpolicy — Referrer policy for fetches initiated by the element

DOM interface:

```
IDL [Exposed=Window,
     HTMLConstructor]
interface HTMLAnchorElement : HTMLElement {
    [CEReactions] attribute DOMString target;
    [CEReactions] attribute DOMString download;
    [CEReactions] attribute USVString ping;
    [CEReactions] attribute DOMString rel;
    [SameObject, PutForwards=value] readonly attribute DOMTokenList rellist;
    [CEReactions] attribute DOMString hreflang;
    [CEReactions] attribute DOMString type;
    [CEReactions] attribute DOMString text;
    [CEReactions] attribute DOMString refererPolicy;
};
```

If the element has an href attribute, then it represents a hyperlink (a hypertext anchor) labeled by its contents.

If the element has no href attribute, then the element represents a placeholder for where a link might otherwise have been placed, if it had been relevant, consisting of just the element's contents.

The target, download, ping, rel, hreflang, type, and referrerpolicy attributes must be omitted if the href attribute is not present.

If the itemprop attribute is specified on an element, then the href attribute must also be specified.

Example:

If a site uses a consistent navigation toolbar on every page, then the link that would normally link to the page itself could be marked up using an element:

```
<nav>
  <ul>
    <li> <a href="/">Home</a> </li>
    <li> <a href="/news">News</a> </li>
    <li> <a href="/examples">Examples</a> </li>
    <li> <a href="/legal">Legal</a> </li>
  </ul>
</nav>
```
The href, target, download, ping, and refererPolicy attributes affect what happens when users follow hyperlinks or download hyperlinks, created using the a element. The rel, hreflang, and type attributes may be used to indicate to the user the likely nature of the target resource before the user follows the link.

The activation behavior of a elements that create hyperlinks is to run the following steps:

1. If the target of the click event is an img element with an ismap attribute specified, then server-side image map processing must be performed, as follows:
   1. Let x and y be zero.
   2. If the click event was a real pointing-device-triggered click event on the img element, then set x to the distance in CSS pixels from the left edge of the image to the location of the click, and set y to the distance in CSS pixels from the top edge of the image to the location of the click.
   3. If x is negative, set x to zero.
   4. If y is negative, set y to zero.
   5. Let hyperlink suffix be a U+003F QUESTION MARK character, the value of x expressed as a base-ten integer using ASCII digits, a U+002C COMMA character (,), and the value of y expressed as a base-ten integer using ASCII digits.

2. Follow the hyperlink or download the hyperlink created by the a element, as determined by the download attribute and any expressed user preference, passing hyperlink suffix, if the steps above defined it.

For web developers (non-normative)

```
a . text
```

Same as textContent.

The IDL attributes download, ping, target, rel, hreflang, and type, must reflect the respective content attributes of the same name.

The IDL attribute relList must reflect the rel content attribute.

The IDL attribute refererPolicy must reflect the refererPolicy content attribute, limited to only known values.

The text IDL attribute, on getting, must return the same value as the textContent IDL attribute on the element, and on setting, must act as if the textContent IDL attribute on the element had been set to the new value.

Example

The a element may be wrapped around entire paragraphs, lists, tables, and so forth, even entire sections, so long as there is no interactive content within (e.g. buttons or other links). This example shows how this can be used to make an entire advertising block into a link:

```html
<aside class="advertising">
  <h1>Advertising</h1>
  <a href="https://ad.example.com/?adid=1929&amp;pubid=1422">
    <section>
      <h1>Mellblomatic 9000!</h1>
      <p>Turn all your widgets into mellbloms!</p>
      <p>Only $9.99 plus shipping and handling.</p>
    </section>
  </a>
  <a href="https://ad.example.com/?adid=375&amp;pubid=1422">
    <section>
      <!-- More advertising content -->
    </section>
  </a>
</aside>
```
4.5.2 The **em** element

Categories:
- Flow content
- Phrasing content
- Palpable content

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
- Phrasing content

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:
- Uses `HTMLElement`

The **em** element represents stress emphasis of its contents.

The level of stress that a particular piece of content has is given by its number of ancestor **em** elements.

The placement of stress emphasis changes the meaning of the sentence. The element thus forms an integral part of the content. The precise way in which stress is used in this way depends on the language.

**Example**

These examples show how changing the stress emphasis changes the meaning. First, a general statement of fact, with no stress:

```html
<p>Cats are cute animals.</p>
```

By emphasizing the first word, the statement implies that the kind of animal under discussion is in question (maybe someone is asserting that dogs are cute):

```html
<p><em>Cats</em> are cute animals.</p>
```

Moving the stress to the verb, one highlights that the truth of the entire sentence is in question (maybe someone is saying cats are not cute):

```html
<p>Cats <em>are</em> cute animals.</p>
```

By moving it to the adjective, the exact nature of the cats is reasserted (maybe someone suggested cats were *mean* animals):

```html
<p>Cats are <em>cute</em> animals.</p>
```

Similarly, if someone asserted that cats were vegetables, someone correcting this might emphasize the last word:
By emphasizing the entire sentence, it becomes clear that the speaker is fighting hard to get the point across. This kind of stress emphasis also typically affects the punctuation, hence the exclamation mark here.

Anger mixed with emphasizing the cuteness could lead to markup such as:

```
<p>&lt;em&gt;Cats are cute animals!&lt;/em&gt;&lt;/p&gt;
```

**Note**

The `<em>` element isn't a generic "italics" element. Sometimes, text is intended to stand out from the rest of the paragraph, as if it was in a different mood or voice. For this, the `<i>` element is more appropriate.

The `<em>` element also isn't intended to convey importance; for that purpose, the `<strong>` element is more appropriate.

### 4.5.3 The `<strong>` element

#### Categories:
- Flow content
- Phrasing content
- Palpable content

#### Contexts in which this element can be used:
Where phrasing content is expected.

#### Content model:
- Phrasing content

#### Tag omission in text/html:
Neither tag is omissible.

#### Content attributes:
- Global attributes

#### DOM interface:
Uses `HTMLElement`.

The `<strong>` element represents strong importance, seriousness, or urgency for its contents.

**Importance:** the `<strong>` element can be used in a heading, caption, or paragraph to distinguish the part that really matters from other parts that might be more detailed, more jovial, or merely boilerplate. (This is distinct from marking up subheadings, for which the `<hgroup>` element is appropriate.)

**Example**

For example, the first word of the previous paragraph is marked up with `<strong>` to distinguish it from the more detailed text in the rest of the paragraph.

**Seriousness:** the `<strong>` element can be used to mark up a warning or caution notice.

**Urgency:** the `<strong>` element can be used to denote contents that the user needs to see sooner than other parts of the document.

The relative level of importance of a piece of content is given by its number of ancestor `<strong>` elements; each `<strong>` element increases the importance of its contents.

Changing the importance of a piece of text with the `<strong>` element does not change the meaning of the sentence.
Here, the word “chapter” and the actual chapter number are mere boilerplate, and the actual name of the chapter is marked up with `strong`:

```html
<h1>Chapter 1: <strong>The Praxis</strong></h1>
```

In the following example, the name of the diagram in the caption is marked up with `strong`, to distinguish it from boilerplate text (before) and the description (after):

```html
<figcaption>Figure 1. <strong>Ant colony dynamics</strong>. The ants in this colony are affected by the heat source (upper left) and the food source (lower right). </figcaption>
```

In this example, the heading is really “Flowers, Bees, and Honey”, but the author has added a light-hearted addition to the heading. The `strong` element is thus used to mark up the first part to distinguish it from the latter part.

```html
<h1><strong>Flowers, Bees, and Honey</strong> and other things I don’t understand</h1>
```

Here is an example of a warning notice in a game, with the various parts marked up according to how important they are:

```html
<p><strong>Warning.</strong> This dungeon is dangerous. <strong>Avoid the ducks.</strong> Take any gold you find. <strong>Do not take any of the diamonds</strong>, they are explosive and <strong>will destroy anything within ten meters.</strong> You have been warned.</p>
```

In this example, the `strong` element is used to denote the part of the text that the user is intended to read first.

```html
<p>Welcome to Remy, the reminder system.</p>
<p>Your tasks for today:</p>
<ul>
  <li><p><strong>Turn off the oven.</strong></p></li>
  <li><p><strong>Put out the trash.</strong></p></li>
  <li><p><strong>Do the laundry.</strong></p></li>
</ul>
```

### 4.5.4 The `small` element

**Categories**: `p124`

- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used**: `p125`

Where phrasing content is expected.

**Content model**: `p125`

- Phrasing content

**Tag omission in text/html**: `p125`

Neither tag is omissible.

**Content attributes**: `p125`

- Global attributes
The `small` element represents side comments such as small print.

**Note**

Small print typically features disclaimers, caveats, legal restrictions, or copyrights. Small print is also sometimes used for attribution, or for satisfying licensing requirements.

**Note**

The `small` element does not "de-emphasize" or lower the importance of text emphasized by the `em` element or marked as important with the `strong` element. To mark text as not emphasized or important, simply do not mark it up with the `em` or `strong` elements respectively.

The `small` element should not be used for extended spans of text, such as multiple paragraphs, lists, or sections of text. It is only intended for short runs of text. The text of a page listing terms of use, for instance, would not be a suitable candidate for the `small` element: in such a case, the text is not a side comment, it is the main content of the page.

The `small` element must not be used for subheadings; for that purpose, use the `hgroup` element.

**Example**

In this example, the `small` element is used to indicate that value-added tax is not included in a price of a hotel room:

```html
<dl>
  <dt>Single room</dt>
  <dd>199 € <small>breakfast included, VAT not included</small></dd>
  <dt>Double room</dt>
  <dd>239 € <small>breakfast included, VAT not included</small></dd>
</dl>
```

**Example**

In this second example, the `small` element is used for a side comment in an article.

```
<p>Example Corp today announced record profits for the second quarter <small>(Full Disclosure: Foo News is a subsidiary of Example Corp)</small>, leading to speculation about a third quarter merger with Demo Group.</p>
```

This is distinct from a sidebar, which might be multiple paragraphs long and is removed from the main flow of text. In the following example, we see a sidebar from the same article. This sidebar also has small print, indicating the source of the information in the sidebar.

```html
<aside>
  <h1>Example Corp</h1>
  <p>This company mostly creates small software and Web sites.</p>
  <p>The Example Corp company mission is "To provide entertainment and news on a sample basis".</p>
  <p><small>Information obtained from <a href="https://example.com/about.html">example.com</a> home page.</small></p>
</aside>
```
In this last example, the `small` element is marked as being *important* small print.

```
<p><strong><small>Continued use of this service will result in a kiss.</small></strong></p>
```

### 4.5.5 The * element

**Categories**:
- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used**:
- Where *phrasing content* is expected.

**Content model**:
- Phrasing content

**Tag omission in text/html**:
- Neither tag is omissible.

**Content attributes**:
- Global attributes

**DOM interface**:
- Uses `HTMLElement`

The * element represents contents that are no longer accurate or no longer relevant.

**Note**

The * element is not appropriate when indicating document edits; to mark a span of text as having been removed from a document, use the `del` element.

**Example**

In this example a recommended retail price has been marked as no longer relevant as the product in question has a new sale price.

```
<p>Buy our Iced Tea and Lemonade!</p>
<p><s>Recommended retail price: $3.99 per bottle</s></p>
<p><strong>Now selling for just $2.99 a bottle!</strong></p>
```

### 4.5.6 The cite element

**Categories**:
- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used**:
- Where *phrasing content* is expected.

**Content model**:
- Phrasing content

**Tag omission in text/html**:
- Neither tag is omissible.
The `cite` element represents the title of a work (e.g. a book, a paper, an essay, a poem, a score, a song, a script, a film, a TV show, a game, a sculpture, a painting, a theatre production, a play, an opera, a musical, an exhibition, a legal case report, a computer program, etc). This can be a work that is being quoted or referenced in detail (i.e. a citation), or it can just be a work that is mentioned in passing.

A person's name is not the title of a work — even if people call that person a piece of work — and the element must therefore not be used to mark up people's names. (In some cases, the `b` element might be appropriate for names; e.g. in a gossip article where the names of famous people are keywords rendered with a different style to draw attention to them. In other cases, if an element is really needed, the `span` element can be used.)

This next example shows a typical use of the `cite` element:

```html
<p>My favorite book is <cite>The Reality Dysfunction</cite> by Peter F. Hamilton. My favorite comic is <cite>Pearls Before Swine</cite> by Stephan Pastis. My favorite track is <cite>Jive Samba</cite> by the Cannonball Adderley Sextet.</p>
```

This is correct usage:

```html
<p>According to the Wikipedia article <cite>HTML</cite>, as it stood in mid-February 2008, leaving attribute values unquoted is unsafe. This is obviously an over-simplification.</p>
```

The following, however, is incorrect usage, as the `cite` element here is containing far more than the title of the work:

```html
<!-- do not copy this example, it is an example of bad usage! -->
<p>According to <cite>the Wikipedia article on HTML</cite>, as it stood in mid-February 2008, leaving attribute values unquoted is unsafe. This is obviously an over-simplification.</p>
```

The `cite` element is obviously a key part of any citation in a bibliography, but it is only used to mark the title:

```html
```

A citation is not a quote (for which the `q` element is appropriate).

This is incorrect usage, because `cite` is not for quotes:

```html
<p>This is wrong!</p>
```

---

238
This is also incorrect usage, because a person is not a work:

```html
<p><q>This is still wrong!</q>, said <cite>Ian</cite>.</p>
```

The correct usage does not use a `cite` element:

```html
<p><q>This is correct</q>, said Ian.</p>
```

As mentioned above, the `b` element might be relevant for marking names as being keywords in certain kinds of documents:

```html
<p>And then <b>Ian</b> said <q>this might be right, in a gossip column, maybe!</q>.</p>
```

### 4.5.7 The `q` element

- **Categories**:
  - Flow content
  - Phrasing content
  - Palpable content

- **Contexts in which this element can be used**:
  - Where phrasing content is expected.

- **Content model**:
  - Phrasing content

- **Tag omission in text/html**:
  - Neither tag is omissible.

- **Content attributes**:
  - Global attributes
    - `cite` — Link to the source of the quotation or more information about the edit

- **DOM interface**:
  - Uses `HTMLQuoteElement`.

The `q` element represents some phrasing content quoted from another source.

Quotation punctuation (such as quotation marks) that is quoting the contents of the element must not appear immediately before, after, or inside `q` elements; they will be inserted into the rendering by the user agent.

Content inside a `q` element must be quoted from another source, whose address, if it has one, may be cited in the `cite` attribute. The source may be fictional, as when quoting characters in a novel or screenplay.

If the `cite` attribute is present, it must be a valid URL potentially surrounded by spaces. To obtain the corresponding citation link, the value of the attribute must be parsed relative to the element's node document. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g., by server-side scripts collecting statistics about a site's use of quotations), not for readers.

The `q` element must not be used in place of quotation marks that do not represent quotes; for example, it is inappropriate to use the `q` element for marking up sarcastic statements.

The use of `q` elements to mark up quotations is entirely optional; using explicit quotation punctuation without `q` elements is just as correct.

**Example**

Here is a simple example of the use of the `q` element:
The man said Things that are impossible just take longer. I disagreed with him.

Here is an example with both an explicit citation link in the q element, and an explicit citation outside:

The W3C page About W3C says the W3C’s mission is To lead the World Wide Web to its full potential by developing protocols and guidelines that ensure long-term growth for the Web. I disagree with this mission.

In the following example, the quotation itself contains a quotation:

In Example One, he writes The man said Things that are impossible just take longer. I disagreed with him. Well, I disagree even more!

In the following example, quotation marks are used instead of the q element:

His best argument was “I disagree”, which I thought was laughable.

In the following example, there is no quote — the quotation marks are used to name a word. Use of the q element in this case would be inappropriate.

The word "ineffable" could have been used to describe the disaster resulting from the campaign's mismanagement.

4.5.8 The dfn element

Categories:
Flow content
Phrasing content
Palpable content

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
Phrasing content, but there must be no dfn element descendants.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
Global attributes
Also, the title attribute has special semantics on this element: Full term or expansion of abbreviation.
DOM interface:

Uses `HTMLElement`.

The `dfn` element represents the defining instance of a term. The `paragraph`, `description list group`, or `section` that is the nearest ancestor of the `dfn` element must also contain the definition(s) for the term given by the `dfn` element.

**Defining term:** if the `dfn` element has a `title` attribute, then the exact value of that attribute is the term being defined. Otherwise, if it contains exactly one element child node and no child text nodes, and that child element is an `abbr` element with a `title` attribute, then the exact value of that attribute is the term being defined. Otherwise, it is the exact `textContent` of the `dfn` element that gives the term being defined.

If the `title` attribute of the `dfn` element is present, then it must contain only the term being defined.

**Note**

*The `title` attribute of ancestor elements does not affect `dfn` elements.*

An `a` element that links to a `dfn` element represents an instance of the term defined by the `dfn` element.

**Example**

In the following fragment, the term "Garage Door Opener" is first defined in the first paragraph, then used in the second. In both cases, its abbreviation is what is actually displayed.

```html
<p>The <dfn><abbr title="Garage Door Opener">GDO</abbr></dfn> is a device that allows off-world teams to open the iris.</p>

<p>Teal'c activated his <abbr title="Garage Door Opener">GDO</abbr> and so Hammond ordered the iris to be opened.</p>
```

With the addition of an `a` element, the reference can be made explicit:

```html
<p>The <dfn id="gdo"><abbr title="Garage Door Opener">GDO</abbr></dfn> is a device that allows off-world teams to open the iris.</p>

<p>Teal'c activated his <a href="#gdo"><abbr title="Garage Door Opener">GDO</abbr></a> and so Hammond ordered the iris to be opened.</p>
```

**4.5.9 The `abbr` element**

**Categories:**

Flow content, Phrasing content, Palpable content.

**Contexts in which this element can be used:**

Where `phrasing content` is expected.

**Content model:**

Phrasing content.

**Tag omission in text/html:**

Neither tag is omissible.

**Content attributes:**

Global attributes.

Also, the `title` attribute has special semantics on this element: Full term or expansion of abbreviation.

**DOM interface:**

Uses `HTMLElement`.
The `abbr` element represents an abbreviation or acronym, optionally with its expansion. The `title` attribute may be used to provide an expansion of the abbreviation. The attribute, if specified, must contain an expansion of the abbreviation, and nothing else.

### Example

The paragraph below contains an abbreviation marked up with the `abbr` element. This paragraph defines the term "Web Hypertext Application Technology Working Group".

```html
<p>The <dfn id=whatwg><abbr title="Web Hypertext Application Technology Working Group">WHATWG</abbr></dfn> is a loose unofficial collaboration of Web browser manufacturers and interested parties who wish to develop new technologies designed to allow authors to write and deploy Applications over the World Wide Web.</p>
```

An alternative way to write this would be:

```html
<p>The <dfn id=whatwg>Web Hypertext Application Technology Working Group</dfn> (<abbr title="Web Hypertext Application Technology Working Group">WHATWG</abbr>) is a loose unofficial collaboration of Web browser manufacturers and interested parties who wish to develop new technologies designed to allow authors to write and deploy Applications over the World Wide Web.</p>
```

### Example

This paragraph has two abbreviations. Notice how only one is defined; the other, with no expansion associated with it, does not use the `abbr` element.

```html
<p>The <abbr title="Web Hypertext Application Technology Working Group">WHATWG</abbr> started working on HTML5 in 2004.</p>
```

### Example

This paragraph links an abbreviation to its definition.

```html
<p>The <a href="#whatwg"><abbr title="Web Hypertext Application Technology Working Group">WHATWG</abbr></a> community does not have much representation from Asia.</p>
```

### Example

This paragraph marks up an abbreviation without giving an expansion, possibly as a hook to apply styles for abbreviations (e.g. smallcaps).

```html
<p>Philip’ and Dashiva both denied that they were going to get the issue counts from past revisions of the specification to backfill the <abbr>WHATWG</abbr> issue graph.</p>
```

If an abbreviation is pluralized, the expansion's grammatical number (plural vs singular) must match the grammatical number of the contents of the element.

### Example

Here the plural is outside the element, so the expansion is in the singular:
Abbreviations do not have to be marked up using this element. It is expected to be useful in the following cases:

- Abbreviations for which the author wants to give expansions, where using the `<abbr>` element with a `title` attribute is an alternative to including the expansion inline (e.g. in parentheses).
- Abbreviations that are likely to be unfamiliar to the document's readers, for which authors are encouraged to either mark up the abbreviation using an `<abbr>` element with a `title` attribute or include the expansion inline in the text the first time the abbreviation is used.
- Abbreviations whose presence needs to be semantically annotated, e.g. so that they can be identified from a style sheet and given specific styles, for which the `<abbr>` element can be used without a `title` attribute.

Providing an expansion in a `title` attribute once will not necessarily cause other `<abbr>` elements in the same document with the same contents but without a `title` attribute to behave as if they had the same expansion. Every `<abbr>` element is independent.

### 4.5.10 The `ruby` element

**Categories:**
- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used:**
Where phrasing content is expected.

**Content model:**
See prose.

**Tag omission in text/html:**
Neither tag is omissible.

**Content attributes:**
- Global attributes

**DOM interface:**
Uses `HTMLElement`.

The `ruby` element allows one or more spans of phrasing content to be marked with ruby annotations. Ruby annotations are short runs of text presented alongside base text, primarily used in East Asian typography as a guide for pronunciation or to include other annotations. In Japanese, this form of typography is also known as *furigana*.

The content model of `ruby` elements consists of one or more of the following sequences:

1. One or the other of the following:
   - Phrasing content, but with no `ruby` elements and with no `ruby` element descendants
   - A single `ruby` element that itself has no `ruby` element descendants
2. One or the other of the following:
   - One or more `rt` elements
   - An `rp` element followed by one or more `rt` elements, each of which is itself followed by an `rp` element

The `ruby` and `rt` elements can be used for a variety of kinds of annotations, including in particular (though by no means limited
to) those described below. For more details on Japanese Ruby in particular, and how to render Ruby for Japanese, see Requirements for Japanese Text Layout. [ILREQ][1224]

**Note**
At the time of writing, CSS does not yet provide a way to fully control the rendering of the HTML `ruby` element. It is hoped that CSS will be extended to support the styles described below in due course.

**Mono-ruby for individual base characters in Japanese**

One or more hiragana or katakana characters (the ruby annotation) are placed with each ideographic character (the base text). This is used to provide readings of kanji characters.

**Example**

```
<ruby>B<rt>annotation</rt></ruby>
```

In this example, notice how each annotation corresponds to a single base character.

```
<ruby>君<rt>くん</rt>くん</ruby>くん<ruby>子<rt>し</rt>し</ruby>は<ruby>和<rt>わ</rt>わ</ruby>して<ruby>同<rt>どう</rt>どう</ruby>ぜず。
君くん子し和わして同どうぜず。
```

This example can also be written as follows, using one `ruby` element with two segments of base text and two annotations (one for each) rather than two back-to-back `ruby` elements each with one base text segment and annotation (as in the markup above):

```
<ruby>君<rt>くん</rt>くん</ruby>くん<ruby>子<rt>し</rt>し</ruby>は<ruby>和<rt>わ</rt>わ</ruby>して<ruby>同<rt>どう</rt>どう</ruby>ぜず。
```

**Mono-ruby for compound words (jukugo)**

This is similar to the previous case: each ideographic character in the compound word (the base text) has its reading given in hiragana or katakana characters (the ruby annotation). The difference is that the base text segments form a compound word rather than being separate from each other.

**Example**

```
<ruby>B<rt>annotation</rt>B<rt>annotation</rt></ruby>
```

In this example, notice again how each annotation corresponds to a single base character. In this example, each compound word (jukugo) corresponds to a single `ruby` element.

The rendering here is expected to be that each annotation be placed over (or next to, in vertical text) the corresponding base character, with the annotations not overhanging any of the adjacent characters.

```
鬼<rt>き</rt>門<rt>もん</rt>の<ruby>方<rt>ほう</rt>ほう</ruby>角<rt>がく</rt>角<rt>がく</rt>を<ruby>凝<rt>ぎょう</rt>ぎょう</ruby>視<rt>し</rt>視<rt>し</rt>する
鬼き門もんのほう角がくを凝ぎょう視しする
```

**Jukugo-ruby**

This is semantically identical to the previous case (each individual ideographic character in the base compound word has its reading given in an annotation in hiragana or katakana characters), but the rendering is the more complicated Jukugo Ruby rendering.

**Example**

This is the same example as above for mono-ruby for compound words. The different rendering is expected to be achieved using different styling (e.g. in CSS), and is not shown here.

```
鬼<rt>き</rt>門<rt>もん</rt>の<ruby>方<rt>ほう</rt>ほう</ruby>角<rt>がく</rt>角<rt>がく</rt>を<ruby>凝<rt>ぎょう</rt>ぎょう</ruby>視<rt>し</rt>視<rt>し</rt>する
```

244
Group ruby for describing meanings

The annotation describes the meaning of the base text, rather than (or in addition to) the pronunciation. As such, both the base text and the annotation can be multiple characters long.

Example

```xml
<ruby>BASE<rt>annotation</ruby>
```

Example

Here a compound ideographic word has its corresponding katakana given as an annotation.

```xml
<ruby>境界面<rt>インターフェース</ruby>
境界面インターフェース
```

Example

Here a compound ideographic word has its translation in English provided as an annotation.

```xml
<ruby lang="ja">編集者<rt lang="en">editor</rt></ruby>
編集者editor
```

Group ruby for Jukuji readings

A phonetic reading that corresponds to multiple base characters, because a one-to-one mapping would be difficult. (In English, the words "Colonel" and "Lieutenant" are examples of words where a direct mapping of pronunciation to individual letters is, in some dialects, rather unclear.)

Example

In this example, the name of a species of flowers has a phonetic reading provided using group ruby:

```xml
<ruby>紫陽花<rt>あじさい</rt></ruby>
紫陽花あじさい
```

Text with both phonetic and semantic annotations (double-sided ruby)

Sometimes, ruby styles described above are combined.

If this results in two annotations covering the same single base segment, then the annotations can just be placed back to back.

Example

```xml
<ruby>BASE<rt>annotation 1<rt>annotation 2</rt></ruby>
```

Example

```xml
<ruby>B<rt>a<rt>a</rt><ruby>A<rt>a</rt></ruby><ruby>S<rt>a</rt></ruby><ruby>E<rt>a</rt></ruby></ruby>
```

Example

In this contrived example, some symbols are given names in English and French.

```xml
<ruby>
♥ <rt>Heart <rt lang="fr">Cœur</rt></rt>
☘ <rt>Shamrock <rt lang="fr">Trèfle</rt></rt>
✶ <rt>Star <rt lang="fr">Étoile</rt></rt>
```
In more complicated situations such as following examples, a nested `ruby` element is used to give the inner annotations, and then that whole `ruby` is then given an annotation at the "outer" level.

**Example**

```html
<ruby><ruby>B<rt>A</rt>ん</ruby><ruby>と</ruby>E<rt>n</rt><ruby>方角</ruby>
```  

**Example**

Here both a phonetic reading and the meaning are given in ruby annotations. The annotation on the nested `ruby` element gives a mono-ruby phonetic annotation for each base character, while the annotation in the `rt` element that is a child of the outer `ruby` element gives the meaning using hiragana.

```html
<ruby>東<rt>とう</rt>南<rt>なん</rt>たつみ<ruby>の方角</ruby>東とう南なんたつみの方角
```  

**Example**

This is the same example, but the meaning is given in English instead of Japanese:

```html
<ruby>東<rt>とう</rt>南<rt>なん</rt><ruby lang=en>Southeast</ruby><ruby>の方角</ruby>東とう南なんSoutheastの方角
```  

Within a `ruby` element that does not have a `ruby` element ancestor, content is segmented and segments are placed into three categories: base text segments, annotation segments, and ignored segments. Ignored segments do not form part of the document's semantics (they consist of some `inter-element whitespace` and `rp` elements, the latter of which are used for legacy user agents that do not support ruby at all). Base text segments can overlap (with a limit of two segments overlapping any one position in the DOM, and with any segment having an earlier start point than an overlapping segment also having an equal or later end point, and any segment have a later end point than an overlapping segment also having an equal or earlier start point). Annotation segments correspond to `rt` elements. Each annotation segment can be associated with a base text segment, and each base text segment can have annotation segments associated with it. (In a conforming document, each base text segment is associated with at least one annotation segment, and each annotation segment is associated with one base text segment.) A `ruby` element represents the union of the segments of base text it contains, along with the mapping from those base text segments to annotation segments. Segments are described in terms of DOM ranges; annotation segment ranges always consist of exactly one element. [DOM]

At any particular time, the segmentation and categorization of content of a `ruby` element is the result that would be obtained from running the following algorithm:

1. Let `base text segments` be an empty list of base text segments, each potentially with a list of base text subsegments.
2. Let `annotation segments` be an empty list of annotation segments, each potentially being associated with a base text segment or subsegment.
3. Let `root` be the `ruby` element for which the algorithm is being run.
4. If `root` has a `ruby` element ancestor, then jump to the step labeled `end`.
5. Let `current parent` be `root`.
6. Let `index` be 0.
7. Let `start index` be null.
8. Let `parent start index` be null.
9. Let `current base text` be null.
10. **Start mode**: If `index` is equal to or greater than the number of child nodes in `current parent`, then jump to the step labeled...
end mode.

11. If the indexth node in current parent is an \texttt{rt} or \texttt{rp} element, jump to the step labeled \textit{annotation mode}.

12. Set start index to the value of index.

13. \textbf{Base mode}: If the indexth node in current parent is a \texttt{ruby} element, and if current parent is the same element as root, then \textbf{push a ruby level}, and then jump to the step labeled \textit{start mode}.

14. If the indexth node in current parent is an \texttt{rt} or \texttt{rp} element, then \textbf{set the current base text} and then jump to the step labeled \textit{annotation mode}.

15. Increment index by one.

16. \textbf{Base mode post-increment}: If index is equal to or greater than the number of child nodes in current parent, then jump to the step labeled \textit{end mode}.

17. Jump back to the step labeled \textit{base mode}.

18. \textbf{Annotation mode}: If the indexth node in current parent is an \texttt{rt} element, then \textbf{push a ruby annotation} and jump to the step labeled \textit{annotation mode increment}.

19. If the indexth node in current parent is an \texttt{rp} element, jump to the step labeled \textit{annotation mode increment}.

20. If the indexth node in current parent is not a Text node, or is a Text node that is not \textit{inter-element whitespace}, then jump to the step labeled \textit{base mode}.

21. \textbf{Annotation mode increment}: Let lookahead index be index plus one.

22. \textbf{Annotation mode white-space skipper}: If lookahead index is equal to the number of child nodes in current parent then jump to the step labeled \textit{end mode}.

23. If the lookahead indexth node in current parent is an \texttt{rt} element or an \texttt{rp} element, then set index to lookahead index and jump to the step labeled \textit{annotation mode}.

24. If the lookahead indexth node in current parent is not a Text node, or is a Text node that is not \textit{inter-element whitespace}, then jump to the step labeled \textit{base mode} (without further incrementing index, so the \textit{inter-element whitespace} seen so far becomes part of the next base text segment).

25. Increment lookahead index by one.

26. Jump to the step labeled \textit{annotation mode white-space skipper}.

27. \textbf{End mode}: If current parent is not the same element as root, then \textbf{pop a ruby level} and jump to the step labeled \textit{base mode post-increment}.

28. \textbf{End}: Return base text segments and annotation segments. Any content of the \texttt{ruby} element not described by segments in either of those lists is implicitly in an \textit{ignored segment}.

When the steps above say to \textbf{set the current base text}, it means to run the following steps at that point in the algorithm:

1. Let text range be a DOM range whose start is the boundary point (current parent, start index) and whose end is the boundary point (current parent, index).
2. Let new text segment be a base text segment described by the range annotation range.
3. Add new text segment to base text segments.
4. Let current base text be new text segment.
5. Let start index be null.

When the steps above say to \textbf{push a ruby level}, it means to run the following steps at that point in the algorithm:

1. Let current parent be the indexth node in current parent.
2. Let index be 0.
3. Set saved start index to the value of start index.
4. Let start index be null.
When the steps above say to **pop a ruby level**, it means to run the following steps at that point in the algorithm:

1. Let `index` be the position of `current parent` in `root`.
2. Let `current parent` be `root`.
3. Increment `index` by one.
4. Set `start index` to the value of `saved start index`.
5. Let `saved start index` be null.

When the steps above say to **push a ruby annotation**, it means to run the following steps at that point in the algorithm:

1. Let `rt` be the `rt` element that is the `index`th node of `current parent`.
2. Let `annotation range` be a DOM range whose `start` is the `boundary point` (`current parent`, `index`) and whose `end` is the `boundary point` (`current parent`, `index` plus one) (i.e. that contains only `rt`).
3. Let `new annotation segment` be an annotation segment described by the range `annotation range`.
4. If `current base text` is not null, associate `new annotation segment` with `current base text`.
5. Add `new annotation segment` to `annotation segments`.

---

**Example**

In this example, each ideograph in the Japanese text 漢字 is annotated with its reading in hiragana.

```html
... <ruby>漢<rt>かん</rt>字<rt>じ</rt></ruby> ...
```

This might be rendered as:

![kan ji... kanji...](image)

---

**Example**

In this example, each ideograph in the traditional Chinese text 漢字 is annotated with its bopomofo reading.

```html
<ruby>漢<rt>ㄏㄢ</rt>字<rt>ㄗ</rt></ruby>
```

This might be rendered as:

![han zi](image)

---

**Example**

In this example, each ideograph in the simplified Chinese text 汉字 is annotated with its pinyin reading.

```html
... <ruby>汉<rt>hàn</rt>字<rt>zì</rt></ruby> ...
```

This might be rendered as:

![han zi](image)
This might be rendered as:

```
... 汉字 ...
```

In this more contrived example, the acronym "HTML" has four annotations: one for the whole acronym, briefly describing what it is, one for the letters "HT" expanding them to "Hypertext", one for the letter "M" expanding it to "Markup", and one for the letter "L" expanding it to "Language".

```
<ruby>
  <ruby>HT<rt>Hypertext</rt>M<rt>Markup</rt>L<rt>Language</rt></ruby>
  <rt>An abstract language for describing documents and applications</rt>
</ruby>
```

### 4.5.11 The rt element

**Categories**: None.

**Contexts in which this element can be used**: As a child of a `ruby` element, either immediately before or immediately after an `rt` element.

**Content model**: Text.

**Tag omission in text/html**: An `rt` element's end tag can be omitted if the `rt` element is immediately followed by an `rt` or `rp` element, or if there is no more content in the parent element.

**Content attributes**: Global attributes.

**DOM interface**: Uses `HTMLElement`.

The `rt` element marks the ruby text component of a ruby annotation. When it is the child of a `ruby` element, it doesn't represent anything itself, but the `ruby` element uses it as part of determining what it represents.

An `rt` element that is not a child of a `ruby` element represents the same thing as its children.

### 4.5.12 The rp element

**Categories**: None.

**Contexts in which this element can be used**: As a child of a `ruby` element, either immediately before or immediately after an `rt` element.

**Content model**: Text.
Tag omission in text/html

An `rp` element's end tag can be omitted if the `rp` element is immediately followed by an `rt` or `rp` element, or if there is no more content in the parent element.

Content attributes:

Global attributes

DOM interface:

Uses `HTMLElement`.

The `rp` element can be used to provide parentheses or other content around a ruby text component of a ruby annotation, to be shown by user agents that don't support ruby annotations.

An `rp` element that is a child of a `ruby` element represents nothing. An `rp` element whose parent element is not a `ruby` element represents its children.

Example

The example above, in which each ideograph in the text 漢字 is annotated with its phonetic reading, could be expanded to use `rp` so that in legacy user agents the readings are in parentheses:

```html
... <ruby>漢<rp>(</rp><rt>かん</rt><rp>)</rp>字<rp>(</rp><rt>じ</rt><rp>)</rp></ruby> ... 
```

In conforming user agents the rendering would be as above, but in user agents that do not support ruby, the rendering would be:

```html
... 漢（かん）字（じ）...
```

Example

When there are multiple annotations for a segment, `rp` elements can also be placed between the annotations. Here is another copy of an earlier contrived example showing some symbols with names given in English and French, but this time with `rp` elements as well:

```html
<ruby>♥<rp>:</rp><rt>Heart</rt><rp>,</rp> ∀<rp>: <rt lang=fr>Cœur</rt><rp>,</rp> ∧<rp>: <rt lang=fr>Trèfle</rt><rp>,</rp> ∗<rp>: <rt lang=fr>Étoile</rt><rp>.</rp></ruby>
```

This would make the example render as follows in non-ruby-capable user agents:

```
```

4.5.13 The data element

Categories:

Flow content

Phrasing content

Palpable content

Contexts in which this element can be used:

```
Where phrasing content is expected.
```

Content model:

Phrasing content
Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- **Global attributes**
  - `value` — Machine-readable value

DOM interface:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLDataElement : HTMLElement {
  [CFEReactions] attribute DOMString value;
};
```

The `data` element **represents** its contents, along with a machine-readable form of those contents in the `value` attribute.

The `value` attribute must be present. Its value must be a representation of the element’s contents in a machine-readable format.

**Note**

> When the value is date- or time-related, the more specific `time` element can be used instead.

The element can be used for several purposes.

When combined with microformats or the `microdata attributes` defined in this specification, the element serves to provide both a machine-readable value for the purposes of data processors, and a human-readable value for the purposes of rendering in a Web browser. In this case, the format to be used in the `value` attribute is determined by the microformats or microdata vocabulary in use.

The element can also, however, be used in conjunction with scripts in the page, for when a script has a literal value to store alongside a human-readable value. In such cases, the format to be used depends only on the needs of the script. (The `data-*` attributes can also be useful in such situations.)

The `value` IDL attribute must **reflect** the content attribute of the same name.

**Example**

Here, a short table has its numeric values encoded using the `data` element so that the table sorting JavaScript library can provide a sorting mechanism on each column despite the numbers being presented in textual form in one column and in a decomposed form in another.

```html
<script src="sortable.js"></script>
<table class="sortable">
  <thead>
    <tr>
      <th>Game</th>
      <th>Corporations</th>
      <th>Map Size</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>1830</td>
      <td data=value="8">Eight</td>
      <td data=value="93">19+74 hexes (93 total)</td>
    </tr>
    <tr>
      <td>1856</td>
      <td data=value="11">Eleven</td>
      <td data=value="99">12+87 hexes (99 total)</td>
    </tr>
    <tr>
      <td>1870</td>
      <td data=value="10">Ten</td>
      <td data=value="149">4+145 hexes (149 total)</td>
    </tr>
  </tbody>
</table>
```

### 4.5.14 The `time` element

Categories:
- Flow content
- Phrasing content
Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
If the element has a `datetime` attribute: Phrasing content.
Otherwise: Text, but must match requirements described in prose below.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
Global attributes:
`datetime` — Machine-readable value

DOM interface:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLTimeElement : HTMLElement {
  [CFReactions] attribute DOMString dateTime;
};
```

The `time` element represents its contents, along with a machine-readable form of those contents in the `datetime` attribute. The kind of content is limited to various kinds of dates, times, time-zone offsets, and durations, as described below.

The `datetime` attribute may be present. If present, its value must be a representation of the element's contents in a machine-readable format.

A `time` element that does not have a `datetime` content attribute must not have any element descendants.

The `datetime` value of a `time` element is the value of the element's `datetime` content attribute, if it has one, otherwise the child text content of the `time` element.

The `datetime` value of a `time` element must match one of the following syntaxes.

A valid month string

Example

```html
<time>2011-11</time>
```

A valid date string

Example

```html
<time>2011-11-18</time>
```

A valid yearless date string

Example

```html
<time>11-18</time>
```

A valid time string

Example

```html
<time>14:54</time>
```

Example

```html
<time>14:54:39</time>
```
A valid local date and time string

Example

\(<\text{time}>2011-11-18T14:54</\text{time}>\)

A valid time-zone offset string

Example

\(<\text{time}>+00:00</\text{time}>\)

A valid global date and time string

\(<\text{time}>2020-01-01T00:00</\text{time}>\)

Note

Times with dates but without a time zone offset are useful for specifying events that are observed at the same specific time in each time zone, throughout a day. For example, the 2020 new year is celebrated at 2020-01-01 00:00 in each time zone, not at the same precise moment across all time zones. For events that occur at the same time across all time zones, for example a videoconference meeting, a valid global date and time string is likely more useful.

Note

For times without dates (or times referring to events that recur on multiple dates), specifying the geographic location that controls the time is usually more useful than specifying a time zone offset, because geographic locations change time zone offsets with daylight saving time. In some cases, geographic locations even change time zone, e.g. when the boundaries of those time zones are redrawn, as happened with Samoa at the end of 2011. There exists a time zone database that describes the boundaries of time zones and what rules apply within each such zone, known as the time zone database. [TZDATABASE]
A valid global date and time string

Example

<time>2011-11-18T14:54Z</time>

Example

<time>2011-11-18T14:54:39Z</time>

Example

<time>2011-11-18T14:54:39.929Z</time>

Example

<time>2011-11-18T14:54+0000</time>

Example

<time>2011-11-18T14:54:39+0000</time>

Example

<time>2011-11-18T14:54:39.929+0000</time>

Example

<time>2011-11-18T14:54+00:00</time>

Example

<time>2011-11-18T14:54:39+00:00</time>

Example

<time>2011-11-18T14:54:39.929+00:00</time>

Example

<time>2011-11-18T06:54-0800</time>

Example

<time>2011-11-18T06:54:39-0800</time>

Example

<time>2011-11-18T06:54:39.929-0800</time>

Example

<time>2011-11-18T06:54-08:00</time>

Example

<time>2011-11-18T06:54:39-08:00</time>

Example

<time>2011-11-18T06:54:39.929-08:00</time>
Times with dates and a time zone offset are useful for specifying specific events, or recurring virtual events where the time is not anchored to a specific geographic location. For example, the precise time of an asteroid impact, or a particular meeting in a series of meetings held at 1400 UTC every day, regardless of whether any particular part of the world is observing daylight savings time or not.
saving time or not. For events where the precise time varies by the local time zone offset of a specific geographic location, a valid local date and time string combined with that geographic location is likely more useful.

A **valid week string**

Example

<time>2011-W47</time>

Four or more **ASCII digits**, at least one of which is not U+0030 DIGIT ZERO (0)

Example

<time>2011</time>

Example

<time>0001</time>

A **valid duration string**

Example

<time>PT4H18M3S</time>

Example

<time>4h 18m 3s</time>

The **machine-readable equivalent of the element's contents** must be obtained from the element's **datetime value** by using the following algorithm:

1. If **parsing a month string** from the element's **datetime value** returns a **month**, that is the machine-readable equivalent; return.
2. If **parsing a date string** from the element's **datetime value** returns a **date**, that is the machine-readable equivalent; return.
3. If **parsing a yearless date string** from the element's **datetime value** returns a **yearless date**, that is the machine-readable equivalent; return.
4. If **parsing a time string** from the element's **datetime value** returns a **time**, that is the machine-readable equivalent; return.
5. If **parsing a local date and time string** from the element's **datetime value** returns a **local date and time**, that is the machine-readable equivalent; return.
6. If **parsing a time-zone offset string** from the element's **datetime value** returns a **time-zone offset**, that is the machine-readable equivalent; return.
7. If **parsing a global date and time string** from the element's **datetime value** returns a **global date and time**, that is the machine-readable equivalent; return.
8. If **parsing a week string** from the element's **datetime value** returns a **week**, that is the machine-readable equivalent; return.
9. If the element's **datetime value** consists of only **ASCII digits**, at least one of which is not U+0030 DIGIT ZERO (0), then the machine-readable equivalent is the base-ten interpretation of those digits, representing a year; return.
10. If **parsing a duration string** from the element's **datetime value** returns a **duration**, that is the machine-readable equivalent; return.
11. There is no machine-readable equivalent.

**Note**

The algorithms referenced above are intended to be designed such that for any arbitrary string $s$, only one of the algorithms
The `date-time` IDL attribute must reflect the element's `datetime` content attribute.

Example

The `time` element can be used to encode dates, for example in microformats. The following shows a hypothetical way of encoding an event using a variant on hCalendar that uses the `time` element:

```html
<div class="vevent">
  <a class="url" href="http://www.web2con.com/">http://www.web2con.com/</a>
  <span class="summary">Web 2.0 Conference</span>
  <time class="dtstart" datetime="2005-10-05">October 5</time> -
  <time class="dtend" datetime="2005-10-07">7</time>,
  at the <span class="location">Argent Hotel, San Francisco, CA</span>
</div>
```

Example

Here, a fictional microdata vocabulary based on the Atom vocabulary is used with the `time` element to mark up a blog post's publication date.

```html
<article itemscope itemtype="https://n.example.org/rfc4287">
  <h1 itemprop="title">Big tasks</h1>
  <footer>Published <time itemprop="published" datetime="2009-08-29">two days ago</time>.</footer>
  <p itemprop="content">Today, I went out and bought a bike for my kid.</p>
</article>
```

Example

In this example, another article's publication date is marked up using the `time` element, this time using the schema.org microdata vocabulary:

```html
<article itemscope itemtype="http://schema.org/BlogPosting">
  <h1 itemprop="headline">Small tasks</h1>
  <footer>Published <time itemprop="datePublished" datetime="2009-08-30">yesterday</time>.</footer>
  <p itemprop="articleBody">I put a bike bell on her bike.</p>
</article>
```

Example

In the following snippet, the `time` element is used to encode a date in the ISO8601 format, for later processing by a script:

```html
<p>Our first date was <time datetime="2006-09-23">a Saturday</time>.</p>
```

In this second snippet, the value includes a time:

```html
<p>We stopped talking at <time datetime="2006-09-24T05:00-07:00">5am the next morning</time>.</p>
```

A script loaded by the page (and thus privy to the page's internal convention of marking up dates and times using the `time` element) could scan through the page and look at all the `time` elements therein to create an index of dates and times.

Example

For example, this element conveys the string "Friday" with the additional semantic that the 18th of November 2011 is the meaning...
that corresponds to "Friday":

Today is <time datetime="2011-11-18">Friday</time>.

Example

In this example, a specific time in the Pacific Standard Time timezone is specified:

Your next meeting is at <time datetime="2011-11-18T15:00-08:00">3pm</time>.

4.5.15 The code element

Categories:
- Flow content
- Phrasing content
- Palpable content

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
- Phrasing content

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:
Uses HTMLElement.

The code element represents a fragment of computer code. This could be an XML element name, a file name, a computer program, or any other string that a computer would recognize.

There is no formal way to indicate the language of computer code being marked up. Authors who wish to mark code elements with the language used, e.g. so that syntax highlighting scripts can use the right rules, can use the class attribute, e.g. by adding a class prefixed with "language-" to the element.

Example

The following example shows how the element can be used in a paragraph to mark up element names and computer code, including punctuation.

<p>The <code>code</code> element represents a fragment of computer code.</p>

<p>When you call the <code>activate()</code> method on the <code>robotSnowman</code> object, the eyes glow.</p>

<p>The example below uses the <code>begin</code> keyword to indicate the start of a statement block. It is paired with an <code>end</code> keyword, which is followed by the <code>.</code> punctuation character (full stop) to indicate the end of the program.</p>
The following example shows how a block of code could be marked up using the `<pre>` and `<code>` elements.

```xml
<pre><code class="language-pascal">var i: Integer;
begin
  i := 1;
end.</code></pre>
```

A class is used in that example to indicate the language used.

---

**Note**

See the `<pre>` element for more details.

---

### 4.5.16 The `var` element

**Categories**: Flow content, Phrasing content, Palpable content.

**Contexts in which this element can be used**:

Where phrasing content is expected.

**Content model**:

Phrasing content.

**Tag omission in text/html**:

Neither tag is omissible.

**Content attributes**:

Global attributes.

**DOM interface**:

Uses `HTMLElement`.

The `var` element represents a variable. This could be an actual variable in a mathematical expression or programming context, an identifier representing a constant, a symbol identifying a physical quantity, a function parameter, or just be a term used as a placeholder in prose.

**Example**

In the paragraph below, the letter "n" is being used as a variable in prose:

```xml
<p>If there are <var>n</var> pipes leading to the ice cream factory then I expect at <em>least</em> <var>n</var> flavors of ice cream to be available for purchase!</p>
```

For mathematics, in particular for anything beyond the simplest of expressions, MathML is more appropriate. However, the `var` element can still be used to refer to specific variables that are then mentioned in MathML expressions.

**Example**

In this example, an equation is shown, with a legend that references the variables in the equation. The expression itself is marked up with MathML, but the variables are mentioned in the figure's legend using `var`.

```xml
<figure>
  <math>
```

---

259
Here, the equation describing mass-energy equivalence is used in a sentence, and the `var` element is used to mark the variables and constants in that equation:

```
<p>Then she turned to the blackboard and picked up the chalk. After a few moment's thought, she wrote `<var>E</var>` = `<var>m</var>` `<var>c</var>`<sup>2</sup>. The teacher looked pleased.</p>
```

Example 4.5.17 The `samp` element

Categories:
- Flow content
- Phrasing content
- Palpable content

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
Phrasing content

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
Global attributes

DOM interface:
Uses `HTMLElement`

The `samp` element represents sample or quoted output from another program or computing system.

Note
See the `pre` and `kbd` elements for more details.

Note
This element can be contrasted with the `output` element, which can be used to provide immediate output in a Web application.

Example
This example shows the `samp` element being used inline:
The computer said `<samp>`Too much cheese in tray two`</samp> but I didn't know what that meant.`</p>

This second example shows a block of sample output from a console program. Nested `<samp>` and `<kbd>` elements allow for the styling of specific elements of the sample output using a style sheet. There's also a few parts of the `<samp>` that are annotated with even more detailed markup, to enable very precise styling. To achieve this, `<span>` elements are used.

```
<pre><samp><span class="prompt">jdoe@mowmow:~$</span> <kbd>ssh demo.example.com</kbd>
Last login: Tue Apr 12 09:10:17 2005 from mowmow.example.com on pts/1
Linux demo 2.6.10-grsec+gg3+e+fhs6b+nfs+gr0501+++p3+c4a+gr2b-reslog-v6.189 #1 SMP Tue Feb 1
11:22:36 PST 2005 1686 unknown
<span class="prompt">jdoe@demo:~$</span> <span class="cursor"></span><span class="prompt"></span></samp></pre>
```

This third example shows a block of input and its respective output. The example uses both `<code>` and `<samp>` elements.

```
<pre><code class="language-javascript">console.log(2.3 + 2.4)
</code><samp>4.699999999999999</samp></pre>
```

### 4.5.18 The `<kbd>` element

**Categories**: Flow content, Phrasing content, Palpable content.

**Contexts in which this element can be used**: Where phrasing content is expected.

**Content model**: Phrasing content.

**Tag omission in `text/html`**: Neither tag is omissible.

**Content attributes**: Global attributes.

**DOM interface**: Uses `HTMLInputElement`.

The `<kbd>` element represents user input (typically keyboard input, although it may also be used to represent other input, such as voice commands).

When the `<kbd>` element is nested inside a `<samp>` element, it represents the input as it was echoed by the system.

When the `<kbd>` element contains a `<samp>` element, it represents input based on system output, for example invoking a menu item.

When the `<kbd>` element is nested inside another `<kbd>` element, it represents an actual key or other single unit of input as appropriate for the input mechanism.
Here the `<kbd>` element is used to indicate keys to press:

```html
<p>To make George eat an apple, press `<kbd>Shift</kbd>+<kbd>F3</kbd>`.</p>
```

In this second example, the user is told to pick a particular menu item. The outer `<kbd>` element marks up a block of input, with the inner `<kbd>` elements representing each individual step of the input, and the `<samp>` elements inside them indicating that the steps are input based on something being displayed by the system, in this case menu labels:

```html
<p>To make George eat an apple, select
<br>`<kbd>&lt;kbd>&lt;kbd>&lt;samp>&lt;/samp>&lt;/kbd>&gt;&lt;kbd>&lt;samp&gt;Eat Apple...&lt;/samp&gt;&lt;/kbd&gt;</p>
```

Such precision isn't necessary; the following is equally fine:

```html
<p>To make George eat an apple, select `<kbd>File | Eat Apple...</kbd>`.</p>
```

### 4.5.19 The `sub` and `sup` elements

**Categories**: Flow content, Phrasing content, Palpable content.

**Contexts in which this element can be used**: Where phrasing content is expected.

**Content model**: Phrasing content.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**: Global attributes.

**DOM interface**: Use `HTMLElement`.

The `sup` element represents a superscript and the `sub` element represents a subscript.

These elements must be used only to mark up typographical conventions with specific meanings, not for typographical presentation for presentation's sake. For example, it would be inappropriate for the `sub` and `sup` elements to be used in the name of the LaTeX document preparation system. In general, authors should use these elements only if the absence of those elements would change the meaning of the content.

In certain languages, superscripts are part of the typographical conventions for some abbreviations.

Here the `sup` element can be used inside a `var` element, for variables that have subscripts.

```html
<p>Their names are `M<sup>lle</sup>` Gwendoline and `M<sup>me</sup>` Denise.</p>
```

The `sub` element can be used inside a `var` element, for variables that have subscripts.
Mathematical expressions often use subscripts and superscripts. Authors are encouraged to use MathML for marking up mathematics, but authors may opt to use `sub` and `sup` if detailed mathematical markup is not desired. [MathML]

Example

```
<var>E</var>=<var>m</var><var>c</var><sup>2</sup>
```

\[ f(<var>x</var>, <var>n</var>) = \log<sub>4</sub><var>x</var><sup><var>n</var></sup> \]

4.5.20 The \textit{i} element §p26

Categories\textsuperscript{p124}:

- Flow content\textsuperscript{p128}
- Phrasing content\textsuperscript{p128}
- Palpable content\textsuperscript{p129}

Contexts in which this element can be used\textsuperscript{p125}:

Where phrasing content\textsuperscript{p128} is expected.

Content model\textsuperscript{p125}:

- Phrasing content\textsuperscript{p128}

Tag omission in text/html\textsuperscript{p125}:

Neither tag is omissible.

Content attributes\textsuperscript{p125}:

- Global attributes\textsuperscript{p132}

DOM interface\textsuperscript{p125}:

Uses \texttt{HTMLElement}\textsuperscript{p120}.

The \textit{i} element represents\textsuperscript{p120} a span of text in an alternate voice or mood, or otherwise offset from the normal prose in a manner indicating a different quality of text, such as a taxonomic designation, a technical term, an idiomatic phrase from another language, transliteration, a thought, or a ship name in Western texts.

Terms in languages different from the main text should be annotated with \texttt{lang}\textsuperscript{p136} attributes (or, in XML, \texttt{lang attributes in the XML namespace}\textsuperscript{p136}).

Example

The examples below show uses of the \textit{i} element:

```
<p>The \texttt{i class="taxonomy"}Felis silvestris catus</i> is cute.</p>
<p>The term \texttt{i}prose content</i> is defined above.</p>
<p>There is a certain \texttt{i lang="fr"}je ne sais quoi</i> in the air.</p>
```

In the following example, a dream sequence is marked up using \textit{i} elements.

```
<p>Raymond tried to sleep.</p>
<p><i>The ship sailed away on Thursday</i>, he
```
Authors can use the `class` attribute on the `i` element to identify why the element is being used, so that if the style of a particular use (e.g. dream sequences as opposed to taxonomic terms) is to be changed at a later date, the author doesn't have to go through the entire document (or series of related documents) annotating each use.

Authors are encouraged to consider whether other elements might be more applicable than the `i` element, for instance the `em` element for marking up stress emphasis, or the `dfn` element to mark up the defining instance of a term.

**Note**

*Style sheets can be used to format `i` elements, just like any other element can be restyled. Thus, it is not the case that content in `i` elements will necessarily be italicized.*

### 4.5.21 The `b` element

**Categories:**
- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used:**
Where phrasing content is expected.

**Content model:**
- Phrasing content

**Tag omission in text/html:**
Neither tag is omissible.

**Content attributes:**
- Global attributes

**DOM interface:**
Uses `HTMLElement`.

The `b` element represents a span of text to which attention is being drawn for utilitarian purposes without conveying any extra importance and with no implication of an alternate voice or mood, such as key words in a document abstract, product names in a review, actionable words in interactive text-driven software, or an article lede.

**Example**

The following example shows a use of the `b` element to highlight key words without marking them up as important:

```
<p>The <b>frobonitor</b> and <b>barbinator</b> components are fried.</p>
```

**Example**

In the following example, objects in a text adventure are highlighted as being special by use of the `b` element.

```
<p>You enter a small room. Your <b>sword</b> glows brighter. A <b>rat</b> scurries past the corner wall.</p>
```
Another case where the `b` element is appropriate is in marking up the lede (or lead) sentence or paragraph. The following example shows how a BBC article about kittens adopting a rabbit as their own could be marked up:

```html
<article>
  <h2>Kittens 'adopted' by pet rabbit</h2>
  <p class="lede">Six abandoned kittens have found an unexpected new mother figure – a pet rabbit.</p>
  <p>Veterinary nurse Melanie Humble took the three-week-old kittens to her Aberdeen home.</p>
</article>
```

As with the `i` element, authors can use the `class` attribute on the `b` element to identify why the element is being used, so that if the style of a particular use is to be changed at a later date, the author doesn't have to go through annotating each use.

The `b` element should be used as a last resort when no other element is more appropriate. In particular, headings should use the `h1` to `h6` elements, stress emphasis should use the `em` element, importance should be denoted with the `strong` element, and text marked or highlighted should use the `mark` element.

**Example**

The following would be incorrect usage:

```html
<p><b class="lede">WARNING!</b> Do not frob the barbinator!</p>
```

In the previous example, the correct element to use would have been `strong`, not `b`.

**Note**

Style sheets can be used to format `b` elements, just like any other element can be restyled. Thus, it is not the case that content in `b` elements will necessarily be boldened.

### 4.5.22 The `u` element

**Categories**:
- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used**:
Where phrasing content is expected.

**Content model**:
- Phrasing content

**Tag omission in text/html**:
Neither tag is omissible.

**Content attributes**:
- Global attributes

**DOM interface**:
Uses `HTMLElement`.

The `u` element represents a span of text with an unarticulated, though explicitly rendered, non-textual annotation, such as labeling the text as being a proper name in Chinese text (a Chinese proper name mark), or labeling the text as being misspelt.

In most cases, another element is likely to be more appropriate: for marking stress emphasis, the `em` element should be used; for marking key words or phrases either the `b` element or the `mark` element should be used, depending on the context; for marking book titles, the `cite` element should be used; for labeling text with explicit textual annotations, the `ruby` element should be
used; for technical terms, taxonomic designation, transliteration, a thought, or for labeling ship names in Western texts, the \texttt{i} element should be used.

**Note**

The default rendering of the \texttt{u} element in visual presentations clashes with the conventional rendering of hyperlinks (underlining). Authors are encouraged to avoid using the \texttt{u} element where it could be confused for a hyperlink.

**Example**

In this example, a \texttt{u} element is used to mark a word as misspelt:

\begin{verbatim}
<p>The <u>see</u> is full of fish.</p>
\end{verbatim}

### 4.5.23 The \texttt{mark} element

**Categories**

- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used**:

Where phrasing content is expected.

**Content model**

- Phrasing content

**Tag omission in text/html**

Neither tag is omissible.

**Content attributes**

- Global attributes

**DOM interface**

Uses \texttt{HTMLElement}.

The \texttt{mark} element represents a run of text in one document marked or highlighted for reference purposes, due to its relevance in another context. When used in a quotation or other block of text referred to from the prose, it indicates a highlight that was not originally present but which has been added to bring the reader’s attention to a part of the text that might not have been considered important by the original author when the block was originally written, but which is now under previously unexpected scrutiny. When used in the main prose of a document, it indicates a part of the document that has been highlighted due to its likely relevance to the user’s current activity.

**Example**

This example shows how the \texttt{mark} element can be used to bring attention to a particular part of a quotation:

\begin{verbatim}
<p lang="en-US">Consider the following quote:</p>
<blockquote lang="en-GB">
  <p>Look around and you will find, no-one’s really blind.</p>
</blockquote>
<p lang="en-US">As we can tell from the <em>spelling</em> of the word, the person writing this quote is clearly not American.</p>
\end{verbatim}

(If the goal was to mark the element as misspelt, however, the \texttt{u} element, possibly with a class, would be more appropriate.)
Another example of the \texttt{mark} element is highlighting parts of a document that are matching some search string. If someone looked at a document, and the server knew that the user was searching for the word "kitten", then the server might return the document with one paragraph modified as follows:

\begin{verbatim}
\textless p \rangle
I also have some \texttt{mark}kitten\texttt{mark}s who are visiting me these days. They're really cute. I think they like my garden! Maybe I should adopt a \texttt{mark}kitten\texttt{mark}.
\end{verbatim}

In the following snippet, a paragraph of text refers to a specific part of a code fragment.

\begin{verbatim}
\textless p \rangle
The highlighted part below is where the error lies:
\end{verbatim}

\begin{verbatim}
\texttt{var i: Integer; begin
i := \texttt{mark}1.1\texttt{mark};
end.}
\end{verbatim}

This is separate from \textit{syntax highlighting}, for which \texttt{span} is more appropriate. Combining both, one would get:

\begin{verbatim}
\textless p \rangle
The highlighted part below is where the error lies:
\end{verbatim}

\begin{verbatim}
\texttt{\texttt{var i: Integer; begin
i := \texttt{mark}1.1\texttt{mark};
end.}
\end{verbatim}

This example shows the use of \texttt{mark} to highlight a part of quoted text that was originally not emphasized. In this example, common typographic conventions have led the author to explicitly style \texttt{mark} elements in quotes to render in italics.

\begin{verbatim}
<br/\rangle
blockquote \textless p \rangle
I didn't \texttt{em}want\texttt{em} to believe. \texttt{mark}Of course on some level I realized it was a known-plaintext attack.\texttt{mark} But I couldn't admit it until I saw for myself.\texttt{mark}
\end{verbatim}

Note, incidentally, the distinction between the \texttt{em} element in this example, which is part of the original text being quoted, and the \texttt{mark} element, which is highlighting a part for comment.
The following example shows the difference between denoting the importance of a span of text (strong) as opposed to denoting the relevance of a span of text (mark). It is an extract from a textbook, where the extract has had the parts relevant to the exam highlighted. The safety warnings, important though they may be, are apparently not relevant to the exam.

```html
<h3>Wormhole Physics Introduction</h3>
<p><mark>A wormhole in normal conditions can be held open for a maximum of just under 39 minutes.</mark> Conditions that can increase the time include a powerful energy source coupled to one or both of the gates connecting the wormhole, and a large gravity well (such as a black hole).</p>
<p><mark>Momentum is preserved across the wormhole. Electromagnetic radiation can travel in both directions through a wormhole, but matter cannot.</mark></p>
<p>When a wormhole is created, a vortex normally forms. <strong>Warning: The vortex caused by the wormhole opening will annihilate anything in its path.</strong> Vortexes can be avoided when using sufficiently advanced dialing technology.</p>
<p><mark>An obstruction in a gate will prevent it from accepting a wormhole connection.</mark></p>
```

### 4.5.24 The `bdi` element

**Categories**: Flow content, Phrasing content, Palpable content.

**Contexts in which this element can be used**: Where phrasing content is expected.

**Content model**: Phrasing content.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**: Global attributes.

**DOM interface**: Uses HTMLElement.

The `bdi` element represents a span of text that is to be isolated from its surroundings for the purposes of bidirectional text formatting. [BID]

**Note**

The `dir` global attribute defaults to `auto` on this element (it never inherits from the parent element like with other elements).

**Note**

This element has rendering requirements involving the bidirectional algorithm.
This element is especially useful when embedding user-generated content with an unknown directionality.

In this example, usernames are shown along with the number of posts that the user has submitted. If the `<bdi>` element were not used, the username of the Arabic user would end up confusing the text (the bidirectional algorithm would put the colon and the number "3" next to the word "User" rather than next to the word "posts").

```html
<ul>
  <li>User <bdi>jcranmer</bdi>: 12 posts.</li>
  <li>User <bdi>hober</bdi>: 5 posts.</li>
  <li>User <bdi>إيان</bdi>: 3 posts.</li>
</ul>
```

When using the `<bdi>` element, the username acts as expected.

```html
• User jcranmer: 12 posts.
• User hober: 5 posts.
• User إيان: 3 posts.
```

If the `<bdi>` element were to be replaced by a `<b>` element, the username would confuse the bidirectional algorithm and the third bullet would end up saying "User 3 :", followed by the Arabic name (right-to-left), followed by "posts" and a period.

4.5.25 The `<bdo>` element

Categories:
- Flow content
- Phrasing content
- Palpable content

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
- Phrasing content

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes
  Also, the `dir` global attribute has special semantics on this element.

DOM interface:
- Uses `HTMLElement`.

The `<bdo>` element represents explicit text directionality formatting control for its children. It allows authors to override the Unicode bidirectional algorithm by explicitly specifying a direction override. ([BIDI])

Authors must specify the `dir` attribute on this element, with the value `ltr` to specify a left-to-right override and with the value `rtl` to specify a right-to-left override. The `auto` value must not be specified.

**Note**
This element has rendering requirements involving the bidirectional algorithm.
4.5.26 The `span` element

**Categories**:
- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used**:
Where phrasing content is expected.

**Content model**:
- Phrasing content

**Tag omission in text/html**:
Neither tag is omissible.

**Content attributes**:
- Global attributes

**DOM interface**:

```
IDL [Exposed=Window, HTMLConstructor]
interface HTMLSpanElement : HTMLElement {};
```

The `span` element doesn't mean anything on its own, but can be useful when used together with the global attributes, e.g. `class`, `lang`, or `dir`. It represents its children.

---

Example

In this example, a code fragment is marked up using `span` elements and `class` attributes so that its keywords and identifiers can be color-coded from CSS:

```html
<pre><code class="lang-c">for</code><span class="ident">j</span> = 0; <span class="ident">j</span> &lt; 256; <span class="ident">j</span><span class="ident">+</span><span class="ident">+</span> { 
  "ident"<span class="ident">i_t3</span><span class="ident"></span> = (<span class="ident">i_t3</span>&lt;&lt;3) ^ (<span class="ident">i_t3</span>&lt;&lt;1) ^ <span class="ident">i_t3</span>; 
  <span class="keyword">if</span> (<span class="ident">i_t6</span> == <span class="ident">i_t1</span>) <span class="keyword">break</span>;
}<code class="keyword"></code></pre>
```

---

4.5.27 The `br` element

**Categories**:
- Flow content
- Phrasing content

**Contexts in which this element can be used**:
Where phrasing content is expected.

**Content model**:
- Nothing

**Tag omission in text/html**:
No end tag.

**Content attributes**:
- Global attributes

---

270
DOM interface:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLBRElement : HTMLElement {
};
```

The `br` element represents a line break.

**Note**

While line breaks are usually represented in visual media by physically moving subsequent text to a new line, a style sheet or user agent would be equally justified in causing line breaks to be rendered in a different manner, for instance as green dots, or as extra spacing.

**Example**

The following example is correct usage of the `br` element:

```html
<p>P. Sherman<br>
42 Wallaby Way<br>
Sydney</p>
```

`br` elements must not be used for separating thematic groups in a paragraph.

**Example**

The following examples are non-conforming, as they abuse the `br` element:

```html
<p><a ...>34 comments.</a><br>
Add a comment.</p>
<p><label>Name: <input name="name"/></label><br>
Address: <input name="address"/></p>
```

Here are alternatives to the above, which are correct:

```html
<p><a ...>34 comments.</a></p>
<p>Add a comment.</p>
<p><label>Name: <input name="name"/></label></p>
<p>Address: <input name="address"/></p>
```

If a paragraph consists of nothing but a single `br` element, it represents a placeholder blank line (e.g. as in a template). Such blank lines must not be used for presentation purposes.

Any content inside `br` elements must not be considered part of the surrounding text.

**Note**

This element has rendering requirements involving the bidirectional algorithm.

### 4.5.28 The `wbr` Element

**Categories**:

- Flow content
- Phrasing content

The `wbr` element represents a line break that is automatically adjusted to fit the text as closely as possible. It is used to help the text layout process by indicating where a line break can be placed without affecting the rendering of subsequent text.
Contexts in which this element can be used\textsuperscript{p125}:

Where phrasing content\textsuperscript{p128} is expected.

Content model\textsuperscript{p125}:

Nothing\textsuperscript{p126}.

Tag omission in text/html\textsuperscript{p125}:

No end tag\textsuperscript{p1013}.

Content attributes\textsuperscript{p125}:

Global attributes\textsuperscript{p132}.

DOM interface\textsuperscript{p125}:

Uses HTMLInputElement\textsuperscript{p120}.

The \texttt{wbr}\textsuperscript{p271} element represents\textsuperscript{p120} a line break opportunity.

\textbf{Example}

In the following example, someone is quoted as saying something which, for effect, is written as one long word. However, to ensure that the text can be wrapped in a readable fashion, the individual words in the quote are separated using a \texttt{wbr}\textsuperscript{p271} element.

\begin{verbatim}
<p>So then she pointed at the tiger and screamed
"there\texttt{wbr}is\texttt{wbr}no\texttt{wbr}way\texttt{wbr}you\texttt{wbr}are\texttt{wbr}ever\texttt{wbr}going\texttt{wbr}to\texttt{wbr}catch\texttt{wbr}me"!</p>
\end{verbatim}

Any content inside \texttt{wbr}\textsuperscript{p271} elements must not be considered part of the surrounding text.

\textbf{Example}

\begin{verbatim}
var wbr = document.createElement("wbr");
wbr.textContent = "This is wrong";
document.body.appendChild(wbr);
\end{verbatim}

\textbf{Note}

This element has rendering requirements involving the bidirectional algorithm\textsuperscript{p147}.

4.6 Links

4.6.1 Introduction

Links are a conceptual construct, created by `a` and `area` elements, that represent a connection between two resources, one of which is the current Document. There are two kinds of links in HTML:

**Links to external resources**

These are links to resources that are to be used to augment the current document, generally automatically processed by the user agent.

**Hyperlinks**

These are links to other resources that are generally exposed to the user by the user agent so that the user can cause the user agent to navigate to those resources, e.g. to visit them in a browser or download them.

For `link` elements with an `href` attribute and a `rel` attribute, links must be created for the keywords of the `rel` attribute, as defined for those keywords in the `link types` section.

Similarly, for `a` and `area` elements with an `href` attribute and a `rel` attribute, links must be created for the keywords of the `rel` attribute as defined for those keywords in the `link types` section. Unlike `link` elements, however, `a` and `area` elements with an `href` attribute that either do not have a `rel` attribute, or whose `rel` attribute has no keywords that are defined as specifying hyperlinks, must also create a `hyperlink` attribute. This implied hyperlink has no special meaning (it has no `link type` beyond linking the element's `node document` to the resource given by the element's `href` attribute.

A `hyperlink` can have one or more `hyperlink annotations` that modify the processing semantics of that hyperlink.
4.6.2 Links created by a and area elements

The href attribute on a and area elements must have a value that is a valid URL potentially surrounded by spaces.[86]

Note

The href attribute on a and area elements is not required; when those elements do not have href attributes they do not create hyperlinks.

The target attribute, if present, must be a valid browsing context name or keyword.[86] It gives the name of the browsing context[86] that will be used. User agents use this name when following hyperlinks[86].

When an a or area element's activation behavior is invoked, the user agent may allow the user to indicate a preference regarding whether the hyperlink is to be used for navigation[86], or whether the resource it specifies is to be downloaded.

In the absence of a user preference, the default should be navigation if the element has no download[86] attribute, and should be to download the specified resource if it does.

Whether determined by the user's preferences or via the presence or absence of the attribute, if the decision is to use the hyperlink for navigation[86], then the user agent must follow the hyperlink[86], and if the decision is to use the hyperlink to download a resource, the user agent must download the hyperlink[86]. These terms are defined in subsequent sections below.

The download attribute, if present, indicates that the author intends the hyperlink to be used for downloading a resource.[86] The attribute may have a value; the value, if any, specifies the default file name that the author recommends for use in labeling the resource in a local file system. There are no restrictions on allowed values, but authors are cautioned that most file systems have limitations with regard to what punctuation is supported in file names, and user agents are likely to adjust file names accordingly.

The ping attribute, if present, gives the URLs of the resources that are interested in being notified if the user follows the hyperlink. The value must be a set of space-separated tokens[84], each of which must be a valid non-empty URL[85] whose scheme is an HTTP(S) scheme. The value is used by the user agent for hyperlink auditing.[86]

The rel attribute on a and area elements controls what kinds of links the elements create. The attribute's value must be a set of space-separated tokens[84]. The allowed keywords and their meanings[86] are defined below.

rel's supported tokens are the keywords defined in HTML link types[86] which are allowed on a and area elements, impact the processing model, and are supported by the user agent. The possible supported tokens are noreferrer[86] and noopen[86]. rel's supported tokens must only include the tokens from this list that the user agent implements the processing model for.

Other specifications may add HTML link types[86] as defined in Other link types[86], with the following additional requirements:

- Such specifications may require that their link types be included in rel's supported tokens.
- Such specifications may specify that their link types are body-ok's supported tokens.

The rel attribute has no default value. If the attribute is omitted or if none of the values in the attribute are recognized by the user agent, then the document has no particular relationship with the destination resource other than there being a hyperlink between the two.

The hreflang attribute on a elements that create hyperlinks[86], if present, gives the language of the linked resource. It is purely advisory. The value must be a valid BCP 47 language tag. [BCP47] User agents must not consider this attribute authoritative — upon fetching the resource, user agents must use only language information associated with the resource to determine its language, not metadata included in the link to the resource.

The type attribute, if present, gives the MIME type of the linked resource. It is purely advisory. The value must be a valid MIME type string. User agents must not consider the type attribute authoritative — upon fetching the resource, user agents must not use metadata included in the link to the resource to determine its type.

The referrerpolicy attribute is a referrer policy attribute[86]. Its purpose is to set the referrer policy used when following hyperlinks[86]. [REFERRERPOLICY][325]
IDL interface mixin HTMLHyperlinkElementUtils {
    [CEReactions] stringifier attribute USVString href;
    readonly attribute USVString origin;
    [CEReactions] attribute USVString protocol;
    [CEReactions] attribute USVString username;
    [CEReactions] attribute USVString password;
    [CEReactions] attribute USVString host;
    [CEReactions] attribute USVString hostname;
    [CEReactions] attribute USVString port;
    [CEReactions] attribute USVString pathname;
    [CEReactions] attribute USVString search;
    [CEReactions] attribute USVString hash;
};

For web developers (non-normative)

hyperlink . toString()

hyperlink . href
    Returns the hyperlink's URL.
    Can be set, to change the URL.

hyperlink . origin
    Returns the hyperlink's URL's origin.

hyperlink . protocol
    Returns the hyperlink's URL's scheme.
    Can be set, to change the URL's scheme.

hyperlink . username
    Returns the hyperlink's URL's username.
    Can be set, to change the URL's username.

hyperlink . password
    Returns the hyperlink's URL's password.
    Can be set, to change the URL's password.

hyperlink . host
    Returns the hyperlink's URL's host and port (if different from the default port for the scheme).
    Can be set, to change the URL's host and port.

hyperlink . hostname
    Returns the hyperlink's URL's host.
    Can be set, to change the URL's host.

hyperlink . port
    Returns the hyperlink's URL's port.
    Can be set, to change the URL's port.

hyperlink . pathname
    Returns the hyperlink's URL's path.
    Can be set, to change the URL's path.

hyperlink . search
    Returns the hyperlink's URL's query (includes leading "?" if non-empty).
    Can be set, to change the URL's query (ignores leading "?").
An element implementing the HTMLHyperlinkElementUtils mixin has an associated url (null or a URL). It is initially null.

An element implementing the HTMLHyperlinkElementUtils mixin has an associated set the url algorithm, which runs these steps:

1. If this element’s href content attribute is absent, set this element’s url to null.
2. Otherwise, parse this element’s href content attribute value relative to this element’s node document. If parsing is successful, set this element’s url to the result; otherwise, set this element’s url to null.

When elements implementing the HTMLHyperlinkElementUtils mixin are created, and whenever those elements have their href content attribute set, changed, or removed, the user agent must set the url.

An element implementing the HTMLHyperlinkElementUtils mixin has an associated reinitialize url algorithm, which runs these steps:

1. If element's url is non-null, its scheme is "blob", and its cannot-be-a-base-URL flag is set, terminate these steps.
2. Set the url.

To update href, set the element’s href content attribute’s value to the element’s url, serialized.

The href attribute’s getter must run these steps:

1. Reinitialize url.
2. Let url be this element's url.
3. If url is null and this element has no href content attribute, return the empty string.
4. Otherwise, if url is null, return this element's href content attribute's value.
5. Return url, serialized.

The href attribute’s setter must set this element’s href content attribute’s value to the given value.

The origin attribute’s getter must run these steps:

1. Reinitialize url.
2. If this element's url is null, return the empty string.
3. Return the serialization of this element's url’s origin.

The protocol attribute’s getter must run these steps:

1. Reinitialize url.
2. If this element's url is null, return "::".
3. Return this element's url's scheme, followed by "::".

The protocol attribute’s setter must run these steps:

1. Reinitialize url.
2. If this element's `url` is null, terminate these steps.

3. Basic URL parse the given value, followed by ":", with this element's `url` as url and `scheme start state` as state override.

   **Note**

   Because the URL parser ignores multiple consecutive colons, providing a value of "https:" (or even "https::") is the same as providing a value of "https".

4. Update `href`.

The `username` attribute's getter must run these steps:

1. **Reinitialize url**.

2. If this element's `url` is null, return the empty string.

3. Return this element's `url`'s `username`.

The `username` attribute's setter must run these steps:

1. **Reinitialize url**.

2. Let `url` be this element's `url`.

3. If `url` is null or `url` cannot have a `username/password/port`, then return.

4. **Set the username**, given `url` and the given value.

5. **Update href**.

The `password` attribute's getter must run these steps:

1. **Reinitialize url**.

2. Let `url` be this element's `url`.

3. If `url` is null, then return the empty string.

4. Return `url`'s `password`.

The `password` attribute's setter must run these steps:

1. **Reinitialize url**.

2. Let `url` be this element's `url`.

3. If `url` is null or `url` cannot have a `username/password/port`, then return.

4. **Set the password**, given `url` and the given value.

5. **Update href**.

The `host` attribute's getter must run these steps:

1. **Reinitialize url**.

2. Let `url` be this element's `url`.

3. If `url` or `url`'s `host` is null, return the empty string.

4. If `url`'s `port` is null, return `url`'s `host`, `serialized`.

5. Return `url`'s `host`, `serialized`, followed by ":" and `url`'s `port`, `serialized`.

The `host` attribute's setter must run these steps:

1. **Reinitialize url**.

2. Let `url` be this element's `url`.
3. If url is null or url's cannot-be-a-base-URL flag is set, terminate these steps.
4. Basic URL parse the given value, with url as url and host state as state override.
5. Update href.

The hostname attribute's getter must run these steps:

1. Reinitialize url.
2. Let url be this element's url.
3. If url or url's host is null, return the empty string.
4. Return url's host, serialized.

The hostname attribute's setter must run these steps:

1. Reinitialize url.
2. Let url be this element's url.
3. If url is null or url's cannot-be-a-base-URL flag is set, terminate these steps.
4. Basic URL parse the given value, with url as url and hostname state as state override.
5. Update href.

The port attribute's getter must run these steps:

1. Reinitialize url.
2. Let url be this element's url.
3. If url or url's port is null, return the empty string.
4. Return url's port, serialized.

The port attribute's setter must run these steps:

1. Reinitialize url.
2. Let url be this element's url.
3. If url is null or url cannot have a username/password/port, then return.
4. If the given value is the empty string, then set url's port to null.
5. Otherwise, basic URL parse the given value, with url as url and port state as state override.
6. Update href.

The pathname attribute's getter must run these steps:

1. Reinitialize url.
2. Let url be this element's url.
3. If url is null, return the empty string.
4. If url's cannot-be-a-base-URL flag is set, return the first string in url's path.
5. If url's path is empty, then return the empty string.
6. Return "/", followed by the strings in url's path (including empty strings), separated from each other by "/".

The pathname attribute's setter must run these steps:

1. Reinitialize url.
2. Let url be this element's url.
3. If url is null or url's cannot-be-a-base-URL flag is set, terminate these steps.

4. Set url's path to the empty list.

5. Basic URL parse the given value, with url as url and path start state as state override.

6. Update href.

The search attribute's getter must run these steps:

1. Reinitialize url.

2. Let url be this element's url.

3. If url is null, or url's query is either null or the empty string, return the empty string.

4. Return "?", followed by url's query.

The search attribute's setter must run these steps:

1. Reinitialize url.

2. Let url be this element's url.

3. If url is null, terminate these steps.

4. If the given value is the empty string, set url's query to null.

5. Otherwise:

   1. Let input be the given value with a single leading "?" removed, if any.

   2. Set url's query to the empty string.

   3. Basic URL parse input, with url as url and query state as state override, and this element's node document's character encoding as encoding override.

6. Update href.

The hash attribute's getter must run these steps:

1. Reinitialize url.

2. Let url be this element's url.

3. If url is null, or url's fragment is either null or the empty string, return the empty string.

4. Return "#", followed by url's fragment.

The hash attribute's setter must run these steps:

1. Reinitialize url.

2. Let url be this element's url.

3. If url is null, then return.

4. If the given value is the empty string, set url's fragment to null.

5. Otherwise:

   1. Let input be the given value with a single leading "#" removed, if any.

   2. Set url's fragment to the empty string.

   3. Basic URL parse input, with url as url and fragment state as state override.

6. Update href.
4.6.4 Following hyperlinks

An element `element` cannot navigate if one of the following is true:

- `element`'s node document is not fully active.
- `element` is not an `a` or `area` element and is not connected.

Note

This is also used by form submission for the `form` element. The exception for `a` elements is for compatibility with web content.

When a user follows a hyperlink created by an element `subject`, optionally with a hyperlink suffix, the user agent must run the following steps:

1. If `subject` cannot navigate, then return.
2. Let replace be false.
3. Let source be `subject`'s node document's browsing context.
4. Let `getAttributeValue` be the empty string.
5. If `subject` is an `a` or `area` element, then set `getAttributeValue` to the result of getting an element's target given `subject`.
6. Let noopener be true if `subject`'s link types include the `noreferrer` or `noopener` keyword.
7. Let `getTarget` be the result of applying the rules for choosing a browsing context given `getAttributeValue`, `source`, and `noopener`.
8. If `target` is null, then return.
9. If `noopener` and `replace` are true, then disown target.
10. Parse the URL given by `subject`'s `href` attribute, relative to `subject`'s node document.
11. If that is successful, let URL be the resulting URL string.
   Otherwise, if parsing the URL failed, the user agent may report the error to the user in a user-agent-specific manner, may queue a task to navigate the target browsing context to an error page to report the error, or may ignore the error and do nothing. In any case, the user agent must then return.
12. If there is a hyperlink suffix, append it to URL.
13. Let resource be a new request whose `url` is URL and whose referer policy is the current state of `subject`'s referer policy.
14. Queue a task to navigate the target browsing context to resource. If `replace` is true, the navigation must be performed with replacement enabled. The source browsing context must be source.

The task source for the tasks mentioned above is the DOM manipulation task source.

4.6.5 Downloading resources

In some cases, resources are intended for later use rather than immediate viewing. To indicate that a resource is intended to be downloaded for use later, rather than immediately used, the `download` attribute can be specified on the `a` or `area` element that creates the hyperlink to that resource.

The attribute can furthermore be given a value, to specify the file name that user agents are to use when storing the resource in a file system. This value can be overridden by the `Content-Disposition` HTTP header's filename parameters.

In cross-origin situations, the `download` attribute has to be combined with the `Content-Disposition` HTTP header, specifically with the attachment disposition type, to avoid the user being warned of possibly nefarious activity. (This is to protect users from being made to download sensitive personal or confidential information without their full understanding.)
When a user downloads a hyperlink created by an element subject, optionally with a hyperlink suffix, the user agent must run the following steps:

1. If subject cannot navigate, then return.
2. Parse the URL given by subject's href attribute, relative to subject's node document.
3. If parsing the URL fails, the user agent may report the error to the user in a user-agent-specific manner, may navigate to an error page to report the error, or may ignore the error and do nothing. In either case, the user agent must return.
4. Otherwise, let URL be the resulting URL string.
5. If there is a hyperlink suffix, append it to URL.
6. Run these steps in parallel:
   1. Let request be a new request whose url is URL, client is entry settings object, initiator is "download", destination is the empty string, and whose synchronous flag and use-URL-credentials flag are set.
   2. Handle the result of fetching request as a download.

When a user agent is to handle a resource obtained from a fetch as a download, it should provide the user with a way to save the resource for later use, if a resource is successfully obtained; or otherwise should report any problems downloading the file to the user.

If the user agent needs a file name for a resource being handled as a download, it should select one using the following algorithm.

⚠Warning! This algorithm is intended to mitigate security dangers involved in downloading files from untrusted sites, and user agents are strongly urged to follow it.

1. Let filename be the void value.
2. If the resource has a `Content-Disposition` header, that header specifies the attachment disposition type, and the header includes file name information, then let filename have the value specified by the header, and jump to the step labeled sanitize below. [RFC6266]
3. Let interface origin be the origin of the Document in which the download or navigate action resulting in the download was initiated, if any.
4. Let resource origin be the origin of the URL of the resource being downloaded, unless that URL's scheme component is data, in which case let resource origin be the same as the interface origin, if any.
5. If there is no interface origin, then let trusted operation be true. Otherwise, let trusted operation be true if resource origin is the same origin as interface origin, and false otherwise.
6. If trusted operation is true and the resource has a `Content-Disposition` header and that header includes file name information, then let filename have the value specified by the header, and jump to the step labeled sanitize below. [RFC6266]
7. If the download was not initiated from a hyperlink created by an or area element, or if the element of the hyperlink from which it was initiated did not have a download attribute when the download was initiated, or if there was such an attribute but its value when the download was initiated was the empty string, then jump to the step labeled no proposed file name.
8. Let proposed filename have the value of the download attribute of the element of the hyperlink that initiated the download at the time the download was initiated.
9. If trusted operation is true, let filename have the value of proposed filename, and jump to the step labeled sanitize below.
10. If the resource has a `Content-Disposition` header and that header specifies the attachment disposition type, let filename have the value of proposed filename, and jump to the step labeled sanitize below. [RFC6266]
11. No proposed file name: If trusted operation is true, or if the user indicated a preference for having the resource in question downloaded, let filename have a value derived from the URL of the resource in a user-agent-defined manner, and jump to the step labeled sanitize below.
12. Act in a user-agent-defined manner to safeguard the user from a potentially hostile cross-origin download. If the download is not to be aborted, then let filename be set to the user's preferred file name or to a file name selected by the user agent, and
13. **Sanitize**: Optionally, allow the user to influence `filename`. For example, a user agent could prompt the user for a file name, potentially providing the value of `filename` as determined above as a default value.

14. Adjust `filename` to be suitable for the local file system.

**Example**

For example, this could involve removing characters that are not legal in file names, or trimming leading and trailing whitespace.

15. If the platform conventions do not in any way use `extensions` to determine the types of file on the file system, then return `filename` as the file name.

16. Let `claimed type` be the type given by the resource's `Content-Type metadata`, if any is known. Let `named type` be the type given by `filename`'s `extension`, if any is known. For the purposes of this step, a type is a mapping of a MIME type to an extension.

17. If `named type` is consistent with the user's preferences (e.g. because the value of `filename` was determined by prompting the user), then return `filename` as the file name.

18. If `claimed type` and `named type` are the same type (i.e. the type given by the resource's `Content-Type metadata` is consistent with the type given by `filename`'s `extension`), then return `filename` as the file name.

19. If the `claimed type` is known, then alter `filename` to add an `extension` corresponding to `claimed type`.

   Otherwise, if `named type` is known to be potentially dangerous (e.g. it will be treated by the platform conventions as a native executable, shell script, HTML application, or executable-macro-capable document) then optionally alter `filename` to add a known-safe `extension` (e.g. ".txt").

**Note**

This last step would make it impossible to download executables, which might not be desirable. As always, implementers are forced to balance security and usability in this matter.

20. Return `filename` as the file name.

For the purposes of this algorithm, a file `extension` consists of any part of the file name that platform conventions dictate will be used for identifying the type of the file. For example, many operating systems use the part of the file name following the last dot (".") in the file name to determine the type of the file, and from that the manner in which the file is to be opened or executed.

User agents should ignore any directory or path information provided by the resource itself, its `URL`, and any `download` attribute, in deciding where to store the resulting file in the user's file system.

### 4.6.5.1 Hyperlink auditing

If a hyperlink created by an `a` or `area` element has a `ping` attribute, and the user follows the hyperlink, and the value of the element's `href` attribute can be parsed, relative to the element's `node document`, without failure, then the user agent must take the `ping` attribute's value, split that string on ASCII whitespace, parse each resulting token relative to the element's `node document`, and then run these steps for each resulting `URL record`, `ping URL`, ignoring tokens that fail to parse:
1. If ping URL's `scheme` is not an HTTP(S) scheme, then return.

2. Optionally, return. (For example, the user agent might wish to ignore any or all ping URLs in accordance with the user’s expressed preferences.)

3. Let `request` be a new `request` whose `url` is ping URL, `method` is `POST`, `body` is `PING`, `client` is the `environment settings object` of the `Document` containing the `hyperlink`, `destination` is the empty string, `credentials mode` is "include", `referrer` is "no-referrer", and whose `use-URL-credentials flag` is set.

4. Let `target URL` be the `resulting URL string` obtained from parsing the value of the element’s `href` attribute and then:
   ↪ If the `URL of the Document` object containing the hyperlink being audited and ping URL have the `same origin`, `request` must include a `Ping-From` header with, as its value, the `URL` of the document containing the hyperlink, and a `Ping-To` HTTP header with, as its value, the `target URL`.
   ↪ If the origins are different, but the `HTTPS state` of the `Document` containing the hyperlink being audited is "none" `request` must include a `Ping-From` header with, as its value, the `URL` of the document containing the hyperlink, and a `Ping-To` HTTP header with, as its value, the `target URL`.
   ↪ Otherwise `request` must include a `Ping-To` HTTP header with, as its value, `target URL`. `request` does not include a `Ping-From` header.

5. Fetch `request`.

This may be done in parallel with the primary fetch, and is independent of the result of that fetch.

User agents should allow the user to adjust this behavior, for example in conjunction with a setting that disables the sending of HTTP `Referer` (sic) headers. Based on the user’s preferences, UAs may either ignore the ping attribute altogether, or selectively ignore URLs in the list (e.g. ignoring any third-party URLs); this is explicitly accounted for in the steps above.

User agents must ignore any entity bodies returned in the responses. User agents may close the connection prematurely once they start receiving a response body.

When the ping attribute is present, user agents should clearly indicate to the user that following the hyperlink will also cause secondary requests to be sent in the background, possibly including listing the actual target URLs.

**Example**

For example, a visual user agent could include the hostnames of the target ping URLs along with the hyperlink’s actual URL in a status bar or tooltip.

**Note**

The `ping` attribute is redundant with pre-existing technologies like HTTP redirects and JavaScript in allowing Web pages to track which off-site links are most popular or allowing advertisers to track click-through rates.

However, the `ping` attribute provides these advantages to the user over those alternatives:

- It allows the user to see the final target URL unobscured.
- It allows the UA to inform the user about the out-of-band notifications.
- It allows the user to disable the notifications without losing the underlying link functionality.
- It allows the UA to optimize the use of available network bandwidth so that the target page loads faster.

Thus, while it is possible to track users without this feature, authors are encouraged to use the `ping` attribute so that the user agent can make the user experience more transparent.

### 4.6.6 Link types

The following table summarizes the link types that are defined by this specification, by their corresponding keywords. This table is non-normative; the actual definitions for the link types are given in the next few sections.

---

283
In this section, the term *referenced document* refers to the resource identified by the element representing the link, and the term *current document* refers to the resource within which the element representing the link finds itself.

To determine which link types apply to a `link` element, the `a` element, or an `area` element, the element’s `rel` attribute must be split on ASCII whitespace. The resulting tokens are the keywords for the link types that apply to that element.

Except where otherwise specified, a keyword must not be specified more than once per `rel` attribute.

Some of the sections that follow the table below list synonyms for certain keywords. The indicated synonyms are to be handled as specified by user agents, but must not be used in documents (for example, the keyword "copyright").

Keywords are always ASCII case-insensitive, and must be compared as such.

### Example

Thus, `rel="next"` is the same as `rel="NEXT"`.

Keywords that are `body-ok` affect whether `link` elements are allowed in the body. The `body-ok` keywords defined by this specification are `dns-prefetch`, `modulepreload`, `pingback`, `preconnect`, `prefetch`, `preload`, `prerender`, and `stylesheets`. Other specifications can also define `body-ok` keywords.

<table>
<thead>

</tbody>
</table>
4.6.6.1 Link type "alternate" §p285

The alternate\(^{\text{p285}}\) keyword may be used with link\(^{\text{p153}}\), a\(^{\text{p230}}\), and area\(^{\text{p428}}\) elements.

The meaning of this keyword depends on the values of the other attributes.

→ If the element is a link\(^{\text{p153}}\) element and the rel\(^{\text{p154}}\) attribute also contains the keyword stylesheet\(^{\text{p294}}\)

The alternate\(^{\text{p285}}\) keyword modifies the meaning of the stylesheet\(^{\text{p294}}\) keyword in the way described for that keyword. The alternate\(^{\text{p285}}\) keyword does not create a link of its own.

Example

Here, a set of link\(^{\text{p153}}\) elements provide some style sheets:

```html
<!-- a persistent style sheet -->
<link rel="stylesheet" href="default.css">

<!-- the preferred alternate style sheet -->
<link rel="stylesheet" href="green.css" title="Green styles">

<!-- some alternate style sheets -->
<link rel="alternate stylesheet" href="contrast.css" title="High contrast">
<link rel="alternate stylesheet" href="big.css" title="Big fonts">
<link rel="alternate stylesheet" href="wide.css" title="Wide screen">
```

→ If the alternate\(^{\text{p285}}\) keyword is used with the type\(^{\text{p274}}\) attribute set to the value application/rss+xml or the value application/atom+xml

The keyword creates a hyperlink\(^{\text{p273}}\) referencing a syndication feed (though not necessarily syndicating exactly the same content as the current page).

For the purposes of feed autodiscovery, user agents should consider all link\(^{\text{p153}}\) elements in the document with the alternate\(^{\text{p285}}\) keyword used and with their type\(^{\text{p274}}\) attribute set to the value application/rss+xml or the value application/atom+xml. If the user agent has the concept of a default syndication feed, the first such element (in tree order) should be used as the default.

Example

The following link\(^{\text{p153}}\) elements give syndication feeds for a blog:

```html
<link rel="alternate" type="application/atom+xml" href="posts.xml" title="Cool Stuff Blog">
<link rel="alternate" type="application/atom+xml" href="posts.xml?category=robots" title="Cool Stuff Blog: robots category">
<link rel="alternate" type="application/atom+xml" href="comments.xml" title="Cool Stuff Blog: Comments">
```

Such link\(^{\text{p153}}\) elements would be used by user agents engaged in feed autodiscovery, with the first being the default (where applicable).

The following example offers various different syndication feeds to the user, using a\(^{\text{p230}}\) elements:

```html
<p>You can access the planets database using Atom feeds:</p>
<ul>
  <li><a href="recently-visited-planets.xml" rel="alternate" type="application/atom+xml">Recently Visited Planets</a></li>
  <li><a href="known-bad-planets.xml" rel="alternate" type="application/atom+xml">Known Bad Planets</a></li>
  <li><a href="unexplored-planets.xml" rel="alternate" type="application/atom+xml">Unexplored Planets</a></li>
</ul>
```

These links would not be used in feed autodiscovery.

→ Otherwise

The keyword creates a hyperlink\(^{\text{p273}}\) referencing an alternate representation of the current document.
The nature of the referenced document is given by the `hreflang` and `type` attributes.

If the `alternate` keyword is used with the `hreflang` attribute, and that attribute's value differs from the document element's language, it indicates that the referenced document is a translation.

If the `alternate` keyword is used with the `type` attribute, it indicates that the referenced document is a reformulation of the current document in the specified format.

The `hreflang` and `type` attributes can be combined when specified with the `alternate` keyword.

This relationship is transitive — that is, if a document links to two other documents with the link type "`alternate`", then, in addition to implying that those documents are alternative representations of the first document, it is also implying that those two documents are alternative representations of each other.

4.6.6.2 Link type "author" §

The `author` keyword may be used with `link`, `a`, and `area` elements. This keyword creates a hyperlink.

For `a` and `area` elements, the `author` keyword indicates that the referenced document provides further information about the author of the nearest `article` element ancestor of the element defining the hyperlink, if there is one, or of the page as a whole, otherwise.

For `link` elements, the `author` keyword indicates that the referenced document provides further information about the author for the page as a whole.

**Note**: For historical reasons, user agents must also treat `link`, `a`, and `area` elements that have a `rev` attribute with the value "made" as having the `author` keyword specified as a link relationship.

4.6.6.3 Link type "bookmark" §

The `bookmark` keyword may be used with `a` and `area` elements. This keyword creates a hyperlink.

The `bookmark` keyword gives a permalink for the nearest ancestor `article` element of the linking element in question, or of the section the linking element is most closely associated with, if there are no ancestor `article` elements.

**Example**

The following snippet has threepermalink. A user agent could determine which permalink applies to which part of the spec by looking at where the permalinks are given.

```xml
<body>

... 
</body>
```
4.6.6.4 Link type "canonical" §28

The *canonical* keyword may be used with link element. This keyword creates a hyperlink.

The *canonical* keyword indicates that URL given by the *href* attribute is the preferred URL for the current document. That helps search engines reduce duplicate content, as described in more detail in The Canonical Link Relation specification. [RFC6596]§226

4.6.6.5 Link type "dns-prefetch" §28

The *dns-prefetch* keyword may be used with link elements. This keyword creates an external resource link. This keyword is body-ok.

The *dns-prefetch* keyword indicates that preemptively performing DNS resolution for the *origin* of the specified resource is likely to be beneficial, as it is highly likely that the user will require resources located at that *origin*, and the user experience would be improved by preempting the latency costs associated with DNS resolution. User agents must implement the processing model of the *dns-prefetch* keyword described in the Resource Hints specification. [RESOURCEHINTS]§125

There is no default type for resources given by the *dns-prefetch* keyword.

4.6.6.6 Link type "external" §28

The *external* keyword may be used with *a* and *area* elements. This keyword does not create a hyperlink, but annotates any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The *external* keyword indicates that the link is leading to a document that is not part of the site that the current document forms a part of.

4.6.6.7 Link type "help" §28

The *help* keyword may be used with link, *a*, and *area* elements. This keyword creates a hyperlink.

For *a* and *area* elements, the *help* keyword indicates that the referenced document provides further help information for the parent of the element defining the hyperlink, and its children.
For link elements, the help keyword indicates that the referenced document provides help for the page as a whole.

For a and area elements, on some browsers, the help keyword causes the link to use a different cursor.

### 4.6.6.8 Link type "icon" §

The icon element may be used with link elements. This keyword creates an external resource link.

The specified resource is an icon representing the page or site, and should be used by the user agent when representing the page in the user interface.

Icons could be auditory icons, visual icons, or other kinds of icons. If multiple icons are provided, the user agent must select the most appropriate icon according to the type, media, and sizes attributes. If there are multiple equally appropriate icons, user agents must use the last one declared in tree order at the time that the user agent collected the list of icons. If the user agent tries to use an icon but that icon is determined, upon closer examination, to in fact be inappropriate (e.g. because it uses an unsupported format), then the user agent must try the next-most-appropriate icon as determined by the attributes.

**Note**

*User agents are not required to update icons when the list of icons changes, but are encouraged to do so.*

There is no default type for resources given by the icon keyword. However, for the purposes of determining the type of the resource, user agents must expect the resource to be an image.

The sizes keywords represent icon sizes in raw pixels (as opposed to CSS pixels).

**Note**

*An icon that is 50 CSS pixels wide intended for displays with a device pixel density of two device pixels per CSS pixel (2x, 192dpi) would have a width of 100 raw pixels. This feature does not support indicating that a different resource is to be used for small high-resolution icons vs large low-resolution icons (e.g. 50×50 2x vs 100×100 1x).*

To parse and process the attribute's value, the user agent must first split the attribute's value on ASCII whitespace, and must then parse each resulting keyword to determine what it represents.

The any keyword represents that the resource contains a scalable icon, e.g. as provided by an SVG image.

Other keywords must be further parsed as follows to determine what they represent:

- If the keyword doesn't contain exactly one U+0078 LATIN SMALL LETTER X or U+0058 LATIN CAPITAL LETTER X character, then this keyword doesn't represent anything. Return for that keyword.
- Let width string be the string before the "x" or "X".
- Let height string be the string after the "x" or "X".
- If either width string or height string start with a U+0030 DIGIT ZERO (0) character or contain any characters other than ASCII digits, then this keyword doesn't represent anything. Return for that keyword.
- Apply the rules for parsing non-negative integers to width string to obtain width.
- Apply the rules for parsing non-negative integers to height string to obtain height.
- The keyword represents that the resource contains a bitmap icon with a width of width device pixels and a height of height device pixels.

The keywords specified on the sizes attribute must not represent icon sizes that are not actually available in the linked resource.
In the absence of a `link` with the `icon` keyword, for `Document` objects whose URL’s `scheme` is an HTTP(S) scheme, user agents may instead run these steps in parallel:

1. Let `request` be a new `request` whose `url` is the URL record obtained by resolving the URL “/favicon.ico” against the `Document` object’s `URL` client is the `Document` object’s relevant settings object, `destination` is "image", `synchronous` flag is set, `credentials mode` is "include", and whose `use-URL-credentials flag` is set.

2. Let `response` be the result of fetching `request`.

3. Use `response`’s `unsafe response` as an icon as if it had been declared using the `icon` keyword.

For historical reasons, the `icon` keyword may be preceded by the keyword “shortcut”. If the "shortcut" keyword is present, the `rel` attribute’s entire value must be an ASCII case-insensitive match for the string "shortcut icon" (with a single U+0020 SPACE character between the tokens and no other ASCII whitespace).

4.6.6.9 Link type “license”

The `license` keyword may be used with `link`, `a`, and `area` elements. This keyword creates a hyperlink.

The `license` keyword indicates that the referenced document provides the copyright license terms under which the main content of the current document is provided.

This specification does not specify how to distinguish between the main content of a document and content that is not deemed to be part of that main content. The distinction should be made clear to the user.

Example

Consider a photo sharing site. A page on that site might describe and show a photograph, and the page might be marked up as follows:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
<title>Examples: Kissat</title>
<link rel="stylesheet" href="/style/default">
</head>
<body>
<h1>Kissat</h1>
<nav>
<a href="../">Return to photo index</a>
</nav>
</body>
</html>
```
In this case the license helps apply to just the photo (the main content of the document), not the whole document. In particular not the design of the page itself, which is covered by the copyright given at the bottom of the document. This could be made clearer in the styling (e.g. making the license link prominently positioned near the photograph, while having the page copyright in light small text at the foot of the page).

**Synonyms:** For historical reasons, user agents must also treat the keyword *copyright* like the license keyword.

---

### 4.6.6.10 Link type "modulepreload"

The modulepreload keyword may be used with link elements. This keyword creates an external resource link. This keyword is body-ok.

The modulepreload keyword is a specialized alternative to the preload keyword, with a processing model geared toward preloading module scripts. In particular, it uses the specific fetch behavior for module scripts (including, e.g., a different interpretation of the crossorigin attribute), and places the result into the appropriate module map for later evaluation. In contrast, a similar external resource link using the preload keyword would place the result in the preload cache, without affecting the document's module map.

Additionally, implementations can take advantage of the fact that module scripts declare their dependencies in order to fetch the specified module's dependency as well. This is intended as an optimization opportunity, since the user agent knows that, in all likelihood, those dependencies will also be needed later. It will not generally be observable without using technology such as service workers, or monitoring on the server side. Notably, the appropriate load or error events will occur after the specified module is fetched, and will not wait for any dependencies.

The appropriate times to fetch the resource for such a link are:

- When the external resource link is created on a link element that is already browsing-context connected.
- When the external resource link a link element becomes browsing-context connected.
- When the href attribute of the link element of an external resource link that is already browsing-context connected is changed.

**Note**

Unlike some other link relations, changing the relevant attributes (such as as, crossorigin, and referrerpolicy) of such a link attribute does not trigger a new fetch. This is because the document's module map has already been populated by a previous fetch, and so re-fetching would be pointless.

To obtain the resource for such a link:

1. If the href attribute's value is the empty string, then return.
2. Let destination be the current state of the as attribute (a destination), or "script" if it is in no state.
3. If destination is not script-like, then queue a task on the networking task source to fire an event named error at the link element, and return.

4. Parse the URL given by the href attribute, relative to the element's node document. If that fails, then return. Otherwise, let url be the resulting URL record.

5. Let settings object be the link element's node document's relevant settings object.

6. Let credentials mode be the module script credentials mode for the crossorigin attribute.

7. Let cryptographic nonce be the current value of the element's [[CryptographicNonce]] internal slot.

8. Let integrity metadata be the value of the integrity attribute, if it is specified, or the empty string otherwise.

9. Let referrer policy be the current state of the element's referrerpolicy attribute.

10. Let options be a script fetch options whose cryptographic nonce is cryptographic nonce, integrity metadata is integrity metadata, parser metadata is "not-parser-inserted", credentials mode is credentials mode, and referrer policy is referrer policy.

11. Fetch a single module script given url, settings object, destination, options, settings object, "client", and with the top-level module fetch flag set. Wait until algorithm asynchronously completes with result.

12. If result is null, fire an event named error at the link element, and return.

13. Fire an event named load at the link element.

14. Optionally, perform the following steps:

   1. Let visited set be « url ».

   2. Fetch the descendants of and instantiate result given settings object, destination, and visited set.

**Note**

Generally, performing these steps will be beneficial for performance, as it allows pre-loading the modules that will invariably be requested later, when fetch a module script graph is called. However, user agents might wish to skip them in bandwidth-constrained situations, or situations where the relevant fetches are already in flight.

**Example**

The following snippet shows the top part of an application with several modules preloaded:

```html
<!DOCTYPE html>
<html lang="en">
<title>IRCFog</title>

<link rel="modulepreload" href="app.mjs">
<link rel="modulepreload" href="helpers.mjs">
<link rel="modulepreload" href="irc.mjs">
<link rel="modulepreload" href="fog-machine.mjs">

<script type="module" src="app.mjs">
...
```

Assume that the module graph for the application is as follows:

```
app.mjs
  irc.mjs
  fog-machine.js

helpers.mjs
```
Here we see the application developer has used `modulepreload` all of the modules in their module graph, ensuring that the user agent initiates fetches for them all. Without such preloading, the user agent might need to go through multiple network roundtrips before discovering `helpers.mjs`, if technologies such as HTTP/2 Server Push are not in play. In this way, `modulepreload` elements can be used as a sort of "manifest" of the application's modules.

Example

The following code shows how `modulepreload` links can be used in conjunction with `import()` to ensure network fetching is done ahead of time, so that when `import()` is called, the module is already ready (but not evaluated) in the `module map`:

```html
<link rel="modulepreload" href="awesome-viewer.mjs">
<button onclick="import('./awesome-viewer.mjs').then(m => m.view())">View awesome thing</button>
```

4.6.6.11 Link type "nofollow"

The `nofollow` keyword may be used with `a` and `area` elements. This keyword does not create a hyperlink, but annotates any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The `nofollow` keyword indicates that the link is not endorsed by the original author or publisher of the page, or that the link to the referenced document was included primarily because of a commercial relationship between people affiliated with the two pages.

4.6.6.12 Link type "noopener"

The `noopener` keyword may be used with `a` and `area` elements. This keyword does not create a hyperlink, but annotates any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The keyword indicates that any newly created browsing context which results from following the hyperlink will be disowned, which means that its `window.opener` attribute will be null.

4.6.6.13 Link type "noreferrer"

The `noreferrer` keyword may be used with `a` and `area` elements. This keyword does not create a hyperlink, but annotates any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

It indicates that no referrer information is to be leaked when following the link.

If a user agent follows a link defined by an `a` or `area` element that has the `noreferrer` keyword, the user agent must set their `request`'s referrer to "no-referrer".

Note

For historical reasons, the `noreferrer` keyword implies the behavior associated with the `noopener` keyword when present on a hyperlink that creates a new browsing context. That is, `<a href="..." rel="noreferrer" target="_blank">` has the same behavior as `<a href="..." rel="noreferrer noopener" target="_blank">`.

4.6.6.14 Link type "pingback"

The `pingback` keyword may be used with `link` elements. This keyword creates an external resource link. This keyword is body-ok.

292
For the semantics of the pingback keyword, see the Pingback 1.0 specification. [PINGBACK]

4.6.6.15 Link type "preconnect" §

The preconnect keyword may be used with link elements. This keyword creates an external resource link. This keyword is body-ok.

The preconnect keyword indicates that preemptively initiating a connection to the origin of the specified resource is likely to be beneficial, as it is highly likely that the user will require resources located at that origin, and the user experience would be improved by preempting the latency costs associated with establishing the connection. User agents must implement the processing model of the preconnect keyword described in Resource Hints. [RESOURCEHINTS]

There is no default type for resources given by the preconnect keyword.

4.6.6.16 Link type "prefetch" §

The prefetch keyword may be used with link elements. This keyword creates an external resource link. This keyword is body-ok.

The prefetch keyword indicates that preemptively fetching and caching the specified resource is likely to be beneficial, as it is highly likely that the user will require this resource for future navigations. User agents must implement the processing model of the prefetch keyword described in Resource Hints. [RESOURCEHINTS]

There is no default type for resources given by the prefetch keyword.

4.6.6.17 Link type "preload" §

The preload keyword may be used with link elements. This keyword creates an external resource link. This keyword is body-ok.

The preload keyword indicates that the user agent must preemptively fetch and cache the specified resource according to the potential destination given by the as attribute (and the priority associated with the corresponding destination), as it is highly likely that the user will require this resource for the current navigation. User agents must implement the processing model of the preload keyword described in Preload, as well as in this specification's obtain the resource algorithm. [PRELOAD]

There is no default type for resources given by the preload keyword.

4.6.6.18 Link type "prerender" §

The prerender keyword may be used with link elements. This keyword creates an external resource link. This keyword is body-ok.

The prerender keyword indicates that the specified resource might be required by the next navigation, and so it may be beneficial to not only preemptively fetch the resource, but also to process it, e.g. by fetching its subresources or performing some rendering. User agents must implement the processing model of the prerender keyword described in Resource Hints. [RESOURCEHINTS]

There is no default type for resources given by the prerender keyword.

4.6.6.19 Link type "search" §

The search keyword may be used with link, a, and area elements. This keyword creates a hyperlink.

The search keyword indicates that the referenced document provides an interface specifically for searching the document and its related resources.
4.6.6.20 Link type "stylesheet" §294

The stylesheet keyword may be used with link elements. This keyword creates an external resource link that contributes to the styling processing model. This keyword is body-ok.

The specified resource is a CSS style sheet that describes how to present the document.

If the alternate keyword is also specified on the link element, then the link is an alternative style sheet; in this case, the title attribute must be specified on the link element, with a non-empty value.

The default type for resources given by the stylesheet keyword is text/css.

The appropriate times to obtain the resource are:

• When the external resource link is created on a link element that is already browsing-context connected.
• When the external resource link's link element becomes browsing-context connected.
• When the href attribute of the link element of an external resource link that is already browsing-context connected is changed.
• When the crossorigin attribute of the link element of an external resource link that is already browsing-context connected is set, changed, or removed.
• When the type attribute of the link element of an external resource link that is already browsing-context connected is set or changed to a value that does not or no longer matches the Content-Type metadata of the previous obtained external resource, if any.
• When the type attribute of the link element of an external resource link that is already browsing-context connected, but was previously not obtained due to the type attribute specifying an unsupported type, is set, removed, or changed.
• When the external resource link that is already browsing-context connected changes from being an alternative style sheet to not being one, or vice versa.

Quirk: If the document has been set to quirks mode, has the same origin as the URL of the external resource, and the Content-Type metadata of the external resource is not a supported style sheet type, the user agent must instead assume it to be text/css.

Once a resource has been obtained, if its Content-Type metadata is text/css, then run these steps:

1. Let element be the link element that created the external resource link.
2. If element has an associated CSS style sheet, remove the CSS style sheet in question.
3. If element no longer creates an external resource link that contributes to the styling processing model, or if, since the resource in question was obtained, it has become appropriate to obtain again for a newly obtained resource, then return.
4. Create a CSS style sheet with the following properties:

   type
   text/css

   location
   The resulting URL string determined during the obtain algorithm.

Note
This is before any redirects get applied.
**owner node**

*element*

**media**

The *media* attribute of *element*.

**title**

The *title* attribute of *element*, if *element* is in a document tree, or the empty string otherwise.

**alternate flag**

Set if the link is an alternative style sheet; unset otherwise.

**origin-clean flag**

Set if the resource is CORS-same-origin; unset otherwise.

**parent CSS style sheet**

**owner CSS rule**

null

**disabled flag**

Left at its default value.

**CSS rules**

Left uninitialized.

This doesn't seem right. Presumably we should be using the response body? Tracked as issue #2997.

The CSS environment encoding is the result of running the following steps: [CSSSYNTAX]

1. If the element has a *charset* attribute, get an encoding from that attribute's value. If that succeeds, return the resulting encoding. [ENCODING]
2. Otherwise, return the document's character encoding. [DOM]

### 4.6.6.21 Link type "tag" §

The *tag* keyword may be used with *a* and *area* elements. This keyword creates a hyperlink.

The *tag* keyword indicates that the tag that the referenced document represents applies to the current document.

**Note**

Since it indicates that the tag applies to the current document, it would be inappropriate to use this keyword in the markup of a tag cloud, which lists the popular tags across a set of pages.

**Example**

This document is about some gems, and so it is tagged with "https://en.wikipedia.org/wiki/Gemstone" to unambiguously categorize it as applying to the "jewel" kind of gems, and not to, say, the towns in the US, the Ruby package format, or the Swiss locomotive class:

```html
<!DOCTYPE HTML>
<html lang="en">
```
Some documents form part of a sequence of documents.

A sequence of documents is one where each document can have a previous sibling and a next sibling. A document with no previous sibling is the start of its sequence, a document with no next sibling is the end of its sequence.

A document may be part of multiple sequences.
4.6.6.22.1 Link type "next" §7

The next keyword may be used with link, a, and area elements. This keyword creates a hyperlink.

The next keyword indicates that the document is part of a sequence, and that the link is leading to the document that is the next logical document in the sequence.

When the next keyword is used with a link element, user agents should implement one of the processing models described in Resource Hints, i.e. should process such links as if they were using one of the dns-prefetch, preconnect, prefetch, or prerender keywords. Which resource hint the user agent wishes to use is implementation-dependent; for example, a user agent may wish to use the less-costly preconnect hint when trying to conserve data, battery power, or processing power, or may wish to pick a resource hint depending on heuristic analysis of past user behavior in similar scenarios. [RESOURCEHINTS]

4.6.6.22.2 Link type "prev" §7

The prev keyword may be used with link, a, and area elements. This keyword creates a hyperlink.

The prev keyword indicates that the document is part of a sequence, and that the link is leading to the document that is the previous logical document in the sequence.

Synonyms: For historical reasons, user agents must also treat the keyword "previous" like the prev keyword.

4.6.6.23 Other link types §7

Extensions to the predefined set of link types may be registered in the microformats wiki existing-rel-values page. [MFREL]

Anyone is free to edit the microformats wiki existing-rel-values page at any time to add a type. Extension types must be specified with the following information:

Keyword
The actual value being defined. The value should not be confusingly similar to any other defined value (e.g. differing only in case).

If the value contains a U+003A COLON character (:), it must also be an absolute URL.

Effect on... link
One of the following:

Not allowed
The keyword must not be specified on link elements.

Hyperlink
The keyword may be specified on a link element; it creates a hyperlink.

External Resource
The keyword may be specified on a link element; it creates an external resource link.

Effect on... a and area
One of the following:

Not allowed
The keyword must not be specified on a and area elements.

Hyperlink
The keyword may be specified on a and area elements; it creates a hyperlink.

External Resource
The keyword may be specified on a and area elements; it creates an external resource link.

Hyperlink Annotation
The keyword may be specified on a and area elements; it annotates other hyperlinks created by the element.

Brief description
A short non-normative description of what the keyword's meaning is.
**Specification**

A link to a more detailed description of the keyword's semantics and requirements. It could be another page on the Wiki, or a link to an external page.

**Synonyms**

A list of other keyword values that have exactly the same processing requirements. Authors should not use the values defined to be synonyms, they are only intended to allow user agents to support legacy content. Anyone may remove synonyms that are not used in practice; only names that need to be processed as synonyms for compatibility with legacy content are to be registered in this way.

**Status**

One of the following:

- **Proposed**
  The keyword has not received wide peer review and approval. Someone has proposed it and is, or soon will be, using it.

- **Ratified**
  The keyword has received wide peer review and approval. It has a specification that unambiguously defines how to handle pages that use the keyword, including when they use it in incorrect ways.

- **Discontinued**
  The keyword has received wide peer review and it has been found wanting. Existing pages are using this keyword, but new pages should avoid it. The "brief description" and "specification" entries will give details of what authors should use instead, if anything.

If a keyword is found to be redundant with existing values, it should be removed and listed as a synonym for the existing value.

If a keyword is registered in the "proposed" state for a period of a month or more without being used or specified, then it may be removed from the registry.

If a keyword is added with the "proposed" status and found to be redundant with existing values, it should be removed and listed as a synonym for the existing value. If a keyword is added with the "proposed" status and found to be harmful, then it should be changed to "discontinued" status.

Anyone can change the status at any time, but should only do so in accordance with the definitions above.

Conformance checkers must use the information given on the microformats wiki existing-rel-values page to establish if a value is allowed or not: values defined in this specification or marked as "proposed" or "ratified" must be accepted when used on the elements for which they apply as described in the "Effect on..." field, whereas values marked as "discontinued" or not listed in either this specification or on the aforementioned page must be rejected as invalid. Conformance checkers may cache this information (e.g. for performance reasons or to avoid the use of unreliable network connectivity).

When an author uses a new type not defined by either this specification or the Wiki page, conformance checkers should offer to add the value to the Wiki, with the details described above, with the "proposed" status.

Types defined as extensions in the microformats wiki existing-rel-values page with the status "proposed" or "ratified" may be used with the rel attribute on link, a, and area elements in accordance to the "Effect on..." field. [MFREL](#)

### 4.7 Edits

The ins and del elements represent edits to the document.

#### 4.7.1 The ins element

**Categories**: Flow content, Phrasing content, Palpable content.

**Contexts in which this element can be used**: Where phrasing content is expected.
Content model:

*Transparent*.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:

*Global attributes:*

- **cite** — Link to the source of the quotation or more information about the edit
- **datetime** — Date and (optionally) time of the change

DOM interface:
Uses **HTMLModElement**.

The **ins** element represents an addition to the document.

**Example**

The following represents the addition of a single paragraph:

```html
<aside>
  <ins>
    <p>I like fruit.</p>
  </ins>
</aside>
```

As does the following, because everything in the **aside** element here counts as **phrasing content** and therefore there is just one **paragraph**.

```html
<aside>
  <ins>
    Apples are <em>tasty</em>.
  </ins>
  <ins>
    So are pears.
  </ins>
</aside>
```

**ins** elements should not cross **implied paragraph** boundaries.

**Example**

The following example represents the addition of two paragraphs, the second of which was inserted in two parts. The first **ins** element in this example thus crosses a paragraph boundary, which is considered poor form.

```html
<aside>
  <!-- don't do this -->
  <ins datetime="2005-03-16 00:00Z">
    <p>I like fruit.</p>
    Apples are <em>tasty</em>.
  </ins>
  <ins datetime="2007-12-19 00:00Z">
    So are pears.
  </ins>
</aside>
```

Here is a better way of marking this up. It uses more elements, but none of the elements cross implied paragraph boundaries.

```html
<aside>
</aside>
4.7.2 The del element

Categories:
- Flow content
- Phrasing content

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
- Transparent

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes
  - cite — Link to the source of the quotation or more information about the edit
  - datetime — Date and (optionally) time of the change

DOM interface:
- Uses HTMLModElement.

The del element represents a removal from the document.

de1 elements should not cross implied paragraph boundaries.

Example

The following shows a "to do" list where items that have been done are crossed-off with the date and time of their completion.

```html
<h1>To Do</h1>
<ul>
  <li>Empty the dishwasher</li>
  <li><del datetime="2009-10-11T01:25-07:00">Watch Walter Lewin's lectures</del></li>
  <li><del datetime="2009-10-10T23:38-07:00">Download more tracks</del></li>
  <li>Buy a printer</li>
</ul>
```

4.7.3 Attributes common to ins and del elements

The cite attribute may be used to specify the URL of a document that explains the change. When that document is long, for instance the minutes of a meeting, authors are encouraged to include a fragment pointing to the specific part of that document that discusses the change.
If the cite\textsuperscript{30} attribute is present, it must be a valid URL potentially surrounded by spaces\textsuperscript{86} that explains the change. To obtain the corresponding citation link, the value of the attribute must be parsed\textsuperscript{88} relative to the element’s node document. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g., by server-side scripts collecting statistics about a site's edits), not for readers.

The \texttt{datetime} attribute may be used to specify the time and date of the change. If present, the \texttt{datetime}\textsuperscript{301} attribute's value must be a valid date string with optional time\textsuperscript{82}.

User agents must parse the \texttt{datetime}\textsuperscript{301} attribute according to the \texttt{parse a date or time string}\textsuperscript{82} algorithm. If that doesn't return a date\textsuperscript{72} or a global date and time\textsuperscript{077}, then the modification has no associated timestamp (the value is non-conforming; it is not a valid date string with optional time\textsuperscript{82}). Otherwise, the modification is marked as having been made at the given date\textsuperscript{72} or global date and time\textsuperscript{077}. If the given value is a global date and time\textsuperscript{077} then user agents should use the associated time-zone offset information to determine which time zone to present the given datetime in.

This value may be shown to the user, but it is primarily intended for private use.

The \texttt{ins}\textsuperscript{298} and \texttt{del}\textsuperscript{300} elements must implement the \texttt{HTMLModElement}\textsuperscript{301} interface:

\begin{verbatim}
IDL
[Exposed=Window, HTMLConstructor]
interface HTMLModElement : HTMLElement {
  [CEReactions] attribute USVString cite;
  [CEReactions] attribute DOMString dateTime;
};
\end{verbatim}

The \texttt{cite} IDL attribute must reflect\textsuperscript{90} the element’s \texttt{cite}\textsuperscript{300} content attribute. The \texttt{dateTime} IDL attribute must reflect\textsuperscript{90} the element’s \texttt{datetime}\textsuperscript{301} content attribute.

\section*{4.7.4 Edits and paragraphs\textsuperscript{30}1

\textit{This section is non-normative.}

Since the \texttt{ins}\textsuperscript{298} and \texttt{del}\textsuperscript{300} elements do not affect \texttt{paragraphing}\textsuperscript{6130}, it is possible, in some cases where paragraphs are \texttt{implied}\textsuperscript{6130} (without explicit \texttt{p}\textsuperscript{205} elements), for an \texttt{ins}\textsuperscript{298} or \texttt{del}\textsuperscript{300} element to span both an entire paragraph or other non-\texttt{phrasing content}\textsuperscript{6128} elements and part of another paragraph. For example:

\begin{verbatim}
<section>
  <ins>
    <p>
      This is a paragraph that was inserted.
    </p>
    This is another paragraph whose first sentence was inserted at the same time as the paragraph above.
  </ins>
  This is a second sentence, which was there all along.
</section>
\end{verbatim}

By only wrapping some paragraphs in \texttt{p}\textsuperscript{205} elements, one can even get the end of one paragraph, a whole second paragraph, and the start of a third paragraph to be covered by the same \texttt{ins}\textsuperscript{298} or \texttt{del}\textsuperscript{300} element (though this is very confusing, and not considered good practice):

\begin{verbatim}
<section>
  This is the first paragraph. <ins>This sentence was inserted.</ins>
  <p>This second paragraph was inserted.</p>
  This sentence was inserted too.</ins> This is the third paragraph in this example.<ins>!
</section>
\end{verbatim}
However, due to the way implied paragraphs are defined, it is not possible to mark up the end of one paragraph and the start of the very next one using the same \texttt{ins} or \texttt{del} element. You instead have to use one (or two) \texttt{p} element(s) and two \texttt{ins} or \texttt{del} elements, as for example:

\begin{verbatim}
<\section>
  <p>This is the first paragraph. <del>This sentence was deleted.</del></p>
  <p><del>This sentence was deleted too.</del> That sentence needed a separate <del>element.</del></p>
</\section>
\end{verbatim}

Partly because of the confusion described above, authors are strongly encouraged to always mark up all paragraphs with the \texttt{p} element, instead of having \texttt{ins} or \texttt{del} elements that cross implied paragraphs boundaries.

4.7.5 Edits and lists

This section is non-normative.

The content models of the \texttt{ol} and \texttt{ul} elements do not allow \texttt{ins} and \texttt{del} elements as children. Lists always represent all their items, including items that would otherwise have been marked as deleted.

To indicate that an item is inserted or deleted, an \texttt{ins} or \texttt{del} element can be wrapped around the contents of the \texttt{li} element. To indicate that an item has been replaced by another, a single \texttt{li} element can have one or more \texttt{del} elements followed by one or more \texttt{ins} elements.

Example

In the following example, a list that started empty had items added and removed from it over time. The bits in the example that have been emphasized show the parts that are the "current" state of the list. The list item numbers don't take into account the edits, though.

\begin{verbatim}
<\h1>Stop-ship bugs</h1>
<\ol>
  <li><ins datetime="2008-02-12T15:20Z">Bug 225: Rain detector doesn't work in snow</ins></li>
  <li><ins datetime="2008-02-16T13:50Z">Bug 230: Water heater doesn't use renewable fuels</ins></li>
</\ol>
\end{verbatim}

Example

In the following example, a list that started with just fruit was replaced by a list with just colors.

\begin{verbatim}
<\h1>List of fruits</h1>
<\ul>
  <li><del>Lime</del><ins>Green</ins></li>
  <li><del>Apple</del></li>
  <li><del>Pear</del></li>
  <li><ins>Teal</ins></li>
  <li><del>Lemon</del><ins>Yellow</ins></li>
  <li><ins>Olive</ins></li>
  <li><ins>Purple</ins></li>
</\ul>
4.7.6 Edits and tables

This section is non-normative.

The elements that form part of the table model have complicated content model requirements that do not allow for the \texttt{ins} and \texttt{del} elements, so indicating edits to a table can be difficult.

To indicate that an entire row or an entire column has been added or removed, the entire contents of each cell in that row or column can be wrapped in \texttt{ins} or \texttt{del} elements (respectively).

\begin{example}

Here, a table's row has been added:

\begin{verbatim}
<table>
<thead>
<tr>
<th> Game name </th>  
<th> Game publisher </th>  
<th> Verdict </th>
</tr>
</thead>
<tbody>
<tr>
<td> Diablo 2 </td>  
<td> Blizzard </td>  
<td> 8/10 </td>
</tr>
<tr>
<td> Portal </td>  
<td> Valve </td>  
<td> 10/10 </td>
</tr>
<tr>
<td> <del cite="/edits/r192" datetime="2011-05-02 14:23Z">Portal 2</del> </td>  
<td> <del cite="/edits/r192" datetime="2011-05-02 14:23Z">Valve</del> </td>  
<td> <del cite="/edits/r192" datetime="2011-05-02 14:23Z">10/10</del> </td>
</tr>
</tbody>
</table>

Here, a column has been removed (the time at which it was removed is given also, as is a link to the page explaining why):

\begin{verbatim}
<table>
<thead>
<tr>
<th> Game name </th>  
<th> Game publisher </th>  
<th> Verdict </th>
</tr>
</thead>
<tbody>
<tr>
<td> Diablo 2 </td>  
<td> Blizzard </td>  
<td> <del cite="/edits/r192" datetime="2011-05-02 14:23Z">8/10</del> </td>
</tr>
<tr>
<td> Portal </td>  
<td> Valve </td>  
<td> <del cite="/edits/r192" datetime="2011-05-02 14:23Z">10/10</del> </td>
</tr>
<tr>
<td> Portal 2 </td>  
<td> Valve </td>  
<td> <del cite="/edits/r192" datetime="2011-05-02 14:23Z">10/10</del> </td>
</tr>
</tbody>
</table>
\end{verbatim}

Generally speaking, there is no good way to indicate more complicated edits (e.g. that a cell was removed, moving all subsequent cells up or to the left).
\end{example}

4.8 Embedded content

4.8.1 The picture element

Categories:\texttt{Flow content}, \texttt{Phrasing content}, \texttt{Embedded content}.

Contexts in which this element can be used:

Where \texttt{embedded content} is expected.

Content model:

Zero or more \texttt{source} elements, followed by one \texttt{img} element, optionally intermixed with \texttt{script-supporting element}.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

\texttt{Global attributes}.
DOM interface:

```html
[Exposed=Window,
     HTMLConstructor]
interface HTMLPictureElement : HTMLElement {
    [CEReactions] attribute USVString src;
    [CEReactions] attribute DOMString type;
    [CEReactions] attribute USVString srcset;
    [CEReactions] attribute DOMString sizes;
    [CEReactions] attribute DOMString media;
};
```

The `picture` element is a container which provides multiple sources to its contained `img` element to allow authors to declaratively control or give hints to the user agent about which image resource to use, based on the screen pixel density, `viewport` size, image format, and other factors. It represents its children.

Note: The `picture` element is somewhat different from the similar-looking `video` and `audio` elements. While all of them contain `source` elements, the `source` element's `src` attribute has no meaning when the element is nested within a `picture` element, and the resource selection algorithm is different. Also, the `picture` element itself does not display anything; it merely provides a context for its contained `img` element that enables it to choose from multiple URLs.

4.8.2 The `source` element

Categories:
None.

Contexts in which this element can be used:
As a child of a `picture` element, before the `img` element.
As a child of a `media element`, before any `flow content` or `track` elements.

Content model:
`Nothing`.

Tag omission in text/html:
No end tag.

Content attributes:

- `Global attributes`
  - `src` — Address of the resource
  - `type` — Type of embedded resource
  - `srcset` — Images to use in different situations (e.g. high-resolution displays, small monitors, etc)
  - `sizes` — Image sizes for different page layouts
  - `media` — Applicable media

DOM interface:

```html
[Exposed=Window,
     HTMLConstructor]
interface HTMLSourceElement : HTMLElement {
    [CEReactions] attribute USVString src;
    [CEReactions] attribute DOMString type;
    [CEReactions] attribute USVString srcset;
    [CEReactions] attribute DOMString sizes;
    [CEReactions] attribute DOMString media;
};
```

The `source` element allows authors to specify multiple alternative `source` elements or multiple alternative `media resources` for `img` elements. It does not represent anything on its own.

The `type` attribute may be present. If present, the value must be a valid MIME type string.

The remainder of the requirements depend on whether the parent is a `picture` element or a `media element`.
source element's parent is a picture element

The src attribute must be present, and is a src attribute.

The srcset attribute contributes the image sources to the source set, if the source element is selected.

If the srcset attribute has any image candidate strings using a width descriptor, the sizes attribute must also be present, and is a sizes attribute. The sizes attribute contributes the source size to the source set, if the source element is selected.

The media attributes may also be present. If present, the value must contain a valid media query list. The user agent will skip to the next source element if the value does not match the environment.

The type attribute gives the type of the images in the source set, to allow the user agent to skip to the next source element if it does not support the given type.

The src attribute gives the URL of the media resource. The value must be a valid non-empty URL potentially surrounded by spaces. This attribute must be present.

The type attribute gives the type of the media resource, to help the user agent determine if it can play this media resource before fetching it. Generally, manipulating source elements manually after the document has been parsed is an unnecessarily complicated approach.

Example

The following list shows some examples of how to use the codecs MIME parameter in the type attribute.

H.264 Constrained baseline profile video (main and extended video compatible) level 3 and Low-Complexity AAC audio in MP4 container

<source src='video.mp4' type='video/mp4; codecs="avc1.42E01E, mp4a.40.2"'>

H.264 Extended profile video (baseline-compatible) level 3 and Low-Complexity AAC audio in MP4 container

<source src='video.mp4' type='video/mp4; codecs="avc1.58A01E, mp4a.40.2"'>

H.264 Main profile video level 3 and Low-Complexity AAC audio in MP4 container

<source src='video.mp4' type='video/mp4; codecs="avc1.4D401E, mp4a.40.2"'>

H.264 'High' profile video (incompatible with main, baseline, or extended profiles) level 3 and Low-Complexity AAC audio in MP4 container

<source src='video.mp4' type='video/mp4; codecs="avc1.64001E, mp4a.40.2"'>
The `srcset`, `sizes`, and `media` attributes must not be present.

If a `source` element is inserted as a child of a `media` element that has no `src` attribute and whose `networkState` has the value `NETWORK_EMPTY`, the user agent must invoke the `media` element’s resource selection algorithm.

The IDL attributes `src`, `type`, `srcset`, `sizes` and `media` must reflect the respective content attributes of the same name.

If the author isn’t sure if user agents will all be able to render the media resources provided, the author can listen to the `error` event on the last `source` element and trigger fallback behavior:

```html
<script>
function fallback(video) {
  // replace <video> with its contents
  while (video.hasChildNodes()) {
    if (video.firstChild instanceof HTMLSourceElement)
      video.removeChild(video.firstChild);
    else
      video.parentNode.insertBefore(video.firstChild, video);
  }
  video.parentNode.removeChild(video);
}</script>

<video controls autoplay>
  <source src='video.mp4' type='video/mp4; codecs="avc1.42E01E, mp4a.40.2"'>
  <source src='video.ogv' type='video/ogg; codecs="theora, vorbis"'>
  onerror="fallback(parentNode)"
</video>
```
4.8.3 The `img` element

Categories:
- Flow content
- Phrasing content
- Embedded content
- Form-associated element

If the element has a `usemap` attribute: Interactive content.

Palpable content.

Contexts in which this element can be used:
Where embedded content is expected.

Content model:
Nothing.

Tag omission in text/html:
No end tag.

Content attributes:
- Global attributes:
  - `alt` — Replacement text for use when images are not available
  - `src` — Address of the resource
  - `srcset` — Images to use in different situations (e.g. high-resolution displays, small monitors, etc)
  - `sizes` — Image sizes for different page layouts
  - `crossorigin` — How the element handles crossorigin requests
  - `usemap` — Name of image map to use
  - `ismap` — Whether the image is a server-side image map
  - `width` — Horizontal dimension
  - `height` — Vertical dimension
  - `referrerpolicy` — Referrer policy for fetches initiated by the element
  - `decoding` — Decoding hint to use when processing this image for presentation

DOM interface:

```idl
[Exposed=Window,
NamedConstructor=Image(optional unsigned long width, optional unsigned long height)]
interface HTMLImageElement : HTMLElement {
  [CEReactions] attribute DOMString alt;
  [CEReactions] attribute USVString src;
  [CEReactions] attribute USVString srcset;
  [CEReactions] attribute DOMString sizes;
  [CEReactions] attribute DOMString? crossOrigin;
  [CEReactions] attribute DOMString useMap;
  [CEReactions] attribute boolean isMap;
  [CEReactions] attribute unsigned long width;
  [CEReactions] attribute unsigned long height;
  readonly attribute unsigned long naturalWidth;
  readonly attribute unsigned long naturalHeight;
  readonly attribute boolean complete;
  readonly attribute USVString currentSrc;
  [CEReactions] attribute DOMString referrerPolicy;
  [CEReactions] attribute DOMString decoding;

  Promise<void> decode();
};
```

An `img` element represents an image.

The image given by the `src` and `srcset` attributes, and any previous sibling `source` elements' `srcset` attributes if the parent is a `picture` element, is the embedded content; the value of the `alt` attribute provides equivalent content for those who cannot process images or who have image loading disabled (i.e. it is the `img` element's fallback content).
The requirements on the \texttt{alt} attribute's value are described in a separate section\textsuperscript{334}.

The \texttt{src} attribute must be present, and must contain a valid non-empty URL potentially surrounded by spaces\textsuperscript{386} referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.

The requirements above imply that images can be static bitmaps (e.g. PNGs, GIFs, JPEGs), single-page vector documents (single-page PDFs, XML files with an SVG document element), animated bitmaps (APNGs, animated GIFs), animated vector graphics (XML files with an SVG document element that use declarative SMIL animation), and so forth. However, these definitions preclude SVG files with script, multipage PDF files, interactive MNG files, HTML documents, plain text documents, and so forth.\textsuperscript{PNG} [PNG]\textsuperscript{APNG} [APNG] [SVG] [SVG] [MNG] [MNG]

The \texttt{srcset} attribute may also be present, and is a \texttt{srcset attribute}\textsuperscript{322}.

The \texttt{srcset} attribute and the \texttt{src} attribute (if width descriptors\textsuperscript{321} are not used) contribute the image sources\textsuperscript{522} to the \texttt{source set}\textsuperscript{522} (if no \texttt{source} element was selected).

If the \texttt{srcset} attribute is present and has any image candidate strings\textsuperscript{321} using a width descriptor\textsuperscript{321}, the \texttt{sizes} attribute must also be present, and is a \texttt{sizes attribute}\textsuperscript{322}. The \texttt{sizes} attribute contributes the \texttt{source size}\textsuperscript{523} to the \texttt{source set}\textsuperscript{523} (if no \texttt{source} element was selected).

The \texttt{crossorigin} attribute is a CORS settings attribute\textsuperscript{589}. Its purpose is to allow images from third-party sites that allow cross-origin access to be used with \texttt{canvas}\textsuperscript{8614}.

The \texttt{referrerpolicy} attribute is a referrer policy attribute\textsuperscript{89}. Its purpose is to set the referrer policy used when fetching the image.\texttt{[REFERRERPOLICY]}\textsuperscript{1275}

The \texttt{decoding} attribute indicates the preferred method to decode\textsuperscript{522} this image. The attribute, if present, must be an image decoding hint\textsuperscript{522}. This attribute's missing value default\textsuperscript{65} and invalid value default\textsuperscript{65} are both the auto\textsuperscript{522} state.

The \texttt{img} element must not be used as a layout tool. In particular, \texttt{img} elements should not be used to display transparent images, as such images rarely convey meaning and rarely add anything useful to the document.

What an \texttt{img} element represents depends on the \texttt{src} attribute and the \texttt{alt} attribute.

\begin{description}
\item[\textbullet If the \texttt{src} attribute is set and the \texttt{alt} attribute is set to the empty string] The image is either decorative or supplemental to the rest of the content, redundant with some other information in the document.

If the image is available\textsuperscript{323} and the user agent is configured to display that image, then the element represents\textsuperscript{120} the element's image data.

Otherwise, the element represents\textsuperscript{120} nothing, and may be omitted completely from the rendering. User agents may provide the user with a notification that an image is present but has been omitted from the rendering.

\item[\textbullet If the \texttt{src} attribute is set and the \texttt{alt} attribute is set to a value that isn't empty] The image is a key part of the content; the \texttt{alt} attribute gives a textual equivalent or replacement for the image.

If the image is available\textsuperscript{323} and the user agent is configured to display that image, then the element represents\textsuperscript{120} the element's image data.

Otherwise, the element represents\textsuperscript{120} the text given by the \texttt{alt} attribute. User agents may provide the user with a notification that an image is present but has been omitted from the rendering.

\item[\textbullet If the \texttt{src} attribute is set and the \texttt{alt} attribute is not] The image might be a key part of the content, and there is no textual equivalent of the image available.
\end{description}

\begin{quote}
\textbf{Note:} In a conforming document, the absence of the \texttt{alt} attribute indicates that the image is a key part of the content but that a textual replacement for the image was not available when the image was generated.
\end{quote}
If the image is available and the user agent is configured to display that image, then the element represents the element’s image data.

If the image has a src attribute whose value is the empty string, then the element represents nothing.

Otherwise, the user agent should display some sort of indicator that there is an image that is not being rendered, and may, if requested by the user, or if so configured, or when required to provide contextual information in response to navigation, provide caption information for the image, derived as follows:

1. If the image has a title attribute whose value is not the empty string, then return the value of that attribute.
2. If the image is a descendant of a figure element that has a child figcaption element, and, ignoring the figcaption element and its descendants, the figure element has no flow content descendants other than inter-element whitespace and the img element, then return the contents of the first such figcaption element.
3. Return nothing. (There is no caption information.)

If the src attribute is not set and either the alt attribute is set to the empty string or the alt attribute is not set at all, The element represents nothing.

Otherwise, The element represents the text given by the alt attribute.

The alt attribute does not represent advisory information. User agents must not present the contents of the alt attribute in the same way as content of the title attribute.

User agents may always provide the user with the option to display any image, or to prevent any image from being displayed. User agents may also apply heuristics to help the user make use of the image when the user is unable to see it, e.g. due to a visual disability or because they are using a text terminal with no graphics capabilities. Such heuristics could include, for instance, optical character recognition (OCR) of text found within the image.

⚠ Warning! While user agents are encouraged to repair cases of missing alt attributes, authors must not rely on such behavior. Requirements for providing text to act as an alternative for images are described in detail below.

The contents of img elements, if any, are ignored for the purposes of rendering.

The usemap attribute, if present, can indicate that the image has an associated image map.

The ismap attribute, when used on an element that is a descendant of an a element with an href attribute, indicates by its presence that the element provides access to a server-side image map. This affects how events are handled on the corresponding a element.

The ismap attribute is a boolean attribute. The attribute must not be specified on an element that does not have an ancestor a element with an href attribute.

Note The usemap and ismap attributes can result in confusing behavior when used together with source elements with the media attribute specified in a picture element.

The img element supports dimension attributes.

The alt, src, srcset and sizes IDL attributes must reflect the respective content attributes of the same name.

The crossOrigin IDL attribute must reflect the crossorigin content attribute, limited to only known values.

The useMap IDL attribute must reflect the usemap content attribute.

The isMap IDL attribute must reflect the ismap content attribute.

The referrerPolicy IDL attribute must reflect the referrerpolicy content attribute, limited to only known values.
The decoding IDL attribute must reflect the decoding content attribute, limited to only known values.

For web developers (non-normative)

```javascript
image.width [ = value ]
image.height [ = value ]
```

These attributes return the actual rendered dimensions of the image, or zero if the dimensions are not known. They can be set, to change the corresponding content attributes.

```javascript
image.naturalWidth
image.naturalHeight
```

These attributes return the intrinsic dimensions of the image, or zero if the dimensions are not known.

```javascript
image.complete
```

Returns true if the image has been completely downloaded or if no image is specified; otherwise, returns false.

```javascript
image.currentSrc
```

Returns the image’s absolute URL.

```javascript
image.decode()
```

This method causes the user agent to decode the image in parallel, returning a promise that fulfills when decoding is complete. The promise will be rejected with an "EncodingError" DOMException if the image cannot be decoded.

```javascript
image = new Image([width [, height ]])
```

Returns a new img element, with the width and height attributes set to the values passed in the relevant arguments, if applicable.

The IDL attributes width and height must return the rendered width and height of the image, in CSS pixels, if the image is being rendered and is being rendered to a visual medium; or else the density-corrected intrinsic width and height of the image, in CSS pixels, if the image has intrinsic dimensions and is available but not being rendered to a visual medium; or else 0, if the image is not available or does not have intrinsic dimensions. [CSS]

On setting, they must act as if they reflected the respective content attributes of the same name.

The IDL attributes naturalWidth and naturalHeight must return the density-corrected intrinsic width and height of the image, in CSS pixels, if the image has intrinsic dimensions and is available, or else 0. [CSS]

The IDL attribute complete must return true if any of the following conditions is true:

- Both the src attribute and the srcset attribute are omitted.
- The srcset attribute is omitted and the src attribute's value is the empty string.
- The final task that is queued by the networking task source, once the resource has been fetched has been queued.
- The img element's current request's state is completely available.
- The img element's current request's state is broken.

Otherwise, the attribute must return false.

Note

The value of complete can thus change while a script is executing.

The currentSrc IDL attribute must return the img element's current request's current URL.

The decode() method, when invoked, must perform the following steps:
1. Let promise be a new promise.

2. Queue a microtask\(^{989}\) to perform the following steps:

   \[
   \text{Note}
   \]
   
   *This is done because updating the image data\(^{325}\) takes place in a microtask as well. Thus, to make code such as*
   
   ```javascript
   img.src = "stars.jpg";
   img.decode();
   ```
   
   *properly decode stars.jpg, we need to delay any processing by one microtask.*
   
   1. If any of the following conditions are true about this `img` element:
      - its node document is not an active document\(^{978}\);
      - its current request\(^{322}\)’s state\(^{322}\) is broken\(^{322}\).
    
    then reject promise with an "EncodingError" DOMException.

   2. Otherwise, in parallel\(^{943}\), wait for one of the following cases to occur, and perform the corresponding actions:

      - This `img` element’s node document stops being an active document\(^{978}\).
      - This `img` element’s current request\(^{322}\) changes or is mutated.
      - This `img` element’s current request\(^{322}\)’s state\(^{322}\) becomes broken\(^{322}\).
    
    Reject promise with an "EncodingError" DOMException.

      - This `img` element’s current request\(^{322}\)’s state\(^{322}\) becomes completely available\(^{322}\).
    
    Decode\(^{325}\) the image.
    
    If decoding does not need to be performed for this image (for example because it is a vector graphic),
    resolve promise with undefined.

    If decoding fails (for example due to invalid image data), reject promise with an "EncodingError" DOMException.

    If the decoding process completes successfully, resolve promise with undefined.

   User agents should ensure that the decoded media data stays readily available until at least the end of the
   next successful update the rendering step in the event loop\(^{989}\). This is an important part of the API
   contract, and should not be broken if at all possible. (Typically, this would only be violated in low-memory
   situations that require evicting decoded image data, or when the image is too large to keep in decoded form
   for this period of time.)

   \[
   \text{Note}
   \]
   
   *Animated images will become completely available\(^{322}\) only after all their frames are loaded. Thus, even
   though an implementation could decode the first frame before that point, the above steps will not do so,
   instead waiting until all frames are available.*

3. Return promise.

\[
\text{Example}
\]

Without the \(\text{decode}()\)\(^{931}\) method, the process of loading an `img` element and then displaying it might look like the following:

```javascript
const img = new Image();
img.src = "nebula.jpg";
img.onload = () => {
    document.body.appendChild(img);
};
img.onerror = () => {
```
A constructor is provided for creating `HTMLImageElement` objects (in addition to the factory methods from DOM such as `createElement()`): `Image(width, height)`. When invoked, the constructor must perform the following steps:

1. Let `document` be the current global object's associated `Document`.
2. Let `img` be the result of creating an element given `document`, `img`, and the HTML namespace.
3. If `width` is given, then set an attribute value for `img` using "width" and `width`.
4. If `height` is given, then set an attribute value for `img` using "height" and `height`.
5. Return `img`.

Example

A single image can have different appropriate alternative text depending on the context.

In each of the following cases, the same image is used, yet the `alt` text is different each time. The image is the coat of arms of...
the Carouge municipality in the canton Geneva in Switzerland.

Here it is used as a supplementary icon:

```html
<p>I lived in <img src="carouge.svg" alt="Carouge." /></p>
```

Here it is used as an icon representing the town:

```html
<p>Home town: <img src="carouge.svg" alt="Carouge" /></p>
```

Here it is used as part of a text on the town:

```html
<p>Carouge has a coat of arms.</p>
<p><img src="carouge.svg" alt="The coat of arms depicts a lion, sitting in front of a tree." /></p>
<p>It is used as decoration all over the town.</p>
```

Here it is used as a way to support a similar text where the description is given as well as, instead of as an alternative to, the image:

```html
<p>Carouge has a coat of arms.</p>
<p><img src="carouge.svg" alt="" /></p>
<p>The coat of arms depicts a lion, sitting in front of a tree. It is used as decoration all over the town.</p>
```

Here it is used as part of a story:

```html
<p>She picked up the folder and a piece of paper fell out.</p>
<p><img src="carouge.svg" alt="Shaped like a shield, the paper had a red background, a green tree, and a yellow lion with its tongue hanging out and whose tail was shaped like an S." /></p>
<p>She stared at the folder. S! The answer she had been looking for all this time was simply the letter S! How had she not seen that before? It all came together now. The phone call where Hector had referred to a lion's tail, the time Maria had stuck her tongue out...</p>
```

Here it is not known at the time of publication what the image will be, only that it will be a coat of arms of some kind, and thus no replacement text can be provided, and instead only a brief caption for the image is provided, in the `title` attribute:

```html
<p>The last user to have uploaded a coat of arms uploaded this one:</p>
<p><img src="last-uploaded-coat-of-arms.cgi" title="User-uploaded coat of arms." /></p>
```

Ideally, the author would find a way to provide real replacement text even in this case, e.g. by asking the previous user. Not providing replacement text makes the document more difficult to use for people who are unable to view images, e.g. blind users, or users or very low-bandwidth connections or who pay by the byte, or users who are forced to use a text-only Web browser.

---

Example

Here are some more examples showing the same picture used in different contexts, with different appropriate alternate texts each time.

```html
<article>
<h1>My cats</h1>
<h2>Fluffy</h2>
<p>Fluffy is my favorite.</p>
<img src="fluffy.jpg" alt="She likes playing with a ball of yarn." />
<p>She's just too cute.</p>
</article>
```
This section is non-normative.

To embed an image in HTML, when there is only a single image resource, use the `img` element and its `src` attribute.

However, there are a number of situations for which the author might wish to use multiple image resources that the user agent can choose from:

- Different users might have different environmental characteristics:
  - The users' physical screen size might be different from one another.
The users' screen pixel density might be different from one another.

Example

A mobile phone's screen might have three times as many physical pixels per inch compared to another mobile phone's screen, regardless of their physical screen size.

The users' zoom level might be different from one another, or might change for a single user over time.

Example

A user might zoom in to a particular image to be able to get a more detailed look.

The zoom level and the screen pixel density (the previous point) can both affect the number of physical screen pixels per CSS pixel. This ratio is usually referred to as device-pixel-ratio.

The users' screen orientation might be different from one another, or might change for a single user over time.

Example

A tablet can be held upright or rotated 90 degrees, so that the screen is either “portrait” or “landscape”.

Note

This is only relevant when an image's rendered size depends on the viewport size.

A mobile phone's screen might be 4 inches diagonally, while a laptop's screen might be 14 inches diagonally.
The users’ network speed, network latency and bandwidth cost might be different from one another, or might change for a single user over time.

Example

A user might be on a fast, low-latency and constant-cost connection while at work, on a slow, low-latency and constant-cost connection while at home, and on a variable-speed, high-latency and variable-cost connection anywhere else.

• Authors might want to show the same image content but with different rendered size depending on, usually, the width of the viewport. This is usually referred to as viewport-based selection.

Example

A Web page might have a banner at the top that always spans the entire viewport width. In this case, the rendered size of the image depends on the physical size of the screen (assuming a maximised browser window).

Example

Another Web page might have images in columns, with a single column for screens with a small physical size, two columns for screens with medium physical size, and three columns for screens with big physical size, with the images varying in rendered size in each case to fill up the viewport. In this case, the rendered size of an image might be bigger in the one-column layout compared to the two-column layout, despite the screen being smaller.
• Authors might want to show different image content depending on the rendered size of the image. This is usually referred to as **art direction**.

**Example**

When a Web page is viewed on a screen with a large physical size (assuming a maximised browser window), the author might wish to include some less relevant parts surrounding the critical part of the image. When the same Web page is viewed on a screen with a small physical size, the author might wish to show only the critical part of the image.

![Image example](image1.png)

• Authors might want to show the same image content but using different image formats, depending on which image formats the user agent supports. This is usually referred to as **image format-based selection**.

**Example**

A Web page might have some images in the JPEG, WebP and JPEG XR image formats, with the latter two having better compression abilities compared to JPEG. Since different user agents can support different image formats, with some formats offering better compression ratios, the author would like to serve the better formats to user agents that support them, while providing JPEG fallback for user agents that don’t.

The above situations are not mutually exclusive. For example, it is reasonable to combine different resources for different device-pixel-ratio with different resources for art direction.

While it is possible to solve these problems using scripting, doing so introduces some other problems:

• Some user agents aggressively download images specified in the HTML markup, before scripts have had a chance to run, so that Web pages complete loading sooner. If a script changes which image to download, the user agent will potentially start two separate downloads, which can instead cause worse page loading performance.

• If the author avoids specifying any image in the HTML markup and instead instantiates a single download from script, that avoids the double download problem above but then no image will be downloaded at all for users with scripting disabled and the aggressive image downloading optimization will also be disabled.

With this in mind, this specification introduces a number of features to address the above problems in a declarative manner.

**Device-pixel-ratio-based selection when the rendered size of the image is fixed**

The `src` and `srcset` attributes on the `img` element can be used, using the `x` descriptor, to provide multiple images that only vary in their size (the smaller image is a scaled-down version of the bigger image).

**Note**

The `x` descriptor is not appropriate when the rendered size of the image depends on the viewport width (viewport-based selection), but can be used together with art direction.

**Example**

```html
<h2>From today's featured article</h2>
<img src="/uploads/100-marie-lloyd.jpg"
     srcset="/uploads/150-marie-lloyd.jpg 1.5x, /uploads/200-marie-lloyd.jpg 2x"
     alt=" width="100" height="150">
<p><a href="/wiki/Marie_Lloyd">Marie Lloyd</a> (1870–1922) was an English singer, ...</p>
```

The user agent can choose any of the given resources depending on the user's screen's pixel density, zoom level, and possibly...
other factors such as the user's network conditions.

For backwards compatibility with older user agents that don't yet understand the srcset attribute, one of the URLs is specified in the img element's src attribute. This will result in something useful (though perhaps lower-resolution than the user would like) being displayed even in older user agents. For new user agents, the src attribute participates in the resource selection, as if it was specified in srcset with a 1x descriptor.

The image's rendered size is given in the width and height attributes, which allows the user agent to allocate space for the image before it is downloaded.

**Viewport-based selection**

The srcset and sizes attributes can be used, using the w descriptor, to provide multiple images that only vary in their size (the smaller image is a scaled-down version of the bigger image).

**Example**

In this example, a banner image takes up the entire viewport width (using appropriate CSS).

```html
<h1><img sizes="100vw" srcset="wolf-400.jpg 400w, wolf-800.jpg 800w, wolf-1600.jpg 1600w"
src="wolf-400.jpg" alt="The rad wolf"></h1>
```

The user agent will calculate the effective pixel density of each image from the specified w descriptors and the specified rendered size in the sizes attribute. It can then choose any of the given resources depending on the user's screen's pixel density, zoom level, and possibly other factors such as the user's network conditions.

If the user's screen is 320 CSS pixels wide, this is equivalent to specifying `wolf-400.jpg 1.25x`, `wolf-800.jpg 2.5x`, `wolf-1600.jpg 5x`. On the other hand, if the user's screen is 1200 CSS pixels wide, this is equivalent to specifying `wolf-400.jpg 0.33x`, `wolf-800.jpg 0.67x`, `wolf-1600.jpg 1.33x`. By using the w descriptors and the sizes attribute, the user agent can choose the correct image source to download regardless of how large the user's device is.

For backwards compatibility, one of the URLs is specified in the img element's src attribute. In new user agents, the src attribute is ignored when the srcset attribute uses w descriptors.

**Example**

In this example, the Web page has three layouts depending on the width of the viewport. The narrow layout has one column of images (the width of each image is about 100%), the middle layout has two columns of images (the width of each image is about 50%), and the widest layout has three columns of images, and some page margin (the width of each image is about 33%). It breaks between these layouts when the viewport is 30em wide and 50em wide, respectively.

```html
<img sizes="(max-width: 30em) 100vw, (max-width: 50em) 50vw, calc(33vw - 100px)"
srcset="swing-200.jpg 200w, swing-400.jpg 400w, swing-800.jpg 800w, swing-1600.jpg 1600w"
src="swing-400.jpg" alt="Kettlebell Swing">
```

The sizes attribute sets up the layout breakpoints at 30em and 50em, and declares the image sizes between these breakpoints to be 100vw, 50vw, or calc(33vw - 100px). These sizes do not necessarily have to match up exactly with the actual image width as specified in the CSS.

The user agent will pick a width from the sizes attribute, using the first item with a <media-condition> (the part in parentheses) that evaluates to true, or using the last item (calc(33vw - 100px)) if they all evaluate to false.

For example, if the viewport width is 29em, then (max-width: 30em) evaluates to true and 100vw is used, so the image size, for the purpose of resource selection, is 29em. If the viewport width is instead 32em, then (max-width: 30em) evaluates to false, but (max-width: 50em) evaluates to true and 50vw is used, so the image size, for the purpose of resource selection, is 16em (half the viewport width). Notice that the slightly wider viewport results in a smaller image because of the different layout.

The user agent can then calculate the effective pixel density and choose an appropriate resource similarly to the previous example.

**Art direction**

The picture element and the source element, together with the media attribute, can be used, to provide multiple images that vary the image content (for instance the smaller image might be a cropped version of the bigger image).
The type attribute on the source element can be used, to provide multiple images in different formats.

This section is non-normative.

CSS and media queries can be used to construct graphical page layouts that adapt dynamically to the user's environment, in particular to different viewport dimensions and pixel densities. For content, however, CSS does not help; instead, we have the img element's srcset attribute and the picture element. This section walks through a sample case showing how to use these features.

Consider a situation where on wide screens (wider than 600 CSS pixels) a 300×150 image named a-rectangle.png is to be used, but on smaller screens (600 CSS pixels and less), a smaller 100×100 image called a-square.png is to be used. The markup for this would look like this:

```
<picture>
  <source media="(min-width: 45em)" srcset="large.jpg">
  <source media="(min-width: 32em)" srcset="med.jpg">
  <img src="small.jpg" alt="The wolf runs through the snow.">
</picture>
```

The user agent will choose the first source element for which the media query in the media attribute matches, and then choose an appropriate URL from its srcset attribute.

The rendered size of the image varies depending on which resource is chosen. To specify dimensions that the user agent can use before having downloaded the image, CSS can be used.

```
css
img { width: 300px; height: 300px }
@media (min-width: 32em) { img { width: 500px; height:300px } }
@media (min-width: 45em) { img { width: 700px; height:400px } }
```

Example

This example combines art direction- and device-pixel-ratio-based selection. A banner that takes half the viewport is provided in two versions, one for wide screens and one for narrow screens.

```
<h1>
  <picture>
    <source media="(max-width: 500px)" srcset="banner-phone.jpeg, banner-phone-HD.jpeg 2x">
    <img src="banner.jpeg" srcset="banner-HD.jpeg 2x" alt="The Breakfast Combo">
  </picture>
</h1>
```

In this example, the user agent will choose the first source that has a type attribute with a supported MIME type. If the user agent supports WebP images, the first source element will be chosen. If not, but the user agent does support JPEG XR images, the second source element will be chosen. If neither of those formats are supported, the img element will be chosen.

```
Example
```

4.8.4.1.1 Adaptive images

This section is non-normative.

CSS and media queries can be used to construct graphical page layouts that adapt dynamically to the user's environment, in particular to different viewport dimensions and pixel densities. For content, however, CSS does not help; instead, we have the img element's srcset attribute and the picture element. This section walks through a sample case showing how to use these features.

Consider a situation where on wide screens (wider than 600 CSS pixels) a 300×150 image named a-rectangle.png is to be used, but on smaller screens (600 CSS pixels and less), a smaller 100×100 image called a-square.png is to be used. The markup for this would look like this:
The problem with this is that the user agent does not necessarily know what dimensions to use for the image when the image is loading. To avoid the layout having to be reflowed multiple times as the page is loading, CSS and CSS media queries can be used to provide the dimensions:

```html
<figure>
  <picture>
    <source srcset="a-square.png" media="(max-width: 600px)"
    <img src="a-rectangle.png" alt="Barney Frank wears a suit and glasses." id="a">
  </picture>
  <figcaption>Barney Frank, 2011</figcaption>
</figure>
```

Alternatively, the `width` and `height` attributes can be used to provide the width and height for legacy user agents, using CSS just for the user agents that support `picture`:

```html
<figure>
  <picture>
    <source srcset="a-square.png" media="(max-width: 600px)"
    <img src="a-rectangle.png" width="300" height="150"
    alt="Barney Frank wears a suit and glasses." id="a">
  </picture>
  <figcaption>Barney Frank, 2011</figcaption>
</figure>
```

The `img` element is used with the `src` attribute, which gives the URL of the image to use for legacy user agents that do not support the `picture` element. This leads to a question of which image to provide in the `src` attribute.

If the author wants the biggest image in legacy user agents, the markup could be as follows:

```html
<figure>
  <source srcset="pear-mobile.jpeg" media="(max-width: 720px)"
  <source srcset="pear-tablet.jpeg" media="(max-width: 1280px)"
  <img src="pear-desktop.jpeg" alt="The pear is juicy.""
</figure>
```

However, if legacy mobile user agents are more important, one can list all three images in the `source` elements, overriding the `src` attribute entirely.

```html
<figure>
  <source srcset="pear-mobile.jpeg" media="(max-width: 720px)"
</figure>
```
Since at this point the `src` attribute is actually being ignored entirely by `picture`, supporting user agents, the `src` attribute can default to any image, including one that is neither the smallest nor biggest:

```html
<picture>
  <source srcset="pear-mobile.jpeg" media="(max-width: 720px)" />
  <source srcset="pear-tablet.jpeg" media="(max-width: 1280px)" />
  <source srcset="pear-desktop.jpeg" media="(max-width: 1920px)" />
  <img src="pear-tablet.jpeg" alt="The pear is juicy." />
</picture>
```

Above the `max-width` media feature is used, giving the maximum (viewport) dimensions that an image is intended for. It is also possible to use `min-width` instead:

```html
<picture>
  <source srcset="pear-desktop.jpeg" media="(min-width: 1281px)" />
  <source srcset="pear-tablet.jpeg" media="(min-width: 721px)" />
  <img src="pear-mobile.jpeg" alt="The pear is juicy." />
</picture>
```

4.8.4.2 Attributes common to `source` and `img` elements

4.8.4.2.1 `srcset` attributes

A `srcset` attribute is an attribute with requirements defined in this section.

If present, its value must consist of one or more image candidate strings, each separated from the next by a U+002C COMMA character (,). If an image candidate string contains no descriptors and no ASCII whitespace after the URL, the following image candidate string, if there is one, must begin with one or more ASCII whitespace.

An image candidate string consists of the following components, in order, with the further restrictions described below this list:

1. Zero or more ASCII whitespace.
2. A valid non-empty URL that does not start or end with a U+002C COMMA character (,), referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.
3. Zero or more ASCII whitespace.
4. Zero or one of the following:
   - A width descriptor, consisting of: ASCII whitespace, a valid non-negative integer giving a number greater than zero representing the width descriptor value, and a U+0077 LATIN SMALL LETTER W character.
   - A pixel density descriptor, consisting of: ASCII whitespace, a valid floating-point number giving a number greater than zero representing the pixel density descriptor value, and a U+0078 LATIN SMALL LETTER X character.
5. Zero or more ASCII whitespace.

There must not be an image candidate string for an element that has the same width descriptor value as another image candidate string’s width descriptor value, for the same element.

There must not be an image candidate string for an element that has the same pixel density descriptor value as another image candidate string’s pixel density descriptor value, for the same element. For the purpose of this requirement, an image candidate string with no descriptors is equivalent to an image candidate string with a 1x descriptor.
If an image candidate string for an element has the width descriptor specified, all other image candidate strings for that element must also have the width descriptor specified.

The specified width in an image candidate string's width descriptor must match the intrinsic width in the resource given by the image candidate string's URL, if it has an intrinsic width.

If an element has a srcset attribute present, all image candidate strings for that element must have the width descriptor specified.

### 4.8.4.2 Sizes attributes

A sizes attribute is an attribute with requirements defined in this section.

If present, the value must be a valid source size list.

A valid source size list is a string that matches the following grammar:

```
<source-size-list> = [ <source-size>#, ]? <source-size-value>
<source-size> = <media-condition> <source-size-value>
<source-size-value> = <length>
```

A `<source-size-value>` must not be negative, and must not use CSS functions other than the math functions.

The `<source-size-value>` gives the intended layout width of the image. The author can specify different widths for different environments with `<media-condition>`s.

**Note**

Percentages are not allowed in a `<source-size-value>`, to avoid confusion about what it would be relative to. The 'vw' unit can be used for sizes relative to the viewport width.

### 4.8.4.3 Processing model

The task source for the tasks queued by algorithms in this section is the DOM manipulation task source.

An `img` element has a current request and a pending request. The current request is initially set to a new image request. The pending request is initially set to null.

An image request has a state, current URL, and image data.

An image request's state is one of the following:

**Unavailable**

The user agent hasn't obtained any image data, or has obtained some or all of the image data but hasn't yet decoded enough of the image to get the image dimensions.

**Partially available**

The user agent has obtained some of the image data and at least the image dimensions are available.

**Completely available**

The user agent has obtained all of the image data and at least the image dimensions are available.

**Broken**

The user agent has obtained all of the image data that it can, but it cannot even decode the image enough to get the image dimensions (e.g. the image is corrupted, or the format is not supported, or no data could be obtained).

An image request's current URL is initially the empty string.

An image request's image data is the decoded image data.
When an image request's state is either partially available or completely available, the image request is said to be available.

When an img element's current request's state is completely available and the user agent can decode the media data without errors, then the img element is said to be fully decodable.

An image request's state is initially unavailable.

When an img element's current request is available, the img element provides a paint source whose width is the image's density-corrected intrinsic width (if any), whose height is the image's density-corrected intrinsic height (if any), and whose appearance is the intrinsic appearance of the image.

An img element is said to use srcset or picture if it has a srcset attribute specified or if it has a parent that is a picture element.

Each img element has a last selected source, which must initially be null.

Each image request has a current pixel density, which must initially be undefined.

When an img element has a current pixel density that is not 1.0, the element's image data must be treated as if its resolution, in device pixels per CSS pixels, was the current pixel density. The image's density-corrected intrinsic width and height are the intrinsic width and height after taking into account the current pixel density.

An img element is associated with a source set.

A source set is an ordered set of zero or more image sources and a source size.

An image source is a URL, and optionally either a pixel density descriptor, or a width descriptor.

A source size is a <source-size-value>. When a source size has a unit relative to the viewport, it must be interpreted relative to the img element's node document's viewport. Other units must be interpreted the same as in Media Queries.

A parse error for algorithms in this section indicates a non-fatal mismatch between input and requirements. User agents are encouraged to expose parse error somehow.

Whether the image is fetched successfully or not (e.g. whether the response status was an ok status) must be ignored when determining the image's type and whether it is a valid image.

This allows servers to return images with error responses, and have them displayed.

The user agent should apply the image sniffing rules to determine the type of the image, with the image's associated Content-Type headers giving the official type. If these rules are not applied, then the type of the image must be the type given by the image's associated Content-Type headers.

User agents must not support non-image resources with the img element (e.g. XML files whose document element is an HTML element). User agents must not run executable code (e.g. scripts) embedded in the image resource. User agents must only display the first page of a multipage resource (e.g. a PDF file). User agents must not allow the resource to act in an interactive fashion, but should honour any animation in the resource.

This specification does not specify which image types are to be supported.
4.8.4.3.1 When to obtain images

In a browsing context where scripting is disabled, user agents may obtain images immediately or on demand. In a browsing context where scripting is enabled, user agents must obtain images immediately.

A user agent that obtains images immediately must synchronously update the image data of an `img` element, with the restart animation flag set if so stated, whenever that element is created or has experienced relevant mutations.

A user agent that obtains images on demand must update the image data of an `img` element whenever it needs the image data (i.e., on demand), but only if the `img` element's current request's state is unavailable. When an `img` element has experienced relevant mutations, if the user agent only obtains images on demand, the `img` element's current request's state must return to unavailable.

The relevant mutations for an `img` element are as follows:

- The element's `src`, `srcset`, `width`, or `sizes` attributes are set, changed, or removed.
- The element's `src` attribute is set to the same value as the previous value. This must set the restart animation flag for the update the image data algorithm.
- The element's `crossorigin` attribute's state is changed.
- The element is inserted into or removed from a `picture` parent element.
- The element's parent is a `picture` element and a `source` element that was a previous sibling is removed.
- The element's parent is a `picture` element and a `source` element that is a previous sibling has its `srcset`, `sizes`, `media`, or `type` attributes set, changed, or removed.
- The element's adopting steps are run.

4.8.4.3.2 Reacting to DOM mutations

The relevant mutations for an `img` element as are as follows:

- The `doc` object must have a list of available images. Each image in this list is identified by a tuple consisting of an absolute URL, a CORS settings attribute, and, if the mode is not No CORS, an origin.

4.8.4.3.3 The list of available images

Each Document object must have a list of available images. Each image in this list is identified by a tuple consisting of an absolute URL, a CORS settings attribute, and, if the mode is not No CORS, an origin.

Note: The list of available images is intended to enable synchronous switching when changing the `src` attribute to a URL that has previously been loaded, and to avoid re-downloading images in the same document even when they don't allow caching per HTTP. It is not used to avoid re-downloading the same image while the previous image is still loading.

Note: The user agent can also store the image data separately from the list of available images.

Example: For example, if a resource has the HTTP response header `Cache-Control: must-revalidate`, and its ignore higher-layer caching flag is unset, the user agent would remove it from the list of available images but could keep the image data separately, and use that if the server responds with a 304 Not Modified status.
4.8.4.3.4 Decoding images

Image data is usually encoded in order to reduce file size. This means that in order for the user agent to present the image to the screen, the data needs to be decoded. **Decoding** is the process which converts an image's media data into a bitmap form, suitable for presentation to the screen. Note that this process can be slow relative to other processes involved in presenting content. Thus, the user agent can choose when to perform decoding, in order to create the best user experience.

Image decoding is said to be synchronous if it prevents presentation of other content until it is finished. Typically, this has an effect of atomically presenting the image and any other content at the same time. However, this presentation is delayed by the amount of time it takes to perform the decode.

Image decoding is said to be asynchronous if it does not prevent presentation of other content. This has an effect of presenting non-image content faster. However, the image content is missing on screen until the decode finishes. Once the decode is finished, the screen is updated with the image.

In both synchronous and asynchronous decoding modes, the final content is presented to screen after the same amount of time has elapsed. The main difference is whether the user agent presents non-image content ahead of presenting the final content.

In order to aid the user agent in deciding whether to perform synchronous or asynchronous decode, the `decoding` attribute can be set on `img` elements. The possible values of the `decoding` attribute are the following **image decoding hint** keywords:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sync</td>
<td>Sync</td>
<td>Indicates a preference to decode this image synchronously for atomic presentation with other content.</td>
</tr>
<tr>
<td>async</td>
<td>Async</td>
<td>Indicates a preference to decode this image asynchronously to avoid delaying presentation of other content.</td>
</tr>
<tr>
<td>auto</td>
<td>Auto</td>
<td>Indicates no preference in decoding mode (the default).</td>
</tr>
</tbody>
</table>

When an image, the user agent should respect the preference indicated by the `decoding` attribute's state. If the state indicated is `auto`, then the user agent is free to choose any decoding behavior.

> **Note**
> It is also possible to control the decoding behavior using the `decode()` method. Since the `decode()` method performs decoding independently from the process responsible for presenting content to screen, it is unaffected by the `decoding` attribute.

4.8.4.3.5 Updating the image data

When the user agent is to update the image data of an `img` element, optionally with the restart animations flag set, it must run the following steps:

1. If the element's `node document` is not the active document, then:
   1. Continue running this algorithm in parallel.
   2. Wait until the element's `node document` is the active document.
   3. If another instance of this algorithm for this `img` element was started after this instance (even if it aborted and is no longer running), then return.
   4. Queue a microtask to continue this algorithm.

2. If the user agent cannot support images, or its support for images has been disabled, then abort the image request for the current request and the pending request, set current request's state to unavailable, set pending request to null, and return.

3. Let `selected source` be null and `selected pixel density` be undefined.

4. If the element does not have `srcset` or `picture` and it has a `src` attribute specified whose value is not the empty string, then set `selected source` to the value of the element's `src` attribute and set `selected pixel density` to 1.0.

5. Set the element's `last selected source` to `selected source`.

6. If `selected source` is not null, then:
   1. Parse `selected source`, relative to the element's `node document`. If that is not successful, then abort this inner
set of steps. Otherwise, let `urlString` be the resulting URL string.

2. Let `key` be a tuple consisting of `urlString` of the `<img>` element’s `crossorigin` attribute’s mode, and, if that mode is not No CORS, the node document’s origin.

3. If the list of available images contains an entry for `key`, then:
   1. Set the ignore higher-layer caching flag for that entry.
   2. Abort the image request for the current request and the pending request.
   3. Set pending request to null.
   4. Let `current request` be a new image request whose image data is that of the entry and whose state is completely available.
   5. Update the presentation of the image appropriately.
   6. Set current request’s current pixel density to selected pixel density.
   7. Queue a task to:
      1. If restart animation is set, then restart the animation.
      2. Set current request’s current URL to `urlString`.
      3. Fire an event named `load` at the image element.
   8. Abort the update the image data algorithm.

7. Await a stable state, allowing the task that invoked this algorithm to continue. The synchronous section consists of all the remaining steps of this algorithm until the algorithm says the synchronous section has ended. (Steps in synchronous sections are marked with ⌛.)

8. If another instance of this algorithm for this image element was started after this instance (even if it aborted and is no longer running), then return.

Note

Only the last instance takes effect, to avoid multiple requests when, for example, the `src`, `srcset`, and `crossorigin` attributes are all set in succession.

9. Let selected source and selected pixel density be the URL and pixel density that results from selecting an image source, respectively.

10. If selected source is null, then:
    1. Set the current request’s state to broken, abort the image request for the current request and the pending request, and set pending request to null.
    2. Queue a task to change the current request’s current URL to selected source.
    3. Fire an event named `load` at the image element.
    4. Return.

11. Queue a task to fire a progress event named `loadstart` at the image element.

12. Parse selected source, relative to the element’s node document, and let `urlString` be the resulting URL string. If that is not successful, then:
    1. Abort the image request for the current request and the pending request.
    2. Set the current request’s state to broken.
    3. Set pending request to null.
    4. Queue a task to change the current request’s current URL to selected source.
    5. Return.
13. If the pending request is not null and urlString is the same as the pending request's current URL, then return.

14. If urlString is the same as the current request's current URL and current request's state is partially available, then abort the image request for the pending request, queue a task to restart the animation if restart animation is set, and return.

15. If the pending request is not null, then abort the image request for the pending request.

16. Set image request to a new image request whose current URL is urlString.

17. If current request's state is unavailable or broken, then set the current request to image request. Otherwise, set the pending request to image request.

18. Let request be the result of creating a potential-CORS request given urlString, "image", and the current state of the element's crossorigin content attribute.

20. If the element uses srcset or picture, set request's initiator to "imageset".

21. Set request's referrer policy to the current state of the element's referrerpolicy attribute.

22. Fetch request. Let this instance of the fetching algorithm be associated with image request.

The resource obtained in this fashion, if any, is image request's image data. It can be either CORS-same-origin or CORS-cross-origin; this affects the origin of the image itself (e.g. when used on a canvas).

Fetcheding the image must delay the load event of the element's node document until the task is queued by the networking task source once the resource has been fetched (defined below) has been run.

⚠️ Warning! This, unfortunately, can be used to perform a rudimentary port scan of the user's local network (especially in conjunction with scripting, though scripting isn't actually necessary to carry out such an attack). User agents may implement cross-origin access control policies that are stricter than those described above to mitigate this attack, but unfortunately such policies are typically not compatible with existing Web content.

If the resource is CORS-same-origin, each task that is queued by the networking task source while the image is being fetched, if image request is the current request, must fire a progress event named progress at the img element.

23. End the synchronous section, continuing the remaining steps in parallel, but without missing any data from fetching.

24. As soon as possible, jump to the first applicable entry from the following list:

→ If the resource type is multipart/x-mixed-replace

The next task that is queued by the networking task source while the image is being fetched must run the following steps:

1. If image request is the pending request and at least one body part has been completely decoded, abort the image request for the current request, upgrade the pending request to the current request.

2. Otherwise, if image request is the pending request and the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, abort the image request for the current request, upgrade the pending request to the current request, and set the current request's state to broken.

3. Otherwise, if image request is the current request, its state is unavailable, and the user agent is able to determine image request's image's width and height, set the current request's state to partially available.

4. Otherwise, if image request is the current request, its state is unavailable, and the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, set the current request's state to broken.

Each task that is queued by the networking task source while the image is being fetched must update the presentation of the image, but as each new body part comes in, it must replace the previous image. Once one body part has been completely decoded, the user agent must set the img element's current request's state to...
completely available\textsuperscript{\textsuperscript{322}} and queue a task\textsuperscript{\textsuperscript{\textsuperscript{893}}} to fire an event named \texttt{Load}\textsuperscript{\textsuperscript{1217}} at the \texttt{img}\textsuperscript{\textsuperscript{397}} element.

\begin{warning}
The \texttt{progress}\textsuperscript{\textsuperscript{1217}} and \texttt{loadend}\textsuperscript{\textsuperscript{1217}} events are not fired for multipart/x-mixed-replace\textsuperscript{\textsuperscript{3198}} image streams.
\end{warning}

\begin{itemize}
\item \textbf{If the resource type and data corresponds to a supported image format, as described below}\textsuperscript{\textsuperscript{323}}
\end{itemize}

The next task\textsuperscript{\textsuperscript{893}} that is queued\textsuperscript{\textsuperscript{\textsuperscript{893}}} by the networking task source\textsuperscript{\textsuperscript{\textsuperscript{897}}} while the image is being fetched must run the following steps:

1. If the user agent is able to determine image request's image's width and height, and image request is pending request\textsuperscript{\textsuperscript{311}}, set image request's state\textsuperscript{\textsuperscript{322}} to partially available\textsuperscript{\textsuperscript{311}}.  
2. Otherwise, if the user agent is able to determine image request's image's width and height, and image request is current request\textsuperscript{\textsuperscript{\textsuperscript{322}}}, update the \texttt{img}\textsuperscript{\textsuperscript{307}} element's presentation appropriately and set image request's state\textsuperscript{\textsuperscript{322}} to partially available\textsuperscript{\textsuperscript{322}}.  
3. Otherwise, if the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, and image request is pending request\textsuperscript{\textsuperscript{322}}, abort the image request\textsuperscript{\textsuperscript{328}} for the current request\textsuperscript{\textsuperscript{\textsuperscript{322}}} and the pending request\textsuperscript{\textsuperscript{322}}, upgrade the pending request to the current request\textsuperscript{\textsuperscript{\textsuperscript{328}}} set current request\textsuperscript{\textsuperscript{\textsuperscript{322}}} state\textsuperscript{\textsuperscript{322}} to broken\textsuperscript{\textsuperscript{322}}, fire an event named error\textsuperscript{\textsuperscript{31217}} at the \texttt{img}\textsuperscript{\textsuperscript{307}} element, fire an event named loadend\textsuperscript{\textsuperscript{1217}} at the \texttt{img}\textsuperscript{\textsuperscript{397}} element.
4. Otherwise, if the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, and image request is current request\textsuperscript{\textsuperscript{\textsuperscript{322}}}, abort the image request\textsuperscript{\textsuperscript{328}} for image request, fire an event named error\textsuperscript{\textsuperscript{\textsuperscript{31217}}} at the \texttt{img}\textsuperscript{\textsuperscript{397}} element, fire an event named loadend\textsuperscript{\textsuperscript{1217}} at the \texttt{img}\textsuperscript{\textsuperscript{397}} element.

That task\textsuperscript{\textsuperscript{893}}, and each subsequent task\textsuperscript{\textsuperscript{893}}, that is queued\textsuperscript{\textsuperscript{\textsuperscript{893}}} by the networking task source\textsuperscript{\textsuperscript{\textsuperscript{897}}} while the image is being fetched, if image request is the current request\textsuperscript{\textsuperscript{\textsuperscript{322}}}, must update the presentation of the image appropriately (e.g., if the image is a progressive JPEG, each packet can improve the resolution of the image).

Furthermore, the last task\textsuperscript{\textsuperscript{893}} that is queued\textsuperscript{\textsuperscript{\textsuperscript{893}}} by the networking task source\textsuperscript{\textsuperscript{\textsuperscript{897}}} once the resource has been fetched must additionally run these steps:

1. If image request is the pending request\textsuperscript{\textsuperscript{322}}, abort the image request\textsuperscript{\textsuperscript{328}} for the current request\textsuperscript{\textsuperscript{\textsuperscript{322}}}, upgrade the pending request to the current request\textsuperscript{\textsuperscript{\textsuperscript{328}}}, and update the \texttt{img}\textsuperscript{\textsuperscript{307}} element's presentation appropriately.  
2. Set image request to the completely available\textsuperscript{\textsuperscript{322}} state.  
3. Add the image to the list of available images\textsuperscript{\textsuperscript{324}} using the key key, with the ignore higher-layer caching\textsuperscript{\textsuperscript{324}} flag set.  
4. Fire a progress event or event\textsuperscript{\textsuperscript{\textsuperscript{329}}} named load\textsuperscript{\textsuperscript{1217}} at the \texttt{img}\textsuperscript{\textsuperscript{307}} element, depending on the resource in image request.  
5. Fire a progress event or event\textsuperscript{\textsuperscript{\textsuperscript{329}}} named loadend\textsuperscript{\textsuperscript{1217}} at the \texttt{img}\textsuperscript{\textsuperscript{397}} element, depending on the resource in image request.

\begin{itemize}
\item \textbf{Otherwise}
\end{itemize}

The image data is not in a supported file format; the user agent must set image request's state\textsuperscript{\textsuperscript{322}} to broken\textsuperscript{\textsuperscript{322}}, abort the image request\textsuperscript{\textsuperscript{328}} for the current request\textsuperscript{\textsuperscript{\textsuperscript{322}}}, and the pending request\textsuperscript{\textsuperscript{\textsuperscript{322}}}, upgrade the pending request to the current request\textsuperscript{\textsuperscript{\textsuperscript{328}}} if image request is the pending request\textsuperscript{\textsuperscript{\textsuperscript{322}}}, and then queue a task\textsuperscript{\textsuperscript{\textsuperscript{893}}} to first fire an event named error\textsuperscript{\textsuperscript{\textsuperscript{31217}}} at the \texttt{img}\textsuperscript{\textsuperscript{307}} element and then fire an event named loadend\textsuperscript{\textsuperscript{1217}} at the \texttt{img}\textsuperscript{\textsuperscript{397}} element.

While a user agent is running the above algorithm for an element \texttt{x}, there must be a strong reference from the element's node document to the element \texttt{x}, even if that element is not connected.

To \textbf{abort the image request} for an image request\textsuperscript{\textsuperscript{\textsuperscript{327}}} image request means to run the following steps:

1. Forget image request's image data\textsuperscript{\textsuperscript{\textsuperscript{322}}}, if any.  
2. Abort any instance of the fetching algorithm for image request, discarding any pending tasks generated by that algorithm.

To \textbf{upgrade the pending request to the current request} for an \texttt{img}\textsuperscript{\textsuperscript{397}} element means to run the following steps:

1. Let the \texttt{img}\textsuperscript{\textsuperscript{397}} element's current request\textsuperscript{\textsuperscript{\textsuperscript{322}}} be the pending request\textsuperscript{\textsuperscript{\textsuperscript{322}}}. 

328
2. Let the `img` element's `pending request` be null.

To fire a progress event or event named type at an element e, depending on resource r, means to fire a progress event named type at e if r is CORS-same-origin, and otherwise fire an event named type at e.

### 4.8.4.3.6 Selecting an image source

When asked to select an image source for a given `img` element el, user agents must do the following:

1. Update the source set for el.
2. If el's source set is empty, return null as the URL and undefined as the pixel density.
3. Otherwise, take el's source set and let it be source set.
4. If an entry b in source set has the same associated pixel density descriptor as an earlier entry a in source set, then remove entry b. Repeat this step until none of the entries in source set have the same associated pixel density descriptor as an earlier entry.
5. In a user agent-specific manner, choose one image source from source set. Let this be selected source.
6. Return selected source and its associated pixel density.

### 4.8.4.3.7 Updating the source set

When asked to update the source set for a given `img` element el, user agents must do the following:

1. Set el's source set to an empty source set.
2. If el has a parent node and that is a `picture` element, let elements be an array containing el's parent node's child elements, retaining relative order. Otherwise, let elements be array containing only el.
3. If el has a width attribute, and parsing that attribute's value using the rules for parsing dimension values doesn't generate an error or a percentage value, then let width be the returned integer value. Otherwise, let width be null.
4. Iterate through elements, doing the following for each item child:
   1. If child is el:
      1. If child has a `srcset` attribute, parse child's srcset attribute and let the returned source set be source set. Otherwise, let source set be an empty source set.
      2. Parse child's sizes attribute with the fallback width width, and let source set's source size be the returned value.
      3. If child has a `src` attribute whose value is not the empty string and source set does not contain an image source with a pixel density descriptor value of 1, and no image source with a width descriptor value of 1, append child's src attribute value to source set.
      4. Normalize the source densities of source set.
      5. Let el's source set be source set.
   6. Return.
2. If child is not a `source` element, continue to the next child. Otherwise, child is a `source` element.
3. If child does not have a `srcset` attribute, continue to the next child.
4. Parse child's srcset attribute and let the returned source set be source set.
5. If source set has zero image sources, continue to the next child.
6. If child has a `media` attribute, and its value does not match the environment, continue to the next child.
7. Parse child's sizes attribute with the fallback width width, and let source set's source size be the returned
value.

8. If child has a type attribute, and its value is an unknown or unsupported MIME type, continue to the next child.

10. Let el's source set be source set.

11. Return.

Each img element independently considers its previous sibling source elements plus the img element itself for selecting an image source, ignoring any other (invalid) elements, including other img elements in the same picture element, or source elements that are following siblings of the relevant img element.

4.8.4.3.8 Parsing a srcset attribute

When asked to parse a srcset attribute from an element, parse the value of the element's srcset attribute as follows:

1. Let input be the value passed to this algorithm.

2. Let position be a pointer into input, initially pointing at the start of the string.

3. Let candidates be an initially empty source set.

4. Splitting loop: Collect a sequence of code points that are ASCII whitespace or U+002C COMMA characters from input given position. If any U+002C COMMA characters were collected, that is a parse error.

5. If position is past the end of input, return candidates.

6. Collect a sequence of code points that are not ASCII whitespace from input given position, and let that be url.

7. Let descriptors be a new empty list.

8. If url ends with U+002C (,), then:

   1. Remove all trailing U+002C COMMA characters from url. If this removed more than one character, that is a parse error.

Otherwise:

   1. Descriptor tokenizer: Skip ASCII whitespace within input given position.

   2. Let current descriptor be the empty string.

   3. Let state be in descriptor.

   4. Let c be the character at position. Do the following depending on the value of state. For the purpose of this step, "EOF" is a special character representing that position is past the end of input.

      ↪ In descriptor

      Do the following, depending on the value of c:

      ↪ ASCII whitespace

      If current descriptor is not empty, append current descriptor to descriptors and let current descriptor be the empty string. Set state to after descriptor.

      ↪ U+002C COMMA (,)

      Advance position to the next character in input. If current descriptor is not empty, append current descriptor to descriptors. Jump to the step labeled descriptor parser.

      ↪ U+0028 LEFT PARENTHESIS (

      Append c to current descriptor. Set state to in parens.

      ↪ EOF

      If current descriptor is not empty, append current descriptor to descriptors. Jump to the step labeled descriptor parser.
Anything else
Append c to current descriptor.

In parens
Do the following, depending on the value of c:

U+0029 RIGHT PARENTHESIS ()
Append c to current descriptor. Set state to in descriptor.

EOF
Append current descriptor to descriptors. Jump to the step labeled descriptor parser.

Anything else
Append c to current descriptor.

After descriptor
Do the following, depending on the value of c:

ASCII whitespace
Stay in this state.

EOF
Jump to the step labeled descriptor parser.

Anything else
Set state to in descriptor. Set position to the previous character in input.

Advance position to the next character in input. Repeat this step.

Note
In order to be compatible with future additions, this algorithm supports multiple descriptors and descriptors with parens.

9. Descriptor parser: Let error be no.

10. Let width be absent.

11. Let density be absent.

12. Let future-compat-h be absent.

13. For each descriptor in descriptors, run the appropriate set of steps from the following list:

If the descriptor consists of a valid non-negative integer\textsuperscript{p66} followed by a U+0077 LATIN SMALL LETTER W character

1. If the user agent does not support the sizes\textsuperscript{p308} attribute, let error be yes.

Note
A conforming user agent will support the sizes\textsuperscript{p308} attribute. However, user agents typically implement and ship features in an incremental manner in practice.

2. If width and density are not both absent, then let error be yes.

3. Apply the rules for parsing non-negative integers\textsuperscript{p66} to the descriptor. If the result is zero, let error be yes. Otherwise, let width be the result.

If the descriptor consists of a valid floating-point number\textsuperscript{p66} followed by a U+0078 LATIN SMALL LETTER X character

1. If width, density and future-compat-h are not all absent, then let error be yes.

2. Apply the rules for parsing floating-point number values\textsuperscript{p67} to the descriptor. If the result is less than zero, let error be yes. Otherwise, let density be the result.

Note
If density is zero, the intrinsic dimensions will be infinite. User agents are expected to have limits in how
If the descriptor consists of a valid non-negative integer followed by a U+0068 LATIN SMALL LETTER H character, this is a parse error.

1. If future-compat-h and density are not both absent, then let error be yes.
2. Apply the rules for parsing non-negative integers to the descriptor. If the result is zero, let error be yes. Otherwise, let future-compat-h be the result.

Anything else
Let error be yes.

14. If future-compat-h is not absent and width is absent, let error be yes.
15. If error is still no, then append a new image source to candidates whose URL is url, associated with a width width if not absent and a pixel density density if not absent. Otherwise, there is a parse error.
16. Return to the step labeled splitting loop.

4.8.4.9 Parsing a sizes attribute
When asked to parse a sizes attribute from an element, with a fallback width width, parse a comma-separated list of component values from the value of the element’s sizes attribute (or the empty string, if the attribute is absent), and let unparsed sizes list be the result. [CSSSYNTAX]

For each unparsed size in unparsed sizes list:

1. Remove all consecutive whitespace-token>s from the end of unparsed size. If unparsed size is now empty, that is a parse error; continue to the next iteration of this algorithm.
2. If the last component value in unparsed size is a valid non-negative source-size-value, let size be its value and remove the component value from unparsed size. Any CSS function other than the math functions is invalid. Otherwise, there is a parse error; continue to the next iteration of this algorithm.
3. Remove all consecutive whitespace-token>s from the end of unparsed size. If unparsed size is now empty, return size and exit this algorithm. If this was not the last item in unparsed sizes list, that is a parse error.
4. Parse the remaining component values in unparsed size as a media-condition. If it does not parse correctly, or it does parse correctly but the media-condition evaluates to false, continue to the next iteration of this algorithm. [MQ]
5. Return size and exit this algorithm.

If the above algorithm exhausts unparsed sizes list without returning a size value, follow these steps:

1. If width is not null, return a length with the value width and the unit ‘px’.
2. Return 100vw.

Note
While a valid source list only contains a bare source-size-value (without an accompanying media-condition) as the last entry in the source-size-list, the parsing algorithm technically allows such at any point in the list, and will accept it immediately as the size if the preceding entries in the list weren’t used. This is to enable future extensions, and protect against simple author errors such as a final trailing comma.

4.8.4.10 Normalizing the source densities
An image source can have a pixel density descriptor, a width descriptor, or no descriptor at all accompanying its URL. Normalizing a source set gives every image source a pixel density descriptor.

big images can be rendered, which is allowed by the hardware limitations clause.

An image source can have a pixel density descriptor, a width descriptor, or no descriptor at all accompanying its URL. Normalizing a source set gives every image source a pixel density descriptor.

While a valid source list only contains a bare source-size-value (without an accompanying media-condition) as the last entry in the source-size-list, the parsing algorithm technically allows such at any point in the list, and will accept it immediately as the size if the preceding entries in the list weren’t used. This is to enable future extensions, and protect against simple author errors such as a final trailing comma.
When asked to normalize the source densities of a source set\textsuperscript{333} source set, the user agent must do the following:

1. Let source size be source set's source size\textsuperscript{323}.
2. For each image source\textsuperscript{333} in source set:
   1. If the image source\textsuperscript{333} has a pixel density descriptor\textsuperscript{321}, continue to the next image source\textsuperscript{333}.
   2. Otherwise, if the image source\textsuperscript{333} has a width descriptor\textsuperscript{321}, replace the width descriptor\textsuperscript{321} with a pixel density descriptor\textsuperscript{321} with a value\textsuperscript{321} of the width descriptor value\textsuperscript{321} divided by the source size\textsuperscript{333} and a unit of $x$.

   \begin{footnotesize}
   \textbf{Note}
   \begin{itemize}
   \item If the source size\textsuperscript{333} is zero, the density would be infinity, which results in the intrinsic dimensions being zero by zero.
   \end{itemize}
   \end{footnotesize}
3. Otherwise, give the image source\textsuperscript{333} a pixel density descriptor\textsuperscript{321} of $1x$.

\subsection*{4.8.4.3.11 Reacting to environment changes \textsuperscript{333}2}

The user agent may at any time run the following algorithm to update an img\textsuperscript{387} element's image in order to react to changes in the environment. (User agents are not required to ever run this algorithm; for example, if the user is not looking at the page any more, the user agent might want to wait until the user has returned to the page before determining which image to use, in case the environment changes again in the meantime.)

\begin{footnotesize}
\textbf{Note}
User agents are encouraged to run this algorithm in particular when the user changes the viewport's size (e.g. by resizing the window or changing the page zoom), and when an img\textsuperscript{387} element is inserted into a document\textsuperscript{384}, so that the density-corrected intrinsic width and height\textsuperscript{323} match the new viewport and so that the correct image is chosen when art direction\textsuperscript{327} is involved.
\end{footnotesize}

1. Await a stable\textsuperscript{906}. The synchronous section\textsuperscript{906} consists of all the remaining steps of this algorithm until the algorithm says the synchronous section\textsuperscript{906} has ended. (Steps in synchronous sections\textsuperscript{906} are marked with $\mathbb{E}$.)
2. If the img\textsuperscript{387} element does not use srcset or picture\textsuperscript{323}, its node document is not the active document\textsuperscript{786}, has image data whose resource type is multipart/x-mixed-replace\textsuperscript{5190}, or the pending request\textsuperscript{342} is not null, then return.
3. Let selected source and selected pixel density be the URL and pixel density that results from selecting an image source\textsuperscript{329}, respectively.
4. If selected source is null, then return.
5. If selected source and selected pixel density are the same as the element's last selected source\textsuperscript{323} and current pixel density\textsuperscript{323}, then return.
6. Parse\textsuperscript{986} selected source, relative to the element's node document, and let urlString be the resulting URL string\textsuperscript{986}. If that is not successful, then return.
7. Let corsAttributeState be the state of the element's crossorigin\textsuperscript{986} content attribute.
8. Let origin be the origin\textsuperscript{483} of the img\textsuperscript{387} element's node document.
9. Let client be the img\textsuperscript{387} element's node document's window\textsuperscript{971} object's environment settings object\textsuperscript{988}.
10. Let key be a tuple consisting of urlString, corsAttributeState, and, if corsAttributeState is not No CORS\textsuperscript{988}, origin.
11. Let image request be a new image request\textsuperscript{332} whose current URL\textsuperscript{342} is urlString.
12. Let the element's pending request\textsuperscript{342} be image request.
13. End the synchronous section\textsuperscript{906}, continuing the remaining steps in parallel\textsuperscript{942}.
14. If the list of available images\textsuperscript{334} contains an entry for key, then set image request's image data\textsuperscript{332} to that of the entry. Continue to the next step.

Otherwise:

1. Let request be the result of creating a potential-CORS request\textsuperscript{987} given urlString, "image", and corsAttributeState.
2. Set request's client to client, initiator to "imageset", and set request's synchronous flag.

3. Set request's referer policy to the current state of the element's refererpolicy attribute.

4. Let response be the result of fetching request.

5. If response's unsafe response is a network error or if the image format is unsupported (as determined by applying the image sniffing rules, again as mentioned earlier), or if the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, or if the resource type is multipart/x-mixed-replace, then let pending request be null and abort these steps.

6. Otherwise, response's unsafe response is image request's image data. It can be either CORS-same-origin or CORS-cross-origin; this affects the origin of the image itself (e.g., when used on a canvas).

15. Queue a task to run these steps:
   1. If the img element has experienced relevant mutations since this algorithm started, then let pending request be null and abort these steps.
   2. Let the img element's last selected source be selected source and the img element's current pixel density be selected pixel density.
   3. Set the image request's state to completely available.
   4. Add the image to the list of available images using the key key, with the ignore higher-layer caching flag set.
   5. Upgrade the pending request to the current request.
   6. Update the img element's presentation appropriately.
   7. Fire an event named load at the img element.

4.4.4 Requirements for providing text to act as an alternative for images

4.4.4.1 General guidelines

Except where otherwise specified, the alt attribute must be specified and its value must not be empty; the value must be an appropriate replacement for the image. The specific requirements for the alt attribute depend on what the image is intended to represent, as described in the following sections.

The most general rule to consider when writing alternative text is the following: the intent is that replacing every image with the text of its alt attribute not change the meaning of the page.

So, in general, alternative text can be written by considering what one would have written had one not been able to include the image.

A corollary to this is that the alt attribute's value should never contain text that could be considered the image's caption, title, or legend. It is supposed to contain replacement text that could be used by users instead of the image; it is not meant to supplement the image. The title attribute can be used for supplemental information.

Another corollary is that the alt attribute's value should not repeat information that is already provided in the prose next to the image.

Note: One way to think of alternative text is to think about how you would read the page containing the image to someone over the phone, without mentioning that there is an image present. Whatever you say instead of the image is typically a good start for writing the alternative text.

4.4.4.2 A link or button containing nothing but the image

When an a element that creates a hyperlink, or a button element, has no textual content but contains one or more images, the alt attributes must contain text that together convey the purpose of the link or button.
In this example, a user is asked to pick their preferred color from a list of three. Each color is given by an image, but for users who have configured their user agent not to display images, the color names are used instead:

```html
<h1>Pick your color</h1>
<ul>
  <li><a href="green.html"><img src="green.jpeg" alt="Green"></a></li>
  <li><a href="blue.html"><img src="blue.jpeg" alt="Blue"></a></li>
  <li><a href="red.html"><img src="red.jpeg" alt="Red"></a></li>
</ul>
```

Since each image represents one part of the text, it could also be written like this:

```html
<button name="rgb"><img src="red" alt="R"><img src="green" alt="G"><img src="blue" alt="B"></button>
<button name="cmyk"><img src="cyan" alt="C"><img src="magenta" alt="M"><img src="black" alt="K"></button>
```

However, with other alternative text, this might not work, and putting all the alternative text into one image in each case might make more sense:

```html
<button name="rgb"><img src="red" alt="sRGB profile"><img src="green" alt=""><img src="blue" alt=""></button>
<button name="cmyk"><img src="cyan" alt="CMYK profile"><img src="magenta" alt=""><img src="black" alt=""></button>
```

### 4.8.4.4.3 A phrase or paragraph with an alternative graphical representation: charts, diagrams, graphs, maps, illustrations

Sometimes something can be more clearly stated in graphical form, for example as a flowchart, a diagram, a graph, or a simple map showing directions. In such cases, an image can be given using the `img` element, but the lesser textual version must still be given, so that users who are unable to view the image (e.g. because they have a very slow connection, or because they are using a text-only browser, or because they are listening to the page being read out by a hands-free automobile voice Web browser, or simply because they are blind) are still able to understand the message being conveyed.

The text must be given in the `alt` attribute, and must convey the same message as the image specified in the `src` attribute.

It is important to realize that the alternative text is a replacement for the image, not a description of the image.

**Example**

In the following example we have a flowchart in image form, with text in the `alt` attribute rephrasing the flowchart in prose form:

```html
<p>In the common case, the data handled by the tokenization stage comes from the network, but it can also come from script.</p>
<p><img src="images/parsing-model-overview.svg" alt="The Network"
```
passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using `document.write()`, passes data to the Tokenizer.”

Here's another example, showing a good solution and a bad solution to the problem of including an image in a description.

First, here's the good solution. This sample shows how the alternative text should just be what you would have put in the prose if the image had never existed.

<!-- This is the correct way to do things. -->

```html
<p>You are standing in an open field west of a house.  
<img src="house.jpeg" alt="The house is white, with a boarded front door."/>  
There is a small mailbox here.</p>
```

Second, here's the bad solution. In this incorrect way of doing things, the alternative text is simply a description of the image, instead of a textual replacement for the image. It's bad because when the image isn't shown, the text doesn't flow as well as in the first example.

<!-- This is the wrong way to do things. -->

```html
<p>You are standing in an open field west of a house.  
<img src="house.jpeg" alt="A white house, with a boarded front door."/>  
There is a small mailbox here.</p>
```

Text such as "Photo of white house with boarded door" would be equally bad alternative text (though it could be suitable for the `title` attribute or in the `figcaption` element of a `figure` with this image).

### 4.8.4.4 A short phrase or label with an alternative graphical representation: icons, logos

A document can contain information in iconic form. The icon is intended to help users of visual browsers to recognize features at a glance.

In some cases, the icon is supplemental to a text label conveying the same meaning. In those cases, the `alt` attribute must be present but must be empty.

Here the icons are next to text that conveys the same meaning, so they have an empty `alt` attribute:

```html
<nav>  
<p><a href="/help/"> <img src="/icons/help.png" alt=""> Help</a></p>  
<p><a href="/configure/"> <img src="/icons/configuration.png" alt="">  
Configuration Tools</a></p> 
</nav>
```

In other cases, the icon has no text next to it describing what it means; the icon is supposed to be self-explanatory. In those cases, an equivalent textual label must be given in the `alt` attribute.
Many pages include logos, insignia, flags, or emblems, which stand for a particular entity such as a company, organization, project, band, software package, country, or some such.

If the logo is being used to represent the entity, e.g. as a page heading, the alt attribute must contain the name of the entity being represented by the logo. The alt attribute must not contain text like the word "logo", as it is not the fact that it is a logo that is being conveyed, it's the entity itself.

If the logo is being used next to the name of the entity that it represents, then the logo is supplemental, and its alt attribute must instead be empty.

If the logo is merely used as decorative material (as branding, or, for example, as a side image in an article that mentions the entity to which the logo belongs), then the entry below on purely decorative images applies. If the logo is actually being discussed, then it is being used as a phrase or paragraph (the description of the logo) with an alternative graphical representation (the logo itself), and the first entry above applies.

In the following snippets, all four of the above cases are present. First, we see a logo used to represent a company:

```html
<h1><img src="XYZ.gif" alt="The XYZ company" /></h1>
```

Next, we see a paragraph which uses a logo right next to the company name, and so doesn't have any alternative text:

```html
<article>
<h2>News</h2>
<p>We have recently been looking at buying the <img src="alpha.gif" alt=""/> ABΓ company, a small Greek company specializing in our type of product.</p>
</article>
```

In this third snippet, we have a logo being used in an aside, as part of the larger article discussing the acquisition:

```html
<aside><p><img src="alpha-large.gif" alt=""/></p></aside>
<p>The ABΓ company has had a good quarter, and our pie chart studies of their accounts suggest a much bigger blue slice than its green and orange slices, which is always a good sign.</p>
```
Sometimes, an image just consists of text, and the purpose of the image is not to highlight the actual typographic effects used to render the text, but just to convey the text itself. In such cases, the `alt` attribute must be present but must consist of the same text as written in the image itself.

When an image is used to represent a character that cannot otherwise be represented in Unicode, for example gaiji, itaiji, or new characters such as novel currency symbols, the alternative text should be a more conventional way of writing the same thing, e.g. using the phonetic hiragana or katakana to give the character's pronunciation.

An image should not be used if characters would serve an identical purpose. Only when the text cannot be directly represented using...
text, e.g., because of decorations or because there is no appropriate character (as in the case of gaiji), would an image be appropriate.

Note

If an author is tempted to use an image because their default system font does not support a given character, then Web Fonts are a better solution than images.

4.8.4.4.6 A graphical representation of some of the surrounding text

In many cases, the image is actually just supplementary, and its presence merely reinforces the surrounding text. In these cases, the alt attribute must be present but its value must be the empty string.

In general, an image falls into this category if removing the image doesn't make the page any less useful, but including the image makes it a lot easier for users of visual browsers to understand the concept.

Example

A flowchart that repeats the previous paragraph in graphical form:

```html
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using document.write(), passes data to the Tokenizer.</p>
<p><img src="images/parsing-model-overview.svg" alt=""></p>

In these cases, it would be wrong to include alternative text that consists of just a caption. If a caption is to be included, then either the title attribute can be used, or the figure and figcaption elements can be used. In the latter case, the image would in fact be a phrase or paragraph with an alternative graphical representation, and would thus require alternative text.

<!-- This is WRONG. Do not do this. Instead, do what the above examples do. -->

```html
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using document.write(), passes data to the Tokenizer.</p>
<p><img src="images/parsing-model-overview.svg" alt="title="Flowchart representation of the parsing model.""></p>

<!-- Using the title=" attribute -->

```html
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using document.write(), passes data to the Tokenizer.</p>
<p><img src="images/parsing-model-overview.svg" alt="title="Flowchart representation of the parsing model.""></p>

<!-- Using <figure> and <figcaption> -->

```html
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using document.write(), passes data to the Tokenizer.</p>
<figure>
<img src="images/parsing-model-overview.svg" alt="The Network leads to the Input Stream Preprocessor, which leads to the Tokenizer, which leads to the Tree Construction stage. The Tree Construction stage leads to two items. The first is Script Execution, which leads via document.write() back to the Tokenizer. The second item from which Tree Construction leads is the DOM. The DOM is related to the Script Execution.">
<figcaption>Flowchart representation of the parsing model.</figcaption>
</figure>

```html
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution.</p>
```
Sometimes, an image is not critical to the content, but is nonetheless neither purely decorative nor entirely redundant with the text. In these cases, the `alt` attribute must be present, and its value should either be the empty string, or a textual representation of the information that the image conveys. If the image has a caption giving the image's title, then the `alt` attribute's value must not be empty (as that would be quite confusing for non-visual readers).

A graph that repeats the previous paragraph in graphical form:

```
<p>According to a study covering several billion pages, about 62% of documents on the Web in 2007 triggered the Quirks rendering mode of Web browsers, about 30% triggered the Almost Standards mode, and about 9% triggered the Standards mode.</p>
```

4.8.4.4.7 Ancillary images

Sometimes, an image is not critical to the content, but is nonetheless neither purely decorative nor entirely redundant with the text. In these cases, the `alt` attribute must be present, and its value should either be the empty string, or a textual representation of the information that the image conveys. If the image has a caption giving the image's title, then the `alt` attribute's value must not be empty (as that would be quite confusing for non-visual readers).

Consider a news article about a political figure, in which the individual's face was shown in an image that, through a style sheet, is floated to the right. The image is not purely decorative, as it is relevant to the story. The image is not entirely redundant with the story either, as it shows what the politician looks like. Whether any alternative text need be provided is an authoring decision, in part influenced by whether the image colors the interpretation of the prose.

In this first variant, the image is shown without context, and no alternative text is provided:

```
<p><img src="alexsalmond.jpeg" alt=""> Ahead of today's referendum, the First Minister of Scotland, Alex Salmond, wrote an open letter to all registered voters. In it, he admitted that all countries make mistakes.</p>
```

If the picture is just a face, there might be no value in describing it. It's of no interest to the reader whether the individual has red hair or blond hair, whether the individual has white skin or black skin, whether the individual has one eye or two eyes.

However, if the picture is more dynamic, for instance showing the politician as angry, or particularly happy, or devastated, some alternative text would be useful in setting the tone of the article, a tone that might otherwise be missed:

```
<p><img src="alexsalmond.jpeg" alt="Alex Salmond is sad."> Ahead of today's referendum, the First Minister of Scotland, Alex Salmond, wrote an open letter to all registered voters. In it, he admitted that all countries make mistakes.</p>

<p><img src="alexsalmond.jpeg" alt="Alex Salmond is ecstatic!"> Ahead of today's referendum, the First Minister of Scotland, Alex Salmond, wrote an open letter to all registered voters. In it, he admitted that all countries make mistakes.</p>
```

Whether the individual was "sad" or "ecstatic" makes a difference to how the rest of the paragraph is to be interpreted: is he likely saying that he is resigned to the populace making a bad choice in the upcoming referendum, or is he saying that the election was a mistake but the likely turnout will make it irrelevant? The interpretation varies based on the image.
If the image has a caption, then including alternative text avoids leaving the non-visual user confused as to what the caption refers to.

```html
<p>Ahead of today's referendum, the First Minister of Scotland, Alex Salmond, wrote an open letter to all registered voters. In it, he admitted that all countries make mistakes.</p>
</figure>
```

### 4.8.4.4.8 A purely decorative image that doesn't add any information

If an image is decorative but isn't especially page-specific — for example an image that forms part of a site-wide design scheme — the image should be specified in the site's CSS, not in the markup of the document.

However, a decorative image that isn't discussed by the surrounding text but still has some relevance can be included in a page using the `img` element. Such images are decorative, but still form part of the content. In these cases, the `alt` attribute must be present but its value must be the empty string.

#### Example

Examples where the image is purely decorative despite being relevant would include things like a photo of the Black Rock City landscape in a blog post about an event at Burning Man, or an image of a painting inspired by a poem, on a page reciting that poem. The following snippet shows an example of the latter case (only the first verse is included in this snippet):

```html
<h1>The Lady of Shalott</h1>
<p><img src="shalott.jpeg" alt=""></p>
<p>On either side the river lie
Long fields of barley and of rye,
That clothe the wold and meet the sky;
And through the field the road run by
To many-tower'd Camelot;
And up and down the people go,
Gazing where the lilies blow
Round an island there below,
The island of Shalott.</p>
```

### 4.8.4.4.9 A group of images that form a single larger picture with no links

When a picture has been sliced into smaller image files that are then displayed together to form the complete picture again, one of the images must have its `alt` attribute set as per the relevant rules that would be appropriate for the picture as a whole, and then all the remaining images must have their `alt` attribute set to the empty string.

#### Example

In the following example, a picture representing a company logo for XYZ Corp has been split into two pieces, the first containing the letters "XYZ" and the second with the word "Corp". The alternative text ("XYZ Corp") is all in the first image.

```html
<h1><img src="logo1.png" alt="XYZ Corp"><img src="logo2.png" alt=""></h1>
```
In the following example, a rating is shown as three filled stars and two empty stars. While the alternative text could have been "★★★☆☆", the author has instead decided to more helpfully give the rating in the form "3 out of 5". That is the alternative text of the first image, and the rest have blank alternative text.

```html
<p>Rating: <meter max=5 value=3><img src="1" alt="3 out of 5"/>
<img src="1" alt=""/><img src="1" alt=""/></meter></p>
```

### 4.8.4.4.10 A group of images that form a single larger picture with links

Generally, image maps should be used instead of slicing an image for links.

However, if an image is indeed sliced and any of the components of the sliced picture are the sole contents of links, then one image per link must have alternative text in its alt attribute representing the purpose of the link.

**Example**

In the following example, a picture representing the flying spaghetti monster emblem, with each of the left noodly appendages and the right noodly appendages in different images, so that the user can pick the left side or the right side in an adventure.

```html
<h1>The Church</h1>
<p>You come across a flying spaghetti monster. Which side of His Noodliness do you wish to reach out for?</p>
<a href="?go=left"><img src="fsm-left.png" alt="Left side. "></a>
<img src="fsm-middle.png" alt=""/>
<a href="?go=right"><img src="fsm-right.png" alt="Right side."></a>
```

### 4.8.4.4.11 A key part of the content

In some cases, the image is a critical part of the content. This could be the case, for instance, on a page that is part of a photo gallery. The image is the whole point of the page containing it.

How to provide alternative text for an image that is a key part of the content depends on the image's provenance.

**The general case**

When it is possible for detailed alternative text to be provided, for example if the image is part of a series of screenshots in a magazine review, or part of a comic strip, or is a photograph in a blog entry about that photograph, text that can serve as a substitute for the image must be given as the contents of the alt attribute.

**Example**

A screenshot in a gallery of screenshots for a new OS, with some alternative text:

```html
<figure>
<img src="KDE%20Light%20desktop.png" alt="The desktop is blue, with icons along the left hand side in two columns, reading System, Home, K-Mail, etc. A window is open showing that menus wrap to a second line if they cannot fit in the window. The window has a list of icons along the top, with an address bar below it, a list of icons for tabs along the left edge, a status bar on the bottom, and two panes in the middle. The desktop has a bar at the bottom of the screen with a few buttons, a pager, a list of open applications, and a clock.">
<figcaption>Screenshot of a KDE desktop.</figcaption>
</figure>
```
Images that defy a complete description

In certain cases, the nature of the image might be such that providing thorough alternative text is impractical. For example, the image could be indistinct, or could be a complex fractal, or could be a detailed topographical map.

In these cases, the alt attribute must contain some suitable alternative text, but it may be somewhat brief.

Example

Sometimes there simply is no text that can do justice to an image. For example, there is little that can be said to usefully describe a Rorschach inkblot test. However, a description, even if brief, is still better than nothing:

```html
<figure>
  <img src="/commons/a/a7/Rorschach1.jpg" alt="A shape with left-right symmetry with indistinct edges, with a small gap in the center, two larger gaps offset slightly from the center, with two similar gaps under them. The outline is wider in the top half than the bottom half, with the sides extending upwards higher than the center, and the center extending below the sides."/>
  <figcaption>A black outline of the first of the ten cards in the Rorschach inkblot test.</figcaption>
</figure>
```

Note that the following would be a very bad use of alternative text:

```html
<!-- This example is wrong. Do not copy it. -->
<figure>
  <img src="/commons/a/a7/Rorschach1.jpg" alt="A black outline of the first of the ten cards in the Rorschach inkblot test."/>
  <figcaption>A black outline of the first of the ten cards in the Rorschach inkblot test.</figcaption>
</figure>
```

Including the caption in the alternative text like this isn't useful because it effectively duplicates the caption for users who don't have images, taunting them twice yet not helping them any more than if they had only read or heard the caption once.

Example

Another example of an image that defies full description is a fractal, which, by definition, is infinite in detail.

The following example shows one possible way of providing alternative text for the full view of an image of the Mandelbrot set.

```html
<img src="ms1.jpeg" alt="The Mandelbrot set appears as a cardioid with its cusp on the real axis in the positive direction, with a smaller bulb aligned along the same center line, touching it in the negative direction, and with these two shapes being surrounded by smaller bulbs of various sizes."/>
```
In some unfortunate cases, there might be no alternative text available at all, either because the image is obtained in some automated fashion without any associated alternative text (e.g. a Webcam), or because the page is being generated by a script using user-provided images where the user did not provide suitable or usable alternative text (e.g. photograph sharing sites), or because the author does not themself know what the images represent (e.g. a blind photographer sharing an image on their blog).

In such cases, the `alt` attribute may be omitted, but one of the following conditions must be met as well:

- The `img` element is in a `figure` element that contains a `figcaption` element that contains content other than `inter-element whitespace`, and, ignoring the `figcaption` element and its descendants, the `figure` element has no `flow content` descendants other than `inter-element whitespace` and the `img` element.

- The `title` attribute is present and has a non-empty value.

Such cases are to be kept to an absolute minimum. If there is even the slightest possibility of the author having the ability to provide real alternative text, then it would not be acceptable to omit the `alt` attribute.

A photo on a photo-sharing site, if the site received the image with no metadata other than the caption, could be marked up as follows:

```html
<figure>
  <img src="1100670787_6a7c664aef.jpg">
  <figcaption>Bubbles traveled everywhere with us.</figcaption>
</figure>
```

It would be better, however, if a detailed description of the important parts of the image obtained from the user and included on the page.

A blind user's blog in which a photo taken by the user is shown. Initially, the user might not have any idea what the photo they took shows:
I took a photo.

I went out today and took a photo!

Eventually though, the user might obtain a description of the image from their friends and could then include alternative text:

I took a photo.

I went out today and took a photo!

A photograph taken blindly from my front porch.

A photograph taken blindly from my front porch.

Eventually though, the user might obtain a description of the image from their friends and could then include alternative text:

I took a photo.

I went out today and took a photo!

The photograph shows my squirrel feeder hanging from the edge of my roof. It is half full, but there are no squirrels around. In the background, out-of-focus trees fill the shot. The feeder is made of wood with a metal grate, and it contains peanuts. The edge of the roof is wooden too, and is painted white with light blue streaks.

A photograph taken blindly from my front porch.

Sometimes the entire point of the image is that a textual description is not available, and the user is to provide the description. For instance, the point of a CAPTCHA image is to see if the user can literally read the graphic. Here is one way to mark up a CAPTCHA (note the title attribute):

What does this image say?

(If you cannot see the image, you can use an audio test instead.)

Another example would be software that displays images and asks for alternative text precisely for the purpose of then writing a page with correct alternative text. Such a page could have a table of images, like this:

<table>
<thead>
<tr>
<th>Image</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="2421.png" alt="Image" /></td>
<td>Image 640 by 100, filename 'banner.gif'</td>
</tr>
<tr>
<td><img src="alt2421" alt="Image" /></td>
<td></td>
</tr>
<tr>
<td><img src="2422.png" alt="Image" /></td>
<td>Image 200 by 480, filename 'ad3.gif'</td>
</tr>
<tr>
<td><img src="alt2422" alt="Image" /></td>
<td></td>
</tr>
</tbody>
</table>

Notice that even in this example, as much useful information as possible is still included in the title attribute.

**Example**

Sometimes the entire point of the image is that a textual description is not available, and the user is to provide the description. For instance, the point of a CAPTCHA image is to see if the user can literally read the graphic. Here is one way to mark up a CAPTCHA (note the title attribute):

What does this image say?

(If you cannot see the image, you can use an audio test instead.)

Another example would be software that displays images and asks for alternative text precisely for the purpose of then writing a page with correct alternative text. Such a page could have a table of images, like this:

<table>
<thead>
<tr>
<th>Image</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="2421.png" alt="Image" /></td>
<td>Image 640 by 100, filename 'banner.gif'</td>
</tr>
<tr>
<td><img src="alt2421" alt="Image" /></td>
<td></td>
</tr>
<tr>
<td><img src="2422.png" alt="Image" /></td>
<td>Image 200 by 480, filename 'ad3.gif'</td>
</tr>
<tr>
<td><img src="alt2422" alt="Image" /></td>
<td></td>
</tr>
</tbody>
</table>

Notice that even in this example, as much useful information as possible is still included in the title attribute.

**Note**

Since some users cannot use images at all (e.g. because they have a very slow connection, or because they are using a text-only browser, or because they are listening to the page being read out by a hands-free automobile voice Web browser, or simply because they are blind), the alt attribute is only allowed to be omitted rather than being provided with replacement text when no alternative text is available and none can be made available, as in the above examples. Lack of effort from the part of the author is not an acceptable reason for omitting the alt attribute.
Generally authors should avoid using `<img>` elements for purposes other than showing images.

If an `<img>` element is being used for purposes other than showing an image, e.g. as part of a service to count page views, then the `alt` attribute must be the empty string.

In such cases, the `width` and `height` attributes should both be set to zero.

When an image is included in a private communication (such as an HTML e-mail) aimed at a specific person who is known to be able to view images, the `alt` attribute may be omitted. However, even in such cases authors are strongly urged to include alternative text (as appropriate according to the kind of image involved, as described in the above entries), so that the e-mail is still usable should the user use a mail client that does not support images, or should the document be forwarded on to other users whose abilities might not include easily seeing images.

Markup generators (such as WYSIWYG authoring tools) should, wherever possible, obtain alternative text from their users. However, it is recognized that in many cases, this will not be possible.

For images that are the sole contents of links, markup generators should examine the link target to determine the title of the target, or the URL of the target, and use information obtained in this manner as the alternative text.

For images that have captions, markup generators should use the `<figure>` and `<figcaption>` elements, or the `title` attribute, to provide the image's caption.

As a last resort, implementers should either set the `alt` attribute to the empty string, under the assumption that the image is a purely decorative image that doesn't add any information but is still specific to the surrounding content, or omit the `alt` attribute altogether, under the assumption that the image is a key part of the content.

Markup generators may specify a `generator-unable-to-provide-required-alt` attribute on `<img>` elements for which they have been unable to obtain alternative text and for which they have therefore omitted the `alt` attribute. The value of this attribute must be the empty string. Documents containing such attributes are not conforming, but conformance checkers will silently ignore this error.

This is intended to avoid markup generators from being pressured into replacing the error of omitting the `alt` attribute with the even more egregious error of providing phony alternative text, because state-of-the-art automated conformance checkers cannot distinguish phony alternative text from correct alternative text.

Markup generators should generally avoid using the image's own file name as the alternative text. Similarly, markup generators should avoid generating alternative text from any content that will be equally available to presentation user agents (e.g. Web browsers).

This is because once a page is generated, it will typically not be updated, whereas the browsers that later read the page can be updated by the user, therefore the browser is likely to have more up-to-date and finely-tuned heuristics than the markup generator did when generating the page.

A conformance checker must report the lack of an `alt` attribute as an error unless one of the conditions listed below applies:
• The `img` element is in a `figure` element that satisfies the conditions described above.

• The `img` element has a `title` attribute with a value that is not the empty string (also as described above).

• The conformance checker has been configured to assume that the document is an e-mail or document intended for a specific person who is known to be able to view images.

• The `img` element has a (non-conforming) `generator-unable-to-provide-required-alt` attribute whose value is the empty string. A conformance checker that is not reporting the lack of an `alt` attribute as an error must also not report the presence of the empty `generator-unable-to-provide-required-alt` attribute as an error. (This case does not represent a case where the document is conforming, only that the generator could not determine appropriate alternative text — validators are not required to show an error in this case, because such an error might encourage markup generators to include bogus alternative text purely in an attempt to silence validators. Naturally, conformance checkers may report the lack of an `alt` attribute as an error even in the presence of the `generator-unable-to-provide-required-alt` attribute; for example, there could be a user option to report all conformance errors even those that might be the more or less inevitable result of using a markup generator.)

4.8.5 The `iframe` element

Categories:
- Flow content
- Phrasing content
- Embedded content
- Interactive content
- Palpable content

Contexts in which this element can be used:
Where `embedded content` is expected.

Content model:
Nothing.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes:
  - `src` — Address of the resource
  - `srcdoc` — A document to render in the `iframe`
  - `name` — Name of nested browsing context
  - `sandbox` — Security rules for nested content
  - `allow` — Feature policy to be applied to the `iframe`'s contents
  - `allowfullscreen` — Whether to allow the `iframe`'s contents to use `requestFullscreen()`
  - `allowpaymentrequest` — Whether the `iframe`'s contents are allowed to use the `PaymentRequest` interface to make payment requests
  - `allowusermedia` — Whether to allow the `iframe`'s contents to use `getUserMedia()`
  - `width` — Horizontal dimension
  - `height` — Vertical dimension
  - `referrerpolicy` — Referrer policy for fetches initiated by the element

DOM interface:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLIFrameElement : HTMLElement {
    [CEReactions] attribute USVString src;
    [CEReactions] attribute DOMString srcdoc;
    [CEReactions] attribute DOMString name;
    [SameObject, PutForwards={value}] readonly attribute DOMTokenList sandbox;
    [CEReactions] attribute DOMString allow;
    [CEReactions] attribute boolean allowfullscreen;
    [CEReactions] attribute boolean allowpaymentrequest;
    [CEReactions] attribute boolean allowusermedia;
    [CEReactions] attribute DOMString allowpaymentrequest;
} HTMLIFrameElement
```
The `iframe` element represents a nested browsing context.

The `src` attribute gives the URL of a page that the nested browsing context is to contain. The attribute, if present, must be a valid non-empty URL potentially surrounded by spaces. If the `itemprop` attribute is specified on an `iframe` element, then the `src` attribute must also be specified.

The `srcdoc` attribute gives the content of the page that the nested browsing context is to contain. The value of the attribute is the source of an `iframe` `srcdoc` document.

The `srcdoc` attribute, if present, must have a value using the HTML syntax that consists of the following syntactic components, in the given order:

1. Any number of comments and ASCII whitespace.
2. Optionally, a DOCTYPE.
3. Any number of comments and ASCII whitespace.
4. The document element, in the form of an `html` element.
5. Any number of comments and ASCII whitespace.

Note: The above requirements apply in XML documents as well.

Example

Here a blog uses the `srcdoc` attribute in conjunction with the `sandbox` attribute described below to provide users of user agents that support this feature with an extra layer of protection from script injection in the blog post comments:

```html
<article>
  <h1>I got my own magazine!</h1>
  <p>After much effort, I've finally found a publisher, and so now I have my own magazine! Isn't that awesome?! The first issue will come out in September, and we have articles about getting food, and about getting in boxes, it's going to be great!</p>
  <footer>
    Written by <a href="/users/cap">cap</a>, 1 hour ago.
  </footer>
</article>

<article>
  Thirteen minutes ago, <a href="/users/ch">ch</a> wrote: </article>
  <iframe sandbox srcdoc="<p>did you get a cover picture yet?</p>"></iframe>
</article>

<article>
  Nine minutes ago, <a href="/users/cap">cap</a> wrote: </article>
  <iframe sandbox srcdoc="<p>Yeah, you can see it <a href="/gallery?mode=cover&amp;amp;page=1">in my gallery</a>.</p>"></iframe>
</article>

<article>
  Five minutes ago, <a href="/users/ch">ch</a> wrote: </article>
  <iframe sandbox srcdoc="<p>hey that's earl's table.</p>"></iframe>
```
<p>you should get earl&amp;amp;amp;me on the next cover."</p></iframe>

Notice the way that quotes have to be escaped (otherwise the srcdoc attribute would end prematurely), and the way raw ampersands (e.g. in URLs or in prose) mentioned in the sandboxed content have to be doubly escaped — once so that the ampersand is preserved when originally parsing the srcdoc attribute, and once more to prevent the ampersand from being misinterpreted when parsing the sandboxed content.

Furthermore, notice that since the DOCTYPE is optional in iframe srcdoc documents, and the html, head, and body elements have optional start and end tags, and the title element is also optional in iframe srcdoc documents, the markup in a srcdoc attribute can be relatively succinct despite representing an entire document, since only the contents of the body element need appear literally in the syntax. The other elements are still present, but only by implication.

**Note**

In the HTML syntax, authors need only remember to use U+0022 QUOTATION MARK characters (") to wrap the attribute contents and then to escape all U+0026 AMPERSAND (&) and U+003C LESS-THAN SIGN characters (<) characters, and to specify the sandbox attribute, to ensure safe embedding of content. (And remember to escape ampersands before quotation marks, to ensure quotation marks become &quot; and not &amp;quot;.)

**Note**

In XML the U+003C LESS-THAN SIGN character (<) needs to be escaped as well. In order to prevent attribute-value normalization, some of XML's whitespace characters — specifically U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), and U+000D CARRIAGE RETURN (CR) — also need to be escaped. [XML]

**Note**

If the src and srcdoc attributes are both specified together, the srcdoc attribute takes priority. This allows authors to provide a fallback URL for legacy user agents that do not support the srcdoc attribute.

When an iframe element is inserted into a document that has a browsing context, the user agent must create a new browsing context, set the element's nested browsing context to the newly-created browsing context, and then process the iframe attributes for the "first time".

When an iframe element is removed from a document, the user agent must discard the element's nested browsing context, if it is not null, and then set the element's nested browsing context to null.

**Note**

This happens without any unload events firing (the nested browsing context and its Document are discarded, not unloaded).

Whenever an iframe element with a non-null nested browsing context has its srcdoc attribute set, changed, or removed, the user agent must process the iframe attributes.

Similarly, whenever an iframe element with a non-null nested browsing context has no srcdoc attribute specified has its src attribute set, changed, or removed, the user agent must process the iframe attributes.

When the user agent is to process the iframe attributes, it must run the first appropriate steps from the following list:

1. **If the srcdoc attribute is specified**
   - Navigate the element's nested browsing context to a new response whose url list consists of about:srdoc, header list consists of Content-Type, text/html, body is the value of the attribute, CSP list is the CSP list of the iframe element's node document, HTTPS state is the HTTPS state of the iframe element's node document.
   - The resulting Document must be considered an iframe srdoc document.

2. **Otherwise, if the element has no src attribute specified, and the user agent is processing the iframe's attributes for the "first time”**
   - Queue a task to run the iframe load event steps.
The task source[^693] for this task[^693] is the DOM manipulation task source[^687].

Otherwise

Run the otherwise steps for iframe or frame elements[^350].

The otherwise steps for iframe or frame elements are as follows:

1. If the element has no `src` attribute specified, or its value is the empty string, let `url` be the URL "about:blank"[^651]. Otherwise, `parse[^686]` the value of the `src` attribute, relative to the element's node document.

   If that is not successful, then let `url` be the URL "about:blank"[^651]. Otherwise, let `url` be the resulting URL record[^686].

2. If there exists an ancestor browsing context[^782] whose active document[^780]’s URL, ignoring fragments, is equal to `url`, then return.

3. Let `resource` be a new request whose `url` is `url` and whose referrer policy is the current state of the element's referer policy[^354] content attribute.

Any navigation[^925] required of the user agent in the process the iframe attributes[^349] algorithm must use the iframe[^247] element's node document's browsing context[^786] as the source browsing context[^825].

Furthermore, if the active document[^780] of the element's nested browsing context[^781] before such a navigation[^925] was not completely loaded[^1107] at the time of the new navigation[^925], then the navigation[^925] must be completed with replacement enabled[^687].

Similarly, if the nested browsing context[^781]’s session history[^989] contained only one Document[^781] when the process the iframe attributes[^349] algorithm was invoked, and that was the about:blank[^651] Document[^781] created when the nested browsing context[^781] was created, then any navigation[^825] required of the user agent in that algorithm must be completed with replacement enabled[^987].

When a Document[^781] in an iframe[^347] is marked as completely loaded[^1107], the user agent must run the iframe load event steps[^350].

Note

A load[^1217] event is also fired at the iframe[^347] element when it is created if no other data is loaded in it.

Each Document[^781] has an iframe load in progress flag and a mute iframe load flag. When a Document[^781] is created, these flags must be unset for that Document[^781].

The iframe load event steps are as follows:

1. Let child document be the active document[^780] of the iframe[^347] element's nested browsing context[^781] (which cannot be null at this point).

2. If child document has its mute iframe load[^650] flag set, return.

⚠️ Warning!

This, in conjunction with scripting, can be used to probe the URL space of the local network’s HTTP servers. User agents may implement cross-origin[^689] access control policies that are stricter than those described above to mitigate this attack, but unfortunately such policies are typically not compatible with existing Web content.

When the iframe[^347]’s browsing context[^780]’s active document[^780] is not ready for post-load tasks[^1107], and when anything in the iframe[^347] is delaying the load event[^1107] of the iframe[^347]’s browsing context[^780]’s active document[^780], and when the iframe[^347]’s browsing context[^780] is in the delaying load events mode[^789], the iframe[^347] must delay the load event[^1107] of its document.

Note

If, during the handling of the load[^1217] event, the browsing context[^780] in the iframe[^347] is again navigated[^925], that will further delay the load event[^1107].
If, when the element is created, the `srcdoc` attribute is not set, and the `src` attribute is either also not set or set but its value cannot be parsed, the browsing context will remain at the initial `about:blank` page.

If the user navigates away from this page, the `iframe`'s corresponding `WindowProxy` object will proxy new `Window` objects for new `Document` objects, but the `src` attribute will not change.

The `name` attribute, if present, must be a valid browsing context name. The given value is used to name the nested browsing context. When the browsing context is created, if the attribute is present, the `browsing context name` must be set to the value of this attribute; otherwise, the `browsing context name` must be set to the empty string.

Whenever the `name` attribute is set, the nested `browsing context`'s `name` must be changed to the new value. If the attribute is removed, the `browsing context name` must be set to the empty string.

The `sandbox` attribute, when specified, enables a set of extra restrictions on any content hosted by the `iframe`. Its value must be an unordered set of unique space-separated tokens that are ASCII case-insensitive. The allowed values are `allow-forms`, `allow-modals`, `allow-orientation-lock`, `allow-pointer-lock`, `allow-popups`, `allow-popups-to-escape-sandbox`, `allow-presentation`, `allow-same-origin`, `allow-scripts`, `allow-top-navigation`, and `allow-top-navigation-by-user-activation`.

When the attribute is set, the content is treated as being from a unique origin, forms, scripts, and various potentially annoying APIs are disabled, links are prevented from targeting other `browsing contexts`, and plugins are secured. The `allow-same-origin` keyword causes the content to be treated from its real origin instead of forcing it into a unique origin; the `allow-top-navigation` keyword allows the content to `navigate` its `top-level browsing context`; the `allow-top-navigation-by-user-activation` keyword behaves similarly but only allows such `navigation` when triggered by user activation; and the `allow-forms`, `allow-modals`, `allow-orientation-lock`, `allow-pointer-lock`, `allow-popups`, `allow-presentation`, `allow-scripts`, `allow-top-navigation`, `allow-top-navigation-by-user-activation`, `allow-popups-to-escape-sandbox` keywords re-enable forms, modal dialogs, screen orientation lock, the pointer lock API, popups, the presentation API, scripts, and the creation of unsandboxed auxiliary browsing contexts respectively.

The `allow-top-navigation` and `allow-top-navigation-by-user-activation` keywords must not both be specified, as doing so is redundant; only `allow-top-navigation` will have an effect in such non-conformant markup.

### Warning!

**Setting both the `allow-scripts` and `allow-same-origin` keywords together when the embedded page has the same origin as the page containing the `iframe`** allows the embedded page to simply remove the `sandbox` attribute and then reload itself, effectively breaking out of the sandbox altogether.

### Warning!

These flags only take effect when the nested browsing context of the `iframe` is navigated. Removing them, or removing the entire `sandbox` attribute, has no effect on an already-loaded page.

### Warning!

Potentially hostile files should not be served from the same server as the file containing the `iframe` element. Sandboxing hostile content is of minimal help if an attacker can convince the user to just visit the hostile content directly, rather than in the `iframe`. To limit the damage that can be caused by hostile HTML content, it should be served from a separate dedicated domain. Using a different domain ensures that scripts in the files are unable to attack the site, even if the user is tricked into visiting those pages directly, without the protection of the `sandbox` attribute.

When an `iframe` element with a `sandbox` attribute has its `nested browsing context` created, and when an `iframe` element's `sandbox` attribute is set or changed while it has a `nested browsing context`, the user agent must parse the sandboxing directive using the attribute's value as the input and the `iframe` element's `nested browsing context`'s `iframe sandboxing flag set` as the output.

When an `iframe` element's `sandbox` attribute is removed while it has a non-null `nested browsing context`, the user agent must empty the `iframe` element's `nested browsing context`'s `iframe sandboxing flag set` as the output.
The **allow** attribute, when specified, determines the container policy that will be used when the **feature policy** for a Document in the **iframe**’s nested browsing context is initialized. Its value must be a serialized feature policy. 

```html
<iframe sandbox src="https://usercontent.example.net/getusercontent.cgi?id=12193"></iframe>
```

⚠ **Warning!**

It is important to use a separate domain so that if the attacker convinces the user to visit that page directly, the page doesn't run in the context of the site’s origin, which would make the user vulnerable to any attack found in the page.

In this example, some completely-unknown, potentially hostile, user-provided HTML content is embedded in a page. Because it is served from a separate domain, it is affected by all the normal cross-site restrictions. In addition, the embedded page has scripting disabled, plugins disabled, forms disabled, and it cannot navigate any frames or windows other than itself (or any frames or windows it itself embeds).

```html
<p>We're not scared of you! Here is your content, unedited:</p>
<iframe sandbox src="https://usercontent.example.net/getusercontent.cgi?id=12193"></iframe>
```

In this example, a gadget from another site is embedded. The gadget has scripting and forms enabled, and the origin sandbox restrictions are lifted, allowing the gadget to communicate with its originating server. The sandbox is still useful, however, as it disables plugins and popups, thus reducing the risk of the user being exposed to malware and other annoyances.

```html
<iframe sandbox="allow-same-origin allow-forms allow-scripts" src="https://maps.example.com/embedded.html"></iframe>
```

Example

Suppose a file A contained the following fragment:

```html
<iframe sandbox="allow-same-origin allow-forms" src=B"></iframe>
```

Suppose that file B contained an iframe also:

```html
<iframe sandbox="allow-scripts" src=C"></iframe>
```

Further, suppose that file C contained a link:

```html
<a href=D>Link</a>
```

For this example, suppose all the files were served as **text/html**.

Page C in this scenario has all the sandboxing flags set. Scripts are disabled, because the **iframe** in A has scripts disabled, and this overrides the **allow-scripts** keyword set on the **iframe** in B. Forms are also disabled, because the inner **iframe** (in B) does not have the **allow-forms** keyword set.

Suppose now that a script in A removes all the **sandbox** attributes in A and B. This would change nothing immediately. If the user clicked the link in C, loading page D into the **iframe** in B, page D would now act as if the **iframe** in B had the **allow-same-origin** and **allow-forms** keywords set, because that was the state of the nested browsing context in the **iframe** in A when page B was loaded.

Generally speaking, dynamically removing or changing the **sandbox** attribute is ill-advised, because it can make it quite hard to reason about what will be allowed and what will not.

The **allow** attribute, when specified, determines the container policy that will be used when the **feature policy** for a Document in the **iframe**’s nested browsing context is initialized. Its value must be a serialized feature policy. 

Example
In this example, an iframe is used to embed a map from an online navigation service. The allow attribute is used to enable the Geolocation API within the nested context.

```html
<iframe src="https://maps.example.com/" allow="geolocation"></iframe>
```

The allowfullscreen attribute is a boolean attribute. When specified, it indicates that Document objects in the iframe element's browsing context will be initialized with a feature policy which allows the "fullscreen" feature to be used from any origin. This is enforced by the Process feature policy attributes algorithm. [FEATUREPOLICY]

**Example**

Here, an iframe is used to embed a player from a video site. The allowfullscreen attribute is needed to enable the player to show its video full screen.

```html
<article>
<header>
<p><img src="/usericons/1627591962735"> Fred Flintstone</p>
<p><a href="/posts/3095182851" rel=bookmark>12:44</a> — <a href="#acl-3095182851">Private Post</a></p>
</header>
<p>Check out my new ride!</p>
<iframe src="https://video.example.com/embed?id=92469812" allowfullscreen></iframe>
</article>
```

The allowpaymentrequest attribute is a boolean attribute. When specified, it indicates that Document objects in the iframe element's browsing context will be initialized with a feature policy which allows the "payment" feature to be used to make payment requests from any origin. This is enforced by the Process feature policy attributes algorithm. [FEATUREPOLICY]

The allowusermedia attribute is a boolean attribute. When specified, it indicates that Document objects in the iframe element's browsing context will be initialized with a feature policy which allows the "camera" and "microphone" features to be used to call getUserMedia() from any origin. This is enforced by the Process feature policy attributes algorithm. [FEATUREPOLICY]

**Note**

None of these attributes, allow, allowfullscreen, allowpaymentrequest or allowusermedia, can grant access to a feature in a nested browsing context if the iframe element's node document is not already allowed to use that feature.

To determine whether a Document object document is allowed to use the policy-controlled-feature feature, run these steps:

1. If document has no browsing context, then return false.
2. If document's browsing context's active document is not document, then return false.
3. If the result of running Is feature enabled in document for origin on feature, document, and document's origin is "Enabled", then return true.
4. Return false.

⚠️ **Warning!**

Because they only influence the feature policy of the nested browsing context's active document, the allow, allowfullscreen, allowpaymentrequest and allowusermedia attributes only take effect when the nested browsing context of the iframe is navigated. Adding or removing them has no effect on an already-loaded document.

The iframe element supports dimension attributes for cases where the embedded content has specific dimensions (e.g. ad units have well-defined dimensions).

An iframe element never has fallback content, as it will always create a nested browsing context, regardless of whether the specified initial contents are successfully used.
The `referrerPolicy` attribute is a `referrer policy attribute`. Its purpose is to set the `referrer policy` used when processing the `iframe` attributes.

Descendants of `iframe` elements represent nothing. (In legacy user agents that do not support `iframe` elements, the contents would be parsed as markup that could act as fallback content.)

**Note**

The HTML parser treats markup inside `iframe` elements as text.

The IDL attributes `src`, `srcdoc`, `name`, `sandbox`, and `allow` must reflect the respective content attributes of the same name.

The supported tokens for `sandbox`'s `DOMTokenList` are the allowed values defined in the `sandbox` attribute and supported by the user agent.

The `allowFullScreen` IDL attribute must reflect the `allowfullscreen` content attribute.

The `allowPaymentRequest` IDL attribute must reflect the `allowpaymentrequest` content attribute.

The `allowUserMedia` IDL attribute must reflect the `allowusermedia` content attribute.

The `referrerPolicy` IDL attribute must reflect the `referrerpolicy` content attribute, limited to only known values.

The `contentDocument` IDL attribute, on getting, must return the `iframe` element's content document.

The `contentWindow` IDL attribute must return the `WindowProxy` object of the `iframe` element's nested browsing context, if its nested browsing context is non-null, or null otherwise.

**Example**

Here is an example of a page using an `iframe` to include advertising from an advertising broker:

```html
<iframe src="https://ads.example.com/?customerid=923513721&amp;format=banner" width="468" height="60"></iframe>
```

4.8.6 The `embed` element

**Categories**:

- Flow content
- Phrasing content
- Embedded content
- Interactive content
- Palpable content

**Contexts in which this element can be used**:

Where `embedded content` is expected.

**Content model**:

- `Nothing`

**Tag omission in text/html**:

- No `end tag`

**Content attributes**:

- `Global attributes`
  - `src` — Address of the resource
  - `type` — Type of embedded resource
  - `width` — Horizontal dimension
  - `height` — Vertical dimension
  - Any other attribute that has no namespace (see prose).
The **embed** element provides an integration point for an external (typically non-HTML) application or interactive content.

The **src** attribute gives the URL of the resource being embedded. The attribute, if present, must contain a valid non-empty URL potentially surrounded by spaces.

If the **itemprop** attribute is specified on an **embed** element, then the **src** attribute must also be specified.

The **type** attribute, if present, gives the MIME type by which the plugin to instantiate is selected. The value must be a valid MIME type string. If both the **type** and the **src** attribute are present, then the **type** attribute must specify the same type as the explicit Content-Type metadata of the resource given by the **src** attribute.

While any of the following conditions are occurring, any **plugin** instantiated for the element must be removed, and the **embed** element **represents** nothing:

- The element has neither a **src** attribute nor a **type** attribute.
- The element has a [media element] ancestor.
- The element has an ancestor [object] element that is not showing its fallback content.

An **embed** element is said to be **potentially active** when the following conditions are all met simultaneously:

- The element is in a document or was in a document the last time the event loop reached step 1.
- The element's [node document] is fully active.
- The element has either a **src** attribute set or a **type** attribute set (or both).
- The element's **src** attribute is absent or its value is not the empty string.
- The element is not a descendant of a [media element].
- The element is not a descendant of an [object] element that is not showing its fallback content.
- The element is being rendered, or was being rendered, the last time the event loop reached step 1.

Whenever an **embed** element that was not potentially active becomes potentially active, and whenever a potentially active **embed** element that is remaining potentially active, and has its **src** attribute set, changed, or removed or its **type** attribute set, changed, or removed, the user agent must queue a task using the embed task source to run the embed element setup steps.

The **embed** element setup steps are as follows:

1. If another task has since been queued to run the embed element setup steps for this element, then return.
2. If the Should element be blocked a priori by Content Security Policy? algorithm returns "Blocked" when executed on the element, then return. [CSP]

3. If the element has a **src** attribute set

   The user agent must parse the value of the element's **src** attribute, relative to the element's [node document]. If that is successful, the user agent should run these steps:

   1. Let request be a new request whose **url** is the resulting URL record, **client** is the element's [node document]'s [Window]'s object's environment settings object, **destination** is "embed", credentials mode is "include", and whose use-URL-credentials flag is set.

   2. Fetch request.

   The task that is queued by the networking task source once the resource has been fetched must run the
following steps:

1. If another task has since been queued to run the embed element setup steps for this element, then return.

2. Determine the type of the content being embedded, as follows (stopping at the first substep that determines the type):
   
   1. If the element has a type attribute, and that attribute's value is a type that a plugin supports, then the value of the type attribute is the content's type.
   
   2. Otherwise, if applying the URL parser algorithm to the URL of the specified resource (after any redirects) results in a URL record whose path component matches a pattern that a plugin supports, then the content's type is the type that that plugin can handle.
   
   3. Otherwise, if the specified resource has explicit Content-Type metadata, then that is the content's type.
   
   4. Otherwise, the content has no type and there can be no appropriate plugin for it.

3. If the previous step determined that the content's type is image/svg+xml, then run the following substeps:
   
   1. If the embed element's nested browsing context is null, set the element's nested browsing context to a newly-created browsing context, and, if the element has a name attribute, set the browsing context name of the element's new nested browsing context to the value of this attribute.
   
   2. Navigate the nested browsing context to the fetched resource, with replacement enabled, and with the embed element's node document's browsing context as the source browsing context. (The src attribute of the embed element doesn't get updated if the browsing context gets further navigated to other locations.)
   
   3. The embed element now represents its nested browsing context.

4. Otherwise, find and instantiate an appropriate plugin based on the content's type, and hand that plugin the content of the resource, replacing any previously instantiated plugin for the element. The embed element now represents this plugin instance.

5. Once the resource or plugin has completely loaded, queue a task to fire an event named load at the element.

Whether the resource is fetched successfully or not (e.g. whether the response status was an ok status) must be ignored when determining the content's type and when handing the resource to the plugin.

Fetch the resource must delay the load event of the element's node document.

If the element has no src attribute set

The user agent should find and instantiate an appropriate plugin based on the content's type, and hand that plugin the content of the resource, replacing any previously instantiated plugin for the element. The embed element now represents this plugin instance.

Once the plugin is completely loaded, queue a task to fire an event named load at the element.

The embed element has no fallback content. If the user agent can't find a suitable plugin when attempting to find and instantiate one for the algorithm above, then the user agent must use a default plugin. This default could be as simple as saying "Unsupported Format".

Whenever an embed element that was potentially active stops being potentially active, any plugin that had been
When a plugin is to be instantiated but it cannot be secured and the sandboxed plugins browsing context flag is set on the embed element's node document's active sandboxing flag, then the user agent must not instantiate the plugin, and must instead render the embed element in a manner that conveys that the plugin was disabled. The user agent may offer the user the option to override the sandbox and instantiate the plugin anyway; if the user invokes such an option, the user agent must act as if the conditions above did not apply for the purposes of this element.

⚠ Warning! Plugins that cannot be secured are disabled in sandboxed browsing contexts because they might not honor the restrictions imposed by the sandbox (e.g. they might allow scripting even when scripting in the sandbox is disabled). User agents should convey the danger of overriding the sandbox to the user if an option to do so is provided.

When an embed element has a non-null nested browsing context: if the embed element's nested browsing context's active document is not ready for post-load tasks, and when anything is delaying the load event of the embed element's browsing context's active document, and when the embed element's browsing context is in the delaying load events mode, the embed must delay the load event of its document.

The task source for the tasks mentioned in this section is the DOM manipulation task source.

Any namespace-less attribute other than name, align, hspace, and vspace may be specified on the embed element, so long as its name is XML-compatible and contains no ASCII upper alphas. These attributes are then passed as parameters to the plugin.

Example

Here's a way to embed a resource that requires a proprietary plugin, like Flash:

```html
<embed src="catgame.swf"/>
```

If the user does not have the plugin (for example if the plugin vendor doesn't support the user's platform), then the user will be unable to use the resource.

To pass the plugin a parameter "quality" with the value "high", an attribute can be specified:

```html
<embed src="catgame.swf" quality="high"/>
```

This would be equivalent to the following, when using an object element instead:

```html
<object data="catgame.swf">
  <param name="quality" value="high"/>
</object>
```
4.8.7 The **object** element

**Categories**:
- Flow content
- Phrasing content
- Embedded content

If the element has a *usemap* attribute: Interactive content

**Listed and submittable form-associated element**

**Contexts in which this element can be used**:
Where embedded content is expected.

**Content model**:
Zero or more `param` elements, then, transparent.

**Tag omission in text/html**:
Neither tag is omissible.

**Content attributes**:
- **Global attributes**
  - `data` — Address of the resource
  - `type` — Type of embedded resource
  - `typemustmatch` — Whether the `type` attribute and the `Content-Type` value need to match for the resource to be used
  - `name` — Name of nested browsing context
  - `usemap` — Name of image map to use
  - `form` — Associates the control with a `form` element
  - `width` — Horizontal dimension
  - `height` — Vertical dimension

**DOM interface**:

```idl
define [Exposed=Window, HTMLConstructor] interface HTMLObjectElement : HTMLElement {
  [CEReactions] attribute USVString data;
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute boolean typemustmatch;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString useMap;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute DOMString width;
  [CEReactions] attribute DOMString height;
  readonly attribute Document? contentDocument;
  readonly attribute WindowProxy? contentWindow;
  Document? getSVGDocument();

  readonly attribute boolean willValidate;
  readonly attributeValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  void setCustomValidity(DOMString error);
};
```

Depending on the type of content instantiated by the `object` element, the node also supports other interfaces.

The `object` element can represent an external resource, which, depending on the type of the resource, will either be treated as an image, as a nested browsing context, or as an external resource to be processed by a plugin.

The `data` attribute, if present, specifies the URL of the resource. If present, the attribute must be a valid non-empty URL potentially surrounded by spaces.
Authors who reference resources from other origins that they do not trust are urged to use the typemustmatch attribute defined below. Without that attribute, it is possible in certain cases for an attacker on the remote host to use the plugin mechanism to run arbitrary scripts, even if the author has used features such as the Flash "allowScriptAccess" parameter.

The type attribute, if present, specifies the type of the resource. If present, the attribute must be a valid MIME type string.

At least one of either the data or type attribute must be present.

If the itemprop attribute is specified on an object element, then the data attribute must also be specified.

The typemustmatch attribute is a boolean attribute whose presence indicates that the resource specified by the data attribute is only to be used if the value of the type attribute and the Content-Type of the aforementioned resource match.

The typemustmatch attribute must not be specified unless both the data attribute and the type attribute are present.

The name attribute, if present, must be a valid browsing context name. The given value is used to name the nested browsing context, if applicable.

Whenever one of the following conditions occur:

- the element is created,
- the element is popped off the stack of open elements of an HTML parser or XML parser,
- the element is not on the stack of open elements of an HTML parser or XML parser, and it is either inserted into a document or removed from a document,
- the element's node document changes whether it is fully active,
- one of the element's ancestor object elements changes to or from showing its fallback content,
- the element's classid attribute is set, changed, or removed,
- the element's classid attribute is not present, and its data attribute is set, changed, or removed,
- neither the element's classid attribute nor its data attribute are present, and its type attribute is set, changed, or removed,
- the element changes from being rendered to not being rendered, or vice versa,

...the user agent must queue a task to run the following steps to (re)determine what the object element represents. This task being queued or actively running must delay the load event of the element's node document.

1. If the user has indicated a preference that this object element's fallback content be shown instead of the element's usual behavior, then jump to the step below labeled fallback.

   For example, a user could ask for the element's fallback content to be shown because that content uses a format that the user finds more accessible.

2. If the element has an ancestor media element, or has an ancestor object element that is not showing its fallback content, or if the element is not in a document that has a browsing context, or if the element's node document is not fully active, or if the element is still in the stack of open elements of an HTML parser or XML parser, or if the element is not being rendered, or if the Should element be blocked a priori by Content Security Policy? algorithm returns "Blocked" when executed on the element, then jump to the step below labeled fallback. [CSP]

3. If the classid attribute is present, and has a value that isn't the empty string, then: if the user agent can find a plugin suitable according to the value of the classid attribute, and either plugins aren't being sandboxed or that plugin can be secured, then that plugin should be used, and the value of the data attribute, if any, should be passed to the plugin. If no suitable plugin can be found, or if the plugin reports an error, jump to the step below labeled fallback.

4. If the data attribute is present and its value is not the empty string, then:
1. If the `type` attribute is present and its value is not a type that the user agent supports, and is not a type that the user agent can find a plugin for, then the user agent may jump to the step below labeled `fallback` without fetching the content to examine its real type.

2. Parse the URL specified by the `data` attribute, relative to the element's node document.

3. If that failed, fire an event named `error` at the element, then jump to the step below labeled `fallback`.

4. Let `request` be a new request whose `url` is the resulting URL record, `client` is the element's node document's `Window` object's `environment settings object`, `destination` is "object", `credentials mode` is "include", and whose `use-URL-credentials flag` is set.

5. Fetch `request`.

For the purposes of the `application cache` networking model, this fetch operation is not for a child browsing context (though it might end up being used for one after all, as defined below).

6. If the resource is not yet available (e.g. because the resource was not available in the cache, so that loading the resource required making a request over the network), then jump to the step below labeled `fallback`. The task that is queued by the networking task source once the resource has been fetched (defined next) has been run.

7. If the load failed (e.g. there was an HTTP 404 error, there was a DNS error), fire an event named `error` at the element, then jump to the step below labeled `fallback`.

8. Determine the resource type, as follows:

   1. Let the resource type be unknown.

   2. If the `object` element has a `type` attribute and a `typemustmatch` attribute, and the resource has associated Content-Type metadata, and the type specified in the resource's Content-Type metadata is an ASCII case-insensitive match for the value of the element's `type` attribute, then let resource type be that type and jump to the step below labeled `handler`.

   3. If the `object` element has a `typemustmatch` attribute, jump to the step below labeled `handler`.

   4. If the user agent is configured to strictly obey Content-Type headers for this resource, and the resource has associated Content-Type metadata, then let the resource type be the type specified in the resource's Content-Type metadata, and jump to the step below labeled `handler`.

   △ Warning!

   This can introduce a vulnerability, wherein a site is trying to embed a resource that uses a particular plugin, but the remote site overrides that and instead furnishes the user agent with a resource that triggers a different plugin with different security characteristics.

   5. If there is a `type` attribute present on the `object` element, and that attribute's value is not a type that the user agent supports, but it is a type that a plugin supports, then let the resource type be the type specified in that `type` attribute, and jump to the step below labeled `handler`.

6. Run the appropriate set of steps from the following list:

   - If the resource has associated Content-Type metadata

     1. Let `binary` be false.

     2. If the type specified in the resource's Content-Type metadata is "text/plain", and the result of applying the rules for distinguishing if a resource is text or binary to the resource is that the resource is not `text/plain`, then set `binary` to true.

     3. If the type specified in the resource's Content-Type metadata is "application/octet-stream", then set `binary` to true.

     4. If `binary` is false, then let the resource type be the type specified in the resource's
5. If there is a `type` attribute present on the `object` element, and its value is not `application/octet-stream`, then run the following steps:

   1. If the attribute's value is a type that a `plugin` supports, or the attribute's value is a type that starts with "image/" that is not also an XML MIME type, then let the `resource type` be the type specified in that `type` attribute.

   2. Jump to the step below labeled `handler`.

Otherwise, if the resource does not have associated Content-Type metadata.

   1. If there is a `type` attribute present on the `object` element, then let the tentative type be the type specified in that `type` attribute.

   2. If tentative type is not `application/octet-stream`, then let `resource type` be tentative type and jump to the step below labeled `handler`.

7. If applying the `URL parser` algorithm to the `URL` of the specified resource (after any redirects) results in a `URL record` whose `path` component matches a pattern that a `plugin` supports, then let `resource type` be the type that that plugin can handle.

Example

For example, a plugin might say that it can handle resources with `path` components that end with the four character string ".swf".

9. `Handler`: Handle the content as given by the first of the following cases that matches:

   → If the `resource type` is not a type that the user agent supports, but it is a type that a `plugin` supports

     If the `object` element's `nested browsing context` is non-null, then it must be `discarded` and then set to null.

     If plugins are being sandboxed and the plugin that supports `resource type` cannot be `secured`, jump to the step below labeled `fallback`.

   

   Otherwise, the user agent should use the plugin that supports `resource type` and pass the content of the resource to that `plugin`. If the `plugin` reports an error, then jump to the step below labeled `fallback`.

   → If the `resource type` is an XML MIME type, or if the `resource type` does not start with "image/

     If the `object` element's `nested browsing context` is null, set the element's `nested browsing context` to a newly-created `browsing context`.

The `object` element must be associated with a newly created `nested browsing context`, if it does not already have one.

   If the `URL` of the given resource is not `about:blank`, the element's `nested browsing context` must then be navigated to that resource, with `replacement enabled`, and with the `object` element's `node document's browsing context` as the `source browsing context`. (The `data` attribute of the `object` element doesn't get updated if the browsing context gets further navigated to other locations.)

   If the `URL` of the given resource is `about:blank`, then, instead, the user agent must queue a task to fire an event named `load` at the `object` element. No `load` event is fired at the `about:blank` document itself.

The `object` element represents the `nested browsing context`.

   If the `name` attribute is present, the `object` element's `nested browsing context`'s `browsing context name` must be set to the value of this attribute; otherwise, the `browsing context name` must be set to
the empty string.

> If the resource type starts with "image/", and support for images has not been disabled

If the object element's nested browsing context is non-null, then it must be discarded and then set to null.

Apply the image sniffing rules to determine the type of the image.

The object element represents the specified image.

If the image cannot be rendered, e.g. because it is malformed or in an unsupported format, jump to the step below labeled fallback.

> Otherwise

The given resource type is not supported. Jump to the step below labeled fallback.

Note: If the previous step ended with the resource type being unknown, this is the case that is triggered.

10. The element’s contents are not part of what the object element represents.

11. Return. Once the resource is completely loaded, queue a task to fire an event named load at the element.

5. If the data attribute is absent but the type attribute is present, and the user agent can find a plugin suitable according to the value of the type attribute, and either plugins aren’t being sandboxed or the plugin can be secured, then that plugin should be used. If these conditions cannot be met, or if the plugin reports an error, jump to the step below labeled fallback. Otherwise return; once the plugin is completely loaded, queue a task to fire an event named load at the element.

6. Fallback: The object element represents the element’s children, ignoring any leading param element children. This is the element’s fallback content. If the element has an instantiated plugin, then unload it. If the element’s nested browsing context is non-null, then it must be discarded and then set to null.

When the algorithm above instantiates a plugin, the user agent should pass to the plugin the addresses and values of all the attributes on the element, in the order they were added to the element, with the attributes added by the parser being ordered in tree order, followed by a parameter named "PARAM" whose value is null, followed by all the names and values of parameters given by param elements that are children of the object element, in tree order. If the plugin supports a scriptable interface, the HTMLDocumentElement object representing the element should expose that interface. The object element represents the object.

Plugins are considered sandboxed for the purpose of an object element if the sandboxing plugins browsing context flag is set on the object element’s node document’s active sandboxing flag set.

Due to the algorithm above, the contents of object elements act as fallback content, used only when referenced resources can’t be shown (e.g. because it returned a 404 error). This allows multiple object elements to be nested inside each other, targeting multiple user agents with different capabilities, with the user agent picking the first one it supports.

When an object element’s nested browsing context is non-null: if the object element’s nested browsing context is active document is not ready for post-load tasks, and when anything is delaying the load event of the object element’s browsing context’s active document, and when the object element’s browsing context is in the delaying load events mode, the object must delay the load event of its document.

The task source for the task mentioned in this section is the DOM manipulation task source.

The usemap attribute, if present while the object element represents an image, can indicate that the object has an associated image. The attribute must be ignored if the object element doesn’t represent an image.
The `form` attribute is used to explicitly associate the `object` element with its `form owner`.

**Constraint validation:** `object` elements are always barred from constraint validation.

The `object` element supports dimension attributes.

The IDL attributes `data`, `type` and `name` each must reflect the respective content attributes of the same name. The `typeMustMatch` IDL attribute must reflect the `typemustmatch` content attribute. The `useMap` IDL attribute must reflect the `usemap` content attribute.

The `contentDocument` IDL attribute, on getting, must return the `object` element's content document.

The `contentWindow` IDL attribute must return the `WindowProxy` object of the `object` element's nested browsing context, if its nested browsing context is non-null; otherwise, it must return null.

The `willValidate`, `validity`, and `validationMessage` attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the constraint validation API. The `form` IDL attribute is part of the element’s forms API.

**Example**

In this example, an HTML page is embedded in another using the `object` element.

```html
<figure>
  <object data="clock.html"></object>
  <figcaption>My HTML Clock</figcaption>
</figure>
```

**Example**

The following example shows how a plugin can be used in HTML (in this case the Flash plugin, to show a video file). Fallback is provided for users who do not have Flash enabled, in this case using the `video` element to show the video for those using user agents that support `video`, and finally providing a link to the video for those who have neither Flash nor a `video`-capable browser.

```html
<p>Look at my video:
  <object type="application/x-shockwave-flash">
    <param name=movie value="https://video.example.com/library/watch.swf">
    <param name=allowfullscreen value=true>
    <param name=flashvars value="https://video.example.com/vids/315981">
    <video controls src="https://video.example.com/vids/315981">
    </video>
  </object>
</p>
```

### 4.8.8 The `param` element

**Categories:**

None.

**Contexts in which this element can be used:**

As a child of an `object` element, before any `flow content`.

**Content model:**

Nothing.

**Tag omission in text/html:**

No end tag.
Content attributes:

- Global attributes:
  - name — Name of parameter
  - value — Value of parameter

DOM interface:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLParamElement : HTMLElement {
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString value;
};
```

The `param` element defines parameters for plugins invoked by `object` elements. It does not represent anything on its own.

The `name` attribute gives the name of the parameter.

The `value` attribute gives the value of the parameter.

Both attributes must be present. They may have any value.

If both attributes are present, and if the parent element of the `param` is an `object` element, then the element defines a parameter with the given name-value pair.

If either the name or value of a parameter defined by a `param` element that is the child of an `object` element that represents an instantiated plugin changes, and if that plugin is communicating with the user agent using an API that features the ability to update the plugin when the name or value of a parameter so changes, then the user agent must appropriately exercise that ability to notify the plugin of the change.

The IDL attributes `name` and `value` must both reflect the respective content attributes of the same name.

Example

The following example shows how the `param` element can be used to pass a parameter to a plugin, in this case the O3D plugin.

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>O3D Utah Teapot</title>
</head>
<body>
<p>
  <object type="application/vnd.o3d.auto">
    <param name="o3d_features" value="FloatingPointTextures">
      <img src="o3d-teapot.png"
        title="3D Utah Teapot illustration rendered using O3D."
        alt="When O3D renders the Utah Teapot, it appears as a squat teapot with a shiny metallic finish on which the surroundings are reflected, with a faint shadow caused by the lighting."
    </param>
    <p>To see the teapot actually rendered by O3D on your computer, please download and install the <a href="http://code.google.com/apis/o3d/docs/gettingstarted.html#install">O3D plugin</a>.</p>
  </object>

  <script src="o3d-teapot.js"></script>
</p>
</body>
</html>
```
4.8.9 The video element

Categories:
- Flow content
- Phrasing content
- Embedded content
- If the element has a controls attribute: Interactive content
- Palpable content

Contexts in which this element can be used:
Where embedded content is expected.

Content model:
If the element has a src attribute: zero or more track elements, then transparent, but with no media element descendants.
If the element does not have a src attribute: zero or more source elements, then zero or more track elements, then transparent, but with no media element descendants.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes:
  - src — Address of the resource
  - crossorigin — How the element handles crossorigin requests
  - poster — Poster frame to show prior to video playback
  - preload — Hints how much buffering the media resource will likely need
  - autoplay — Hint that the media resource can be started automatically when the page is loaded
  - playsinline — Encourage the user agent to display video content within the element's playback area
  - loop — Whether to loop the media resource
  - muted — Whether to mute the media resource by default
  - controls — Show user agent controls
  - width — Horizontal dimension
  - height — Vertical dimension

DOM interface:

```
IDL
[Exposed=Window, HTMLConstructor]
interface HTMLVideoElement : HTMLMediaElement {
  [CEReactions] attribute unsigned long width;
  [CEReactions] attribute unsigned long height;
  readonly attribute unsigned long videoWidth;
  readonly attribute unsigned long videoHeight;
  [CEReactions] attribute USVString poster;
  [CEReactions] attribute boolean playsInline;
};
```

A video element is used for playing videos or movies, and audio files with captions.

Content may be provided inside the video element. User agents should not show this content to the user; it is intended for older Web browsers which do not support video, so that legacy video plugins can be tried, or to show text to the users of these older browsers informing them of how to access the video contents.

Note: In particular, this content is not intended to address accessibility concerns. To make video content accessible to the partially sighted, the blind, the hard-of-hearing, the deaf, and those with other physical or cognitive disabilities, a variety of features are available. Captions can be provided, either embedded in the video stream or as external files using the track element. Sign-language tracks can be embedded in the video stream. Audio descriptions can be embedded in the video stream or in text form using a WebVTT file referenced using the track element and synthesized into speech by the user agent. WebVTT can also be used to provide chapter titles. For users who would rather not use a media element at all, transcripts or other textual alternatives can be provided by simply linking to them in the prose near the video element.

The video element is a media element whose media data is ostensibly video data, possibly with associated audio data.
The `src`[^src], `preload`[^preload], `autoplay`[^autoplay], `loop`[^loop], `muted`[^muted], and `controls`[^controls] attributes are the attributes common to all media elements[^media].

The `poster` attribute gives the URL of an image file that the user agent can show while no video data is available. The attribute, if present, must contain a valid non-empty URL potentially surrounded by spaces[^spaces].

If the specified resource is to be used, then, when the element is created or when the `poster`[^poster] attribute is set, changed, or removed, the user agent must run the following steps to determine the element's **poster frame** (regardless of the value of the element's `show poster flag`[^showposterflag]):

1. If there is an existing instance of this algorithm running for this `video`[^video] element, abort that instance of this algorithm without changing the `poster frame`[^posterframe].
2. If the `poster`[^poster] attribute's value is the empty string or if the attribute is absent, then there is no `poster frame`[^posterframe], return.
3. Parse[^parse] the `poster`[^poster] attribute's value relative to the element's `node document`. If this fails, then there is no `poster frame`[^posterframe]; return.
4. Let `request` be a new `request` whose `url` is the `resulting URL record`[^resultingurlrecord], `client` is the element's `node document`'s `Window`[^window] object's `environment settings object`[^environmentsettingsobject], `destination` is "image", `credentials mode` is "include", and whose `use-URL-credentials flag` is set.
5. Fetch[^fetch] `request`. This must delay the load event[^loadevent] of the element's `node document`.
6. If an image is thus obtained, the `poster frame`[^posterframe] is that image. Otherwise, there is no `poster frame`[^posterframe].

**Note**

The image given by the `poster`[^poster] attribute, the `poster frame`[^posterframe], is intended to be a representative frame of the video (typically one of the first non-blank frames) that gives the user an idea of what the video is like.

The `playsinline` attribute is a boolean attribute[^playsinline]. If present, it serves as a hint to the user agent that the video ought to be displayed "inline" in the document by default, constrained to the element's playback area, instead of being displayed fullscreen or in an independent resizable window.

**Note**

The absence of the `playsinline`[^playsinline] attributes does not imply that the video will display fullscreen by default. Indeed, most user agents have chosen to play all videos inline by default, and in such user agents the `playsinline`[^playsinline] attribute has no effect.

A `video`[^video] element represents what is given for the first matching condition in the list below:

- When no video data is available (the element’s `readyState`[^readystate] attribute is either `HAVE NOTHING`[^havenothing], or `HAVE METADATA`[^havemetadata] but no video data has yet been obtained at all, or the element’s `readyState`[^readystate] attribute is any subsequent value but the `media resource`[^mediaresource] does not have a video channel)
  
  The `video`[^video] element represents[^represents] its `poster frame`[^posterframe], if any, or else transparent black with no intrinsic dimensions.

- When the `video`[^video] element is `paused`[^paused], the `current playback position`[^currentplaybackposition] is the first frame of video, and the element’s `show poster flag`[^showposterflag] is set
  
  The `video`[^video] element represents[^represents] its `poster frame`[^posterframe], if any, or else the first frame of the video.

- When the `video`[^video] element is `paused`[^paused], and the frame of video corresponding to the `current playback position`[^currentplaybackposition] is not available (e.g. because the video is seeking or buffering)

- When the `video`[^video] element is neither `potentially playing`[^potentiallyplaying] nor `paused`[^paused] (e.g. when seeking or stalled)
  
  The `video`[^video] element represents[^represents] the last frame of the video to have been rendered.

- When the `video`[^video] element is `paused`[^paused]
  
  The `video`[^video] element represents[^represents] the frame of video corresponding to the `current playback position`[^currentplaybackposition].

- Otherwise (the `video`[^video] element has a video channel and is `potentially playing`[^potentiallyplaying])
  
  The `video`[^video] element represents[^represents] the frame of video at the continuously increasing "current" position[^currentposition]. When the `current playback position`[^currentplaybackposition] changes such that the last frame rendered is no longer the frame corresponding to the `current playback position`[^currentplaybackposition] in the video, the new frame must be rendered.

Frames of video must be obtained from the video track that was `selected`[^selected] when the `event loop`[^eventloop] last reached step 1[^step1].
Which frame in a video stream corresponds to a particular playback position is defined by the video stream's format.

The `<video>` element also represents any text track cues whose text track cue active flag is set and whose text track is in the showing mode, and any audio from the media resource, at the current playback position.

Any audio associated with the media resource must, if played, be played synchronized with the current playback position, at the element's effective media volume. The user agent must play the audio from audio tracks that were enabled when the event last reached step 1.

In addition to the above, the user agent may provide messages to the user (such as "buffering", "no video loaded", "error", or more detailed information) by overlaying text or icons on the video or other areas of the element's playback area, or in another appropriate manner.

User agents that cannot render the video may instead make the element represent a link to an external video playback utility or to the video data itself.

When a `<video>` element's media resource has a video channel, the element provides a paint source whose width is the media resource's intrinsic width, whose height is the media resource's intrinsic height, and whose appearance is the frame of video corresponding to the current playback position, if that is available, or else (e.g. when the video is seeking or buffering) its previous appearance, if any, or else (e.g. because the video is still loading the first frame) blackness.

These attributes return the intrinsic dimensions of the video, or zero if the dimensions are not known.

The intrinsic width and intrinsic height of the media resource are the dimensions of the resource in CSS pixels after taking into account the resource's dimensions, aspect ratio, clean aperture, resolution, and so forth, as defined for the format used by the resource. If an anamorphic format does not define how to apply the aspect ratio to the video data's dimensions to obtain the "correct" dimensions, then the user agent must apply the ratio by increasing one dimension and leaving the other unchanged.

The `videoWidth` IDL attribute must return the intrinsic width of the video in CSS pixels. The `videoHeight` IDL attribute must return the intrinsic height of the video in CSS pixels. If the element's `readyState` attribute is `HAVE NOTHING`, then the attributes must return 0.

Whenever the intrinsic width or intrinsic height of the video changes (including, for example, because the selected video track was changed), if the element's `readyState` attribute is not `HAVE NOTHING`, the user agent must queue a task to fire an event named `resize` at the media element.

The video element supports dimension attributes.

In the absence of style rules to the contrary, video content should be rendered inside the element's playback area such that the video content is shown centered in the playback area at the largest possible size that fits completely within it, with the video content's aspect ratio being preserved. Thus, if the aspect ratio of the playback area does not match the aspect ratio of the video, the video will be shown letterboxed or pillarboxed. Areas of the element's playback area that do not contain the video represent nothing.

In user agents that implement CSS, the above requirement can be implemented by using the style rule suggested in the rendering section.

The intrinsic width of a video element's playback area is the intrinsic width of the poster frame, if that is available and the element currently represents its poster frame; otherwise, it is the intrinsic width of the video resource, if that is available; otherwise the intrinsic width is missing.

The intrinsic height of a video element's playback area is the intrinsic height of the poster frame, if that is available and the element currently represents its poster frame; otherwise it is the intrinsic height of the video resource, if that is available; otherwise the intrinsic height is missing.

The default object size is a width of 300 CSS pixels and a height of 150 CSS pixels.
A video element is said to **intersect the viewport** when it is **being rendered** and its associated CSS layout box intersects the viewport.

User agents should provide controls to enable or disable the display of closed captions, audio description tracks, and other additional data associated with the video stream, though such features should, again, not interfere with the page's normal rendering.

User agents may allow users to view the video content in manners more suitable to the user, such as fullscreen or in an independent resizable window. User agents may even trigger such a viewing mode by default upon playing a video, although they should not do so when the `playsinline` attribute is specified. As with the other user interface features, controls to enable this should not interfere with the page's normal rendering unless the user agent is exposing a user interface. In such an independent viewing mode, however, user agents may make full user interfaces visible, even if the `controls` attribute is absent.

User agents may allow video playback to affect system features that could interfere with the user's experience; for example, user agents could disable screensavers while video playback is in progress.

The **poster** IDL attribute must **reflect** the **poster** content attribute.

The **playsInline** IDL attribute must **reflect** the **playsinline** content attribute.

---

### Example

This example shows how to detect when a video has failed to play correctly:

```html
<video src="tgif.vid" autoplay controls onerror="failed(event)"></video>
<p><a href="tgif.vid">Download the video file</a>.</p>
```

---

#### 4.8.10 The `audio` element

**Categories**: Flow content, Phrasing content, Embedded content.

If the element has a `controls` attribute: Interactive content.

If the element has a `controls` attribute: Palpable content.
Contexts in which this element can be used

Where embedded content is expected.

Content model:

If the element has a `src` attribute: zero or more `track` elements, then `transparent`, but with no `media element` descendants.

If the element does not have a `src` attribute: zero or more `source` elements, then zero or more `track` elements, then `transparent`, but with no `media element` descendants.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

**Global attributes**

- **src** — Address of the resource
- **crossorigin** — How the element handles crossorigin requests
- **preload** — Hints how much buffering the `media resource` will likely need
- **autoplay** — Hint that the `media resource` can be started automatically when the page is loaded
- **loop** — Whether to loop the `media resource` by default
- **muted** — Whether to mute the `media resource` by default
- **controls** — Show user agent controls

**DOM interface**:

```javascript
[Exposed=Window, HTMLConstructor, NamedConstructor=Audio(optional DOMString src)]
interface HTMLAudioElement : HTMLMediaElement {
}
```

An `audio` element represents a sound or audio stream.

Content may be provided inside the `audio` element. User agents should not show this content to the user; it is intended for older Web browsers which do not support `audio`, so that legacy audio plugins can be tried, or to show text to the users of these older browsers informing them of how to access the audio contents.

**Note**

In particular, this content is not intended to address accessibility concerns. To make audio content accessible to the deaf or to those with other physical or cognitive disabilities, a variety of features are available. If captions or a sign language video are available, the `video` element can be used instead of the `audio` element to play the audio, allowing users to enable the visual alternatives. Chapter titles can be provided to aid navigation, using the `track` element and a WebVTT file. And, naturally, transcripts or other textual alternatives can be provided by simply linking to them in the prose near the `audio` element. [WEBVTT]

The `audio` element is a `media element` whose `media data` is ostensibly audio data.

The `src`, `preload`, `autoplay`, `loop`, `muted`, and `controls` attributes are the attributes common to all `media elements`.

For web developers (non-normative)

```javascript
audio = new Audio([url])
```

Returns a new `audio` element, with the `src` attribute set to the value passed in the argument, if applicable.

A constructor is provided for creating `HTMLAudioElement` objects (in addition to the factory methods from DOM such as `createElement()`: `Audio(src)`). When invoked, the constructor must perform the following steps:

1. Let `document` be the `current global object`'s associated `Document`.
2. Let `audio` be the result of creating an element given `document`, `audio`, and the `HTML namespace`.
3. Set an attribute value for `audio` using "`preload"" and "`auto"".
4. If src is given, then set an attribute value for audio using "src" and src. (This will cause the user agent to invoke the object's resource selection algorithm before returning.)

5. Return audio.

4.8.11 The track element

Categories:
None.

Contexts in which this element can be used:
As a child of a media element, before any flow content.

Content model:
Nothing.

Tag omission in text/html:
No end tag.

Content attributes:
Global attributes:

kind — The type of text track
src — Address of the resource
srclang — Language of the text track
label — User-visible label
default — Enable the track if no other text track is more suitable

DOM interface:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLTrackElement : HTMLElement {
  [CEReactions] attribute DOMString kind;
  [CEReactions] attribute USVString src;
  [CEReactions] attribute DOMString srclang;
  [CEReactions] attribute DOMString label;
  [CEReactions] attribute boolean default;

  const unsigned short NONE = 0;
  const unsigned short LOADING = 1;
  const unsigned short LOADED = 2;
  const unsigned short ERROR = 3;
  readonly attribute unsigned short readyState;

  readonly attribute TextTrack track;
};
```

The `track` element allows authors to specify explicit external timed text tracks for media elements. It does not represent anything on its own.

The `kind` attribute is an enumerated attribute. The following table lists the keywords defined for this attribute. The keyword given in the first cell of each row maps to the state given in the second cell.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
<th>Brief description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subtitles</td>
<td>Subtitles</td>
<td>Transcription or translation of the dialogue, suitable for when the sound is available but not understood (e.g. because the user does not understand the language of the media resource's audio track). Overlaid on the video.</td>
</tr>
<tr>
<td>captions</td>
<td>Captions</td>
<td>Transcription or translation of the dialogue, sound effects, relevant musical cues, and other relevant audio information, suitable for when sound is unavailable or not clearly audible (e.g. because it is muted, drowned-out by ambient noise, or because the user is deaf). Overlaid on the video; labeled as appropriate for the hard-of-hearing.</td>
</tr>
<tr>
<td>descriptions</td>
<td>Descriptions</td>
<td>Textual descriptions of the video component of the media resource, intended for audio synthesis when the visual component is obscured, unavailable, or not usable (e.g. because the user is interacting with the application without a screen while driving, or because the user is blind). Synthesized as audio.</td>
</tr>
<tr>
<td>Keyword</td>
<td>State</td>
<td>Brief description</td>
</tr>
<tr>
<td>-------------</td>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>chapters</td>
<td>Chapters</td>
<td>Tracks intended for use from script. Not displayed by the user agent.</td>
</tr>
<tr>
<td>metadata</td>
<td>Metadata</td>
<td></td>
</tr>
</tbody>
</table>

The attribute may be omitted. The missing value default is the subtitles state. The invalid value default is the metadata state.

The src attribute gives the URL of the text track data. The value must be a valid non-empty URL potentially surrounded by spaces. This attribute must be present.

If the element has a src attribute whose value is not the empty string and whose value, when the attribute was set, could be successfully parsed relative to the element’s node document, then the element’s track URL is the resulting URL string. Otherwise, the element’s track URL is the empty string.

If the element’s track URL identifies a WebVTT resource, and the element’s kind attribute is not in the chapters metadata or metadata state, then the WebVTT file must be a WebVTT file using cue text. [WEBVTT]

The srclang attribute gives the language of the text track data. The value must be a valid BCP 47 language tag. This attribute must be present if the element’s kind attribute is in the subtitles or captions state. [BCP47]

If the element has a srclang attribute whose value is not the empty string, then the element’s track language is the value of the attribute. Otherwise, the element has no track language.

The label attribute gives a user-readable title for the track. This title is used by user agents when listing subtitle, caption, and audio description tracks in their user interface.

The value of the label attribute, if the attribute is present, must not be the empty string. Furthermore, there must not be two track element children of the same media element whose kind attributes are in the same state, whose srclang attributes are both missing or have values that represent the same language, and whose label attributes are again both missing or both have the same value.

If the element has a label attribute whose value is not the empty string, then the element’s track label is the value of the attribute. Otherwise, the element’s track label is an empty string.

The default attribute is a boolean attribute, which, if specified, indicates that the track is to be enabled if the user’s preferences do not indicate that another track would be more appropriate.

Each media element must have no more than one track element child whose kind attribute is in the subtitles or captions state and whose default attribute is specified.

Each media element must have no more than one track element child whose kind attribute is in the description state and whose default attribute is specified.

Each media element must have no more than one track element child whose kind attribute is in the chapters metadata state and whose default attribute is specified.

Note

There is no limit on the number of track elements whose kind attribute is in the metadata state and whose default attribute is specified.

For web developers (non-normative)

track.readyState

Returns the text track readiness state, represented by a number from the following list:

track.NONE (0)

The text track not loaded state.

track.LOADING (1)

The text track loading state.
The `readyState` attribute must return the numeric value corresponding to the text track readiness state of the track's text track, as defined by the following list:

- **NONE** (numeric value 0)
  - The text track not loaded state.
- **LOADING** (numeric value 1)
  - The text track loading state.
- **LOADED** (numeric value 2)
  - The text track loaded state.
- **ERROR** (numeric value 3)
  - The text track failed to load state.

The `track` IDL attribute must, on getting, return the `TextTrack` object corresponding to the text track of the track's element.

This video has subtitles in several languages:

```html
<video src="brave.webm">
  <track kind=subtitles src="brave.en.vtt" srclang=en label="English" />
  <track kind=captions src="brave.en.hoh.vtt" srclang=en label="English for the Hard of Hearing" />
  <track kind=subtitles src="brave.fr.vtt" srclang=fr lang=fr label="Français" />
  <track kind=subtitles src="brave.de.vtt" srclang=de lang=de label="Deutsch" />
</video>
```

(The `lang` attributes on the last two describe the language of the label attribute, not the language of the subtitles themselves. The language of the subtitles is given by the `srclang` attribute.)

### 4.8.12 Media elements

HTMLMediaElement objects (audio and video, in this specification) are simply known as media elements.
The media element attributes, src\(^375\), crossorigin\(^375\), preload\(^386\), autoplay\(^392\), loop\(^390\), muted\(^342\), and controls\(^348\), apply to all media elements\(^372\). They are defined in this section.

Media elements\(^372\) are used to present audio data, or video and audio data, to the user. This is referred to as media data in this section, since this section applies equally to media elements\(^372\) for audio or for video. The term media resource is used to refer to the complete set of media data, e.g. the complete video file, or complete audio file.
A media resource\(^373\) can have multiple audio and video tracks. For the purposes of a media element\(^372\), the video data of the media resource\(^373\) is only that of the currently selected track (if any) as given by the element’s videoTracks\(^361\) attribute when the event loop\(^369\) last reached step 1\(^894\), and the audio data of the media resource\(^373\) is the result of mixing all the currently enabled tracks (if any) given by the element’s audioTracks\(^361\) attribute when the event loop\(^369\) last reached step 1\(^894\).

---

**Note**

Both audio\(^368\) and video\(^365\) elements can be used for both audio and video. The main difference between the two is simply that the audio\(^368\) element has no playback area for visual content (such as video or captions), whereas the video\(^365\) element does.

---

Except where otherwise explicitly specified, the task source\(^893\) for all the tasks queued\(^893\) in this section and its subsections is the media element event task source of the media element\(^372\) in question.

### 4.8.12.1 Error codes \(^37\)

**For web developers (non-normative)**

```
media . error\(^374\)
```

Returns a MediaError\(^374\) object representing the current error state of the element.

Returns null if there is no error.

---

All media elements\(^372\) have an associated error status, which records the last error the element encountered since its resource selection algorithm\(^378\) was last invoked. The error attribute, on getting, must return the MediaError\(^374\) object created for this last error, or null if there has not been an error.

IDL

```
[Exposed=Window]
interface MediaError {
    const unsigned short MEDIA_ERR_ABORTED = 1;
    const unsigned short MEDIA_ERR_NETWORK = 2;
    const unsigned short MEDIA_ERR_DECODE = 3;
    const unsigned short MEDIA_ERR_SRC_NOT_SUPPORTED = 4;

    readonly attribute unsigned short code;
    readonly attribute DOMString message;
};
```

**For web developers (non-normative)**

```
media . error\(^374\) . code\(^375\)
```

Returns the current error’s error code, from the list below.

```
media . error\(^374\) . message\(^375\)
```

Returns a specific informative diagnostic message about the error condition encountered. The message and message format are not generally uniform across different user agents. If no such message is available, then the empty string is returned.

---

Every MediaError\(^374\) object has a message, which is a string, and a code, which is one of the following:

**MEDIA_ERR_ABORTED** (numeric value 1)

The fetching process for the media resource\(^373\) was aborted by the user agent at the user’s request.

**MEDIA_ERR_NETWORK** (numeric value 2)

A network error of some description caused the user agent to stop fetching the media resource\(^373\), after the resource was established to be usable.

**MEDIA_ERR_DECODE** (numeric value 3)

An error of some description occurred while decoding the media resource\(^373\), after the resource was established to be usable.

**MEDIA_ERR_SRC_NOT_SUPPORTED** (numeric value 4)

The media resource\(^373\) indicated by the src\(^375\) attribute or assigned media provider object\(^375\) was not suitable.
To create a MediaError, given an error code which is one of the above values, return a new MediaError object whose code is the given error code and whose message is a string containing any details the user agent is able to supply about the cause of the error condition, or the empty string if the user agent is unable to supply such details. This message string must not contain only the information already available via the supplied error code; for example, it must not simply be a translation of the code into a string format. If no additional information is available beyond that provided by the error code, the message must be set to the empty string.

The code attribute of a MediaError object must return this MediaError object's code.

The message attribute of a MediaError object must return this MediaError object's message.

4.8.12.2 Location of the media resource

The src content attribute on media elements gives the URL of the media resource (video, audio) to show. The attribute, if present, must contain a valid non-empty URL potentially surrounded by spaces.

If the itemprop attribute is specified on the media element, then the src attribute must also be specified.

The crossOrigin content attribute on media elements is a CORS settings attribute.

If a media element is created with a src attribute, the user agent must immediately invoke the media element's resource selection algorithm.

If a src attribute of a media element is set or changed, the user agent must invoke the media element's media element load algorithm. (Removing the src attribute does not do this, even if there are source elements present.)

The src IDL attribute on media elements must reflect the content attribute of the same name.

The crossOrigin IDL attribute must reflect the crossOrigin content attribute, limited to only known values.

A media provider object is an object that can represent a media resource, separate from a URL. MediaStream objects, MediaSource objects, and Blob objects are all media provider objects.

Each media element can have an assigned media provider object, which is a media provider object. When a media element is created, it has no assigned media provider object.

For web developers (non-normative)

media . srcObject { = source }

Allows the media element to be assigned a media provider object.

media . currentSrc

Returns the URL of the current media resource, if any.

Returns the empty string when there is no media resource, or it doesn't have a URL.

The currentSrc IDL attribute must initially be set to the empty string. Its value is changed by the resource selection algorithm defined below.

The srcObject IDL attribute, on getting, must return the element's assigned media provider object, if any, or null otherwise. On setting, it must set the element's assigned media provider object to the new value, and then invoke the element's media element load algorithm.

Note

There are three ways to specify a media resource: the srcObject, src, and source elements. The IDL attribute takes priority, followed by the content attribute, followed by the elements.
4.8.12.3 MIME types

A media resource can be described in terms of its type, specifically a MIME type, in some cases with a codecs parameter. (Whether the codecs parameter is allowed or not depends on the MIME type.) [RFC6381]

Types are usually somewhat incomplete descriptions; for example "video/mpeg" doesn't say anything except what the container type is, and even a type like "video/mp4; codecs="avc1.42E01E, mp4a.40.2"" doesn't include information like the actual bitrate (only the maximum bitrate). Thus, given a type, a user agent can often only know whether it might be able to play media of that type (with varying levels of confidence), or whether it definitely cannot play media of that type.

A type that the user agent knows it cannot render is one that describes a resource that the user agent definitely does not support, for example because it doesn't recognize the container type, or it doesn't support the listed codecs.

The MIME type "application/octet-stream" with no parameters is never a type that the user agent knows it cannot render. User agents must treat that type as equivalent to the lack of any explicit Content-Type metadata when it is used to label a potential media resource.

Note

Only the MIME type "application/octet-stream" with no parameters is special-cased here; if any parameter appears with it, it will be treated just like any other MIME type. This is a deviation from the rule that unknown MIME type parameters should be ignored.

For web developers (non-normative)

media . canPlayType(type)

Returns the empty string (a negative response), "maybe", or "probably" based on how confident the user agent is that it can play media resources of the given type.

The canPlayType(type) method must return the empty string if type is a type that the user agent knows it cannot render, or is the type "application/octet-stream"; it must return "probably" if the user agent is confident that the type represents a media resource that it can render if used in with this audio or video element; and it must return "maybe" otherwise. Implementors are encouraged to return "maybe" unless the type can be confidently established as being supported or not. Generally, a user agent should never return "probably" for a type that allows the codecs parameter if that parameter is not present.

Example

This script tests to see if the user agent supports a (fictional) new format to dynamically decide whether to use a video element or a plugin:

```html
<section id="video">
  <p><a href="playing-cats.nfv">Download video</a></p>
</section>
<script>
  var videoSection = document.getElementById('video');
  var videoElement = document.createElement('video');
  var support = videoElement.canPlayType('video/x-new-fictional-format;codecs="kittens,bunnies"');
  if (support != "probably" && "New Fictional Video Plugin" in navigator.plugins) {
    // not confident of browser support
    // but we have a plugin
    // so use plugin instead
    videoElement = document.createElement('embed');
  } else if (support == "") {
    // no support from browser and no plugin
    // do nothing
    videoElement = null;
  }
  if (videoElement) {
    while (videoSection.hasChildNodes())
      videoSection.removeChild(videoSection.firstChild);
    videoElement.setAttribute("src", "playing-cats.nfv");
    videoSection.appendChild(videoElement);
  }
</script>
```
As media elements interact with the network, their current network activity is represented by the networkState attribute. On getting, it must return the current network state of the element, which must be one of the following values:

**NETWORK_EMPTY** (numeric value 0)
The element has not yet been initialized. All attributes are in their initial states.

**NETWORK_IDLE** (numeric value 1)
The element’s resource selection algorithm is active and has selected a resource, but it is not actually using the network at this time.

**NETWORK_LOADING** (numeric value 2)
The user agent is actively trying to download data.

**NETWORK_NO_SOURCE** (numeric value 3)
The element’s resource selection algorithm is active, but it has not yet found a resource to use.

The resource selection algorithm defined below describes exactly when the networkState attribute changes value and what events fire to indicate changes in this state.

### 4.8.12.4 Network states

**media . networkState**

Returns the current state of network activity for the element, from the codes in the list below.

As media elements interact with the network, their current network activity is represented by the networkState attribute. On getting, it must return the current network state of the element, which must be one of the following values:

**NETWORK_EMPTY** (numeric value 0)
The element has not yet been initialized. All attributes are in their initial states.

**NETWORK_IDLE** (numeric value 1)
The element’s resource selection algorithm is active and has selected a resource, but it is not actually using the network at this time.

**NETWORK_LOADING** (numeric value 2)
The user agent is actively trying to download data.

**NETWORK_NO_SOURCE** (numeric value 3)
The element’s resource selection algorithm is active, but it has not yet found a resource to use.

The resource selection algorithm defined below describes exactly when the networkState attribute changes value and what events fire to indicate changes in this state.

### 4.8.12.5 Loading the media resource

**media . load**

Causes the element to reset and start selecting and loading a new media resource from scratch.

All media elements have a can autoplay flag, which must begin in the true state, and a delaying-the-load-event flag, which must begin in the false state. While the delaying-the-load-event flag is true, the element must delay the load event of its document.

When the load() method on a media element is invoked, the user agent must run the media element load algorithm.

The media element load algorithm consists of the following steps.

1. Abort any already-running instance of the resource selection algorithm for this element.
2. Let pending tasks be a list of all tasks from the media element’s media element event task source in one of the task queues.
3. For each task in pending tasks that would resolve pending play promises or reject pending play promises, immediately resolve or reject those promises in the order the corresponding tasks were queued.
4. Remove each task\textsuperscript{893} in pending tasks from its task queue\textsuperscript{893}.

**Note**

Basically, pending events and callbacks are discarded and promises in-flight to be resolved/rejected are resolved/rejected immediately when the media element starts loading a new resource.

5. If the media element\textsuperscript{372}’s networkState\textsuperscript{377} is set to NETWORK\_LOADING\textsuperscript{377} or NETWORK\_IDLE\textsuperscript{377}, queue a task\textsuperscript{893} to fire an event named abort\textsuperscript{422} at the media element\textsuperscript{372}.

6. If the media element\textsuperscript{372}’s networkState\textsuperscript{377} is not set to NETWORK\_EMPTY\textsuperscript{377}, then:
   1. Queue a task\textsuperscript{893} to fire an event named emptied\textsuperscript{424} at the media element\textsuperscript{372}.
   2. If a fetching process is in progress for the media element\textsuperscript{372}, the user agent should stop it.
   3. If the media element\textsuperscript{372}’s assigned media provider object\textsuperscript{375} is a MediaSource object, then detach\textsuperscript{326} it.
   4. Forget the media element’s media-resource-specific tracks\textsuperscript{386}.
   5. If readyState\textsuperscript{392} is not set to HAVE\_NOTHING\textsuperscript{390}, then set it to that state.
   6. If the paused\textsuperscript{393} attribute is false, then:
      1. Set the paused\textsuperscript{393} attribute to true.
      2. Take pending play promises\textsuperscript{395} and reject pending play promises\textsuperscript{395} with the result and an "AbortError" DOMException.
   7. If seeking\textsuperscript{399} is true, set it to false.
   8. Set the current playback position\textsuperscript{389} to 0.
      Set the official playback position\textsuperscript{389} to 0.
      If this changed the official playback position\textsuperscript{389}, then queue a task\textsuperscript{893} to fire an event named timeupdate\textsuperscript{424} at the media element\textsuperscript{372}.
   9. Set the timeline offset\textsuperscript{390} to Not-a-Number (NaN).
   10. Update the duration\textsuperscript{389} attribute to Not-a-Number (NaN).

**Note**

The user agent will not\textsuperscript{389} fire a durationchange\textsuperscript{424} event for this particular change of the duration.

7. Set the playbackRate\textsuperscript{394} attribute to the value of the defaultPlaybackRate\textsuperscript{394} attribute.

8. Set the error\textsuperscript{374} attribute to null and the can autoplay flag\textsuperscript{377} to true.

9. Invoke the media element\textsuperscript{372}’s resource selection algorithm\textsuperscript{378}.

**Note**

Playback of any previously playing media resource\textsuperscript{373} for this element stops.

The resource selection algorithm for a media element\textsuperscript{372} is as follows. This algorithm is always invoked as part of a task\textsuperscript{893}, but one of the first steps in the algorithm is to return and continue running the remaining steps in parallel\textsuperscript{42}. In addition, this algorithm interacts closely with the event loop\textsuperscript{489} mechanism; in particular, it has synchronous sections\textsuperscript{486} (which are triggered as part of the event loop\textsuperscript{489} algorithm). Steps in such sections are marked with ☢️.

1. Set the element’s networkState\textsuperscript{377} attribute to the NETWORK\_NO\_SOURCE\textsuperscript{377} value.
2. Set the element’s show poster flag\textsuperscript{389} to true.
3. Set the media element\textsuperscript{372}’s delaying-the-load-event flag\textsuperscript{377} to true (this delays the load event\textsuperscript{4107}).
4. Await a stable state\textsuperscript{486}, allowing the task\textsuperscript{893} that invoked this algorithm to continue. The synchronous section\textsuperscript{486} consists of all the remaining steps of this algorithm until the algorithm says the synchronous section\textsuperscript{486} has ended. (Steps in synchronous sections\textsuperscript{486} are marked with ☢️.)
5. ☢️ If the media element\textsuperscript{372}’s blocked-on-parser\textsuperscript{407} flag is false, then populate the list of pending text tracks\textsuperscript{407}.  

378
6. ✡ If the media element\textsuperscript{p372} has an assigned media provider object\textsuperscript{p375}, then let mode be object.

✡ Otherwise, if the media element\textsuperscript{p372} has no assigned media provider object\textsuperscript{p375} but has a src\textsuperscript{p375} attribute, then let mode be attribute.

✡ Otherwise, if the media element\textsuperscript{p372} does not have an assigned media provider object\textsuperscript{p375} and does not have a src\textsuperscript{p375} attribute, but does have a source\textsuperscript{p384} element child, then let mode be children and let candidate be the first such source\textsuperscript{p304} element child in tree order.

✡ Otherwise the media element\textsuperscript{p372} has no assigned media provider object\textsuperscript{p375} and has neither a src\textsuperscript{p375} attribute nor a source\textsuperscript{p384} element child: set the networkState\textsuperscript{p372} to NETWORK_EMPTY\textsuperscript{p377}, and return; the synchronous section\textsuperscript{p896} ends.

7. ✡ Set the media element\textsuperscript{p372}'s networkState\textsuperscript{p372} to NETWORK_LOADING\textsuperscript{p377}.

8. ✡ Queue a task\textsuperscript{p893} to fire an event named loadstart\textsuperscript{p423} at the media element\textsuperscript{p372}.

9. Run the appropriate steps from the following list:

→ If mode is object

1. ✡ Set the currentSrc\textsuperscript{p375} attribute to the empty string.

2. End the synchronous section\textsuperscript{p896}, continuing the remaining steps in parallel\textsuperscript{p42}.

3. Run the resource fetch algorithm\textsuperscript{p381} with the assigned media provider object\textsuperscript{p375}. If that algorithm returns without aborting this one, then the load failed.

4. Failed with media provider: Reaching this step indicates that the media resource failed to load. Take pending play promises\textsuperscript{p395} and queue a task\textsuperscript{p893} to run the dedicated media source failure steps\textsuperscript{p896} with the result.

5. Wait for the task\textsuperscript{p893} queued by the previous step to have executed.

6. Return. The element won't attempt to load another resource until this algorithm is triggered again.

→ If mode is attribute

1. ✡ If the src\textsuperscript{p375} attribute's value is the empty string, then end the synchronous section\textsuperscript{p896}, and jump down to the failed with attribute step below.

2. ✡ Let urlString and urlRecord be the resulting URL string\textsuperscript{p486} and the resulting URL record\textsuperscript{p486}, respectively, that would have resulted from parsing\textsuperscript{p486} the URL specified by the src\textsuperscript{p375} attribute's value relative to the media element\textsuperscript{p372}'s node document when the src\textsuperscript{p375} attribute was last changed.

3. ✡ If urlString was obtained successfully, set the currentSrc\textsuperscript{p375} attribute to urlString.

4. End the synchronous section\textsuperscript{p896}, continuing the remaining steps in parallel\textsuperscript{p42}.

5. If urlRecord was obtained successfully, run the resource fetch algorithm\textsuperscript{p381} with urlRecord. If that algorithm returns without aborting this one, then the load failed.

6. Failed with attribute: Reaching this step indicates that the media resource failed to load or that the given URL could not be parsed\textsuperscript{p486}. Take pending play promises\textsuperscript{p395} and queue a task\textsuperscript{p893} to run the dedicated media source failure steps\textsuperscript{p896} with the result.

7. Wait for the task\textsuperscript{p893} queued by the previous step to have executed.

8. Return. The element won't attempt to load another resource until this algorithm is triggered again.

→ Otherwise (mode is children)

1. ✡ Let pointer be a position defined by two adjacent nodes in the media element\textsuperscript{p372}'s child list, treating the start of the list (before the first child in the list, if any) and end of the list (after the last child in the list, if any) as nodes in their own right. One node is the node before pointer, and the other node is the node after pointer. Initially, let pointer be the position between the candidate node and the next node, if there are any, or the end of the list, if it is the last node.

As nodes are inserted\textsuperscript{p44} and removed\textsuperscript{p44} into the media element\textsuperscript{p372}, pointer must be updated as follows:

If a new node is inserted\textsuperscript{p44} between the two nodes that define pointer

   Let pointer be the point between the node before pointer and the new node. In other words, insertions at

379
If the node before pointer is removed

Let pointer be the point between the node after pointer and the node before the node after pointer. In other words, pointer doesn't move relative to the remaining nodes.

If the node after pointer is removed

Let pointer be the point between the node before pointer and the node after the node before pointer. Just as with the previous case, pointer doesn't move relative to the remaining nodes.

Other changes don't affect pointer.

2. If candidate does not have a src attribute, or if its src attribute's value is the empty string, then end the synchronous section, and jump down to the failed with elements step below.

3. Let urlString and urlRecord be the resulting URL string and the resulting URL record, respectively, that would have resulted from parsing the URL specified by candidate's src attribute's value relative to the candidate's node document when the src attribute was last changed.

4. If urlString was not obtained successfully, then end the synchronous section, and jump down to the failed with elements step below.

5. If candidate has a type attribute whose value, when parsed as a MIME type (including any codecs described by the codecs parameter, for types that define that parameter), represents a type that the user agent knows it cannot render, then end the synchronous section, and jump down to the failed with elements step below.

6. Set the currentSrc attribute to urlString.

7. End the synchronous section, continuing the remaining steps in parallel.

8. Run the resource fetch algorithm with urlRecord. If that algorithm returns without aborting this one, then the load failed.

9. Failed with elements: Queue a task to fire an event named error at the candidate element.

10. Await a stable state. The synchronous section consists of all the remaining steps of this algorithm until the algorithm says the synchronous section has ended. (Steps in synchronous sections are marked with .)

11. Forget the media element's media-resource-specific tracks.

12. Find next candidate: Let candidate be null.

13. Search loop: If the node after pointer is the end of the list, then jump to the waiting step below.

14. If the node after pointer is a source element, let candidate be that element.

15. Advance pointer so that the node before pointer is now the node that was after pointer, and the node after pointer is the node after the node that used to be after pointer, if any.

16. If candidate is null, jump back to the search loop step. Otherwise, jump back to the process candidate step.

17. Waiting: Set the element's networkState attribute to the NETWORK_NO_SOURCE value.

18. Set the element's show poster flag to true.

19. Queue a task to set the element's delaying-the-load-event flag to false. This stops delaying the load event.

20. End the synchronous section, continuing the remaining steps in parallel.

21. Wait until the node after pointer is a node other than the end of the list. (This step might wait forever.)

22. Await a stable state. The synchronous section consists of all the remaining steps of this algorithm until the algorithm says the synchronous section has ended. (Steps in synchronous sections are marked with .)

23. Set the element's delaying-the-load-event flag back to true (this delays the load event again, in
case it hasn't been fired yet).

24. ⌛ Set the `networkState`\(^{377}\) back to `NETWORK_LOADING`\(^{377}\).

25. ⌛ Jump back to the `find next candidate` step above.

The **dedicated media source failure steps** with a list of promises `promises` are the following steps:

1. Set the `error`\(^{374}\) attribute to the result of creating a `MediaError`\(^{375}\) with `MEDIA_ERR_SRC_NOT_SUPPORTED`\(^{374}\).
2. Forget the media element's media-resource-specific tracks\(^{386}\).
3. Set the element's `networkState`\(^{377}\) attribute to the `NETWORK_NO_SOURCE`\(^{377}\) value.
4. Set the element's `show poster flag`\(^{389}\) to true.
5. Fire an event named `error`\(^{3424}\) at the media element\(^{372}\).
6. Reject pending play promises\(^{395}\) with promises and a "`NotSupportedError` DOMException".
7. Set the element's `delaying-the-load-event flag`\(^{377}\) to false. This stops `delaying the load event`\(^{3107}\).

The **resource fetch algorithm** for a media element\(^{372}\) and a given `URL record` or media provider object\(^{375}\) is as follows:

1. If the algorithm was invoked with media provider object\(^{375}\) or a `URL record` whose `object` is a media provider object\(^{375}\), then let `mode` be `local`. Otherwise let `mode` be `remote`.
2. If `mode` is `remote`, then let the current media resource be the resource given by the `URL record` passed to this algorithm; otherwise, let the current media resource be the resource given by the media provider object\(^{375}\). Either way, the current media resource is now the element's media resource\(^{373}\).
3. Remove all media-resource-specific text tracks\(^{409}\) from the media element\(^{372}\)'s list of pending text tracks\(^{407}\), if any.
4. Run the appropriate steps from the following list:

→ If `mode` is remote

1. Optionally, run the following substeps. This is the expected behavior if the user agent intends to not attempt to fetch the resource until the user requests it explicitly (e.g. as a way to implement the `preload`\(^{386}\) attribute's `none`\(^{386}\) keyword).
   1. Set the `networkState`\(^{377}\) to `NETWORK_IDLE`\(^{377}\).
   2. Queue a task\(^{483}\) to fire an event named `suspend`\(^{3423}\) at the element.
   3. Queue a task\(^{483}\) to set the element's `delaying-the-load-event flag`\(^{377}\) to false. This stops `delaying the load event`\(^{3107}\).
   4. Wait for the task to be run.
   5. Wait for an implementation-defined event (e.g. the user requesting that the media element begin playback).
   6. Set the element's `delaying-the-load-event flag`\(^{377}\) back to true (this delays the load event\(^{3107}\) again, in case it hasn't been fired yet).
   7. Set the `networkState`\(^{377}\) to `NETWORK_LOADING`\(^{377}\).
2. Let `destination` be "audio" if the media element\(^{372}\) is an audio\(^{368}\) element and to "video" otherwise.

Let `request` be the result of creating a potential-CORS request\(^{487}\) given current media resource's `URL record`, `destination`, and the media element\(^{372}\)'s `crossorigin`\(^{375}\) content attribute value.

Set `request`'s `client` to the media element\(^{372}\)'s `node document`'s `Window`\(^{791}\) object's `environment settings object`\(^{386}\).

Fetch `request`.

The `response`'s unsafe response\(^{487}\) obtained in this fashion, if any, contains the media data\(^{373}\). It can be CORS-same-origin\(^{487}\) or CORS-cross-origin\(^{487}\); this affects whether subtitles referenced in the media data\(^{373}\) are exposed in the API and, for video\(^{365}\) elements, whether a canvas\(^{364}\) gets tainted when the video is
The **stall timeout** is a user-agent defined length of time, which should be about three seconds. When a **media element** that is actively attempting to obtain **media data** has failed to receive any data for a duration equal to the **stall timeout**, the user agent must **queue a task** to **fire an event** named **stalled**, at the element.

User agents may allow users to selectively block or slow **media data** downloads. When a **media element**’s download has been blocked altogether, the user agent must act as if it was stalled (as opposed to acting as if the connection was closed). The rate of the download may also be throttled automatically by the user agent, e.g. to balance the download with other connections sharing the same bandwidth.

User agents may decide to not download more content at any time, e.g. after buffering five minutes of a one hour media resource, while waiting for the user to decide whether to play the resource or not, while waiting for user input in an interactive resource, or when the user navigates away from the page. When a **media element**’s download has been suspended, the user agent must **queue a task** to set the **networkState** to **NETWORK_IDLE** and fire an event named **suspend** at the element. If and when downloading of the resource resumes, the user agent must **queue a task** to set the **networkState** to **NETWORK_LOADING**. Between the queuing of these tasks, the load is suspended (so **progress** events don’t fire, as described above).

**Note**

The **preload** attribute provides a hint regarding how much buffering the author thinks is advisable, even in the absence of the **autoplay** attribute.

When a user agent decides to completely suspend a download, e.g., if it is waiting until the user starts playback before downloading any further content, the user agent must **queue a task** to set the element’s **delaying-the-load-event flag** to false. This stops **delaying the load event**.

The user agent may use whatever means necessary to fetch the resource (within the constraints put forward by this and other specifications); for example, reconnecting to the server in the face of network errors, using HTTP range retrieval requests, or switching to a streaming protocol. The user agent must consider a resource erroneous only if it has given up trying to fetch it.

To determine the format of the **media resource**, the user agent must use the **rules for sniffing audio and video specifically**.

While the load is not suspended (see below), every 350ms (±200ms) or for every byte received, whichever is least frequent, **queue a task** to **fire an event** named **progress** at the element.

The **networking task source** to process the data as it is being fetched must each **immediately** **queue a task** to run the first appropriate steps from the **media data processing steps list** below. (A new task is used for this so that the work described below occurs relative to the **media element task source** rather than the **networking task source**.)

When the **networking task source** has **queued**, the last **task** as part of fetching the **media resource** (i.e. once the download has completed), if the fetching process completes without errors, including decoding the media data, and if all of the data is available to the user agent without network access, then, the user agent must move on to the **final step** below. This might never happen, e.g. when streaming an infinite resource such as Web radio, or if the resource is longer than the user agent’s ability to cache data.

While the user agent might still need network access to obtain parts of the **media resource**, the user agent must remain on this step.

**Example**

For example, if the user agent has discarded the first half of a video, the user agent will remain at this step even once the **playback has ended**. Because there is always the chance the user will seek back to the start. In fact, in this situation, once **playback has ended**, the user agent will end up firing a **suspend** event, as described earlier.

**Otherwise (mode is local)**

The resource described by the **current media resource**, if any, contains the **media data**. It is **CORS-same-origin**.
If the current media resource is a raw data stream (e.g. from a File object), then to determine the format of the media resource, the user agent must use the rules for sniffing audio and video specifically. Otherwise, if the data stream is pre-decoded, then the format is the format given by the relevant specification.

Whenever new data for the current media resource becomes available, queue a task to run the first appropriate steps from the media data processing steps list below.

When the current media resource is permanently exhausted (e.g. all the bytes of a Blob have been processed), if there were no decoding errors, then the user agent must move on to the final step below. This might never happen, e.g. if the current media resource is a MediaStream.

The media data processing steps list is as follows:

1. If the media data cannot be fetched at all, due to network errors, causing the user agent to give up trying to fetch the resource
2. If the media data can be fetched but is found by inspection to be in an unsupported format, or cannot otherwise be rendered at all
   - DNS errors, HTTP 4xx and 5xx errors (and equivalents in other protocols), and other fatal network errors that occur before the user agent has established whether the current media resource is usable, as well as the file using an unsupported container format, or using unsupported codecs for all the data, must cause the user agent to execute the following steps:
     1. The user agent should cancel the fetching process.
     2. Abort this subalgorithm, returning to the resource selection algorithm.

3. If the media resource is found to have an audio track
   1. Create an AudioTrack object to represent the audio track.
   2. Update the media element's audioTracks attribute's AudioTrackList object with the new AudioTrack object.
   3. Let enable be unknown.
   4. If either the media resource or the URL of the current media resource indicate a particular set of audio tracks to enable, or if the user agent has information that would facilitate the selection of specific audio tracks to improve the user's experience, then: if this audio track is one of the ones to enable, then set enable to true, otherwise, set enable to false.

   Example
   This could be triggered by media fragment syntax, but it could also be triggered e.g. by the user agent selecting a 5.1 surround sound audio track over a stereo audio track.

   5. If enable is still unknown, then, if the media element does not yet have an enabled audio track, then set enable to true, otherwise, set enable to false.
   6. If enable is true, then enable this audio track, otherwise, do not enable this audio track.
   7. Fire an event named addtrack at this AudioTrackList object, using TrackEvent, with the track attribute initialized to the new AudioTrack object.

4. If the media resource is found to have a video track
   1. Create a VideoTrack object to represent the video track.
   2. Update the media element's videoTracks attribute's VideoTrackList object with the new VideoTrack object.
   3. Let enable be unknown.
   4. If either the media resource or the URL of the current media resource indicate a particular set of video tracks to enable, or if the user agent has information that would facilitate the selection of specific video tracks to improve the user's experience, then: if this video track is the first such video track, then set enable to true, otherwise, set enable to false.
5. If `enable` is still unknown, then, if the media element does not yet have a selected video track, then set `enable` to true, otherwise, set `enable` to false.

6. If `enable` is true, then select this track and unselect any previously selected video tracks, otherwise, do not select this video track. If other tracks are unselected, then a change event will be fired.

7. Fire an event named `addtrack` at this VideoTrackList object, using TrackEvent with the attribute initialized to the new VideoTrack object.

Once enough of the media data has been fetched to determine the duration of the media resource, its dimensions, and other metadata. This indicates that the resource is usable. The user agent must follow these substeps:

1. Establish the media timeline for the purposes of the current playback position and the earliest possible position, based on the media data.

2. Update the timeline offset to the date and time that corresponds to the zero time in the media timeline established in the previous step, if any. If no explicit time and date is given by the media resource, the timeline offset must be set to Not-a-Number (NaN).

3. Set the current playback position and the official playback position to the earliest possible position.

4. Update the duration attribute with the time of the last frame of the resource, if known, on the media timeline established above. If it is not known (e.g. a stream that is in principle infinite), update the duration attribute to the value positive infinity.

5. For `video` elements, set the `videoWidth` and `videoHeight` attributes, and queue a task to fire a change event named `resize` at the media element.

6. Set the `readyState` attribute to HAVE_METADATA.

7. Let `jumped` be false.

8. If the media element's default playback start position is greater than zero, then seek to that time, and let `jumped` be true.

9. Let the media element's default playback start position be zero.

10. Let the initial playback position be zero.

11. If either the media resource or the URL of the current media resource indicate a particular start time, then set the initial playback position to that time and, if `jumped` is still false, seek to that time.

Example

For example, with media formats that support media fragment syntax, the fragment can be used to indicate a start position.

12. If there is no enabled audio track, then enable an audio track. This will cause a change event to be fired.

13. If there is no selected video track, then select a video track. This will cause a change event to be fired.
Once the `readyState` attribute reaches `HAVE_CURRENT_DATA`, after the `loadeddata` event has been fired, set the element's `delaying-the-load-event flag` to false. This stops delaying the load event.

A user agent that is attempting to reduce network usage while still fetching the metadata for each media resource would also stop buffering at this point, following the rules described previously, which involve the `networkState` attribute switching to the `NETWORK_IDLE` value and a `suspend` event firing.

The user agent is required to determine the duration of the media resource and go through this step before playing.

Once the entire media resource has been fetched (but potentially before any of it has been decoded) Fire an event named `progress` at the media element.

Set the `networkState` to `NETWORK_IDLE` and fire an event named `suspend` at the media element.

If the user agent ever discards any media data and then needs to resume the network activity to obtain it again, then it must queue a task to set the `networkState` to `NETWORK_LOADING`.

If the user agent can keep the media resource loaded, then the algorithm will continue to its final step below, which aborts the algorithm.

If the connection is interrupted after some media data has been received, causing the user agent to give up trying to fetch the resource

Fatal network errors that occur after the user agent has established whether the current media resource is usable (i.e. once the media element's `readyState` attribute is no longer `HAVE_NOTHING`) must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Set the `error` attribute to the result of creating a `MediaError` with `MEDIA_ERR_NETWORK`.
3. Set the element's `networkState` attribute to the `NETWORK_IDLE` value.
4. Set the element's `delaying-the-load-event flag` to false. This stops delaying the load event.
5. Fire an event named `error` at the media element.
6. Abort the overall resource selection algorithm.

If the media data is corrupted

Fatal errors in decoding the media data that occur after the user agent has established whether the current media resource is usable (i.e. once the media element's `readyState` attribute is no longer `HAVE_NOTHING`) must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Set the `error` attribute to the result of creating a `MediaError` with `MEDIA_ERR_DECODE`.
3. Set the element's `networkState` attribute to the `NETWORK_IDLE` value.
4. Set the element's `delaying-the-load-event flag` to false. This stops delaying the load event.
5. Fire an event named `error` at the media element.
6. Abort the overall resource selection algorithm.

If the fetching process is aborted by the user

The fetching process is aborted by the user, e.g. because the user pressed a "stop" button, the user agent must execute the following steps. These steps are not followed if the `load()` method itself is invoked while these steps are running, as the steps above handle that particular kind of abort.
1. The user agent should cancel the fetching process.
2. Set the `error` attribute to the result of creating a `MediaError` with `MEDIA_ERR_ABORTED`.
3. Fire an event named `abort` at the media element.
4. If the media element's `readyState` attribute has a value equal to `HAVE NOTHING`, set the element's `networkState` attribute to the `NETWORK_EMPTY` value, set the element's `show poster flag` to true, and fire an event named `emptied` at the element.
   Otherwise, set the element's `networkState` attribute to the `NETWORK_IDLE` value.
5. Set the element's `delaying-the-load-event flag` to false. This stops `delaying the load event`.
6. Abort the overall resource selection algorithm.

→ If the media data can be fetched but has non-fatal errors or uses, in part, codecs that are unsupported, preventing the user agent from rendering the content completely correctly but not preventing playback altogether

The server returning data that is partially usable but cannot be optimally rendered must cause the user agent to render just the bits it can handle, and ignore the rest.

→ If the media resource is found to declare a media-resource-specific text track that the user agent supports

If the media data is CORS-same-origin, run the steps to expose a media-resource-specific text track with the relevant data.

Note: Cross-origin videos do not expose their subtitles, since that would allow attacks such as hostile sites reading subtitles from confidential videos on a user’s intranet.

5. Final step: If the user agent ever reaches this step (which can only happen if the entire resource gets loaded and kept available): abort the overall resource selection algorithm.

When a media element is to forget the media element’s media-resource-specific tracks, the user agent must remove from the media element’s list of text tracks all the media-resource-specific text tracks, then empty the media element’s `audioTracks` object’s `AudioTrackList` object, then empty the media element’s `videoTracks` object’s `VideoTrackList` object. No events (in particular, no `removetrack` events) are fired as part of this; the `error` and `emptied` events, fired by the algorithms that invoke this one, can be used instead.

The `preload` attribute is an enumerated attribute. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword. The attribute can be changed even once the media resource is being buffered or played; the descriptions in the table below are to be interpreted with that in mind.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
<th>Brief description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>None</td>
<td>Hints to the user agent that either the author does not expect the user to need the media resource, or that the server wants to minimize unnecessary traffic. This state does not provide a hint regarding how aggressively to actually download the media resource if buffering starts anyway (e.g. once the user hits “play”).</td>
</tr>
<tr>
<td>metadata</td>
<td>Metadata</td>
<td>Hints to the user agent that the author does not expect the user to need the media resource, but that fetching the resource metadata (dimensions, track list, duration, etc), and maybe even the first few frames, is reasonable. If the user agent precisely fetches no more than the metadata, then the media element will end up with its <code>readyState</code> attribute set to <code>HAVE_METADATA</code> typically though, some frames will be obtained as well and it will probably be <code>HAVE_CURRENT_DATA</code> or <code>HAVE_FUTURE_DATA</code>. When the media resource is playing, hints to the user agent that bandwidth is to be considered scarce, e.g. suggesting throttling the download so that the media data is obtained at the slowest possible rate that still maintains consistent playback.</td>
</tr>
<tr>
<td>auto</td>
<td>Automatic</td>
<td>Hints to the user agent that the user agent can put the user’s needs first without risk to the server, up to and including optimistically downloading the entire resource.</td>
</tr>
</tbody>
</table>

The empty string is also a valid keyword, and maps to the Automatic state. The attribute’s `missing value default` and `invalid value default` are user-agent defined, though the `Metadata` state is suggested as a compromise between reducing server load and providing an optimal user experience.

Note: Authors might switch the attribute from “none” or “metadata” to “auto” dynamically once the user begins playback. For
The `preload` attribute is intended to provide a hint to the user agent about what the author thinks will lead to the best user experience. The attribute may be ignored altogether, for example based on explicit user preferences or based on the available connectivity.

The `preload` IDL attribute must reflect the content attribute of the same name, limited to only known values.

Note

The `autoplay` attribute can override the `preload` attribute (since if the media plays, it naturally has to buffer first, regardless of the hint given by the `preload` attribute). Including both is not an error, however.

For web developers (non-normative)

```
media . buffered
```

Returns a `TimeRanges` object that represents the ranges of the `media resource` that the user agent has buffered.

The `buffered` attribute must return a new static normalized `TimeRanges` object that represents the ranges of the `media resource`, if any, that the user agent has buffered, at the time the attribute is evaluated. Users agents must accurately determine the ranges available, even for media streams where this can only be determined by tedious inspection.

Note

Typically this will be a single range anchored at the zero point, but if, e.g. the user agent uses HTTP range requests in response to seeking, then there could be multiple ranges.

User agents may discard previously buffered data.

Note

Thus, a time position included within a range of the objects returned by the `buffered` attribute at one time can end up being not included in the range(s) of objects returned by the same attribute at later times.

⚠ Warning!

`Returning a new object each time is a bad pattern for attribute getters and is only enshrined here as it would be costly to change it. It is not to be copied to new APIs.`

4.8.12.6 Offsets into the media resource

For web developers (non-normative)

```
media . duration
```

Returns the length of the `media resource`, in seconds, assuming that the start of the `media resource` is at time zero.

Returns NaN if the duration isn’t available.

Returns Infinity for unbounded streams.

```
media . currentTime [ = value ]
```

Returns the official playback position, in seconds.

Can be set, to seek to the given time.

A `media resource` has a `media timeline` that maps times (in seconds) to positions in the `media resource`. The origin of a timeline is its earliest defined position. The duration of a timeline is its last defined position.

Establishing the media timeline: if the `media resource` somehow specifies an explicit timeline whose origin is not negative (i.e. gives each frame a specific time offset and gives the first frame a zero or positive offset), then the `media timeline` should be that...
timeline. (Whether the media resource\textsuperscript{373} can specify a timeline or not depends on the media resource's\textsuperscript{377} format.) If the media resource\textsuperscript{373} specifies an explicit start time and date, then that time and date should be considered the zero point in the media timeline\textsuperscript{381}; the timeline offset\textsuperscript{390} will be the time and date, exposed using the getStartDate()\textsuperscript{396} method.

If the media resource\textsuperscript{373} has a discontinuous timeline, the user agent must extend the timeline used at the start of the resource across the entire resource, so that the media timeline\textsuperscript{381} of the media resource\textsuperscript{373} increases linearly starting from the earliest possible position\textsuperscript{386} (as defined below), even if the underlying media data\textsuperscript{373} has out-of-order or even overlapping time codes.

**Example**

For example, if two clips have been concatenated into one video file, but the video format exposes the original times for the two clips, the video data might expose a timeline that goes, say, 00:15..00:29 and then 00:05..00:38. However, the user agent would not expose those times; it would instead expose the times as 00:15..00:29 and 00:29..01:02, as a single video.

In the rare case of a media resource\textsuperscript{373} that does not have an explicit timeline, the zero time on the media timeline\textsuperscript{387} should correspond to the first frame of the media resource\textsuperscript{373}. In the even rarer case of a media resource\textsuperscript{373} with no explicit timings of any kind, not even frame durations, the user agent must itself determine the time for each frame in a user-agent-defined manner.

**Note**

An example of a file format with no explicit timeline but with explicit frame durations is the Animated GIF format. An example of a file format with no explicit timings at all is the JPEG-push format (multipart/x-mixed-replace\textsuperscript{378} with JPEG frames, often used as the format for MJPEG streams).

If, in the case of a resource with no timing information, the user agent will nonetheless be able to seek to an earlier point than the first frame originally provided by the server, then the zero time should correspond to the earliest seekable time of the media resource\textsuperscript{373}; otherwise, it should correspond to the first frame received from the server (the point in the media resource\textsuperscript{373} at which the user agent began receiving the stream).

**Note**

At the time of writing, there is no known format that lacks explicit frame time offsets yet still supports seeking to a frame before the first frame sent by the server.

**Example**

Consider a stream from a TV broadcaster, which begins streaming on a sunny Friday afternoon in October, and always sends connecting user agents the media data on the same media timeline, with its zero time set to the start of this stream. Months later, user agents connecting to this stream will find that the first frame they receive has a time with millions of seconds. The getStartDate()\textsuperscript{396} method would always return the date that the broadcast started; this would allow controllers to display real times in their scrubber (e.g. "2:30pm") rather than a time relative to when the broadcast began ("8 months, 4 hours, 12 minutes, and 23 seconds").

Consider a stream that carries a video with several concatenated fragments, broadcast by a server that does not allow user agents to request specific times but instead just streams the video data in a predetermined order, with the first frame delivered always being identified as the frame with time zero. If a user agent connects to this stream and receives fragments defined as covering timestamps 2010-03-20 23:15:00 UTC to 2010-03-21 00:05:00 UTC and 2010-02-12 14:25:00 UTC to 2010-02-12 14:35:00 UTC, it would expose this with a media timeline\textsuperscript{381} starting at 0s and extending to 3,600s (one hour). Assuming the streaming server disconnected at the end of the second clip, the duration\textsuperscript{388} attribute would then return 3,600. The getStartDate()\textsuperscript{396} method would return a Date object with a time corresponding to 2010-03-20 23:15:00 UTC. However, if a different user agent connected five minutes later, it would (presumably) receive fragments covering timestamps 2010-03-20 23:20:00 UTC to 2010-03-21 00:05:00 UTC and 2010-02-12 14:25:00 UTC to 2010-02-12 14:35:00 UTC, and would expose this with a media timeline\textsuperscript{381} starting at 0s and extending to 3,300s (fifty five minutes). In this case, the getStartDate()\textsuperscript{396} method would return a Date object with a time corresponding to 2010-03-20 23:20:00 UTC.

In both of these examples, the seekable\textsuperscript{400} attribute would give the ranges that the controller would want to actually display in its UI; typically, if the servers don't support seeking to arbitrary times, this would be the range of time from the moment the user agent connected to the stream up to the latest frame that the user agent has obtained; however, if the user agent starts discarding earlier information, the actual range might be shorter.

In any case, the user agent must ensure that the earliest possible position\textsuperscript{386} (as defined below) using the established media timeline\textsuperscript{381}, is greater than or equal to zero.

The media timeline\textsuperscript{381} also has an associated clock. Which clock is used is user-agent defined, and may be media resource\textsuperscript{373} dependent, but it should approximate the user's wall clock.
Media elements\(^{372}\) have a **current playback position**, which must initially (i.e. in the absence of media data\(^{373}\)) be zero seconds. The **current playback position**\(^{386}\) is a time on the media timeline\(^{387}\).

Media elements\(^{372}\) also have an **official playback position**, which must initially be set to zero seconds. The **official playback position**\(^{386}\) is an approximation of the **current playback position**\(^{389}\) that is kept stable while scripts are running.

Media elements\(^{372}\) also have a **default playback start position**, which must initially be set to zero seconds. This time is used to allow the element to be seeked even before the media is loaded.

Each media element\(^{372}\) has a **show poster flag**. When a media element\(^{372}\) is created, this flag must be set to true. This flag is used to control when the user agent is to show a poster frame for a video element instead of showing the video contents.

The **currentTime** attribute must, on getting, return the media element\(^{372}\)’s **default playback start position**\(^{389}\), unless that is zero, in which case it must return the element’s **official playback position**\(^{386}\). The returned value must be expressed in seconds. On setting, if the media element\(^{372}\)’s **readyState**\(^{392}\) is **HAVE NOTHING**\(^{390}\), then it must set the media element\(^{372}\)’s **default playback start position**\(^{386}\) to the new value; otherwise, it must set the **official playback position**\(^{389}\) to the new value and then **seek**\(^{399}\) to the new value. The new value must be interpreted as being in seconds.

If the media resource\(^{373}\) is a streaming resource, then the user agent might be unable to obtain certain parts of the resource after it has expired from its buffer. Similarly, some media resources\(^{373}\) might have a media timeline\(^{387}\) that doesn’t start at zero. The **earliest possible position** is the earliest position in the stream or resource that the user agent can ever obtain again. It is also a time on the media timeline\(^{387}\).

The **earliest possible position**\(^ {389}\) is not explicitly exposed in the API; it corresponds to the start time of the first range in the **seekable**\(^{400}\) attribute’s **TimeRanges**\(^{422}\) object, if any, or the **current playback position**\(^ {389}\) otherwise.

When the **earliest possible position**\(^{389}\) changes, then: if the **current playback position**\(^{386}\) is before the **earliest possible position**\(^{389}\), the user agent must **seek**\(^{399}\) to the **earliest possible position**\(^{389}\); otherwise, if the user agent has not fired a **timeupdate**\(^{424}\) event at the element in the past 15 to 250ms and is not still running event handlers for such an event, then the user agent must **queue a task**\(^{493}\) to **fire an event** named **timeupdate**\(^{424}\) at the element.

Because of the above requirement and the requirement in the **resource fetch algorithm**\(^{381}\) that kicks in when the metadata of the clip becomes known\(^{384}\), the **current playback position**\(^{389}\) can never be less than the **earliest possible position**\(^{389}\).

If at any time the user agent learns that an audio or video track has ended and all media data\(^{373}\) relating to that track corresponds to parts of the media timeline\(^{387}\) that are before the **earliest possible position**\(^{389}\), the user agent may **queue a task**\(^{493}\) to run these steps:

1. Remove the track from the **audioTracks**\(^{401}\) attribute’s **AudioTrackList**\(^{401}\) object or the **videoTracks**\(^{401}\) attribute’s **VideoTrackList**\(^{402}\) object as appropriate.
2. **Fire an event** named **removetrack**\(^{451}\) at the media element\(^{372}\)’s aforementioned **AudioTrackList**\(^{401}\) or **VideoTrackList**\(^{402}\) object, using **TrackEvent**\(^{422}\), with the **track**\(^{422}\) attribute initialized to the **AudioTrack**\(^{402}\) or **VideoTrack**\(^{402}\) object representing the track.

The **duration** attribute must return the time of the end of the media resource\(^{373}\), in seconds, on the media timeline\(^{387}\). If no media data\(^{373}\) is available, then the attributes must return the Not-a-Number (NaN) value. If the media resource\(^{373}\) is not known to be bounded (e.g. streaming radio, or a live event with no announced end time), then the attribute must return the positive Infinity value.

The user agent must determine the duration of the media resource\(^{373}\) before playing any part of the media data\(^{373}\) and before setting **readyState**\(^{392}\) to a value equal to or greater than **HAVE_METADATA**\(^{498}\), even if doing so requires fetching multiple parts of the resource.

When the length of the media resource\(^{373}\) changes to a known value (e.g. from being unknown to known, or from a previously established length to a new length) the user agent must **queue a task**\(^{493}\) to **fire an event** named **durationchange**\(^{424}\) at the media element\(^{372}\). (The event is not fired when the duration is reset as part of loading a new media resource.) If the duration is changed such that the **current playback position**\(^{389}\) ends up being greater than the time of the end of the media resource\(^{373}\), then the user agent must also **seek**\(^{399}\) to the time of the end of the media resource\(^{373}\).

If an “infinite” stream ends for some reason, then the duration would change from positive Infinity to the time of the last frame or sample in the stream, and the **durationchange**\(^{424}\) event would be fired. Similarly, if the user agent initially estimated the media duration...
Some video files also have an explicit date and time corresponding to the zero time in the media timeline, known as the timeline offset. Initially, the timeline offset must be set to Not-a-Number (NaN).

The `getStartDate()` method must return a new `Date` object representing the current timeline offset.

The `loop` attribute is a boolean attribute that, if specified, indicates that the media element is to seek back to the start of the media resource upon reaching the end.

The `loop` IDL attribute must reflect the content attribute of the same name.

4.8.12.7 Ready states

For web developers (non-normative)

```
media . readyState
```

Returns a value that expresses the current state of the element with respect to rendering the current playback position, from the codes in the list below.

Media elements, have a ready state, which describes to what degree they are ready to be rendered at the current playback position. The possible values are as follows; the ready state of a media element at any particular time is the greatest value describing the state of the element:

**HAVE NOTHING** (numeric value 0)

No information regarding the media resource is available. No data for the current playback position is available. Media elements whose `networkState` attribute are set to `NETWORK_EMPTY` are always in the HAVE NOTHING state.

**HAVE_METADATA** (numeric value 1)

Enough of the resource has been obtained that the duration of the resource is available. In the case of a `video` element, the dimensions of the video are also available. No `media data` is available for the immediate current playback position.

**HAVE_CURRENT_DATA** (numeric value 2)

Data for the immediate current playback position is available, but either not enough data is available that the user agent could successfully advance the current playback position in the direction of playback at all without immediately reverting to the HAVE_METADATA, or there is no more data to obtain in the direction of playback. For example, in video this corresponds to the user agent having data from the current frame, but not the next frame, when the current playback position is at the end of the current frame; and to when playback has ended.

**HAVE_FUTURE_DATA** (numeric value 3)

Data for the immediate current playback position is available, as well as enough data for the user agent to advance the current playback position in the direction of playback at least a little without immediately reverting to the HAVE_METADATA state, and the text tracks are ready. For example, in video this corresponds to the user agent having data for at least the current frame and the next frame when the current playback position is at the instant in time between the two frames, or to the user agent having the video data for the current frame and audio data to keep playing at least a little when the current playback position is in the middle of a frame. The user agent cannot be in this state if playback has ended, as the current playback position can never advance in this case.

**HAVE_ENOUGH_DATA** (numeric value 4)

All the conditions described for the HAVE_FUTURE_DATA state are met, and, in addition, either of the following conditions is also true:

- The user agent estimates that data is being fetched at a rate where the current playback position, if it were to advance at the element's playback rate, would not overtake the available data before playback reaches the end of the media resource.
• The user agent has entered a state where waiting longer will not result in further data being obtained, and therefore nothing would be gained by delaying playback any further. (For example, the buffer might be full.)

In practice, the difference between HAVE_METADATA and HAVE_CURRENT_DATA is negligible. Really the only time the difference is relevant is when painting a video element onto a canvas, where it distinguishes the case where something will be drawn (HAVE_CURRENT_DATA or greater) from the case where nothing is drawn (HAVE_METADATA or less). Similarly, the difference between HAVE_CURRENT_DATA (only the current frame) and HAVE_FUTURE_DATA (at least this frame and the next) can be negligible (in the extreme, only one frame). The only time that distinction really matters is when a page provides an interface for "frame-by-frame" navigation.

When the ready state of a media element, whose networkState is not NETWORK_EMPTY, changes, the user agent must follow the steps given below:

1. Apply the first applicable set of substeps from the following list:

   - If the previous ready state was HAVE NOTHING, and the new ready state is HAVE_METADATA
     Queue a task to fire an event named loadedmetadata at the element.

   - If the previous ready state was HAVE_METADATA and the new ready state is HAVE_CURRENT_DATA or greater
     If this is the first time this occurs for this media element since the load() algorithm was last invoked, the user agent must queue a task to fire an event named loadeddata at the element.

     If the new ready state is HAVE_FUTURE_DATA or HAVE_ENOUGH_DATA, then the relevant steps below must then be run also.

   - If the previous ready state was HAVE_CURRENT_DATA or less, and the new ready state is HAVE_FUTURE_DATA or more, and the new ready state is HAVE_CURRENT_DATA or less
     If the media element was potentially playing before its readyState attribute changed to a value lower than HAVE_FUTURE_DATA, and the element has not ended playback, and playback has not stopped due to errors, paused for user interaction, or paused for in-band content, the user agent must queue a task to fire an event named timemarches on at the element, and queue a task to fire an event named waiting at the element.

   - If the previous ready state was HAVE_CURRENT_DATA or less, and the new ready state is HAVE_FUTURE_DATA
     The user agent must queue a task to fire an event named canplay at the element.

     If the element's paused attribute is false, the user agent must notify about playing for the element.

   - If the new ready state is HAVE_ENOUGH_DATA
     If the previous ready state was HAVE_CURRENT_DATA or less, the user agent must queue a task to fire an event named canplay at the element, and, if the element's paused attribute is false, notify about playing for the element.

     The user agent must queue a task to fire an event named canplaythrough at the element.

     If the element is not eligible for autoplay, then the user agent must abort these substeps.

     The user agent may run the following substeps:

     1. Set the paused attribute to false.

     2. If the element's show poster flag is true, set it to false and run the time marches on steps.

     3. Queue a task to fire an event named play at the element.
4. Notify about playing for the element.

Alternatively, if the element is a video element, the user agent may start observing whether the element intersects the viewport. When the element starts intersecting the viewport, if the element is still eligible for autoplay, run the substeps above. Optionally, when the element stops intersecting the viewport, if the can autoplay flag is still true and the autoplay attribute is still specified, run the following substeps:

**Note**

This specification doesn’t define the precise timing for when the intersection is tested, but it is suggested that the timing match that of the Intersection Observer API. [INTERSECTIONOBSERVER]

1. Run the internal pause steps and set the can autoplay flag to true.
2. Queue a task to fire an event named pause at the element.

**Note**

The substeps for playing and pausing can run multiple times as the element starts or stops intersecting the viewport, as long as the can autoplay flag is true.

**Note**

User agents do not need to support autoplay, and it is suggested that user agents honor user preferences on the matter. Authors are urged to use the autoplay attribute rather than using script to force the video to play, so as to allow the user to override the behavior if so desired.

**Note**

It is possible for the ready state of a media element to jump between these states discontinuously. For example, the state of a media element can jump straight from HAVE_METADATA to HAVE_ENOUGH_DATA without passing through the HAVE_CURRENT_DATA and HAVE_FUTURE_DATA states.

The readyState IDL attribute must, on getting, return the value described above that describes the current ready state of the media element.

The autoplay attribute is a boolean attribute. When present, the user agent (as described in the algorithm described herein) will automatically begin playback of the media resource as soon as it can do so without stopping.

**Note**

Authors are urged to use the autoplay attribute rather than using script to trigger automatic playback, as this allows the user to override the automatic playback when it is not desired, e.g. when using a screen reader. Authors are also encouraged to consider not using the automatic playback behavior at all, and instead to let the user agent wait for the user to start playback explicitly.

The autoplay IDL attribute must reflect the content attribute of the same name.

4.8.12.8 Playing the media resource

For web developers (non-normative)

- **media.paused**
  
  Returns true if playback is paused; false otherwise.

- **media.ended**
  
  Returns true if playback has reached the end of the media resource.

- **media.defaultPlaybackRate** [ = value ]
  
  Returns the default rate of playback, for when the user is not fast-forwarding or reversing through the media resource.

  Can be set, to change the default rate of playback.

  The default rate has no direct effect on playback, but if the user switches to a fast-forward mode, when they return to the normal playback mode, it is expected that the rate of playback will be returned to the default rate of playback.
media . playbackRate[^394] [ = value ]
Returns the current rate playback, where 1.0 is normal speed.
Can be set, to change the rate of playback.

media . played[^395]
Returns a TimeRanges[^422] object that represents the ranges of the media resource[^373] that the user agent has played.

media . play[^395]()
Sets the paused[^393] attribute to false, loading the media resource[^373] and beginning playback if necessary. If the playback had ended, will restart it from the start.

media . pause[^396]()
Sets the paused[^393] attribute to true, loading the media resource[^373] if necessary.

The paused attribute represents whether the media element[^372] is paused or not. The attribute must initially be true.

A media element[^372] is a blocked media element if its readyState[^392] attribute is in the HAVE NOTHING[^390] state, the HAVE METADATA[^390] state, or the HAVE CURRENT DATA[^390] state, or if the element has paused for user interaction[^394] or paused for in-band content[^394].

A media element[^372] is said to be potentially playing when its paused[^393] attribute is false, the element has not ended playback[^393], playback has not stopped due to errors[^393], and the element is not a blocked media element[^393].

Note
A waiting[^424] DOM event can be fired[^391] as a result of an element that is potentially playing[^393] stopping playback due to its readyState[^392] attribute changing to a value lower than HAVE FUTURE DATA[^390].

A media element[^372] is said to be eligible for autoplay when its can autoplay flag[^377] is true, its paused[^393] attribute is true, the element has an autoplay[^392] attribute specified, and the element's node document's active sandboxing flag set[^806] does not have the sandboxed automatic features browsing context flag[^807] set.

A media element[^372] is said to be allowed to play if the user agent and the system allow media playback in the current context.

Note
For example, a user agent could require that playback is triggered by user activation[^372], but an exception could be made to allow playback while muted[^421].

A media element[^372] is said to have ended playback when:

- The element’s readyState[^392] attribute is HAVE METADATA[^390] or greater, and
  - Either:
    - The current playback position[^389] is the end of the media resource[^373], and
    - The direction of playback[^396] is forwards, and
    - The media element[^372] does not have a loop[^390] attribute specified.
  - Or:
    - The current playback position[^389] is the earliest possible position[^389], and
    - The direction of playback[^396] is backwards.

The ended attribute must return true if, the last time the event loop[^893] reached step 1[^894], the media element[^372] had ended playback[^393] and the direction of playback[^396] was forwards, and false otherwise.

A media element[^372] is said to have stopped due to errors when the element’s readyState[^392] attribute is HAVE METADATA[^390] or greater, and the user agent encounters a non-fatal error[^386] during the processing of the media data[^377], and due to that error, is not able to play the content at the current playback position[^389].
A media element is said to have **paused for user interaction** when its `paused` attribute is false, the `readyState` attribute is either `HAVE_FUTURE_DATA` or `HAVE_ENOUGH_DATA` and the user agent has reached a point in the media resource where the user has to make a selection for the resource to continue.

It is possible for a media element to have both `ended playback` and `paused for user interaction` at the same time.

When a media element that is potentially playing stops playing because it has `paused for user interaction`, the user agent must queue a task to fire an event named `timeupdate` at the element.

A media element is said to have **paused for in-band content** when its `paused` attribute is false, the `readyState` attribute is either `HAVE_FUTURE_DATA` or `HAVE_ENOUGH_DATA` and the user agent has suspended playback of the media resource in order to play content that is temporally anchored to the media resource, and has a nonzero length, or to play content that is temporally anchored to a segment of the media resource but has a length longer than that segment.

**Example**

One example of when a media element would be `paused for in-band content` is when the user agent is playing audio descriptions from an external WebVTT file, and the synthesized speech generated for a cue is longer than the time between the text track cue start time and the text track cue end time.

When the **current playback position** reaches the end of the media resource when the **direction of playback** is forwards, then the user agent must follow these steps:

1. If the media element has a `loop` attribute specified, then seek to the earliest possible position of the media resource and return.
2. As defined above, the `ended` IDL attribute starts returning true once the `event loop` returns to step 1.
3. Queue a task to run these steps:
   1. Fire an event named `timeupdate` at the media element.
   2. If the media element has `ended`, the **direction of playback** is forwards, and `paused` is false, then:
      1. Set the `paused` attribute to true.
      2. Fire an event named `pause` at the media element.
      3. Take pending play promises and reject pending play promises with the result and an `AbortError` exception.
   3. Fire an event named `ended` at the media element.

When the **current playback position** reaches the earliest possible position of the media resource when the **direction of playback** is backwards, then the user agent must only queue a task to fire an event named `timeupdate` at the element.

### Note

The word "reaches" here does not imply that the **current playback position** needs to have changed during normal playback; it could be via seeking, for instance.

The **defaultPlaybackRate** attribute gives the desired speed at which the media resource is to play, as a multiple of its intrinsic speed. The attribute is mutable: on getting it must return the last value it was set to, or 1.0 if it hasn't yet been set; on setting the attribute must be set to the new value.

### Note

The **defaultPlaybackRate** is used by the user agent when it exposes a user interface to the user.

The **playbackRate** attribute gives the effective playback rate, which is the speed at which the media resource plays, as a multiple of its intrinsic speed. If it is not equal to the **defaultPlaybackRate**, then the implication is that the user is using a feature such as fast forward or slow motion playback. The attribute is mutable: on getting it must return the last value it was set to, or 1.0 if it hasn't yet been set; on setting, the user agent must follow these steps:

1. If the given value is not supported by the user agent, then throw a `NotSupportedError` exception.
2. Set `playbackRate` to the new value, and if the element is potentially playing, change the playback speed.

When the `defaultPlaybackRate` or `playbackRate` attributes change value (either by being set by script or by being changed directly by the user agent, e.g. in response to user control) the user agent must queue a task to fire an event named `ratechange` at the media element.

The `played` attribute must return a new static normalized TimeRanges object that represents the ranges of points on the media timeline of the media resource reached through the usual monotonic increase of the current playback position during normal playback, if any, at the time the attribute is evaluated.

⚠️ Warning! Returning a new object each time is a bad pattern for attribute getters and is only enshrined here as it would be costly to change it. It is not to be copied to new APIs.

Each media element has a list of pending play promises, which must initially be empty.

To take pending play promises for a media element, the user agent must run the following steps:

1. Let promises be an empty list of promises.
2. Copy the media element's list of pending play promises to promises.
3. Clear the media element's list of pending play promises.
4. Return promises.

To resolve pending play promises for a media element with a list of promises promises, the user agent must resolve each promise in promises with undefined.

To reject pending play promises for a media element with a list of promise promises and an exception name error, the user agent must reject each promise in promises with error.

To notify about playing for a media element, the user agent must run the following steps:

1. Take pending play promises and let promises be the result.
2. Queue a task to run these steps:
   1. Fire an event named `playing` at the element.
   2. Resolve pending play promises with promises.

When the `play()` method on a media element is invoked, the user agent must run the following steps.

1. If the media element is not allowed to play, return a promise rejected with a "NotAllowedError" DOMException.
2. If the media element's `error` attribute is not null and its `code` is `MEDIA_ERR_SRC_NOT_SUPPORTED`, return a promise rejected with a "NotSupportedError" DOMException.

This means that the dedicated media source failure steps have run. Playback is not possible until the media element load algorithm clears the error attribute.

3. Let promise be a new promise and append promise to the list of pending play promises.
4. If the media element's `networkState` attribute has the value `NETWORK_EMPTY`, invoke the media element's resource selection algorithm.
5. If the playback has ended and the direction of playback is forwards, seek to the earliest possible position of the media resource.

This will cause the user agent to queue a task to fire an event named `timeupdate` at the media element.
6. If the media element's `paused` attribute is true, then:
   1. Change the value of `paused` to false.
   2. If the `show poster flag` is true, set the element's `show poster flag` to false and run the `time marches on` steps.
   3. Queue a task to fire an event named `play` at the element.
   4. If the media element's `readyState` attribute has the value `HAVE NOTHING`, `HAVE_METADATA`, or `HAVE_CURRENT_DATA`, queue a task to fire an event named `waiting` at the element.
      Otherwise, the media element's `readyState` attribute has the value `HAVE_FUTURE_DATA` or `HAVE_ENOUGH_DATA`:
      - notify about playing for the element.

7. Otherwise, if the media element's `readyState` attribute has the value `HAVE_FUTURE_DATA` or `HAVE_ENOUGH_DATA`, take pending play promises and queue a task to resolve pending play promises with the result.

8. Set the media element's `can autoplay flag` to false.

9. Return promise.

When the `pause()` method is invoked, and when the user agent is required to pause the media element, the user agent must run the following steps:

1. If the media element's `networkState` attribute has the value `NETWORK_EMPTY`, invoke the media element's resource selection algorithm.
2. Run the internal pause steps for the media element.

The internal pause steps for a media element are as follows:

1. Set the media element's `can autoplay flag` to false.
2. If the media element's `paused` attribute is false, run the following steps:
   1. Change the value of `paused` to true.
   2. Take pending play promises and let promises be the result.
   3. Queue a task to run these steps:
      1. Fire an event named `timeupdate` at the element.
      2. Fire an event named `pause` at the element.
      3. Reject pending play promises with promises and an "AbortError" DOMException.
   4. Set the official playback position to the current playback position.

If the element's `playbackRate` is positive or zero, then the direction of playback is forwards. Otherwise, it is backwards.

When a media element is potentially playing and its `playbackRate` is a fully active, its `current playback position` must increase monotonically at the element's `playbackRate` units of media time per unit time of the media timeline's clock. (This specification always refers to this as an increase, but that increase could actually be a decrease if the element's `playbackRate` is negative.)

The element's `playbackRate` can be 0.0, in which case the current playback position doesn't move, despite playback not being paused (paused doesn't become true, and the `pause` event doesn't fire).
This specification doesn’t define how the user agent achieves the appropriate playback rate — depending on the protocol and media available, it is plausible that the user agent could negotiate with the server to have the server provide the media data at the appropriate rate, so that (except for the period between when the rate is changed and when the server updates the stream’s playback rate) the client doesn’t actually have to drop or interpolate any frames.

Any time the user agent provides a stable state, the official playback position must be set to the current playback position.

While the direction of playback is backwards, any corresponding audio must be muted. While the element’s playbackRate is so low or so high that the user agent cannot play audio usefully, the corresponding audio must also be muted. If the element’s playbackRate is not 1.0, the user agent may apply pitch adjustments to the audio as necessary to render it faithfully.

When a media element is potentially playing, its audio data played must be synchronized with the current playback position at the element’s effective media volume. The user agent must play the audio from audio tracks that were enabled when the event loop last reached step 1.

When a media element is not potentially playing, audio must not play for the element.

Media elements that are potentially playing while not in a document must not play any video, but should play any audio component. Media elements must not stop playing just because all references to them have been removed; only once a media element is in a state where no further audio could ever be played by that element may the element be garbage collected.

It is possible for an element to which no explicit references exist to play audio, even if such an element is not still actively playing: for instance, it could be unpaused but stalled waiting for content to buffer, or it could be still buffering, but with a suspend event listener that begins playback. Even a media element whose media resource has no audio tracks could eventually play audio again if it had an event listener that changes the media resource.

Each media element has a list of newly introduced cues, which must be initially empty. Whenever a text track cue is added to the list of cues of a text track that is in the list of text tracks for a media element, that cue must be added to the media element’s list of newly introduced cues. Whenever a text track is added to the list of text tracks for a media element, all of the cues in that text track’s list of cues must be added to the media element’s list of newly introduced cues. When a media element’s list of newly introduced cues has new cues added while the media element’s show poster flag is not set, then the user agent must run the time marches on steps.

When a text track cue is removed from the list of cues of a text track that is in the list of text tracks for a media element, and whenever a text track is removed from the list of text tracks of a media element, if the media element’s show poster flag is not set, then the user agent must run the time marches on steps.

When the current playback position changes (e.g. due to playback or seeking), the user agent must run the time marches on steps. If the current playback position changes while the steps are running, then the user agent must wait for the steps to complete, and then must immediately rerun the steps. (These steps are thus run as often as possible or needed — if one iteration takes a long time, this can cause certain cues to be skipped over as the user agent rushes ahead to “catch up.”)

The time marches on steps are as follows:

1. Let current cues be a list of cues, initialized to contain all the cues of all the hidden or showing text tracks of the media element (not the disabled ones) whose start times are less than or equal to the current playback position and whose end times are greater than the current playback position.
2. Let other cues be a list of cues, initialized to contain all the cues of hidden and showing text tracks of the media element that are not present in current cues.
3. Let last time be the current playback position at the time this algorithm was last run for this media element, if this is not the first time it has run.
4. If the current playback position has, since the last time this algorithm was run, only changed through its usual monotonic increase during normal playback, then let missed cues be the list of cues in other cues whose start times are greater than or equal to last time and whose end times are less than or equal to the current playback position. Otherwise, let missed cues be an empty list.
5. Remove all the cues in missed cues that are also in the media element’s list of newly introduced cues, and then empty the element’s list of newly introduced cues.
6. If the time was reached through the usual monotonic increase of the **current playback position** during normal playback, and if the user agent has not fired a **timeupdate** event at the element in the past 15 to 250ms and is not still running event handlers for such an event, then the user agent must queue a task to fire an event named **timeupdate** at the element. (In the other cases, such as explicit seek, relevant events get fired as part of the overall process of changing the **current playback position**.)

**Note**

The event thus is not to be fired faster than about 66Hz or slower than 4Hz (assuming the event handlers don't take longer than 250ms to run). User agents are encouraged to vary the frequency of the event based on the system load and the average cost of processing the event each time, so that the UI updates are not any more frequent than the user agent can comfortably handle while decoding the video.

7. If all of the cues in current cues have their **text track cue active flag** set, none of the cues in other cues have their **text track cue active flag** set, and missed cues is empty, then return.

8. If the time was reached through the usual monotonic increase of the **current playback position** during normal playback, and there are cues in other cues that have their **text track cue active flag** set and that either have their **text track cue pause-on-exit flag** set or are also in missed cues, then immediately pause the **media element**.

**Note**

In the other cases, such as explicit seek, playback is not paused by going past the end time of a cue, even if that cue has its **text track cue pause-on-exit flag** set.

9. Let events be a list of tasks, initially empty. Each task in this list will be associated with a **text track** or a **text track cue** and a time, which are used to sort the list before the tasks are queued.

Let affected tracks be a list of **text tracks**, initially empty.

When the steps below say to **prepare an event** named event for a **text track** target with a time, the user agent must run these steps:

1. Let track be the **text track** with which the **text track** target is associated.
2. Create a task to fire an event named event at target.
3. Add the newly created task to events, associated with the time, the **text track** track, and the **text track cue** target.
4. Add track to affected tracks.

10. For each **text track cue** in missed cues, **prepare an event** named enter for the **TextTrackCue** object with the **text track cue start time**.

11. For each **text track cue** in other cues that either has its **text track cue active flag** set or is in missed cues, **prepare an event** named exit for the **TextTrackCue** object with the later of the **text track cue end time** and the **text track cue start time**.

12. For each **text track cue** in current cues that does not have its **text track cue active flag** set, **prepare an event** named enter for the **TextTrackCue** object with the **text track cue start time**.

13. Sort the tasks in events in ascending time order with earlier times first.

    Further sort tasks in events that have the same time by the relative **text track cue order** of the **text track cues** associated with these tasks.

    Finally, sort tasks in events that have the same time and same **text track cue order** by placing tasks that fire enter events before those that fire exit events.

14. Queue each task in events, in list order.

15. Sort affected tracks in the same order as the **text tracks** appear in the **media element**'s list of text tracks, and remove duplicates.

16. For each **text track** in affected tracks, in the list order, queue a task to fire an event named cuechange at the **TextTrack** object, and, if the **text track** has a corresponding **track** element, to then fire an event named cuechange at the **track** element as well.
17. Set the `text track cue active flag` of all the cues in the current cues, and unset the `text track cue active flag` of all the cues in the other cues.

18. Run the rules for updating the text track rendering of each of the text tracks in affected tracks that are showing, providing the text track's text track language as the fallback language if it is not the empty string. For example, for text tracks based on WebVTT, the rules for updating the display of WebVTT text tracks.

For the purposes of the algorithm above, a text track cue is considered to be part of a text track only if it is listed in the text track list of cues, not merely if it is associated with the text track.

Note

If the `media element`'s node document stops being a fully active document, then the playback will stop until the document is active again.

Whenever a `media element` is removed from a `Document`, the user agent must run the following steps:

1. Await a stable state, allowing the task that removed the `media element` from the `Document` to continue. The synchronous section consists of all the remaining steps of this algorithm. (Steps in the synchronous section are marked with ⌚.)
2. ⌚ If the `media element` is in a document, return.
3. ⌚ Run the internal pause steps for the `media element`.

### 4.8.12.9 Seeking

For web developers (non-normative)

`media . seeking` Returns true if the user agent is currently seeking.

`media . seekable` Returns a `TimeRanges` object that represents the ranges of the media resource to which it is possible for the user agent to seek.

`media . fastSeek(time)` Seeks to near the given `time` as fast as possible, trading precision for speed. (To seek to a precise time, use the `currentTime` attribute.)

This does nothing if the media resource has not been loaded.

The `seeking` attribute must initially have the value false.

The `fastSeek()` method must `seek` to the time given by the method's argument, with the `approximate-for-speed` flag set.

When the user agent is required to `seek` to a particular new playback position in the `media resource`, optionally with the `approximate-for-speed` flag set, it means that the user agent must run the following steps. This algorithm interacts closely with the `event loop` mechanism; in particular, it has a synchronous section (which is triggered as part of the `event loop` algorithm). Steps in that section are marked with ⌚.

1. Set the `media element`'s `show poster flag` to false.
2. If the `media element`'s `readyState` is `HAVE NOTHING`, return.
3. If the element's `seeking` IDL attribute is true, then another instance of this algorithm is already running. Abort that other instance of the algorithm without waiting for the step that it is running to complete.
4. Set the `seeking` IDL attribute to true.
5. If the seek was in response to a DOM method call or setting of an IDL attribute, then continue the script. The remainder of these steps must be run in parallel. With the exception of the steps marked with ⌚, they could be aborted at any time by another instance of this algorithm being invoked.
6. If the new playback position is later than the end of the media resource, then let it be the end of the media resource instead.

7. If the new playback position is less than the earliest possible position, let it be that position instead.

8. If the (possibly now changed) new playback position is not in one of the ranges given in the seekable attribute, then let it be the position in one of the ranges given in the seekable attribute that is the nearest to the new playback position. If two positions both satisfy that constraint (i.e. the new playback position is exactly in the middle between two ranges in the seekable attribute) then use the position that is closest to the current playback position. If there are no ranges given in the seekable attribute then set the seeking IDL attribute to false and return.

9. If the approximate-for-speed flag is set, adjust the new playback position to a value that will allow for playback to resume promptly. If new playback position before this step is before current playback position, then the adjusted new playback position must also be before the current playback position. Similarly, if the new playback position after this step is after current playback position, then the adjusted new playback position must also be after the current playback position.

10. Queue a task to fire an event named seeking at the element.

11. Set the current playback position to the new playback position.

12. Wait until the user agent has established whether or not the media data for the new playback position is available, and, if it is, until it has decoded enough data to play back that position.

13. Await a stable state. The synchronous section consists of all the remaining steps of this algorithm. (Steps in the synchronous section are marked with ⏳.)

14. Set the seeking IDL attribute to false.

15. Run the time marches on steps.

16. Queue a task to fire an event named timeupdate at the element.

17. Queue a task to fire an event named seeked at the element.

The seekable attribute must return a new static normalized TimeRanges object that represents the ranges of the media resource, if any, that the user agent is able to seek to, at the time the attribute is evaluated.

Note

If the user agent can seek to anywhere in the media resource, e.g. because it is a simple movie file and the user agent and the server support HTTP Range requests, then the attribute would return an object with one range, whose start is the time of the first frame (the earliest possible position, typically zero), and whose end is the same as the time of the first frame plus the duration attribute's value (which would equal the time of the last frame, and might be positive infinity).

Note

The range might be continuously changing, e.g. if the user agent is buffering a sliding window on an infinite stream. This is the behavior seen with DVRs viewing live TV, for instance.
User agents should adopt a very liberal and optimistic view of what is seekable. User agents should also buffer recent content where possible to enable seeking to be fast.

Media resources might be internally scripted or interactive. Thus, a media element could play in a non-linear fashion. If this happens, the user agent must act as if the algorithm for seeking was used whenever the current playback position changes in a discontinuous fashion (so that the relevant events fire).

Example

For instance, consider a large video file served on an HTTP server without support for HTTP Range requests. A browser could implement this by only buffering the current frame and data obtained for subsequent frames, never allow seeking, except for seeking to the very start by restarting the playback. However, this would be a poor implementation. A high quality implementation would buffer the last few minutes of content (or more, if sufficient storage space is available), allowing the user to jump back and rewatch something surprising without any latency, and would in addition allow arbitrary seeking by reloading the file from the start if necessary, which would be slower but still more convenient than having to literally restart the video and watch it all the way through just to get to an earlier unbuffered spot.

Media resources might be internally scripted or interactive. Thus, a media element could play in a non-linear fashion. If this happens, the user agent must act as if the algorithm for seeking was used whenever the current playback position changes in a discontinuous fashion (so that the relevant events fire).

### 4.8.12.10 Media resources with multiple media tracks

A media resource can have multiple embedded audio and video tracks. For example, in addition to the primary video and audio tracks, a media resource could have foreign-language dubbed dialogues, director’s commentaries, audio descriptions, alternative angles, or sign-language overlays.

For web developers (non-normative)

```html
media.audioTracks
```

Returns an AudioTrackList object representing the audio tracks available in the media resource.

```html
media.videoTracks
```

Returns a VideoTrackList object representing the video tracks available in the media resource.

The audioTracks attribute of a media element must return a live AudioTrackList object representing the audio tracks available in the media element's media resource.

The videoTracks attribute of a media element must return a live VideoTrackList object representing the video tracks available in the media element's media resource.

Note

There are only ever one AudioTrackList object and one VideoTrackList object per media element, even if another media resource is loaded into the element: the objects are reused. (The AudioTrack and VideoTrack objects are not, though.)

### 4.8.12.10.1 AudioTrackList and VideoTrackList objects

The AudioTrackList and VideoTrackList interfaces are used by attributes defined in the previous section.

IDL

```javascript
[Exposed=Window]
interface AudioTrackList : EventTarget {
    readonly attribute unsigned long length;
    getter AudioTrack (unsigned long index);
    AudioTrack? getTrackById(DOMString id);
}

attribute EventHandler onchange;
```
attribute EventHandler onaddtrack;
attribute EventHandler onremovetrack;
};

[Exposed=Window]
interface AudioTrack {
  readonly attribute DOMString id;
  readonly attribute DOMString kind;
  readonly attribute DOMString label;
  readonly attribute DOMString language;
  attribute boolean enabled;
};

[Exposed=Window]
interface VideoTrackList : EventTarget {
  readonly attribute unsigned long length;
  getter VideoTrack (unsigned long index);
  VideoTrack? getTrackById(DOMString id);
  readonly attribute long selectedIndex;

  attribute EventHandler onchange;
  attribute EventHandler onaddtrack;
  attribute EventHandler onremovetrack;
};

[Exposed=Window]
interface VideoTrack {
  readonly attribute DOMString id;
  readonly attribute DOMString kind;
  readonly attribute DOMString label;
  readonly attribute DOMString language;
  attribute boolean selected;
};

For web developers (non-normative)

media . audioTracks.length
media . videoTracks.length

Returns the number of tracks in the list.

audioTrack = media . audioTracks[index]
videoTrack = media . videoTracks[index]

Returns the specified AudioTrack or VideoTrack object.

audioTrack = media . audioTracks.getTrackById( id )
videoTrack = media . videoTracks.getTrackById( id )

Returns the AudioTrack or VideoTrack object with the given identifier, or null if no track has that identifier.

audioTrack . id
videoTrack . id

Returns the ID of the given track. This is the ID that can be used with a fragment if the format supports media fragment syntax, and that can be used with the getTrackById() method.

audioTrack . kind
videoTrack . kind

Returns the category the given track falls into. The possible track categories are given below.
An AudioTrackList object represents a dynamic list of zero or more audio tracks, of which zero or more can be enabled at a time. Each audio track is represented by an AudioTrack object.

A VideoTrackList object represents a dynamic list of zero or more video tracks, of which zero or one can be selected at a time. Each video track is represented by a VideoTrack object.

Tracks in AudioTrackList and VideoTrackList objects must be consistently ordered. If the media resource is in a format that defines an order, then that order must be used; otherwise, the order must be the relative order in which the tracks are declared in the media resource. The order used is called the natural order of the list.

An AudioTrackList object represents a dynamic list of zero or more audio tracks, of which zero or more can be enabled at a time. Each audio track is represented by an AudioTrack object.

A VideoTrackList object represents a dynamic list of zero or more video tracks, of which zero or one can be selected at a time. Each video track is represented by a VideoTrack object.

The AudioTrackList.length and VideoTrackList.length attributes must return the number of tracks represented by their objects at the time of getting.

The supported property indices of AudioTrackList and VideoTrackList objects at any instant are the numbers from zero to the number of tracks represented by the respective object minus one, if any tracks are represented. If an AudioTrackList or VideoTrackList object represents no tracks, it has no supported property indices.

To determine the value of an indexed property for a given index index in an AudioTrackList or VideoTrackList object list, the user agent must return the AudioTrack or VideoTrack object that represents the indexth track in list.

The AudioTrackList.getTrackById(id) and VideoTrackList.getTrackById(id) methods must return the first AudioTrack or VideoTrack object (respectively) in the AudioTrackList or VideoTrackList object (respectively) whose identifier is equal to the value of the id argument (in the natural order of the list, as defined above). When no tracks match the given argument, the methods must return null.

The AudioTrack and VideoTrack objects represent specific tracks of a media resource. Each track can have an identifier, category, label, and language. These aspects of a track are permanent for the lifetime of the track; even if a track is removed from a media resource's AudioTrackList or VideoTrackList objects, those aspects do not change.

In addition, AudioTrack objects can each be enabled or disabled; this is the audio track's enabled state. When an AudioTrack is created, its enabled state must be set to false (disabled). The resource fetch algorithm can override this.

Similarly, a single VideoTrack object per VideoTrackList object can be selected, this is the video track's selection state.
a **VideoTrack** is created, its *selection state* must be set to false (not selected). The **resource fetch algorithm** can override this.

The **AudioTrack.id** and **VideoTrack.id** attributes must return the identifier of the track, if it has one, or the empty string otherwise. If the **media resource** is in a format that supports **media fragment syntax**, the identifier returned for a particular track must be the same identifier that would enable the track if used as the name of a track in the track dimension of such a fragment. **[INBAND]**

---

**Example**

For example, in Ogg files, this would be the Name header field of the track. **[OGGSKELETONHEADERS]**

---

The **AudioTrack.kind** and **VideoTrack.kind** attributes must return the category of the track, if it has one, or the empty string otherwise.

The category of a track is the string given in the first column of the table below that is the most appropriate for the track based on the definitions in the table's second and third columns, as determined by the metadata included in the track in the **media resource**. The cell in the third column of a row says what the category given in the cell in the first column of that row applies to; a category is only appropriate for an audio track if it applies to audio tracks, and a category is only appropriate for video tracks if it applies to video tracks. Categories must only be returned for **AudioTrack** objects if they are appropriate for audio, and must only be returned for **VideoTrack** objects if they are appropriate for video.

For Ogg files, the Role header field of the track gives the relevant metadata. For DASH media resources, the **Role** element conveys the information. For WebM, only the FlagDefault element currently maps to a value. The **Sourcing In-band Media Resource Tracks from Media Containers into HTML** specification has further details. **[OGGSKELETONHEADERS]** [DASH] [WEBMCG] [INBAND]

---

<table>
<thead>
<tr>
<th>Category</th>
<th>Definition</th>
<th>Applies to...</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>alternative</td>
<td>A possible alternative to the main track, e.g. a different take of a song (audio), or a different angle (video).</td>
<td>Audio and video.</td>
<td>Ogg: “audio/alternate” or “video/alternate”; DASH: “alternate” without “main” and “commentary” roles, and, for audio, without the “dub” role (other roles ignored).</td>
</tr>
<tr>
<td>captions</td>
<td>A version of the main video track with captions burnt in. (For legacy content; new content would use text tracks.)</td>
<td>Video only.</td>
<td>DASH: “caption” and “main” roles together (other roles ignored).</td>
</tr>
<tr>
<td>descriptions</td>
<td>An audio description of a video track.</td>
<td>Audio only.</td>
<td>Ogg: “audio/audiodesc”.</td>
</tr>
<tr>
<td>main</td>
<td>The primary audio or video track.</td>
<td>Audio and video.</td>
<td>Ogg: “audio/main” or “video/main”; WebM: the FlagDefault element is set; DASH: “main” role without “caption”, “subtitle”, and “dub” roles (other roles ignored).</td>
</tr>
<tr>
<td>main-desc</td>
<td>The primary audio track, mixed with audio descriptions.</td>
<td>Audio only.</td>
<td>AC3 audio in MPEG-2 TS: bsmod=2 and full_svc=1.</td>
</tr>
<tr>
<td>subtitles</td>
<td>A version of the main video track with subtitles burnt in. (For legacy content; new content would use text tracks.)</td>
<td>Video only.</td>
<td>DASH: “subtitle” and “main” roles together (other roles ignored).</td>
</tr>
<tr>
<td>translation</td>
<td>A translated version of the main audio track.</td>
<td>Audio only.</td>
<td>Ogg: “audio/dub”. DASH: “dub” and “main” roles together (other roles ignored).</td>
</tr>
<tr>
<td>commentary</td>
<td>Commentary on the primary audio or video track, e.g. a director's commentary.</td>
<td>Audio and video.</td>
<td>DASH: “commentary” role without “main” role (other roles ignored).</td>
</tr>
<tr>
<td>** (empty string)</td>
<td>No explicit kind, or the kind given by the track's metadata is not recognized by the user agent.</td>
<td>Audio and video.</td>
<td></td>
</tr>
</tbody>
</table>

The **AudioTrack.label** and **VideoTrack.label** attributes must return the label of the track, if it has one, or the empty string otherwise. **[INBAND]**

The **AudioTrack.language** and **VideoTrack.language** attributes must return the BCP 47 language tag of the language of the track, if it has one, or the empty string otherwise. If the user agent is not able to express that language as a BCP 47 language tag (for example because the language information in the **media resource**'s format is a free-form string without a defined interpretation), then the method must return the empty string, as if the track had no language. **[INBAND]**

The **AudioTrack.enabled** attribute, on getting, must return true if the track is currently enabled, and false otherwise. On setting, it must enable the track if the new value is true, and disable it otherwise. (If the track is no longer in an **AudioTrackList** object, then the track being enabled or disabled has no effect beyond changing the value of the attribute on the **AudioTrack** object.)
Whenever an audio track in an AudioTrackList that was disabled is enabled, and whenever one that was enabled is disabled, the user agent must queue a task to fire an event named change at the AudioTrackList object.

An audio track that has no data for a particular position on the media timeline, or that does not exist at that position, must be interpreted as being silent at that point on the timeline.

The VideoTrackList.selectedIndex attribute must return the index of the currently selected track, if any. If the VideoTrackList object does not currently represent any tracks, or if none of the tracks are selected, it must instead return −1.

The VideoTrack.selected attribute, on getting, must return true if the track is currently selected, and false otherwise. On setting, it must select the track if the new value is true, and unselect it otherwise. If the track is in a VideoTrackList object, then all the other VideoTrack objects in that list must be unselected. (If the track is no longer in a VideoTrackList object, then the track being selected or unselected has no effect beyond changing the value of the attribute on the VideoTrack object.)

Whenever a track in a VideoTrackList that was previously not selected is selected, and whenever the selected track in a VideoTrackList is unselected without a new track being selected in its stead, the user agent must queue a task to fire an event named change at the VideoTrackList object. This task must be queued before the task that fires the resize event, if any.

A video track that has no data for a particular position on the media timeline must be interpreted as being transparent black at that point on the timeline, with the same dimensions as the last frame before that position, or, if the position is before all the data for that track, the same dimensions as the first frame for that track. A track that does not exist at all at the current position must be treated as if it existed but had no data.

### Example

For instance, if a video has a track that is only introduced after one hour of playback, and the user selects that track then goes back to the start, then the user agent will act as if that track started at the start of the media resource but was simply transparent until one hour in.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the AudioTrackList and VideoTrackList interfaces:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onchange</td>
<td>change</td>
</tr>
<tr>
<td>onaddtrack</td>
<td>addtrack</td>
</tr>
<tr>
<td>onremovetrack</td>
<td>removetrack</td>
</tr>
</tbody>
</table>

### 4.8.12.10.2 Selecting specific audio and video tracks declaratively

The audioTracks and videoTracks attributes allow scripts to select which track should play, but it is also possible to select specific tracks declaratively, by specifying particular tracks in the fragment of the URL of the media resource. The format of the fragment depends on the MIME type of the media resource.

### Example

In this example, a video that uses a format that supports media fragment syntax is embedded in such a way that the alternative angles labeled "Alternative" are enabled instead of the default video track.

```html
<video src="myvideo#track=Alternative"></video>
```

### 4.8.12.11 Timed text tracks

#### 4.8.12.11.1 Text track model

A media element can have a group of associated text tracks, known as the media element's list of text tracks. The text tracks are sorted as follows:
A **text track** consists of:

### The kind of text track

This decides how the track is handled by the user agent. The kind is represented by a string. The possible strings are:

- subtitles
- captions
- descriptions
- chapters
- metadata

The **kind of track** can change dynamically, in the case of a **text track** corresponding to a **track** element.

### A label

This is a human-readable string intended to identify the track for the user.

The **label of a track** can change dynamically, in the case of a **text track** corresponding to a **track** element.

When a **text track label** is the empty string, the user agent should automatically generate an appropriate label from the text track's other properties (e.g. the kind of text track and the text track's language) for use in its user interface. This automatically-generated label is not exposed in the API.

### An in-band metadata track dispatch type

This is a string extracted from the **media resource** specifically for in-band metadata tracks to enable such tracks to be dispatched to different scripts in the document.

#### Example

For example, a traditional TV station broadcast streamed on the Web and augmented with Web-specific interactive features could include text tracks with metadata for ad targeting, trivia game data during game shows, player states during sports games, recipe information during food programs, and so forth. As each program starts and ends, new tracks might be added or removed from the stream, and as each one is added, the user agent could bind them to dedicated script modules using the value of this attribute.

Other than for in-band metadata text tracks, the **in-band metadata track dispatch type** is the empty string. How this value is populated for different media formats is described in **steps to expose a media-resource-specific text track**.

### A language

This is a string (a BCP 47 language tag) representing the language of the text track's cues. [BCP47]

The **language of a text track** can change dynamically, in the case of a **text track** corresponding to a **track** element.

### A readiness state

One of the following:

#### Not loaded

Indicates that the text track's cues have not been obtained.

#### Loading

Indicates that the text track is loading and there have been no fatal errors encountered so far. Further cues might still be added to the track by the parser.

#### Loaded

Indicates that the text track has been loaded with no fatal errors.

#### Failed to load

Indicates that the text track was enabled, but when the user agent attempted to obtain it, this failed in some way (e.g. URL could not be parsed, network error, unknown text track format). Some or all of the cues are likely missing and will not be obtained.

The **readiness state** of a **text track** changes dynamically as the track is obtained.
A mode
One of the following:

Disabled
Indicates that the text track is not active. Other than for the purposes of exposing the track in the DOM, the user agent is ignoring the text track. No cues are active, no events are fired, and the user agent will not attempt to obtain the track's cues.

Hidden
Indicates that the text track is active, but that the user agent is not actively displaying the cues. If no attempt has yet been made to obtain the track's cues, the user agent will perform such an attempt momentarily. The user agent is maintaining a list of which cues are active, and events are being fired accordingly.

Showing
Indicates that the text track is active. If no attempt has yet been made to obtain the track's cues, the user agent will perform such an attempt momentarily. The user agent is maintaining a list of which cues are active, and events are being fired accordingly. In addition, for text tracks whose kind\(^{406}\) is subtitles\(^{405}\) or captions\(^{405}\), the cues are being overlaid on the video as appropriate; for text tracks whose kind\(^{406}\) is descriptions\(^{405}\), the user agent is making the cues available to the user in a non-visual fashion; and for text tracks whose kind\(^{406}\) is chapters\(^{408}\), the user agent is making available to the user a mechanism by which the user can navigate to any point in the media resource\(^{432}\) by selecting a cue.

A list of zero or more cues
A list of text track cues\(^{408}\) along with rules for updating the text track rendering. For example, for WebVTT, the rules for updating the display of WebVTT text tracks. ([WEBVTT])\(^{1128}\)

The list of cues of a text track\(^{407}\) can change dynamically, either because the text track\(^{405}\) has not yet been loaded\(^{406}\) or is still loading\(^{406}\), or due to DOM manipulation.

Each text track\(^{405}\) has a corresponding TextTrack\(^{414}\) object.

Each media element\(^{372}\) has a list of pending text tracks, which must initially be empty, a blocked-on-parser flag, which must initially be false, and a did-perform-automatic-track-selection flag, which must also initially be false.

When the user agent is required to populate the list of pending text tracks of a media element\(^{372}\), the user agent must add to the element's list of pending text tracks\(^{407}\) each text track\(^{405}\) in the element's list of text tracks\(^{408}\) whose text track mode\(^{407}\) is not disabled\(^{407}\) and whose text track readiness state\(^{406}\) is loading\(^{406}\).

Whenever a track\(^{376}\) element's parent node changes, the user agent must remove the corresponding text track\(^{405}\) from any list of pending text tracks\(^{407}\) that it is in.

Whenever a text track\(^{405}\)'s text track readiness state\(^{406}\) changes to either loaded\(^{406}\) or failed to load\(^{406}\), the user agent must remove it from any list of pending text tracks\(^{407}\) that it is in.

When a media element\(^{372}\) is created by an HTML parser\(^{1022}\) or XML parser\(^{1128}\), the user agent must set the element's blocked-on-parser\(^{407}\) flag to true. When a media element\(^{372}\) is popped off the stack of open elements\(^{1036}\) of an HTML parser\(^{1022}\) or XML parser\(^{1128}\), the user agent must honor user preferences for automatic text track selection\(^{419}\), populate the list of pending text tracks\(^{407}\), and set the element's blocked-on-parser\(^{407}\) flag to false.

The text tracks\(^{405}\) of a media element\(^{372}\) are ready when both the element's list of pending text tracks\(^{407}\) is empty and the element's blocked-on-parser\(^{407}\) flag is false.

Each media element\(^{372}\) has a pending text track change notification flag, which must initially be unset.

Whenever a text track\(^{405}\) that is in a media element\(^{372}\)'s list of text tracks\(^{405}\) has its text track mode\(^{407}\) change value, the user agent must run the following steps for the media element\(^{372}\):

1. If the media element\(^{372}\)'s pending text track change notification flag\(^{407}\) is set, return.
2. Set the media element\(^{372}\)'s pending text track change notification flag\(^{407}\).
3. Queue a task\(^{893}\) to run these steps:
   1. Unset the media element\(^{372}\)'s pending text track change notification flag\(^{407}\).
   2. Fire an event named change\(^{425}\) at the media element\(^{372}\)'s textTracks\(^{413}\) attribute's TextTrackList\(^{413}\) object.
4. If the media element's show poster flag is not set, run the time marches on steps.

The task source for the tasks listed in this section is the DOM manipulation task source.

A text track cue is the unit of time-sensitive data in a text track, corresponding for instance for subtitles and captions to the text that appears at a particular time and disappears at another time.

Each text track cue consists of:

An identifier
An arbitrary string.

A start time
The time, in seconds and fractions of a second, that describes the beginning of the range of the media data to which the cue applies.

An end time
The time, in seconds and fractions of a second, that describes the end of the range of the media data to which the cue applies.

A pause-on-exit flag
A boolean indicating whether playback of the media resource is to pause when the end of the range to which the cue applies is reached.

Some additional format-specific data
Additional fields, as needed for the format, including the actual data of the cue. For example, WebVTT has a text track cue writing direction and so forth. [WEBVTT]

Each text track cue has a corresponding TextTrackCue object (or more specifically, an object that inherits from TextTrackCue — for example, WebVTT cues use the VTTCue interface). A text track cue's in-memory representation can be dynamically changed through this TextTrackCue API. [WEBVTT]

A text track cue is associated with rules for updating the text track rendering, as defined by the specification for the specific kind of text track. These rules are used specifically when the object representing the cue is added to a TextTrack object using the addCue() method.

In addition, each text track cue has two pieces of dynamic information:

The active flag
This flag must be initially unset. The flag is used to ensure events are fired appropriately when the cue becomes active or inactive, and to make sure the right cues are rendered.

The user agent must synchronously unset this flag whenever the text track cue is removed from its text track's text track list of cues; whenever the text track itself is removed from its media element's list of text tracks; or has its text track mode changed to disabled; and whenever the media element's readyState is changed back to HAVE NOTHING. When the flag is unset in this way for one or more cues in text tracks that were showing prior to the relevant incident, the user agent must, after having unset the flag for all the affected cues, apply the rules for updating the display of WebVTT text tracks.

The display state
This is used as part of the rendering model, to keep cues in a consistent position. It must initially be empty. Whenever the text track cue active flag is unset, the user agent must empty the text track cue display state.

The text track cues of a media element's text tracks are ordered relative to each other in the text track cue order, which is determined as follows: first group the cues by their text track, with the groups being sorted in the same order as their text tracks; then, within each group, cues must be sorted by their start time, earliest first; then, any cues with the same start time must be sorted by their end time, latest first; and finally, any cues with identical end times must be sorted in the order they were last added to their respective text track list of cues.
4.8.12.11.2 Sourcing in-band text tracks

A media-resource-specific text track is a text track that corresponds to data found in the media resource. Rules for processing and rendering such data are defined by the relevant specifications, e.g. the specification of the video format if the media resource is a video. For details on how to conclude the relevant specifications can be found in the Sourcing In-band Media Resource Tracks from Media Containers into HTML specification.

When a media resource contains data that the user agent recognizes and supports as being equivalent to a text track, the user agent runs the steps to expose a media-resource-specific text track with the relevant data, as follows.

1. Associate the relevant data with a new text track and its corresponding new TextTrack object. The text track is a media-resource-specific text track.
2. Set the new text track's kind, label, and language based on the semantics of the relevant data, as defined by the relevant specification. If there is no label in that data, then the label must be set to the empty string.
3. Associate the text track list of cues with the rules for updating the text track rendering appropriate for the format in question.
4. If the new text track's kind is chapters or metadata, then set the text track in-band metadata track dispatch type as follows, based on the type of the media resource:
   - If the media resource is an Ogg file
     The text track in-band metadata track dispatch type must be set to the value of the Name header field.
   - If the media resource is a WebM file
     The text track in-band metadata track dispatch type must be set to the value of the CodecID element.
   - If the media resource is an MPEG-2 file
     Let stream type be the value of the "stream_type" field describing the text track's type in the file's program map section, interpreted as an 8-bit unsigned integer. Let length be the value of the "ES_info_length" field for the track in the same part of the program map section, interpreted as an integer as defined by the MPEG-2 specification. Let descriptor bytes be the length bytes following the "ES_info_length" field. The text track in-band metadata track dispatch type must be set to the concatenation of the stream type byte and the zero or more descriptor bytes, expressed in hexadecimal using ASCII upper hex digits.
   - If the media resource is an MPEG-4 file
     Let the first stsd box of the first stbl box of the first minf box of the first media box of the text track's trak box in the first moov box of the file be the stsd box, if any. If the file has no stsd box, or if the stsd box has neither a mett box nor a metx box, then the text track in-band metadata track dispatch type must be set to the empty string. Otherwise, if the stsd box has a mett box then the text track in-band metadata track dispatch type must be set to the concatenation of the string "mett", a U+0020 SPACE character, and the value of the first mime_format field of the first mett box of the stsd box, or the empty string if that field is absent in that box. Otherwise, if the stsd box has no mett box but has a metx box then the text track in-band metadata track dispatch type must be set to the concatenation of the string "metx", a U+0020 SPACE character, and the value of the first namespace field of the first metx box of the stsd box, or the empty string if that field is absent in that box.
5. Populate the new text track's list of cues, with the cues parsed so far, following the guidelines for exposing cues, and begin updating it dynamically as necessary.
6. Set the new text track's readiness state to loaded.
7. Set the new text track's mode to the mode consistent with the user's preferences and the requirements of the relevant specification for the data.

Note: For instance, if there are no other active subtitles, and this is a forced subtitle track (a subtitle track giving subtitles in the audio track's primary language, but only for audio that is actually in another language), then those subtitles might be...
8. Add the new text track to the media element's list of text tracks.

9. Fire an event named addtrack at the media element's textTracks attribute's TextTrackList object, using TrackEvent, with the track attribute initialized to the text track's TextTrack object.

### 4.8.11.3 Sourcing out-of-band text tracks

When a track element is created, it must be associated with a new text track (with its value set as defined below) and its corresponding new TextTrack object.

The text track kind is determined from the state of the element's kind attribute according to the following table; for a state given in a cell of the first column, the kind is the string given in the second column:

<table>
<thead>
<tr>
<th>State</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subtitles</td>
<td>subtitles</td>
</tr>
<tr>
<td>Captions</td>
<td>captions</td>
</tr>
<tr>
<td>Descriptions</td>
<td>descriptions</td>
</tr>
<tr>
<td>Chapters metadata</td>
<td>chapters</td>
</tr>
<tr>
<td>Metadata</td>
<td>metadata</td>
</tr>
</tbody>
</table>

The text track label is the element's track label.

The text track language is the element's track language, if any, or the empty string otherwise.

As the kind and srclang attributes are set, changed, or removed, the text track must update accordingly, as per the definitions above.

**Note**

Changes to the track URL are handled in the algorithm below.

The text track readiness state is initially not loaded, and the text track mode is initially disabled.

The text track list of cues is initially empty. It is dynamically modified when the referenced file is parsed. Associated with the list are the rules for updating the display of WebVTT text tracks. [WEBVTT]

When a track element's parent element changes and the new parent is a media element, then the user agent must add the track element's corresponding text track to the media element's list of text tracks, and then queue a task to fire an event named addtrack at the media element's textTracks attribute's TextTrackList object, using TrackEvent, with the track attribute initialized to the text track's TextTrack object.

When a track element's parent element changes and the old parent was a media element, then the user agent must remove the track element's corresponding text track from the media element's list of text tracks, and then queue a task to fire an event named removetrack at the media element's textTracks attribute's TextTrackList object, using TrackEvent, with the track attribute initialized to the text track's TextTrack object.

When a text track corresponding to a track element is added to a media element's list of text tracks, the user agent must queue a task to run the following steps for the media element:

1. If the element's blocked-on-parser flag is true, then return.
2. If the element's did-perform-automatic-track-selection flag is true, then return.
3. Honor user preferences for automatic text track selection for this element.

When the user agent is required to honor user preferences for automatic text track selection for a media element, the user agent must run the following steps:
Perform automatic text track selection for subtitles and captions.

Perform automatic text track selection for descriptions.

If there are any text tracks in the media element's list of text tracks whose text track kind is chapters or metadata that correspond to track elements with a default attribute set whose text track mode is set to disabled, then set the text track mode of all such tracks to hidden.

Set the element's did-perform-automatic-track-selection flag to true.

When the steps above say to perform automatic text track selection for one or more text track kinds, it means to run the following steps:

1. Let candidates be a list consisting of the text tracks in the media element's list of text tracks whose text track kind is one of the kinds that were passed to the algorithm, if any, in the order given in the list of text tracks.
2. If candidates is empty, then return.
3. If any of the text tracks in candidates have a text track mode set to showing, return.
4. If the user has expressed an interest in having a track from candidates enabled based on its text track kind, text track language, and text track label, then set its text track mode to showing.

Note

For example, the user could have set a browser preference to the effect of "I want French captions whenever possible", or "If there is a subtitle track with 'Commentary' in the title, enable it", or "If there are audio description tracks available, enable one, ideally in Swiss German, but failing that in Standard Swiss German or Standard German".

Otherwise, if there are any text tracks in candidates that correspond to track elements with a default attribute set whose text track mode is set to disabled, then set the text track mode of the first such track to showing.

When a text track corresponding to a track element experiences any of the following circumstances, the user agent must start the track processing model for that text track and its track element:

- The track element is created.
- The text track has its text track mode changed.
- The track element's parent element changes and the new parent is a media element.

When a user agent is to start the track processing model for a text track and its track element, it must run the following algorithm. This algorithm interacts closely with the event loop mechanism; in particular, it has a synchronous section (which is triggered as part of the event loop algorithm). The steps in that section are marked with □.

1. If another occurrence of this algorithm is already running for this text track and its track element, return, letting that other algorithm take care of this element.
2. If the text track's text track mode is not set to one of hidden or showing, then return.
3. If the text track's track element does not have a media element as a parent, return.
4. Run the remainder of these steps in parallel, allowing whatever caused these steps to run to continue.
5. Top: Await a stable state. The synchronous section consists of the following steps. (The steps in the synchronous section are marked with □.)
6. □ Set the text track readiness state to loading.
7. □ Let URL be the track URL of the track element.
8. □ If the track element's parent is a media element's crossorigin content attribute. Otherwise, let corsAttributeState be No CORS.
9. End the synchronous section, continuing the remaining steps in parallel.
10. If URL is not the empty string, then:

    1. Let request be the result of creating a potential-CORS request given URL, "track", and corsAttributeState, and
with the same-origin fallback flag set.

2. Set request’s client to the track element’s node document’s Window object’s environment settings object.

3. Fetch request.

The tasks queued by the fetching algorithm on the networking task source to process the data as it is being fetched must determine the type of the resource. If the type of the resource is not a supported text track format, the load will fail, as described below. Otherwise, the resource’s data must be passed to the appropriate parser (e.g., the WebVTT parser) as it is received, with the text track list of cues, being used for that parser’s output. ([WEBVTT])

Note

The appropriate parser will incrementally update the text track list of cues during these networking task source tasks, as each such task is run with whatever data has been received from the network.

This specification does not currently say whether or how to check the MIME types of text tracks, or whether or how to perform file type sniffing using the actual file data. Implementors differ in their intentions on this matter and it is therefore unclear what the right solution is. In the absence of any requirement here, the HTTP specification’s strict requirement to follow the Content-Type header prevails ("Content-Type specifies the media type of the underlying data." ... "if and only if the media type is not given by a Content-Type field, the recipient MAY attempt to guess the media type via inspection of its content and/or the name extension(s) of the URI used to identify the resource.").

If fetching fails for any reason (network error, the server returns an error code, CORS fails, etc), or if URL is the empty string, then queue a task to first change the text track readiness state to failed to load and then fire an event named error at the track element. This task must use the DOM manipulation task source.

If fetching does not fail, but the type of the resource is not a supported text track format, or the file was not successfully processed (e.g., the format in question is an XML format and the file contained a well-formedness error that the XML specification requires be detected and reported to the application), then the task that is queued by the networking task source, in which the aforementioned problem is found must change the text track readiness state to failed to load and fire an event named error at the track element.

If fetching does not fail, and the file was successfully processed, then the final task that is queued by the networking task source, after it has finished parsing the data, must change the text track readiness state to loaded, and fire an event named load at the track element.

If, while fetching is ongoing, either:

- the track URL changes so that it is no longer equal to URL, while the text track mode is set to hidden or showing; or
- the text track mode changes to hidden or showing, while the track URL is not equal to URL

...then the user agent must abort fetching, discarding any pending tasks generated by that algorithm (and in particular, not adding any cues to the text track list of cues after the moment the URL changed), and then queue a task that first changes the text track readiness state to failed to load and then fires an event named error at the track element. This task must use the DOM manipulation task source.

11. Wait until the text track readiness state is no longer set to loading.

12. Wait until the track URL is no longer equal to URL, at the same time as the text track mode is set to hidden or showing.

13. Jump to the step labeled top.

Whenever a track element has its src attribute set, changed, or removed, the user agent must immediately empty the element’s text track’s text track list of cues. (This also causes the algorithm above to stop adding cues from the resource being obtained using the previously given URL, if any.)

4.8.12.11.4 Guidelines for exposing cues in various formats as text track cues

How a specific format’s text track cues are to be interpreted for the purposes of processing by an HTML user agent is defined by that
format. In the absence of such a specification, this section provides some constraints within which implementations can attempt to consistently expose such formats.

To support the text track model of HTML, each unit of timed data is converted to a text track cue. Where the mapping of the format's features to the aspects of a text track cue as defined in this specification are not defined, implementations must ensure that the mapping is consistent with the definitions of the aspects of a text track cue as defined above, as well as with the following constraints:

The **text track cue identifier**

Should be set to the empty string if the format has no obvious analogue to a per-cue identifier.

The **text track cue pause-on-exit flag**

Should be set to false.

4.8.12.11.5 Text track API

```idl
[Exposed=Window]
interface TextTrackList : EventTarget {
  readonly attribute unsigned long length;
  getter TextTrack (unsigned long index);
  TextTrack? getTrackById(DOMString id);

  attribute EventHandler onchange;
  attribute EventHandler onaddtrack;
  attribute EventHandler onremovetrack;
};
```

For web developers (non-normative)

```javascript
media . textTracks . length

Returns the number of text tracks associated with the media element (e.g. from track elements). This is the number of text tracks in the media element's list of text tracks.

media . textTracks[n]

Returns the TextTrack object representing the n text track in the media element's list of text tracks.

textTrack = media . textTracks.getTrackById(id)

Returns the TextTrack object with the given identifier, or null if no track has that identifier.
```

A `TextTrackList` object represents a dynamically updating list of text tracks in a given order.

The `textTracks` attribute of `media` must return a `TextTrackList` object representing the `TextTrack` objects of the text tracks in the media element's list of text tracks, in the same order as in the list of text tracks.

The `length` attribute of a `TextTrackList` object must return the number of text tracks in the list represented by the `TextTrackList` object.

The **supported property indices** of a `TextTrackList` object at any instant are the numbers from zero to the number of text tracks in the list represented by the `TextTrackList` object minus one, if any. If there are no text tracks in the list, there are no supported property indices.

To determine the value of an indexed property of a `TextTrackList` object for a given index `index`, the user agent must return the `index`th `textTrack` in the list represented by the `TextTrackList` object.

The `getTrackById(id)` method must return the first `TextTrack` in the `TextTrackList` object whose `id` IDL attribute would return a value equal to the value of the `id` argument. When no tracks match the given argument, the method must return null.
enum TextTrackMode {
  "disabled", "hidden", "showing";
}
enum TextTrackKind {
  "subtitles", "captions", "descriptions", "chapters", "metadata";

[Exposed=Window]
interface TextTrack : EventTarget {
  readonly attribute TextTrackKind kind;
  readonly attribute DOMString label;
  readonly attribute DOMString language;
  readonly attribute DOMString id;
  readonly attribute DOMString inBandMetadataTrackDispatchType;

  attribute TextTrackMode mode;
  readonly attribute TextTrackCueList? cues;
  readonly attribute TextTrackCueList? activeCues;

  void addCue(TextTrackCue cue);
  void removeCue(TextTrackCue cue);

  attribute EventHandler oncuechange;
};

For web developers (non-normative)

textTrack = media . addTextTrack(kind [, label [, language ]])

  Creates and returns a new TextTrack object, which is also added to the media element's list of text tracks.

textTrack . kind

  Returns the text track kind string.

textTrack . label

  Returns the text track label, if there is one, or the empty string otherwise (indicating that a custom label probably needs to be generated from the other attributes of the object if the object is exposed to the user).

textTrack . language

  Returns the text track language string.

textTrack . id

  Returns the ID of the given track.

  For in-band tracks, this is the ID that can be used with a fragment if the format supports media fragment syntax, and that can be used with the getTrackById() method.

  For TextTrack objects corresponding to track elements, this is the ID of the track element.

textTrack . inBandMetadataTrackDispatchType

  Returns the text track in-band metadata track dispatch type string.

textTrack . mode [ = value ]

  Returns the text track mode, represented by a string from the following list:

  "disabled"

    The text track disabled mode.

  "hidden"

    The text track hidden mode.

  "showing"

    The text track showing mode.

  Can be set, to change the mode.
The `addTextTrack(kind, label, language)` method of media elements, when invoked, must run the following steps:

1. Create a new `TextTrack` object.
2. Create a new text track corresponding to the new object, and set its text track kind to `kind`, its text track label to `label`, its text track language to `language`, its text track readiness state to the `text track loaded` state, its text track mode to the `text track hidden` mode, and its text track list of cues to an empty list.

Initially, the text track list of cues is not associated with any rules for updating the text track rendering. When a text track cue is added to it, the text track list of cues has its rules permanently set accordingly.

3. Add the new text track to the media element's list of text tracks.
4. Queue a task to fire an event named `addtrack` at the media element's `textTracks` object, using `TrackEvent`, with the `track` attribute initialized to the new text track's `TextTrack` object.
5. Return the new `TextTrack` object.

The `addTextTrack(kind, label, language)` method of media elements, when invoked, must run the following steps:

1. Create a new `TextTrack` object.
2. Create a new text track corresponding to the new object, and set its text track kind to `kind`, its text track label to `label`, its text track language to `language`, its text track readiness state to the `text track loaded` state, its text track mode to the `text track hidden` mode, and its text track list of cues to an empty list.

Initially, the text track list of cues is not associated with any rules for updating the text track rendering. When a text track cue is added to it, the text track list of cues has its rules permanently set accordingly.

3. Add the new text track to the media element's list of text tracks.
4. Queue a task to fire an event named `addtrack` at the media element's `textTracks` object, using `TrackEvent`, with the `track` attribute initialized to the new text track's `TextTrack` object.
5. Return the new `TextTrack` object.

The `kind` attribute must return the text track kind of the text track that the `TextTrack` object represents.

The `label` attribute must return the text track label of the text track that the `TextTrack` object represents.

The `language` attribute must return the text track language of the text track that the `TextTrack` object represents.

The `id` attribute returns the track's identifier, if it has one, or the empty string otherwise. For tracks that correspond to track elements, the track's identifier is the value of the element's `id` attribute, if any. For in-band tracks, the track's identifier is specified by the media resource. If the media resource is in a format that supports media fragment syntax, the identifier returned for a particular track must be the same identifier that would enable the track if used as the name of a track in the track dimension of such a fragment.

The `inBandMetadataTrackDispatchType` attribute must return the text track in-band metadata track dispatch type of the text track that the `TextTrack` object represents.

The `mode` attribute, on getting, must return the string corresponding to the text track mode of the text track that the `TextTrack` object represents, as defined by the following list:

- "disabled" — The text track disabled mode.
- "hidden" — The text track hidden mode.
- "showing" — The text track showing mode.

On setting, if the new value isn't equal to what the attribute would currently return, the new value must be processed as follows:
If the new value is "disabled":
Set the text track mode of the text track that the TextTrack object represents to the text track disabled mode.

If the new value is "hidden":
Set the text track mode of the text track that the TextTrack object represents to the text track hidden mode.

If the new value is "showing":
Set the text track mode of the text track that the TextTrack object represents to the text track showing mode.

If the text track mode of the text track that the TextTrack object represents is not the text track disabled mode, then the cues attribute must return a live TextTrackCueList object that represents the subset of the text track list of cues of the text track that the TextTrack object represents whose end times occur at or after the earliest possible position when the script started, in text track cue order. Otherwise, it must return null. For each TextTrack object, when an object is returned, the same TextTrackCueList object must be returned each time.

The earliest possible position when the script started is whatever the earliest possible position was the last time the event loop reached step 1.

If the text track mode of the text track that the TextTrack object represents is not the text track disabled mode, then the activeCues attribute must return a live TextTrackCueList object that represents the subset of the text track list of cues of the text track that the TextTrack object represents whose active flag was set when the script started, in text track cue order. Otherwise, it must return null. For each TextTrack object, when an object is returned, the same TextTrackCueList object must be returned each time.

A text track cue's active flag was set when the script started if its text track cue active flag was set the last time the event loop reached step 1.

The addCue method of TextTrack objects, when invoked, must run the following steps:

1. If the text track list of cues does not yet have any associated rules for updating the text track rendering, then associate the text track list of cues with the rules for updating the text track rendering appropriate to cue.
2. If text track list of cues associated rules for updating the text track rendering are not the same rules for updating the text track rendering as appropriate for cue, then throw an "InvalidStateError" DOMException.
3. If the given cue is in a text track list of cues, then remove cue from that text track list of cues.
4. Add cue to the TextTrack object's text track list of cues.

The removeCue method of TextTrack objects, when invoked, must run the following steps:

1. If the given cue is not in the TextTrack object's text track list of cues, then throw a "NotFoundError" DOMException.
2. Remove cue from the TextTrack object's text track list of cues.

Example

In this example, an audio element is used to play a specific sound-effect from a sound file containing many sound effects. A cue is used to pause the audio, so that it ends exactly at the end of the clip, even if the browser is busy running some script. If the page had relied on script to pause the audio, then the start of the next clip might be heard if the browser was not able to run the script at the exact time specified.

```javascript
var sfx = new Audio('sfx.wav');
var sounds = sfx.addTextTrack('metadata');

// add sounds we care about
function addFX(start, end, name) {
    var cue = new VTT Cue(start, end, '');
    cue.id = name;
    cue.pauseOnExit = true;
    sounds.addCue(cue);
}
```

416
A `TextTrackCueList` object represents a dynamically updating list of text track cues in a given order.

The `length` attribute must return the number of cues in the list represented by the `TextTrackCueList` object.

The supported property indices of a `TextTrackCueList` object at any instant are the numbers from zero to the number of cues in the list represented by the `TextTrackCueList` object minus one, if any. If there are no cues in the list, there are no supported property indices.

To determine the value of an indexed property for a given index `index`, the user agent must return the `index`th text track cue in the list represented by the `TextTrackCueList` object.

The `getById(id)` method, when called with an argument other than the empty string, must return the first text track cue in the list represented by the `TextTrackCueList` object whose text track cue identifier is `id`, if any, or null otherwise. If the argument is the empty string, then the method must return null.
interface TextTrackCue : EventTarget {
    readonly attribute TextTrack? track;
    attribute DOMString id;
    attribute double startTime;
    attribute double endTime;
    attribute boolean pauseOnExit;
    attribute EventHandler onenter;
    attribute EventHandler onexit;
};

For web developers (non-normative)

cue . track p418
Returns the TextTrack object to which this text track cue belongs, if any, or null otherwise.

cue . id p418 [ = value ]
Returns the text track cue identifier. Can be set.

cue . startTime p418 [ = value ]
Returns the text track cue start time, in seconds. Can be set.

cue . endTime p418 [ = value ]
Returns the text track cue end time, in seconds. Can be set.

cue . pauseOnExit p418 [ = value ]
Returns true if the text track cue pause-on-exit flag is set, false otherwise. Can be set.

The track attribute, on getting, must return the TextTrack object of the text track in whose list of cues the text track cue that the TextTrackCue object represents finds itself, if any; or null otherwise.

The id attribute, on getting, must return the text track cue identifier of the text track cue that the TextTrackCue object represents. On setting, the text track cue identifier must be set to the new value.

The startTime attribute, on getting, must return the text track cue start time of the text track cue that the TextTrackCue object represents, in seconds. On setting, the text track cue start time must be set to the new value, interpreted in seconds; then, if the TextTrackCue object's text track cue is in a text track's list of cues, and that text track is in a media element's list of text tracks, and the media element's show poster flag is not set, then run the time marches on steps for that media element.

The endTime attribute, on getting, must return the text track cue end time of the text track cue that the TextTrackCue object represents, in seconds. On setting, the text track cue end time must be set to the new value, interpreted in seconds; then, if the TextTrackCue object's text track cue is in a text track's list of cues, and that text track is in a media element's list of text tracks, and the media element's show poster flag is not set, then run the time marches on steps for that media element.

The pauseOnExit attribute, on getting, must return true if the text track cue pause-on-exit flag of the text track cue that the TextTrackCue object represents is set; or false otherwise. On setting, the text track cue pause-on-exit flag must be set if the new value is true, and must be unset otherwise.
**4.8.12.11.6 Event handlers for objects of the text track APIs**

The following are the event handlers that (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the `TextTrackList` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onchange</td>
<td>change</td>
</tr>
<tr>
<td>onaddtrack</td>
<td>addtrack</td>
</tr>
<tr>
<td>onremovetrack</td>
<td>removetrack</td>
</tr>
</tbody>
</table>

The following are the event handlers that (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the `TextTrack` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>oncuechange</td>
<td>cuechange</td>
</tr>
</tbody>
</table>

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the `TextTrackCue` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onenter</td>
<td>enter</td>
</tr>
<tr>
<td>onexit</td>
<td>exit</td>
</tr>
</tbody>
</table>

**4.8.12.11.7 Best practices for metadata text tracks**

This section is non-normative.

Text tracks can be used for storing data relating to the media data, for interactive or augmented views.

For example, a page showing a sports broadcast could include information about the current score. Suppose a robotics competition was being streamed live. The image could be overlayed with the scores, as follows:

In order to make the score display render correctly whenever the user seeks to an arbitrary point in the video, the metadata text track cues need to be as long as is appropriate for the score. For example, in the frame above, there would be maybe one cue that lasts the...
length of the match that gives the match number, one cue that lasts until the blue alliance's score changes, and one cue that lasts until the red alliance's score changes. If the video is just a stream of the live event, the time in the bottom right would presumably be automatically derived from the current video time, rather than based on a cue. However, if the video was just the highlights, then that might be given in cues also.

The following shows what fragments of this could look like in a WebVTT file:

```webvtt
WEBVTT

05:10:00.000 --> 05:12:15.000
matchtype:qual
matchnumber:37

05:11:02.251 --> 05:11:17.198
red:78

05:11:03.672 --> 05:11:54.198
blue:66

05:11:17.198 --> 05:11:25.912
red:80

05:11:25.912 --> 05:11:26.522
red:83

05:11:26.522 --> 05:11:26.982
red:86

05:11:26.982 --> 05:11:27.499
red:89

...```

The key here is to notice that the information is given in cues that span the length of time to which the relevant event applies. If, instead, the scores were given as zero-length (or very brief, nearly zero-length) cues when the score changes, for example saying "red+2" at 05:11:17.198, "red+3" at 05:11:25.912, etc, problems arise: primarily, seeking is much harder to implement, as the script has to walk the entire list of cues to make sure that no notifications have been missed; but also, if the cues are short it's possible the script will never see that they are active unless it listens to them specifically.

When using cues in this manner, authors are encouraged to use the `cuechange` event to update the current annotations. (In particular, using the `timeupdate` event would be less appropriate as it would require doing work even when the cues haven't changed, and, more importantly, would introduce a higher latency between when the metadata cues become active and when the display is updated, since `timeupdate` events are rate-limited.)

### 4.8.12.12 Identifying a track kind through a URL

Other specifications or formats that need a URL to identify the return values of the `AudioTrack.kind` or `VideoTrack.kind` IDL attributes, or identify the kind of text track, must use the `about:html-kind` URL.

### 4.8.12.13 User interface

The `controls` attribute is a boolean attribute. If present, it indicates that the author has not provided a scripted controller and would like the user agent to provide its own set of controls.

If the attribute is present, or if `scripting is disabled` for the `media element`, then the user agent should expose a user interface to the user. This user interface should include features to begin playback, pause playback, seek to an arbitrary position in
the content (if the content supports arbitrary seeking), change the volume, change the display of closed captions or embedded sign-language tracks, select different audio tracks or turn on audio descriptions, and show the media content in manners more suitable to the user (e.g. full-screen video or in an independent resizable window). Other controls may also be made available.

Even when the attribute is absent, however, user agents may provide controls to affect playback of the media resource (e.g. play, pause, seeking, track selection, and volume controls), but such features should not interfere with the page's normal rendering. For example, such features could be exposed in the media element's context menu, platform media keys, or a remote control. The user agent may implement this simply by exposing a user interface to the user as described above (as if the controls attribute was present).

If the user agent exposes a user interface to the user by displaying controls over the media element, then the user agent should suppress any user interaction events while the user agent is interacting with this interface. (For example, if the user clicks on a video's playback control, mousedown events and so forth would not simultaneously be fired at elements on the page.)

Where possible (specifically, for starting, stopping, pausing, and unpauing playback, for seeking, for changing the rate of playback, for fast-forwarding or rewinding, for listing, enabling, and disabling text tracks, and for muting or changing the volume of the audio), user interface features exposed by the user agent must be implemented in terms of the DOM API described above, so that, e.g., all the same events fire.

Features such as fast-forward or rewind must be implemented by only changing the playbackRate attribute (and not the defaultPlaybackRate attribute).

Seeking must be implemented in terms of seeking to the requested position in the media element's media timeline. For media resources where seeking to an arbitrary position would be slow, user agents are encouraged to use the approximate-for-speed flag when seeking in response to the user manipulating an approximate position interface such as a seek bar.

The controls IDL attribute must reflect the content attribute of the same name.

For web developers (non-normative)

```javascript
media.volume [ = value ]
```

Returns the current playback volume, as a number in the range 0.0 to 1.0, where 0.0 is the quietest and 1.0 the loudest.

Can be set, to change the volume.

Throws an "IndexSizeError" DOMException if the new value is not in the range 0.0 .. 1.0.

```javascript
media.muted [ = value ]
```

Returns true if audio is muted, overriding the volume attribute, and false if the volume attribute is being honored.

Can be set, to change whether the audio is muted or not.

A media element has a playback volume, which is a fraction in the range 0.0 (silent) to 1.0 (loudest). Initially, the volume should be 1.0, but user agents may remember the last set value across sessions, on a per-site basis or otherwise, so the volume may start at other values.

The volume IDL attribute must return the playback volume of any audio portions of the media element. On setting, if the new value is in the range 0.0 to 1.0 inclusive, the media element's playback volume must be set to the new value. If the new value is outside the range 0.0 to 1.0 inclusive, then, on setting, an "IndexSizeError" DOMException must be thrown instead.

A media element can also be muted. If anything is muting the element, then it is muted. (For example, when the direction of playback is backwards, the element is muted.)

The muted IDL attribute must return the value to which it was last set. When a media element is created, if the element has a content attribute specified, then the muted IDL attribute should be set to true; otherwise, the user agents may set the value to the user's preferred value (e.g. remembering the last set value across sessions, on a per-site basis or otherwise). While the muted IDL attribute is set to true, the media element must be muted.

Whenever either of the values that would be returned by the volume and muted IDL attributes change, the user agent must queue a task to fire an event named volumechange at the media element. Then, if the media element is not allowed to play, the user agent must run the internal pause steps for the media element.

An element's effective media volume is determined as follows:
1. If the user has indicated that the user agent is to override the volume of the element, then return the volume desired by the user.

2. If the element's audio output is muted, then return zero.

3. Let volume be the playback volume of the audio portions of the media element, in range 0.0 (silent) to 1.0 (loudest).

4. Return volume, interpreted relative to the range 0.0 to 1.0, with 0.0 being silent, and 1.0 being the loudest setting, values in between increasing in loudness. The range need not be linear. The loudest setting may be lower than the system's loudest possible setting; for example the user could have set a maximum volume.

The muted content attribute on media elements is a boolean attribute that controls the default state of the audio output of the media resource, potentially overriding user preferences.

The defaultMuted IDL attribute must reflect the muted content attribute.

**Note**

This attribute has no dynamic effect (it only controls the default state of the element).

**Example**

This video (an advertisement) autoplays, but to avoid annoying users, it does so without sound, and allows the user to turn the sound on. The user agent can pause the video if it's unmuted without a user interaction.

```html
<video src="adverts.cgi?kind=video" controls autoplay loop muted></video>
```

### 4.8.12.14 Time ranges

Objects implementing the TimeRanges interface represent a list of ranges (periods) of time.

**IDL**

```idl
[Exposed=Window]
interface TimeRanges {
  readonly attribute unsigned long length;
  double start(unsigned long index);
  double end(unsigned long index);
};
```

**For web developers (non-normative)**

- `media . length` returns the number of ranges in the object.

- `time = media . start(index)`
  
  Returns the time for the start of the range with the given index.

  Throws an `IndexSizeError` DOMException if the index is out of range.

- `time = media . end(index)`
  
  Returns the time for the end of the range with the given index.

  Throws an `IndexSizeError` DOMException if the index is out of range.

The `length` IDL attribute must return the number of ranges represented by the object.

The `start(index)` method must return the position of the start of the `index`th range represented by the object, in seconds measured from the start of the timeline that the object covers.

The `end(index)` method must return the position of the end of the `index`th range represented by the object, in seconds measured from the start of the timeline that the object covers.

These methods must throw `IndexSizeError` DOMExceptions if called with an `index` argument greater than or equal to the number of...
ranges represented by the object.

When a `TimeRanges` object is said to be a **normalized** `TimeRanges` object, the ranges it represents must obey the following criteria:

- The start of a range must be greater than the end of all earlier ranges.
- The start of a range must be less than or equal to the end of that same range.

In other words, the ranges in such an object are ordered, don't overlap, and don't touch (adjacent ranges are folded into one bigger range). A range can be empty (referencing just a single moment in time), e.g. to indicate that only one frame is currently buffered in the case that the user agent has discarded the entire `media resource` except for the current frame, when a `media element` is paused.

Ranges in a `TimeRanges` object must be inclusive.

**Example**

Thus, the end of a range would be equal to the start of a following adjacent (touching but not overlapping) range. Similarly, a range covering a whole timeline anchored at zero would have a start equal to zero and an end equal to the duration of the timeline.

The timelines used by the objects returned by the `buffered`, `seekable` and `played` IDL attributes of `media elements` must be that element's `media timeline`.

### 4.8.12.15 The `TrackEvent` interface

**IDL**

```idl
[Exposed=Window,
 Constructor(DOMString type, optional TrackEventInit eventInitDict)]
interface TrackEvent : Event {
    readonly attribute (VideoTrack or AudioTrack or TextTrack)? track;
};

dictionary TrackEventInit : EventInit {
    (VideoTrack or AudioTrack or TextTrack)? track = null;
};
```

**For web developers (non-normative)**

**event . track**

Returns the track object (TextTrack, AudioTrack, or VideoTrack) to which the event relates.

The `track` attribute must return the value it was initialized to. It represents the context information for the event.

### 4.8.12.16 Events summary

This section is non-normative.

The following events fire on `media elements` as part of the processing model described above:

<table>
<thead>
<tr>
<th>Event name</th>
<th>Interface</th>
<th>Fired when...</th>
<th>Preconditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>loadstart</td>
<td>Event</td>
<td>The user agent begins looking for <code>media data</code>, as part of the resource selection algorithm.</td>
<td><code>networkState.equals NETWORK_LOADING</code>.</td>
</tr>
<tr>
<td>progress</td>
<td>Event</td>
<td>The user agent is fetching <code>media data</code>.</td>
<td><code>networkState.equals NETWORK_LOADING</code>.</td>
</tr>
<tr>
<td>suspend</td>
<td>Event</td>
<td>The user agent is intentionally not currently fetching <code>media data</code>.</td>
<td><code>networkState.equals NETWORK_IDLE</code>.</td>
</tr>
<tr>
<td>abort</td>
<td>Event</td>
<td>The user agent stops fetching the <code>media data</code> before it is completely downloaded.</td>
<td><code>error</code> is an object with the code <code>MEDIA_ERR_ABORTED</code>, <code>networkState.equals either NETWORK_EMPTY</code> or <code>NETWORK_IDLE</code>, depending on when the...</td>
</tr>
<tr>
<td>Event name</td>
<td>Interface</td>
<td>Fired when...</td>
<td>Preconditions</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>error</td>
<td>Event</td>
<td>An error occurs while fetching the <code>media data</code> or the type of the resource is not supported media format.</td>
<td><code>error</code> is an object with the code <code>MEDIA_ERR_NETWORK</code> or higher. <code>networkState</code> equals either <code>NETWORK_EMPTY</code> or <code>NETWORK_IDLE</code>, depending on when the download was aborted.</td>
</tr>
<tr>
<td>emptied</td>
<td>Event</td>
<td>A media element whose <code>networkState</code> was previously not in the <code>NETWORK EMPTY</code> state has just switched to that state (either because of a fatal error during load that's about to be reported, or because the <code>load()</code> method was invoked while the resource selection algorithm was already running).</td>
<td><code>networkState</code> is <code>NETWORK_EMPTY</code>; all the IDL attributes are in their initial states.</td>
</tr>
<tr>
<td>stalled</td>
<td>Event</td>
<td>The user agent is trying to fetch <code>media data</code>, but data is unexpectedly not forthcoming.</td>
<td></td>
</tr>
<tr>
<td>loadedmetadata</td>
<td>Event</td>
<td>The user agent has just determined the duration and dimensions of the <code>media resource</code> and the text tracks are ready.</td>
<td><code>readyState</code> is newly equal to <code>HAVE_METADATA</code> or greater for the first time.</td>
</tr>
<tr>
<td>loadeddata</td>
<td>Event</td>
<td>The user agent can render the <code>media data</code> at the current playback position for the first time.</td>
<td><code>readyState</code> newly increased to <code>HAVE_CURRENT_DATA</code> or greater for the first time.</td>
</tr>
<tr>
<td>canplay</td>
<td>Event</td>
<td>The user agent can resume playback of the <code>media data</code>, but estimates that if playback were to be started now, the <code>media resource</code> could not be rendered at the current playback rate up to its end without having to stop for further buffering of content.</td>
<td><code>readyState</code> newly increased to <code>HAVE_FUTURE_DATA</code> or greater.</td>
</tr>
<tr>
<td>canplaythrough</td>
<td>Event</td>
<td>The user agent estimates that if playback were to be started now, the <code>media resource</code> could be rendered at the current playback rate all the way to its end without having to stop for further buffering.</td>
<td><code>readyState</code> is newly equal to <code>HAVE_ENOUGH_DATA</code>.</td>
</tr>
<tr>
<td>playing</td>
<td>Event</td>
<td>Playback is ready to start after having been paused or delayed due to lack of <code>media data</code>.</td>
<td><code>readyState</code> is newly equal to or greater than <code>HAVE_FUTURE_DATA</code> and <code>paused</code> is false, <code>playing</code> is false and <code>readyState</code> is equal to or greater than <code>HAVE_FUTURE_DATA</code>. Even if this event fires, the element might still not be potentially playing, e.g. if the element is paused for user interaction or paused for in-band content.</td>
</tr>
<tr>
<td>waiting</td>
<td>Event</td>
<td>Playback has stopped because the next frame is not available, but the user agent expects that frame to become available in due course.</td>
<td><code>readyState</code> is equal to or less than <code>HAVE_CURRENT_DATA</code> and <code>paused</code> is false. Either <code>seeking</code> is true, or the <code>current playback position</code> is not contained in any of the ranges in <code>buffered</code>. It is possible for playback to stop for other reasons without <code>paused</code> being false, but those reasons do not fire this event (and when those situations resolve, a separate <code>playing</code> event is not fired either): e.g., <code>playback has ended</code>, or playback stopped due to errors, the element has paused for user interaction, or paused for in-band content.</td>
</tr>
<tr>
<td>seeking</td>
<td>Event</td>
<td>The <code>seeking</code> IDL attribute changed to true, and the user agent has started seeking to a new position.</td>
<td></td>
</tr>
<tr>
<td>sought</td>
<td>Event</td>
<td>The <code>seeking</code> IDL attribute changed to false after the <code>current playback position</code> was changed.</td>
<td></td>
</tr>
<tr>
<td>ended</td>
<td>Event</td>
<td>Playback has stopped because the end of the <code>media resource</code> was reached.</td>
<td><code>currentTime</code> equals the end of the <code>media resource</code>. <code>ended</code> is true.</td>
</tr>
<tr>
<td>durationchange</td>
<td>Event</td>
<td>The <code>duration</code> attribute has just been updated.</td>
<td></td>
</tr>
<tr>
<td>timeupdate</td>
<td>Event</td>
<td>The <code>current playback position</code> changed as part of normal playback or in an especially interesting way, for example discontinuously.</td>
<td></td>
</tr>
<tr>
<td>play</td>
<td>Event</td>
<td>The element is no longer paused. Fired after the <code>play</code> method has returned, or when the <code>autoplay</code> attribute has caused playback to begin.</td>
<td><code>paused</code> is newly false.</td>
</tr>
<tr>
<td>pause</td>
<td>Event</td>
<td>The element has been paused. Fired after the <code>pause</code> method has returned.</td>
<td><code>paused</code> is newly true.</td>
</tr>
<tr>
<td>ratechange</td>
<td>Event</td>
<td>Either the <code>defaultPlaybackRate</code> or the <code>playbackRate</code> attribute has just been updated.</td>
<td></td>
</tr>
<tr>
<td>Event name</td>
<td>Interface</td>
<td>Fired when...</td>
<td>Preconditions</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>--------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>resize</td>
<td>Event</td>
<td>One or both of the <code>videoWidth</code> and <code>videoHeight</code> attributes have just been updated.</td>
<td><code>Media element</code> is a <code>video</code> element; <code>readyState</code> is not <code>HAVE_NOTHING</code>.</td>
</tr>
<tr>
<td>volumechange</td>
<td>Event</td>
<td>Either the <code>volume</code> attribute or the <code>muted</code> attribute has changed. Fired after the relevant attribute’s setter has returned.</td>
<td></td>
</tr>
</tbody>
</table>

The following event fires on `source` element:

<table>
<thead>
<tr>
<th>Event name</th>
<th>Interface</th>
<th>Fired when...</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Event</td>
<td>An error occurs while fetching the <code>media data</code> or the type of the resource is not supported media format.</td>
</tr>
</tbody>
</table>

The following events fire on `AudioTrackList`, `VideoTrackList`, and `TextTrackList` objects:

<table>
<thead>
<tr>
<th>Event name</th>
<th>Interface</th>
<th>Fired when...</th>
</tr>
</thead>
<tbody>
<tr>
<td>change</td>
<td>Event</td>
<td>One or more tracks in the track list have been enabled or disabled.</td>
</tr>
<tr>
<td>addtrack</td>
<td>TrackEvent</td>
<td>A track has been added to the track list.</td>
</tr>
<tr>
<td>removetrack</td>
<td>TrackEvent</td>
<td>A track has been removed from the track list.</td>
</tr>
</tbody>
</table>

The following events fire on `TextTrack` objects and `track` elements:

<table>
<thead>
<tr>
<th>Event name</th>
<th>Interface</th>
<th>Fired when...</th>
</tr>
</thead>
<tbody>
<tr>
<td>cuechange</td>
<td>Event</td>
<td>One or more cues in the track have become active or stopped being active.</td>
</tr>
</tbody>
</table>

The following events fire on `track` elements:

<table>
<thead>
<tr>
<th>Event name</th>
<th>Interface</th>
<th>Fired when...</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Event</td>
<td>An error occurs while fetching the track data or the type of the resource is not supported text track format.</td>
</tr>
<tr>
<td>load</td>
<td>Event</td>
<td>A track data has been fetched and successfully processed.</td>
</tr>
</tbody>
</table>

The following events fire on `TextTrackCue` objects:

<table>
<thead>
<tr>
<th>Event name</th>
<th>Interface</th>
<th>Fired when...</th>
</tr>
</thead>
<tbody>
<tr>
<td>enter</td>
<td>Event</td>
<td>The cue has become active.</td>
</tr>
<tr>
<td>exit</td>
<td>Event</td>
<td>The cue has stopped being active.</td>
</tr>
</tbody>
</table>

### 4.8.12.17 Security and privacy considerations

The main security and privacy implications of the `video` and `audio` elements come from the ability to embed media cross-origin. There are two directions that threats can flow: from hostile content to a victim page, and from a hostile page to victim content.

If a victim page embeds hostile content, the threat is that the content might contain scripted code that attempts to interact with the `Document` that embeds the content. To avoid this, user agents must ensure that there is no access from the content to the embedding page. In the case of media content that uses DOM concepts, the embedded content must be treated as if it was in its own unrelated `top-level browsing context`.

Example

For instance, if an SVG animation was embedded in a `video` element, the user agent would not give it access to the DOM of the outer page. From the perspective of scripts in the SVG resource, the SVG file would appear to be in a lone top-level browsing context with no parent.

If a hostile page embeds victim content, the threat is that the embedding page could obtain information from the content that it would not otherwise have access to. The API does expose some information: the existence of the media, its type, its duration, its size, and the performance characteristics of its host. Such information is already potentially problematic, but in practice the same information can more or less be obtained using the `img` element, and so it has been deemed acceptable.
However, significantly more sensitive information could be obtained if the user agent further exposes metadata within the content, such as subtitles. That information is therefore only exposed if the video resource uses CORS. The `crossorigin` attribute allows authors to enable CORS. [FETCH]

---

### Example

Without this restriction, an attacker could trick a user running within a corporate network into visiting a site that attempts to load a video from a previously leaked location on the corporation's intranet. If such a video included confidential plans for a new product, then being able to read the subtitles would present a serious confidentiality breach.

---

#### 4.8.12.18 Best practices for authors using media elements

This section is non-normative.

Playing audio and video resources on small devices such as set-top boxes or mobile phones is often constrained by limited hardware resources in the device. For example, a device might only support three simultaneous videos. For this reason, it is a good practice to release resources held by `media elements` when they are done playing, either by being very careful about removing all references to the element and allowing it to be garbage collected, or, even better, by removing the element's `src` attribute and any `source` element descendants, and invoking the element's `load()` method.

Similarly, when the playback rate is not exactly 1.0, hardware, software, or format limitations can cause video frames to be dropped and audio to be choppy or muted.

#### 4.8.12.19 Best practices for implementers of media elements

This section is non-normative.

How accurately various aspects of the `media element` API are implemented is considered a quality-of-implementation issue.

For example, when implementing the `buffered` attribute, how precise an implementation reports the ranges that have been buffered depends on how carefully the user agent inspects the data. Since the API reports ranges as times, but the data is obtained in byte streams, a user agent receiving a variable-bitrate stream might only be able to determine precise times by actually decoding all of the data. User agents aren't required to do this, however; they can instead return estimates (e.g. based on the average bitrate seen so far) which get revised as more information becomes available.

As a general rule, user agents are urged to be conservative rather than optimistic. For example, it would be bad to report that everything had been buffered when it had not.

Another quality-of-implementation issue would be playing a video backwards when the codec is designed only for forward playback (e.g. there aren't many key frames, and they are far apart, and the intervening frames only have deltas from the previous frame). User agents could do a poor job, e.g. only showing key frames; however, better implementations would do more work and thus do a better job, e.g. actually decoding parts of the video forwards, storing the complete frames, and then playing the frames backwards.

Similarly, while implementations are allowed to drop buffered data at any time (there is no requirement that a user agent keep all the media data obtained for the lifetime of the media element), it is again a quality of implementation issue: user agents with sufficient resources to keep all the data around are encouraged to do so, as this allows for a better user experience. For example, if the user is watching a live stream, a user agent could allow the user only to view the live video; however, a better user agent would buffer everything and allow the user to seek through the earlier material, pause it, play it forwards and backwards, etc.

When a `media element` that is paused is removed from a document and not reinserted before the next time the `event loop` reaches step 1, implementations that are resource constrained are encouraged to take that opportunity to release all hardware resources (like video planes, networking resources, and data buffers) used by the `media element`. (User agents still have to keep track of the playback position and so forth, though, in case playback is later restarted.)

#### 4.8.13 The `map` element

Categories:

- Flow content
Phrasing content

Palpable content

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:

Transparent

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes:

name — Name of image map to reference from the usemap attribute

DOM interface:

IDL

```javascript
[Exposed=Window, HTMLConstructor]
interface HTMLMapElement : HTMLElement {
  [CEReactions] attribute DOMString name;
  [SameObject] readonly attribute HTMLCollection areas;
};
```

The `map` element, in conjunction with an `img` element and any `area` element descendants, defines an image map. The element represents its children.

The `name` attribute gives the map a name so that it can be referenced. The attribute must be present and must have a non-empty value with no ASCII whitespace. The value of the `name` attribute must not be equal to the value of the `name` attribute of another `map` element in the same tree. If the `id` attribute is also specified, both attributes must have the same value.

For web developers (non-normative)

`map.areas` Returns an `HTMLCollection` of the `area` elements in the `map`.

The `areas` attribute must return an `HTMLCollection` rooted at the `map` element, whose filter matches only `area` elements.

The IDL attribute `name` must `reflect` the content attribute of the same name.

Example

Image maps can be defined in conjunction with other content on the page, to ease maintenance. This example is of a page with an image map at the top of the page and a corresponding set of text links at the bottom.

```html
<!DOCTYPE HTML>
<html lang="en">
<title>Babies™: Toys</title>
<header>
<h1>Toys</h1>
<img src="/images/menu.gif" alt="Babies™ navigation menu. Select a department to go to its page." usemap="#NAV">
</header>

... 

<footer>

<p>
<a href="/clothes/">Clothes</a>

</p>

</footer>
</html>
```
The **area** element represents either a hyperlink with some text and a corresponding area on an image map, or a dead area on an image map. An **area** element with a parent node must have a **map** element ancestor.
If the area element has an href attribute, then the area element represents a hyperlink. In this case, the alt attribute must be present. It specifies the text of the hyperlink. Its value must be text that, when presented with the texts specified for the other hyperlinks of the image map and with the alternative text of the image, but without the image itself, provides the user with the same kind of choice as the hyperlink would when used without its text but with its shape applied to the image. The alt attribute may be left blank if there is another area element in the same image map that points to the same resource and has a non-blank alt attribute.

If the area element has no href attribute, then the area represented by the element cannot be selected, and the alt attribute must be omitted.

In both cases, the shape and coords attributes specify the area.

The shape attribute is an enumerated attribute. The following table lists the keywords defined for this attribute. The states given in the first cell of the rows with keywords give the states to which those keywords map. Some of the keywords are non-conforming, as noted in the last column.

<table>
<thead>
<tr>
<th>State</th>
<th>Keywords</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Circle state</td>
<td>circle</td>
<td>Non-conforming</td>
</tr>
<tr>
<td></td>
<td>circ</td>
<td></td>
</tr>
<tr>
<td>Default state</td>
<td>default</td>
<td></td>
</tr>
<tr>
<td>Polygon state</td>
<td>poly</td>
<td>Non-conforming</td>
</tr>
<tr>
<td></td>
<td>polygon</td>
<td></td>
</tr>
<tr>
<td>Rectangle state</td>
<td>rect</td>
<td>Non-conforming</td>
</tr>
<tr>
<td></td>
<td>rectangle</td>
<td></td>
</tr>
</tbody>
</table>

The attribute may be omitted. The missing value default and invalid value default are the rectangle state.

The coords attribute must, if specified, contain a valid list of floating-point numbers. This attribute gives the coordinates for the shape described by the shape attribute. The processing for this attribute is described as part of the image map processing model.

In the circle state, area elements must have a coords attribute present, with three integers, the last of which must be non-negative. The first integer must be the distance in CSS pixels from the left edge of the image to the center of the circle, the second integer must be the distance in CSS pixels from the top edge of the image to the center of the circle, and the third integer must be the radius of the circle, again in CSS pixels.

In the default state, area elements must not have a coords attribute. (The area is the whole image.)

In the polygon state, area elements must have a coords attribute with at least six integers, and the number of integers must be even. Each pair of integers must represent a coordinate given as the distances from the left and top of the image in CSS pixels respectively, and all the coordinates together must represent the points of the polygon, in order.

In the rectangle state, area elements must have a coords attribute with exactly four integers, the first of which must be less than the third, and the second of which must be less than the fourth. The four points must represent, respectively, the distance from the left edge of the image to the left side of the rectangle, the distance from the top edge to the top side, the distance from the left edge to the right side, and the distance from the top edge to the bottom side, all in CSS pixels.

When user agents allow users to follow hyperlinks or download hyperlinks created using the area element, as described in the next section, the href, target, download, and ping attributes decide how the link is followed. The rel attribute may be used to indicate to the user the likely nature of the target resource before the user follows the link.

The target, download, ping, rel, and referrer attributes must be omitted if the href attribute is not present.

If the itemprop attribute is specified on an area element, then the href attribute must also be specified.

The activation behavior of area elements is to follow the hyperlink or download the hyperlink created by the area element, if any, and as determined by the download attribute and any expressed user preference.

The IDL attributes alt, coords, target, download, ping, and rel, each must reflect the respective content attributes of the same name.

The IDL attribute shape must reflect the shape content attribute.
The IDL attribute `relList` must reflect the `rel` content attribute.

The IDL attribute `referrerPolicy` must reflect the `referrerPolicy` content attribute, limited to only known values.

### 4.8.15 Image maps

#### 4.8.15.1 Authoring

An image map allows geometric areas on an image to be associated with hyperlinks.

An image, in the form of an `img` element or an `object` element representing an image, may be associated with an image map (in the form of a `map` element) by specifying a `usemap` attribute on the `img` or `object` element. The `usemap` attribute, if specified, must be a valid hash-name reference to a `map` element.

**Example**

Consider an image that looks as follows:

![Image Map Example](shapes.png)

If we wanted just the colored areas to be clickable, we could do it as follows:

```html
<p>
  Please select a shape:
  <img src="shapes.png" usemap="#shapes"
       alt="Four shapes are available: a red hollow box, a green circle, a blue triangle, and a yellow four-pointed star."/>
  <map name="shapes">
    <area shape=rect coords="50,50,100,100" href="red.html" alt="Red box."/>
    <area shape=rect coords="25,25,125,125" href="green.html" alt="Green circle."/>
    <area shape=poly coords="325,25,262,125,388,125" href="blue.html" alt="Blue triangle."/>
    <area shape=poly coords="450,25,435,60,400,75,435,90,450,125,465,90,500,75,465,60" href="yellow.html" alt="Yellow star."/>
  </map>
</p>
```

#### 4.8.15.2 Processing model

If an `img` element or an `object` element representing an image has a `usemap` attribute specified, user agents must process it as follows:

1. Parse the attribute's value using the rules for parsing a hash-name reference to a `map` element, with the element as the context node. This will return either an element (the `map`) or null.
2. If that returned null, then return. The image is not associated with an image map after all.
3. Otherwise, the user agent must collect all the `area` elements that are descendants of the `map`. Let those be the areas.

Having obtained the list of `area` elements that form the image map (the areas), interactive user agents must process the list in one of two ways.
If the user agent intends to show the text that the `<img>` element represents, then it must use the following steps.

1. Remove all the `<area>` elements in areas that have no `href` attribute.
2. Remove all the `<area>` elements in areas that have no `alt` attribute, or whose `alt` attribute's value is the empty string, if there is another `<area>` element in areas with the same value in the `href` attribute and with a non-empty `alt` attribute.
3. Each remaining `<area>` element in areas represents a hyperlink. Those hyperlinks should all be made available to the user in a manner associated with the text of the `<img>`.

In this context, user agents may represent `<area>` and `<img>` elements with no specified `alt` attributes, or whose `alt` attributes are the empty string or some other non-visible text, in a user-agent-defined fashion intended to indicate the lack of suitable author-provided text.

If the user agent intends to show the image and allow interaction with the image to select hyperlinks, then the image must be associated with a set of layered shapes, taken from the `<area>` elements in areas, in reverse tree order (so the last specified `<area>` element in the map is the bottom-most shape, and the first element in the map, in tree order, is the top-most shape).

Each `<area>` element in areas must be processed as follows to obtain a shape to layer onto the image:

1. Find the state that the element's `shape` attribute represents.
2. Use the rules for parsing a list of floating-point numbers to parse the element's `coords` attribute, if it is present, and let the result be the `coords` list. If the attribute is absent, let the `coords` list be the empty list.
3. If the number of items in the `coords` list is less than the minimum number given for the `<area>` element's current state, as per the following table, then the shape is empty; return.

<table>
<thead>
<tr>
<th>State</th>
<th>Minimum number of items</th>
</tr>
</thead>
<tbody>
<tr>
<td>Circle state</td>
<td>3</td>
</tr>
<tr>
<td>Default state</td>
<td>0</td>
</tr>
<tr>
<td>Polygon state</td>
<td>6</td>
</tr>
<tr>
<td>Rectangle state</td>
<td>4</td>
</tr>
</tbody>
</table>

4. Check for excess items in the `coords` list as per the entry in the following list corresponding to the `shape` attribute's state:

   - **Circle state**
     - Drop any items in the list beyond the third.
   - **Default state**
     - Drop all items in the list.
   - **Polygon state**
     - Drop the last item if there's an odd number of items.
   - **Rectangle state**
     - Drop any items in the list beyond the fourth.

5. If the `shape` attribute represents the `rectangle state`, and the first number in the list is numerically greater than the third number in the list, then swap those two numbers around.
6. If the `shape` attribute represents the `rectangle state`, and the second number in the list is numerically greater than the fourth number in the list, then swap those two numbers around.
7. If the `shape` attribute represents the `circle state`, and the third number in the list is less than or equal to zero, then the shape is empty; return.
8. Now, the shape represented by the element is the one described for the entry in the list below corresponding to the state of the `shape` attribute:
Let $x$ be the first number in $coords$, $y$ be the second number, and $r$ be the third number.

The shape is a circle whose center is $x$ CSS pixels from the left edge of the image and $y$ CSS pixels from the top edge of the image, and whose radius is $r$ CSS pixels.

The shape is a rectangle that exactly covers the entire image.

Let $x_i$ be the $(2i)$th entry in $coords$, and $y_i$ be the $(2i+1)$th entry in $coords$ (the first entry in $coords$ being the one with index 0).

Let the coordinates be $(x_i, y_i)$, interpreted in CSS pixels measured from the top left of the image, for all integer values of $i$ from 0 to $(N/2)-1$, where $N$ is the number of items in $coords$.

The shape is a polygon whose vertices are given by the coordinates, and whose interior is established using the even-odd rule. [GRAPHICS]

Let $x_1$ be the first number in $coords$, $y_1$ be the second number, $x_2$ be the third number, and $y_2$ be the fourth number.

The shape is a rectangle whose top-left corner is given by the coordinate $(x_1, y_1)$ and whose bottom right corner is given by the coordinate $(x_2, y_2)$, those coordinates being interpreted as CSS pixels from the top left corner of the image.

For historical reasons, the coordinates must be interpreted relative to the *displayed* image after any stretching caused by the CSS *width* and *height* properties (or, for non-CSS browsers, the image element's *width* and *height* attributes — CSS browsers map those attributes to the aforementioned CSS properties).

Pointing device interaction with an image associated with a set of layered shapes per the above algorithm must result in the relevant user interaction events being first fired to the top-most shape covering the point that the pointing device indicated, if any, or to the image element itself, if there is no shape covering that point. User agents may also allow individual *area* elements representing *hyperlinks* to be selected and activated (e.g. using a keyboard).

Because a *map* element (and its *area* elements) can be associated with multiple *img* and *object* elements, it is possible for an *area* element to correspond to multiple *focusable areas* of the document.

Image maps are *live*, if the DOM is mutated, then the user agent must act as if it had rerun the algorithms for image maps.

### 4.8.16 MathML

The MathML *math* element falls into the *embedded content*, *phrasing content*, *flow content*, and *palpable content* categories for the purposes of the content models in this specification.

When the MathML *annotation-xml* element contains elements from the HTML namespace, such elements must all be *flow content*.

When the MathML token elements (*mi*, *mo*, *mn*, and *mtext*) are descendants of HTML elements, they may contain *phrasing content* elements from the HTML namespace.

User agents must handle text other than *inter-element whitespace* found in MathML elements whose content models do not allow straight text by pretending for the purposes of MathML content models, layout, and rendering that the text is actually wrapped in a MathML *mtext* element. (Such text is not, however, conforming.)

User agents must act as if any MathML element whose contents does not match the element's content model was replaced, for the purposes of MathML layout and rendering, by a MathML *merror* element containing some appropriate error message.
To enable authors to use MathML tools that only accept MathML in its XML form, interactive HTML user agents are encouraged to provide a way to export any MathML fragment as an XML namespace-well-formed XML fragment.

The semantics of MathML elements are defined by the MathML specification and other applicable specifications.\[MATHML\] The \textit{SVG} \texttt{svg} element falls into the \texttt{embedded content}, \texttt{phrasing content}, \texttt{flow content}, and \texttt{palpable content} categories for the purposes of the content models in this specification.

To enable authors to use SVG tools that only accept SVG in its XML form, interactive HTML user agents are encouraged to provide a way to export any SVG fragment as an XML namespace-well-formed XML fragment.

When the \texttt{SVG foreignObject} element contains elements from the \texttt{HTML namespace}, such elements must all be \texttt{flow content}.

The content model for the \texttt{SVG title} element inside \texttt{HTML documents} is \texttt{phrasing content}. (This further constrains the requirements given in the SVG specification.)

The semantics of SVG elements are defined by the SVG specification and other applicable specifications.\[SVG\] Here is an example of the use of MathML in an HTML document:

```xml
<!DOCTYPE html>
<html lang="en">
<head>
  <title>The quadratic formula</title>
</head>
<body>
  <h1>The quadratic formula</h1>
  <p>
    <math>
      \[ x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \]
    </math>
  </p>
</body>
</html>
```

4.8.17 \texttt{SVG} \[p43\]

The \texttt{SVG svg} element falls into the \textbf{embedded content}, \textbf{phrasing content}, \textbf{flow content}, and \textbf{palpable content} categories for the purposes of the content models in this specification.

To enable authors to use SVG tools that only accept SVG in its XML form, interactive HTML user agents are encouraged to provide a way to export any SVG fragment as an XML namespace-well-formed XML fragment.

When the \texttt{SVG foreignObject} element contains elements from the \texttt{HTML namespace}, such elements must all be \texttt{flow content}.

The content model for the \texttt{SVG title} element inside \texttt{HTML documents} is \texttt{phrasing content}. (This further constrains the requirements given in the SVG specification.)

The semantics of SVG elements are defined by the SVG specification and other applicable specifications.\[SVG\]
The `getSVGDocument()` method must run the following steps:

1. If the element's nested browsing context is null, then return null.
2. If the origin of the active document of the nested browsing context is not same origin-domain with the element's node document's origin, then return null.
3. If the nested browsing context's active document was created by the page load processing model for XML files section because the computed type of the resource in the navigate algorithm was `image/svg+xml`, then return that Document object.
4. Otherwise, return null.

### 4.8.18 Dimension attributes

**Author requirements**: The **width** and **height** attributes on `img`, `iframe`, `embed`, `object`, `video`, and, when their type attribute is in the Image Button state, `input` elements may be specified to give the dimensions of the visual content of the element (the width and height respectively, relative to the nominal direction of the output medium), in CSS pixels. The attributes, if specified, must have values that are valid non-negative integers.

The specified dimensions given may differ from the dimensions specified in the resource itself, since the resource may have a resolution that differs from the CSS pixel resolution. (On screens, CSS pixels have a resolution of 96ppi, but in general the CSS pixel resolution depends on the reading distance.) If both attributes are specified, then one of the following statements must be true:

- specified width - 0.5 ≤ specified height * target ratio ≤ specified width + 0.5
- specified height - 0.5 ≤ specified width / target ratio ≤ specified height + 0.5
- specified height = specified width = 0

The target ratio is the ratio of the intrinsic width to the intrinsic height in the resource. The specified width and specified height are the values of the `width` and `height` attributes respectively.

The two attributes must be omitted if the resource in question does not have both an intrinsic width and an intrinsic height.

If the two attributes are both zero, it indicates that the element is not intended for the user (e.g. it might be a part of a service to count page views).

**Note**

The dimension attributes are not intended to be used to stretch the image.

**User agent requirements**: User agents are expected to use these attributes as hints for the rendering.

The `width` and `height` IDL attributes on the `iframe`, `embed`, `object`, and `video` elements must reflect the respective content attributes of the same name.

**Note**

For `iframe`, `embed`, and `object` the IDL attributes are `DOMString`; for `video` the IDL attributes are `unsigned long`.

**Note**

The corresponding IDL attributes for `img` and `input` elements are defined in those respective elements' sections, as they are slightly more specific to those elements' other behaviors.
4.9 Tabular data

4.9.1 The table element

Categories:
- Flow content
- Palpable content

Contexts in which this element can be used:
Where flow content is expected.

Content model:
In this order: optionally a caption element, followed by zero or more colgroup elements, followed optionally by a thead element, followed by either zero or more tbody elements or one or more tr elements, followed optionally by a tfoot element, optionally intermixed with one or more script-supporting elements.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes

DOM interface:

```idl
[Intf=Window,
HTMLConstructor]
interface HTMLTableElement : HTMLElement {
  [CEReactions] attribute HTMLTableCaptionElement? caption;
  HTMLTableCaptionElement createCaption();
  [CEReactions] void deleteCaption();

  [CEReactions] attribute HTMLTableSectionElement? tHead;
  HTMLTableSectionElement createTHead();
  [CEReactions] void deleteTHead();

  [CEReactions] attribute HTMLTableSectionElement? tFoot;
  HTMLTableSectionElement createTFoot();
  [CEReactions] void deleteTFoot();

  [SameObject] readonly attribute HTMLCollection tBodies;
  HTMLTableSectionElement createTBody();

  [SameObject] readonly attribute HTMLCollection rows;
  HTMLTableRowElement insertRow(optional long index = -1);
  [CEReactions] void deleteRow(long index);
};
```

The table element represents data with more than one dimension, in the form of a table.

The table element takes part in the table model. Tables have rows, columns, and cells given by their descendants. The rows and columns form a grid; a table's cells must completely cover that grid without overlap.

**Note**

Precise rules for determining whether this conformance requirement is met are described in the description of the table model.

Authors are encouraged to provide information describing how to interpret complex tables. Guidance on how to provide such information is given below.

Tables must not be used as layout aids. Historically, some Web authors have misused tables in HTML as a way to control their page layout. This usage is non-conforming, because tools attempting to extract tabular data from such documents would obtain very confusing results. In particular, users of accessibility tools like screen readers are likely to find it very difficult to navigate pages with tables used for layout.
There are a variety of alternatives to using HTML tables for layout, primarily using CSS positioning and the CSS table model. 

Tables can be complicated to understand and navigate. To help users with this, user agents should clearly delineate cells in a table from each other, unless the user agent has classified the table as a (non-conforming) layout table.

User agents, especially those that do table analysis on arbitrary content, are encouraged to find heuristics to determine which tables actually contain data and which are merely being used for layout. This specification does not define a precise heuristic, but the following are suggested as possible indicators:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Indication</th>
</tr>
</thead>
<tbody>
<tr>
<td>The use of the <code>role</code> attribute with the value <code>presentation</code></td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with the non-conforming value 0</td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>cellspacing</code> and <code>cellpadding</code> attributes with the value 0</td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of <code>caption</code>, <code>thead</code>, or <code>th</code> elements</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>headers</code> and <code>scope</code> attributes</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with a value other than 0</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>Explicit visible borders set using CSS</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>summary</code> attribute</td>
<td>Not a good indicator (both layout and non-layout tables have historically been given this attribute)</td>
</tr>
</tbody>
</table>

Authors and implementers are encouraged to consider using some of the table design techniques described below to make tables easier to navigate for users.

For web developers (non-normative)

```

<table>
<thead>
<tr>
<th>Feature</th>
<th>Indication</th>
</tr>
</thead>
<tbody>
<tr>
<td>The use of the <code>role</code> attribute with the value <code>presentation</code></td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with the non-conforming value 0</td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>cellspacing</code> and <code>cellpadding</code> attributes with the value 0</td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of <code>caption</code>, <code>thead</code>, or <code>th</code> elements</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>headers</code> and <code>scope</code> attributes</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with a value other than 0</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>Explicit visible borders set using CSS</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>summary</code> attribute</td>
<td>Not a good indicator (both layout and non-layout tables have historically been given this attribute)</td>
</tr>
</tbody>
</table>
```

It is quite possible that the above suggestions are wrong. Implementors are urged to provide feedback elaborating on their experiences with trying to create a layout table detection heuristic.

If a `table` element has a (non-conforming) `summary` attribute, and the user agent has not classified the table as a layout table, the user agent may report the contents of that attribute to the user.

For web developers (non-normative)

```

<table>
<thead>
<tr>
<th>Feature</th>
<th>Indication</th>
</tr>
</thead>
<tbody>
<tr>
<td>The use of the <code>role</code> attribute with the value <code>presentation</code></td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with the non-conforming value 0</td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>cellspacing</code> and <code>cellpadding</code> attributes with the value 0</td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of <code>caption</code>, <code>thead</code>, or <code>th</code> elements</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>headers</code> and <code>scope</code> attributes</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with a value other than 0</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>Explicit visible borders set using CSS</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>summary</code> attribute</td>
<td>Not a good indicator (both layout and non-layout tables have historically been given this attribute)</td>
</tr>
</tbody>
</table>
```

Note

Authors and implementers are encouraged to consider using some of the table design techniques described below to make tables easier to navigate for users.

Note

It is quite possible that the above suggestions are wrong. Implementors are urged to provide feedback elaborating on their experiences with trying to create a layout table detection heuristic.

If a `table` element has a (non-conforming) `summary` attribute, and the user agent has not classified the table as a layout table, the user agent may report the contents of that attribute to the user.

For web developers (non-normative)

```

<table>
<thead>
<tr>
<th>Feature</th>
<th>Indication</th>
</tr>
</thead>
<tbody>
<tr>
<td>The use of the <code>role</code> attribute with the value <code>presentation</code></td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with the non-conforming value 0</td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>cellspacing</code> and <code>cellpadding</code> attributes with the value 0</td>
<td>Probably a layout table</td>
</tr>
<tr>
<td>The use of <code>caption</code>, <code>thead</code>, or <code>th</code> elements</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>headers</code> and <code>scope</code> attributes</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with a value other than 0</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>Explicit visible borders set using CSS</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>summary</code> attribute</td>
<td>Not a good indicator (both layout and non-layout tables have historically been given this attribute)</td>
</tr>
</tbody>
</table>
```

It is quite possible that the above suggestions are wrong. Implementors are urged to provide feedback elaborating on their experiences with trying to create a layout table detection heuristic.

If a `table` element has a (non-conforming) `summary` attribute, and the user agent has not classified the table as a layout table, the user agent may report the contents of that attribute to the user.

For web developers (non-normative)

```

<table>
<thead>

<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the non-conforming <code>border</code> attribute with a value other than 0</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>Explicit visible borders set using CSS</td>
<td>Probably a non-layout table</td>
</tr>
<tr>
<td>The use of the <code>summary</code> attribute</td>
<td>Not a good indicator (both layout and non-layout tables have historically been given this attribute)</td>
</tr>
</tbody>
</table>
```
In all of the following attribute and method definitions, when an element is to be table-created, that means to create an element given the table element's node document, the given local name, and the HTML namespace.

The caption IDL attribute must return, on getting, the first caption element child of the table element, if any, or null otherwise. On setting, the first caption element child of the table element, if any, must be removed, and the new value, if not null, must be inserted as the first node of the table element.

The createCaption() method must return the first caption element child of the table element, if any; otherwise a new caption element must be table-created, inserted as the first node of the table element, and then returned.

The deleteCaption() method must remove the first caption element child of the table element, if any.

The tHead IDL attribute must return, on getting, the first thead element child of the table element, if any, or null otherwise. On setting, if the new value is null or a thead element, the first thead element child of the table element, if any, must be removed, and the new value, if not null, must be inserted immediately before the first element in the table element that is neither a caption element nor a colgroup element, if any, or at the end of the table if there are no such elements. If the new value is neither null nor a thead element, then a HierarchyRequestError DOMException must be thrown instead.

The createTHead() method must return the first thead element child of the table element, if any; otherwise a new thead element must be table-created and inserted immediately before the first element in the table element that is neither a caption element nor a colgroup element, if any, or at the end of the table if there are no such elements, and then that new element must be returned.

The deleteTHead() method must remove the first thead element child of the table element, if any.
The `tFoot` IDL attribute must return, on getting, the first `tFoot` element child of the `table` element, if any, or null otherwise. On setting, if the new value is null or a `tFoot` element, the first `tFoot` element child of the `table` element, if any, must be removed, and the new value, if not null, must be inserted at the end of the table. If the new value is neither null nor a `tFoot` element, then a `"HierarchyRequestError" DOMException` must be thrown instead.

The `createTFooter()` method must return the first `tFoot` element child of the `table` element, if any; otherwise a new `tFoot` element must be `table-created` and inserted at the end of the table, and then that new element must be returned.

The `deleteTFooter()` method must remove the first `tFoot` element child of the `table` element, if any.

The `tBodies` attribute must return an `HTMLCollection` rooted at the `table` node, whose filter matches only `tbody` elements that are children of the `table` element.

The `createTBody()` method must `table-create` a new `tbody` element, insert it immediately after the last `tbody` element child in the `table` element, if any, or at the end of the `table` element if the `table` element has no `tbody` element children, and then must return the new `tbody` element.

The `rows` attribute must return an `HTMLCollection` rooted at the `table` node, whose filter matches only `tr` elements that are either children of the `table` element, or children of `thead`, `tbody`, or `tFoot` elements that are themselves children of the `table` element. The elements in the collection must be ordered such that those elements whose parent is a `thead` are included first, in `tree order`, followed by those elements whose parent is either a `table` or `tbody` element, again in `tree order`, followed finally by those elements whose parent is a `tFoot` element, still in `tree order`.

The behavior of the `insertRow(index)` method depends on the state of the table. When it is called, the method must act as required by the first item in the following list of conditions that describes the state of the table and the `index` argument:

- **If `index` is less than −1 or greater than the number of elements in `rows` collection:**
  The method must throw an `"IndexSizeError" DOMException`.

- **If the `rows` collection has zero elements in it, and the `table` has no `tbody` elements in it:**
  The method must `table-create` a `tbody` element, then `table-create` an `tr` element, then append the `tr` element to the `tbody` element, then append the `tbody` element to the `table` element, and finally return the `tr` element.

- **If the `rows` collection has zero elements in it:**
  The method must `table-create` an `tr` element, append it to the last `tbody` element in the table, and return the `tr` element.

- **If `index` is −1 or equal to the number of items in `rows` collection:**
  The method must `table-create` an `tr` element, and append it to the parent of the last `tr` element in the `rows` collection. Then, the newly created `tr` element must be returned.

- **Otherwise:**
  The method must `table-create` an `tr` element, insert it immediately before the `index`th `tr` element in the `rows` collection, in the same parent, and finally must return the newly created `tr` element.

When the `deleteRow(index)` method is called, the user agent must run the following steps:

1. If `index` is less than −1 or greater than or equal to the number of elements in the `rows` collection, then throw an `"IndexSizeError" DOMException`.
2. If `index` is −1, then `remove` the last element in the `rows` collection from its parent, or do nothing if the `rows` collection is empty.
3. Otherwise, `remove` the `index`th element in the `rows` collection from its parent.

Example

Here is an example of a table being used to mark up a Sudoku puzzle. Observe the lack of headers, which are not necessary in such a table.

```html
<style>
  #sudoku { border-collapse: collapse; border: solid thick; }
  #sudoku colgroup, table#sudoku tbody { border: solid medium; }
  #sudoku td { border: solid thin; height: 1.4em; width: 1.4em; text-align: center; padding: 0; }
</style>
```
4.9.1.1 Techniques for describing tables

For tables that consist of more than just a grid of cells with headers in the first row and headers in the first column, and for any table in general where the reader might have difficulty understanding the content, authors should include explanatory information introducing the table. This information is useful for all users, but is especially useful for users who cannot see the table, e.g. users of screen readers.

Such explanatory information should introduce the purpose of the table, outline its basic cell structure, highlight any trends or patterns, and generally teach the user how to use the table.

For instance, the following table:

<table>
<thead>
<tr>
<th>Negative</th>
<th>Characteristic</th>
<th>Positive</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sad</td>
<td>Mood</td>
<td>Happy</td>
</tr>
<tr>
<td>Failing</td>
<td>Grade</td>
<td>Passing</td>
</tr>
</tbody>
</table>

...might benefit from a description explaining the way the table is laid out, something like "Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column".

There are a variety of ways to include this information, such as:

**In prose, surrounding the table**

```
<p>In the following table, characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</p>
<table>
  <caption>Characteristics with positive and negative sides</caption>
  <thead>
    <tr>
      <th id="n">Negative</th>
      <th>Characteristic</th>
      <th>Positive</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>Sad</td>
      <td>Mood</td>
      <td>Happy</td>
    </tr>
    <tr>
      <td>Failing</td>
      <td>Grade</td>
      <td>Passing</td>
    </tr>
  </tbody>
</table>
```
In the table's caption:

```html
<table>
  <caption><strong>Characteristics with positive and negative sides.</strong></caption>
  <thead>
    <tr>
      <th id="n">Negative</th>
      <th>Characteristic</th>
      <th>Positive</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td headers="n r1">Sad</td>
      <td id="r1">Mood</td>
      <td>Happy</td>
    </tr>
    <tr>
      <td headers="n r2">Failing</td>
      <td id="r2">Grade</td>
      <td>Passing</td>
    </tr>
  </tbody>
</table>
```

Example:

```html
<table>
  <caption><strong>Characteristics with positive and negative sides.</strong></caption>
  <details>
    <summary>Help</summary>
    <p>Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</p>
  </details>
  <thead>
    <tr>
      <th id="n">Negative</th>
      <th>Characteristic</th>
      <th>Positive</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td headers="n r1">Sad</td>
      <td id="r1">Mood</td>
      <td>Happy</td>
    </tr>
    <tr>
      <td headers="n r2">Failing</td>
      <td id="r2">Grade</td>
      <td>Passing</td>
    </tr>
  </tbody>
</table>
```
<table>
  <thead>
    <tr>
      <th id="n">Negative</th>
      <th>Characteristic</th>
      <th>Positive</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td headers="n r1">Sad</td>
      <td headers="r1">Mood</td>
      <td>Happy</td>
    </tr>
    <tr>
      <td headers="n r2">Failing</td>
      <td headers="r2">Grade</td>
      <td>Passing</td>
    </tr>
  </tbody>
</table>

Next to the table, in the same figure's figcaption:

Example

<figure>
  <figcaption>Characteristics with positive and negative sides</figcaption>
  <p>Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</p>
  <table>
    <thead>
      <tr>
        <th id="n">Negative</th>
        <th>Characteristic</th>
        <th>Positive</th>
      </tr>
    </thead>
    <tbody>
      <tr>
        <td headers="n r1">Sad</td>
        <td headers="r1">Mood</td>
        <td>Happy</td>
      </tr>
      <tr>
        <td headers="n r2">Failing</td>
        <td headers="r2">Grade</td>
        <td>Passing</td>
      </tr>
    </tbody>
  </table>
</figure>
Authors may also use other techniques, or combinations of the above techniques, as appropriate.

The best option, of course, rather than writing a description explaining the way the table is laid out, is to adjust the table such that no explanation is needed.

Example

In the case of the table used in the examples above, a simple rearrangement of the table so that the headers are on the top and left sides removes the need for an explanation as well as removing the need for the use of headers attributes:

```xml
<table>
  <caption>Characteristics with positive and negative sides</caption>
  <thead>
    <tr>
      <th>Characteristic</th>
      <th>Negative</th>
      <th>Positive</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>Mood</th>
      <td>Sad</td>
      <td>Happy</td>
    </tr>
    <tr>
      <th>Grade</th>
      <td>Failing</td>
      <td>Passing</td>
    </tr>
  </tbody>
</table>
```

4.9.1.2 Techniques for table design

Good table design is key to making tables more readable and usable.

In visual media, providing column and row borders and alternating row backgrounds can be very effective to make complicated tables more readable.

For tables with large volumes of numeric content, using monospaced fonts can help users see patterns, especially in situations where a user agent does not render the borders. (Unfortunately, for historical reasons, not rendering borders on tables is a common default.)

In speech media, table cells can be distinguished by reporting the corresponding headers before reading the cell’s contents, and by allowing users to navigate the table in a grid fashion, rather than serializing the entire contents of the table in source order.

Authors are encouraged to use CSS to achieve these effects.

User agents are encouraged to render tables using these techniques whenever the page does not use CSS and the table is not classified as a layout table.

4.9.2 The caption element

Categories:
None.

Contexts in which this element can be used:
As the first element child of a table element.
Content model:

Flow content, but with no descendant `table` elements.

Tag omission in text/html:

A `caption` element's end tag can be omitted if the `caption` element is not immediately followed by ASCII whitespace or a `comment`.

Content attributes:

Global attributes:

DOM interface:

```
IDL [Exposed=Window, HTMLConstructor]
interface HTMLTableCaptionElement : HTMLElement {};
```

The `caption` element represents the title of the `table` that is its parent, if it has a parent and that is a `table` element.

The `caption` element takes part in the `table model`.

When a `table` element is the only content in a `figure` element other than the `figcaption`, the `caption` element should be omitted in favor of the `figcaption`.

A caption can introduce context for a table, making it significantly easier to understand.

Example

Consider, for instance, the following table:

```
<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
<td>10</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
<td>10</td>
<td>11</td>
</tr>
</tbody>
</table>
```

In the abstract, this table is not clear. However, with a caption giving the table's number (for `reference` in the main prose) and explaining its use, it makes more sense:

```
<caption>
<p>Table 1.</p>
<p>This table shows the total score obtained from rolling two six-sided dice. The first row represents the value of the first die, the first column the value of the second die. The total is given in the cell that corresponds to the values of the two dice.</p>
</caption>
```

This provides the user with more context:

```
Table 1.
This table shows the total score obtained from rolling two six-sided dice. The first row represents the value of the first die, the first column the value of the second die. The total is given in the cell that corresponds to the values of the two dice.
```

```
<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
<td>10</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
<td>10</td>
<td>11</td>
</tr>
</tbody>
</table>
```
4.9.3 The `colgroup` element

**Categories**:
None.

**Contexts in which this element can be used**:
As a child of a `table` element, after any `caption` elements and before any `thead`, `tbody`, `tfoot`, and `tr` elements.

**Content model**:
- If the `span` attribute is present: Nothing.
- If the `span` attribute is absent: Zero or more `col` and `template` elements.

**Tag omission in text/html**:
- A `colgroup` element's `start tag` can be omitted if the first thing inside the `colgroup` element is a `col` element, and if the element is not immediately preceded by another `colgroup` element whose `end tag` has been omitted. (It can’t be omitted if the element is empty.)
- A `colgroup` element's `end tag` can be omitted if the `colgroup` element is not immediately followed by ASCII whitespace or a `comment`.

**Content attributes**:
- **Global attributes**
  - `span` — Number of columns spanned by the element

**DOM interface**:

```idl
[Exposed=Window,
 HTMLConstructor]
interface HTMLTableColElement : HTMLElement {
    [CEReactions] attribute unsigned long span;
};
```

The `colgroup` element represents a group of one or more columns in the `table` that is its parent, if it has a parent and that is a `table` element.

If the `colgroup` element contains no `col` elements, then the element may have a `span` content attribute specified, whose value must be a valid non-negative integer greater than zero and less than or equal to 1000.

The `colgroup` element and its `span` attribute take part in the `table model`.

The `span` IDL attribute must `reflect` the content attribute of the same name. It is `clamped to the range` [1, 1000], and its default value is 1.

4.9.4 The `col` element

**Categories**:
None.

**Contexts in which this element can be used**:
As a child of a `colgroup` element that doesn’t have a `span` attribute.

**Content model**:
- Nothing.

**Tag omission in text/html**:
- No `end tag`.

---

6 7 8 9 10 11 12
Content attributes:

**Global attributes**:

- `span` — Number of columns spanned by the element

**DOM interface**:

Uses the `HTMLTableColElement` as defined for `colgroup` elements.

If a `col` element has a parent and that is a `colgroup` element that itself has a parent that is a `table` element, then the `col` element represents one or more columns in the `columngroup` represented by that `colgroup`.

The element may have a `span` content attribute specified, whose value must be a valid non-negative integer greater than zero and less than or equal to 1000.

The `col` element and its `span` attribute take part in the `table model`.

The `span` IDL attribute must `reflect` the content attribute of the same name. It is clamped to the range `[1, 1000]`, and its default value is 1.

### 4.9.5 The `tbody` element

**Categories**:

None.

**Contexts in which this element can be used**:

As a child of a `table` element, after any `caption`, `colgroup`, and `thead` elements, but only if there are no `tr` elements that are children of the `table` element.

**Content model**:

Zero or more `tr` and script-supporting elements.

**Tag omission in text/html**:

A `tbody` element's `start tag` can be omitted if the first thing inside the `tbody` element is a `tr` element, and if the element is not immediately preceded by a `tbody`, `thead`, or `tfoot` element whose `end tag` has been omitted. (It can't be omitted if the element is empty.)

A `tbody` element's `end tag` can be omitted if the `tbody` element is immediately followed by a `tbody` or `tfoot` element, or if there is no more content in the parent element.

**Content attributes**:

**Global attributes**:

**DOM interface**:

```html
IDL

[Exposed=Window,
  HTMLConstructor]

interface HTMLTableSectionElement : HTMLElement {
  [SameObject] readonly attribute HTMLCollection<
    HTMLTableRowElement> rows;
  HTMLTableRowElement insertRow(optional long index = -1);
  [CEReactions] void deleteRow(long index);
};
```

The `HTMLTableSectionElement` interface is also used for `thead` and `tfoot` elements.

The `tbody` element represents a block of rows that consist of a body of data for the parent `table` element, if the `tbody` element has a parent and it is a `table`.

The `tbody` element takes part in the `table model`.

For web developers (non-normative)
tbody.rows

Returns an HTMLCollection of the tr elements of the table section.

\[ \text{tr} = \text{tbody}.insertRow([\text{index}]) \]

Creates a tr element, inserts it into the table section at the position given by the argument, and returns the tr.

The position is relative to the rows in the table section. The index \(-1\), which is the default if the argument is omitted, is equivalent to inserting at the end of the table section.

If the given position is less than \(-1\) or greater than the number of rows, throws an "IndexSizeError" DOMException.

tbody.deleteRow(index)

Removes the tr element with the given position in the table section.

The position is relative to the rows in the table section. The index \(-1\) is equivalent to deleting the last row of the table section.

If the given position is less than \(-1\) or greater than the index of the last row, or if there are no rows, throws an "IndexSizeError" DOMException.

4.9.6 The thead element

Categories:

None.

Contexts in which this element can be used:

As a child of a table element, after any caption and colgroup elements and before any tbody, tfoot, and tr elements, but only if there are no other thead elements that are children of the table element.

Content model:

Zero or more tr and script-supporting elements.

Tag omission in text/html:

A thead element's end tag can be omitted if the thead element is immediately followed by a tbody or tfoot element.
The `<thead>` element represents the block of rows that consist of the column labels (headers) for the parent `<table>` element, if the `<thead>` element has a parent and it is a `<table>`.

The `<thead>` element takes part in the table model.

### Example

This example shows a `<thead>` element being used. Notice the use of both `<th>` and `<td>` elements in the `<thead>` element: the first row is the headers, and the second row is an explanation of how to fill in the table.

```html
<table>
  <caption>School auction sign-up sheet</caption>
  <thead>
    <tr>
      <th><label for=e1>Name</label></th>
      <th><label for=e2>Product</label></th>
      <th><label for=e3>Picture</label></th>
      <th><label for=e4>Price</label></th>
    </tr>
    <tr>
      <td>Your name here</td>
      <td>What are you selling?</td>
      <td>Link to a picture</td>
      <td>Your reserve price</td>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>Ms Danus</td>
      <td>Doughnuts</td>
      <td><img src="https://example.com/mydoughnuts.png" title="Doughnuts from Ms Danus"> $45</td>
      <td><input id=e1 type=text name=who required form=f></td>
    </tr>
    <tr>
      <td><input id=e2 type=text name=what required form=f></td>
      <td><input id=e3 type=url name=pic form=f></td>
      <td><input id=e4 type=number step=0.01 min=0 value=0 required form=f></td>
    </tr>
  </tbody>
  <form id=f action="/auction.cgi">
    <input type=button name=add value="Submit">
  </form>
</table>
```

### 4.9.7 The `<tfoot>` element

**Categories**:

None.

**Contexts in which this element can be used**:

As a child of a `<table>` element, after any `<caption>`, `<colgroup>`, `<thead>`, `<tbody>`, and `<tr>` elements, but only if there are no other `<tfoot>` elements that are children of the `<table>` element.

**Content model**:

Zero or more `<tr>` and `<script-supporting>` elements.

**Tag omission in text/html**:

A `<tfoot>` element's end tag can be omitted if there is no more content in the parent element.
The `tfoot` element represents the block of rows that consist of the column summaries (footers) for the parent `table` element, if the `tfoot` element has a parent and it is a `table`.

The `tfoot` element takes part in the table model.

### 4.9.8 The `tr` element

#### Categories
None.

#### Contexts in which this element can be used:
As a child of a `thead` element.
As a child of a `tbody` element.
As a child of a `tfoot` element.
As a child of a `table` element, after any `caption`, `colgroup`, and `thead` elements, but only if there are no `tbody` elements that are children of the `table` element.

#### Content model:
Zero or more `td`, `th`, and script-supporting elements.

#### Tag omission in text/html:
A `tr` element's end tag can be omitted if the `tr` element is immediately followed by another `tr` element, or if there is no more content in the parent element.

#### Content attributes:
Global attributes

#### DOM interface:

```idl
[Exposed=Window,
 HTMLConstructor]
interface HTMLTableRowElement : HTMLElement {
    readonly attribute long rowIndex;
    readonly attribute long sectionRowIndex;
    [SameObject] readonly attribute HTMLCollection cells;
    HTMLTableCellElement insertCell(optional long index = -1);
    [CEReactions] void deleteCell(long index);
};
```

The `tr` element represents a row of cells in a `table`.

The `tr` element takes part in the table model.

#### For web developers (non-normative)

- **`tr.rowIndex`**
  - Returns the position of the row in the table's `rows` list.
  - Returns −1 if the element isn't in a table.

- **`tr.sectionRowIndex`**
  - Returns the position of the row in the table section's `rows` list.
  - Returns −1 if the element isn't in a table section.
The `rowIndex` attribute must, if this element has a parent `table` element, or a parent `tbody`, `thead`, or `tfoot` element and a grandparent `table` element, return the index of this `tr` element in that `table` element's `rows` collection. If there is no such `table` element, then the attribute must return −1.

The `sectionRowIndex` attribute must, if this element has a parent `table`, `tbody`, `thead`, or `tfoot` element, return the index of the `tr` element in the parent element's `rows` collection (for tables, that's `HTMLTableElement`'s `rows` collection; for table sections, that's `HTMLTableSectionElement`'s `rows` collection). If there is no such parent element, then the attribute must return −1.

The `cells` attribute must return an `HTMLCollection` rooted at this `tr` element, whose filter matches only `td` and `th` elements that are children of the `tr` element.

The `insertCell(index)` method must act as follows:

1. If `index` is less than −1 or greater than the number of elements in the `cells` collection, then throw an "IndexSizeError" DOMException.
2. Let `table cell` be the result of creating an element given this `tr` element's `node document`, `td`, and the HTML namespace.
3. If `index` is equal to −1 or equal to the number of items in `cells` collection, then append `table cell` to this `tr` element.
4. Otherwise, insert `table cell` as a child of this `tr` element, immediately before the `index`th `td` or `th` element in the `cells` collection.
5. Return `table cell`.

The `deleteCell(index)` method must act as follows:

1. If `index` is less than −1 or greater than or equal to the number of elements in the `cells` collection, then throw an "IndexSizeError" DOMException.
2. If `index` is −1, then remove the last element in the `cells` collection from its parent, or do nothing if the `cells` collection is empty.
3. Otherwise, remove the `index`th element in the `cells` collection from its parent.

4.9.9 The `td` element

Categories: Sectioning root.
Contexts in which this element can be used:
As a child of a `tr` element.

Content model:
Flow content.

Tag omission in text/html:
A `td` element's end tag can be omitted if the `td` element is immediately followed by a `td` or `th` element, or if there is no more content in the parent element.

Content attributes:
- Global attributes:
  - `colspan` — Number of columns that the cell is to span
  - `rowspan` — Number of rows that the cell is to span
  - `headers` — The header cells for this cell

DOM interface:

```idl
[Exposed=Window,
 HTMLConstructor]
interface HTMLTableCellElement : HTMLElement {
    [CFReactions] attribute unsigned long colspan;
    [CFReactions] attribute unsigned long rowspan;
    [CFReactions] attribute DOMString headers;
    readonly attribute long cellIndex;

    [CFReactions] attribute DOMString scope; // only conforming for th elements
    [CFReactions] attribute DOMString abbr; // only conforming for th elements
}
```

The `HTMLTableCellElement` interface is also used for `th` elements.

The `td` element represents a data cell in a table.

The `td` element and its `colspan`, `rowspan`, and `headers` attributes take part in the table model.

User agents, especially in non-visual environments or where displaying the table as a 2D grid is impractical, may give the user context for the cell when rendering the contents of a cell; for instance, giving its position in the table model, or listing the cell's header cells (as determined by the algorithm for assigning header cells). When a cell's header cells are being listed, user agents may use the value of `abbr` attributes on those header cells, if any, instead of the contents of the header cells themselves.

Example

In this example, we see a snippet of a Web application consisting of a grid of editable cells (essentially a simple spreadsheet). One of the cells has been configured to show the sum of the cells above it. Three have been marked as headings, which use `th` elements instead of `td` elements. A script would attach event handlers to these elements to maintain the total.

```html
<table>
  <tr>
    <th><input value="Name"></th>
    <th><input value="Paid ($)"></th>
  </tr>
  <tr>
    <td><input value="Jeff"></td>
    <td><input value="14"></td>
  </tr>
  <tr>
    <td><input value="Britta"></td>
    <td><input value="9"></td>
  </tr>
  <tr>
    <td><input value="Abed"></td>
    <td><input value="25"></td>
  </tr>
```
4.9.10 The th element

Categories:
None.

Contexts in which this element can be used:
As a child of a tr element.

Content model:
Flow content, but with no header, footer, sectioning content, or heading content descendants.

Tag omission in text/html:
A th element’s end tag can be omitted if the th element is immediately followed by a td or th element, or if there is no more content in the parent element.

Content attributes:
Global attributes
- colspan — Number of columns that the cell is to span
- rowspan — Number of rows that the cell is to span
- headers — The header cells for this cell
- scope — Specifies which cells the header cell applies to
- abbr — Alternative label to use for the header cell when referencing the cell in other contexts

DOM interface:
Uses HTMLTableCellElement, as defined for td elements.

The th element represents a header cell in a table.

The th element may have a scope content attribute specified. The scope attribute is an enumerated attribute with five states, four of which have explicit keywords:

The row keyword, which maps to the row state
The row state means the header cell applies to some of the subsequent cells in the same row(s).

The col keyword, which maps to the column state
The column state means the header cell applies to some of the subsequent cells in the same column(s).

The rowgroup keyword, which maps to the row group state
The row group state means the header cell applies to all the remaining cells in the row group. A th element’s scope attribute must not be in the rowgroup state if the element is not anchored in a row group.

The colgroup keyword, which maps to the column group state
The column group state means the header cell applies to all the remaining cells in the column group. A th element’s scope attribute must not be in the column group state if the element is not anchored in a column group.
The auto state makes the header cell apply to a set of cells selected based on context.

The `scope` attribute's `missing value default` and `invalid value default` are the auto state.

The `th` element may have an `abbr` content attribute specified. Its value must be an alternative label for the header cell, to be used when referencing the cell in other contexts (e.g. when describing the header cells that apply to a data cell). It is typically an abbreviated form of the full header cell, but can also be an expansion, or merely a different phrasing.

The `th` element and its `colspan`, `rowspan`, `headers`, and `scope` attributes take part in the table model.

Example

The following example shows how the `scope` attribute's `rowgroup` value affects which data cells a header cell applies to.

Here is a markup fragment showing a table:

```html
<table>
  <thead>
    <tr>
      <th>ID</th>
      <th>Measurement</th>
      <th>Average</th>
      <th>Maximum</th>
    </tr>
    <tr scope=rowgroup>
      <th>Cats</th>
      <td>93</td>
      <td>3.5</td>
      <td>4</td>
    </tr>
    <tr scope=row>
      <th>Tails</th>
      <td>10</td>
      <td>1</td>
      <td>1</td>
    </tr>
  </thead>
  <tbody>
    <tr scope=rowgroup>
      <th>English speakers</th>
      <td>32</td>
      <td>2.67</td>
      <td>4</td>
    </tr>
    <tr scope=row>
      <th>Tails</th>
      <td>35</td>
      <td>0.33</td>
      <td>1</td>
    </tr>
  </tbody>
</table>
```

This would result in the following table:

<table>
<thead>
<tr>
<th>ID</th>
<th>Measurement</th>
<th>Average</th>
<th>Maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cats</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>93</td>
<td>Legs</td>
<td>3.5</td>
<td>4</td>
</tr>
<tr>
<td>10</td>
<td>Tails</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>English speakers</td>
<td></td>
<td></td>
</tr>
<tr>
<td>32</td>
<td>Legs</td>
<td>2.67</td>
<td>4</td>
</tr>
<tr>
<td>35</td>
<td>Tails</td>
<td>0.33</td>
<td>1</td>
</tr>
</tbody>
</table>

The headers in the first row all apply directly down to the rows in their column.

The headers with the explicit `scope` attributes apply to all the cells in their row group other than the cells in the first column.

The remaining headers apply just to the cells to the right of them.
The `td` and `th` elements may have a `colspan` content attribute specified, whose value must be a valid non-negative integer greater than zero and less than or equal to 1000.

The `td` and `th` elements may also have a `rowspan` content attribute specified, whose value must be a valid non-negative integer less than or equal to 65534. For this attribute, the value zero means that the cell is to span all the remaining rows in the row group.

These attributes give the number of columns and rows respectively that the cell is to span. These attributes must not be used to overlap cells, as described in the description of the table model.

The `colspan` IDL attribute must reflect the `colspan` content attribute. It is clamped to the range $[1, 1000]$, and its default value is 1.

The `rowspan` IDL attribute must reflect the `rowspan` content attribute. It is clamped to the range $[0, 65534]$, and its default value is 1.

The `headers` IDL attribute must reflect the content attribute of the same name.
The `cellIndex` IDL attribute must, if the element has a parent `tr` element, return the index of the cell's element in the parent element's `cells` collection. If there is no such parent element, then the attribute must return −1.

The `scope` IDL attribute must `reflect` the content attribute of the same name, limited to only known values.

The `abbr` IDL attribute must `reflect` the content attribute of the same name.

### 4.9.12 Processing model

The various table elements and their content attributes together define the table model.

A table consists of cells aligned on a two-dimensional grid of slots with coordinates (x, y). The grid is finite, and is either empty or has one or more slots. If the grid has one or more slots, then the x coordinates are always in the range 0 ≤ x < `xwidth`, and the y coordinates are always in the range 0 ≤ y < `yheight`. If one or both of `xwidth` and `yheight` are zero, then the table is empty (has no slots). Tables correspond to `table` elements.

A cell is a set of slots anchored at a slot (`cellx`, `celly`), and with a particular `width` and `height` such that the cell covers all the slots with coordinates (x, y) where `cellx` ≤ x < `cellx+width` and `celly` ≤ y < `celly+height`. Cells can either be data cells or header cells. Data cells correspond to `td` elements, and header cells correspond to `th` elements. Cells of both types can have zero or more associated header cells.

It is possible, in certain error cases, for two cells to occupy the same slot.

A row is a complete set of slots from x=0 to x=`xwidth`-1, for a particular value of y. Rows usually correspond to `tr` elements, though a row group can have some implied `rows` at the end in some cases involving `cells` spanning multiple rows.

A column is a complete set of slots from y=0 to y=`yheight`-1, for a particular value of x. Columns can correspond to `col` elements. In the absence of `col` elements, columns are implied.

A row group is a set of `rows` anchored at a slot (0, `groupy`) with a particular `height` such that the row group covers all the slots with coordinates (x, y) where 0 ≤ x < `xwidth` and `groupy` ≤ y < `groupy+height`. Row groups correspond to `tbody`, `thead`, and `tfoot` elements. Not every row is necessarily in a row group.

A column group is a set of `columns` anchored at a slot (`groupx`, 0) with a particular `width` such that the column group covers all the slots with coordinates (x, y) where `groupx` ≤ x < `groupx+width` and 0 ≤ y < `yheight`. Column groups correspond to `colgroup` elements. Not every column is necessarily in a column group.

Row groups cannot overlap each other. Similarly, column groups cannot overlap each other.

A cell cannot cover slots that are from two or more row groups. It is, however, possible for a cell to be in multiple column groups. All the slots that form part of one cell are part of zero or one row groups and zero or more column groups.

In addition to `cells`, `columns`, `rows`, `row groups`, and `column groups`, `table` can have a `caption` element associated with them. This gives the table a heading, or legend.

A table model error is an error with the data represented by `table` elements and their descendants. Documents must not have table model errors.

### 4.9.12.1 Forming a table

To determine which elements correspond to which slots in a table associated with a `table` element, to determine the dimensions of the table (`xwidth` and `yheight`), and to determine if there are any table model errors, user agents must use the following algorithm:

1. Let `xwidth` be zero.
2. Let `yheight` be zero.
3. Let `pending tfoot` elements be a list of `tfoot` elements, initially empty.
4. Let the `table` be the `table` represented by the `table` element. The `xwidth` and `yheight` variables give the table's dimensions. The `table` is initially empty.
5. If the table element has no children elements, then return the table (which will be empty).

6. Associate the first caption element child of the table element with the table. If there are no such children, then it has no associated caption element.

7. Let the current element be the first element child of the table element.

If a step in this algorithm ever requires the current element to be advanced to the next child of the table when there is no such next child, then the user agent must jump to the step labeled end, near the end of this algorithm.

8. While the current element is not one of the following elements, advance the current element to the next child of the table:

- colgroup
- thead
- tbody
- tfoot
- tr

9. If the current element is a colgroup, follow these substeps:

1. Column groups: Process the current element according to the appropriate case below:

   ↪ If the current element has any col element children
   
   Follow these steps:
   
   1. Let xstart have the value of xwidth.
   2. Let the current column be the first col element child of the colgroup element.
   3. Columns: If the current column element has a span attribute, then parse its value using the rules for parsing non-negative integers.

   If the result of parsing the value is not an error or zero, then let span be that value.

   Otherwise, if the col element has no span attribute, or if trying to parse the attribute's value resulted in an error or zero, then let span be 1.

   If span is greater than 1000, let it be 1000 instead.
   4. Increase xwidth by span.
   5. Let the last span columns in the table correspond to the current column element.
   6. If current column is not the last col element child of the colgroup element, then let the current column be the next col element child of the colgroup element, and return to the step labeled columns.
   7. Let all the last columns in the table from x=xstart to x=xwidth-1 form a new column group, anchored at the slot (xwidth-xstart, 0), with width xwidth-xstart, corresponding to the colgroup element.

   ↪ If the current element has no col element children

   1. If the colgroup element has a span attribute, then parse its value using the rules for parsing non-negative integers.

   If the result of parsing the value is not an error or zero, then let span be that value.

   Otherwise, if the colgroup element has no span attribute, or if trying to parse the attribute's value resulted in an error or zero, then let span be 1.

   If span is greater than 1000, let it be 1000 instead.
   2. Increase xwidth by span.
   3. Let the last span columns in the table form a new column group, anchored at the slot (xwidth-span, 0), with width span, corresponding to the colgroup element.

2. Advance the current element to the next child of the table.

3. While the current element is not one of the following elements, advance the current element to the next child.
4. If the current element is a colgroup element, jump to the step labeled column groups above.

10. Let ycurrent be zero.

11. Let the list of downward-growing cells be an empty list.

12. Rows: While the current element is not one of the following elements, advance the current element to the next child of the table:
   - thead
   - tbody
   - tfoot
   - tr

13. If the current element is a tr, then run the algorithm for processing rows, advance the current element to the next child of the table, and return to the step labeled rows.

14. Run the algorithm for ending a row group.

15. If the current element is a tfoot, then add that element to the list of pending tfoot elements, advance the current element to the next child of the table, and return to the step labeled rows.

16. The current element is either a thead or a tbody.

   Run the algorithm for processing row groups.

17. Advance the current element to the next child of the table.

18. Return to the step labeled rows.

19. End: For each tfoot element in the list of pending tfoot elements, in tree order, run the algorithm for processing row groups.

20. If there exists a row or column in the table containing only slots that do not have a cell anchored to them, then this is a table model error.

21. Return the table.

The algorithm for processing row groups, which is invoked by the set of steps above for processing thead, tbody, and tfoot elements, is:

1. Let ystart have the value of yheight.

2. For each tr element that is a child of the element being processed, in tree order, run the algorithm for processing rows.

3. If yheight > ystart, then let all the last rows in the table from y=ystart to y=yheight-1 form a new row group, anchored at the slot with coordinate (0, ystart), with height yheight-ystart, corresponding to the element being processed.

4. Run the algorithm for ending a row group.

The algorithm for ending a row group, which is invoked by the set of steps above when starting and ending a block of rows, is:

1. While ycurrent is less than yheight, follow these steps:
   1. Run the algorithm for growing downward-growing cells.
   2. Increase ycurrent by 1.

2. Empty the list of downward-growing cells.

The algorithm for processing rows, which is invoked by the set of steps above for processing tr elements, is:
1. If y\text{height} is equal to y\text{current}, then increase y\text{height} by 1. (y\text{current} is never greater than y\text{height}.)

2. Let x\text{current} be 0.

3. Run the algorithm for growing downward-growing cells.

4. If the tr element being processed has no td or th element children, then increase y\text{current} by 1, abort this set of steps, and return to the algorithm above.

5. Let current cell be the first td or th element child in the tr element being processed.

6. Cells: While x\text{current} is less than x\text{width} and the slot with coordinate (x\text{current}, y\text{current}) already has a cell assigned to it, increase x\text{current} by 1.

7. If x\text{current} is equal to x\text{width}, increase x\text{width} by 1. (x\text{current} is never greater than x\text{width}.)

8. If the current cell has a colspan attribute, then parse that attribute's value, and let colspan be the result.
   If parsing that value failed, or returned zero, or if the attribute is absent, then let colspan be 1, instead.
   If colspan is greater than 1000, let it be 1000 instead.

9. If the current cell has a rowspan attribute, then parse that attribute's value, and let rowspan be the result.
   If parsing that value failed or if the attribute is absent, then let rowspan be 1, instead.
   If rowspan is greater than 65534, let it be 65534 instead.

10. If rowspan is zero and the table element's node document is not set to quirks mode, then let cell grows downward be true, and set rowspan to 1. Otherwise, let cell grows downward be false.

11. If x\text{width} < x\text{current}+colspan, then let x\text{width} be x\text{current}+colspan.

12. If y\text{height} < y\text{current}+rowspan, then let y\text{height} be y\text{current}+rowspan.

13. Let the slots with coordinates (x, y) such that x\text{current} ≤ x < x\text{current}+colspan and y\text{current} ≤ y < y\text{current}+rowspan be covered by a new cell c, anchored at (x\text{current}, y\text{current}), which has width colspan and height rowspan, corresponding to the current cell element.
   If the current cell element is a th element, let this new cell c be a header cell; otherwise, let it be a data cell.
   To establish which header cells apply to the current cell element, use the algorithm for assigning header cells described in the next section.
   If any of the slots involved already had a cell covering them, then this is a table model error. Those slots now have two cells overlapping.

14. If cell grows downward is true, then add the tuple {c, x\text{current}, colspan} to the list of downward-growing cells.

15. Increase x\text{current} by colspan.

16. If current cell is the last td or th element child in the tr element being processed, then increase y\text{current} by 1, abort this set of steps, and return to the algorithm above.

17. Let current cell be the next td or th element child in the tr element being processed.

18. Return to the step labeled cells.

When the algorithms above require the user agent to run the algorithm for growing downward-growing cells, the user agent must, for each cell, cells, width) tuple in the list of downward-growing cells, if any, extend the cell cell so that it also covers the slots with coordinates (x, y\text{current}), where cellx \leq x < cellx+width.

4.9.12.2 Forming relationships between data cells and header cells

Each cell can be assigned zero or more header cells. The algorithm for assigning header cells to a cell principal cell is as follows.

1. Let header list be an empty list of cells.

2. Let (principalx, principaly) be the coordinate of the slot to which the principal cell is anchored.
If the principal cell has a headers[p453] attribute specified

1. Take the value of the principal cell's headers[p453] attribute and split it on ASCII whitespace, letting id list be the list of tokens obtained.

2. For each token in the id list, if the first element in the Document[p119] with an ID equal to the token is a cell in the same table[p454], and that cell is not the principal cell, then add that cell to header list.

If principal cell does not have a headers[p453] attribute specified

1. Let principal width be the width of the principal cell.

2. Let principal height be the height of the principal cell.

3. For each value of y from principal y to principal y + principal height - 1, run the internal algorithm for scanning and assigning header cells[p458], with the principal cell, the header list, the initial coordinate (principal x, y), and the increments Δx = −1 and Δy = 0.

4. For each value of x from principal x to principal x + principal width - 1, run the internal algorithm for scanning and assigning header cells[p458], with the principal cell, the header list, the initial coordinate (x, principal y), and the increments Δx = 0 and Δy = −1.

5. If the principal cell is anchored in a row group[p454], then add all header cells that are row group headers[p459] and are anchored in the same row group with an x-coordinate less than or equal to principal x + principal width - 1 and a y-coordinate less than or equal to principal y + principal height - 1 to header list.

6. If the principal cell is anchored in a column group[p454], then add all header cells that are column group headers[p459] and are anchored in the same column group with an x-coordinate less than or equal to principal x + principal width - 1 and a y-coordinate less than or equal to principal y + principal height - 1 to header list.

4. Remove all the empty cells[p459] from the header list.

5. Remove any duplicates from the header list.

6. Remove principal cell from the header list if it is there.

7. Assign the headers in the header list to the principal cell.

The internal algorithm for scanning and assigning header cells, given a principal cell, a header list, an initial coordinate (initial x, initial y), and Δx and Δy increments, is as follows:

1. Let x equal initial x.

2. Let y equal initial y.

3. Let opaque headers be an empty list of cells.

4. If principal cell is a header cell

   Let in header block be true, and let headers from current header block be a list of cells containing just the principal cell.

   Otherwise

   Let in header block be false and let headers from current header block be an empty list of cells.

5. Loop: Increment x by Δx; increment y by Δy.

   For each invocation of this algorithm, one of Δx and Δy will be −1, and the other will be 0.

6. If either x or y are less than 0, then abort this internal algorithm.

7. If there is no cell covering slot (x, y), or if there is more than one cell covering slot (x, y), return to the substep labeled loop.

8. Let current cell be the cell covering slot (x, y).
If current cell is a header cell

1. Set in header block to true.
2. Add current cell to headers from current header block.
3. Let blocked be false.
4. If Δx is 0
   If there are any cells in the opaque headers list anchored with the same x-coordinate as the current cell, and with the same width as current cell, then let blocked be true.
   If the current cell is not a column header, then let blocked be true.
5. If Δy is 0
   If there are any cells in the opaque headers list anchored with the same y-coordinate as the current cell, and with the same height as current cell, then let blocked be true.
   If the current cell is not a row header, then let blocked be true.
6. If blocked is false, then add the current cell to the headers list.

If current cell is a data cell and in header block is true

Set in header block to false. Add all the cells in headers from current header block to the opaque headers list, and empty the headers from current header block list.

5 If current cell is a header cell

If current cell is a header cell anchored at the slot with coordinate (x, y) with width width and height height is said to be a column header if any of the following conditions are true:

- The cell's scope attribute is in the column state, or
- The cell's scope attribute is in the auto state, and there are no data cells in any of the cells covering slots with y-coordinates y .. y+height-1.

A header cell anchored at the slot with coordinate (x, y) with width width and height height is said to be a row header if any of the following conditions are true:

- The cell's scope attribute is in the row state, or
- The cell's scope attribute is in the auto state, the cell is not a column header, and there are no data cells in any of the cells covering slots with x-coordinates x .. x+width-1.

A header cell is said to be a column group header if its scope attribute is in the column group state.

A header cell is said to be a row group header if its scope attribute is in the row group state.

A cell is said to be an empty cell if it contains no elements and its text content, if any, consists only of White Space characters.

4.9.13 Examples

This section is non-normative.

The following shows how might one mark up the bottom part of table 45 of the Smithsonian physical tables, Volume 71:

```xml
<table>
<caption>Specification values: <b>Steel</b>, <b>Castings</b>, Ann. A.S.T.M. A27-16, Class B;* P max. 0.06; S max. 0.05.</caption>
<thead>
<tr>
<th rowspan=2>Grade.</th>
<th rowspan=2>Yield Point.</th>
<th colspan=2>Ultimate tensile strength</th>
</tr>
</thead>
</table>
```
This table could look like this:

<table>
<thead>
<tr>
<th>Grade</th>
<th>Yield Point</th>
<th>Ultimate tensile strength</th>
<th>Per cent elong. 50.8mm or 2 in.</th>
<th>Per cent reduct. area.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>kg/mm²</td>
<td>lb/in²</td>
<td>kg/mm²</td>
</tr>
<tr>
<td>Hard</td>
<td>0.45 ultimate</td>
<td>56.2</td>
<td>80,000</td>
<td>15</td>
</tr>
<tr>
<td>Medium</td>
<td>0.45 ultimate</td>
<td>49.2</td>
<td>70,000</td>
<td>18</td>
</tr>
<tr>
<td>Soft</td>
<td>0.45 ultimate</td>
<td>42.2</td>
<td>60,000</td>
<td>22</td>
</tr>
</tbody>
</table>

The following shows how one might mark up the gross margin table on page 46 of Apple, Inc's 10-K filing for fiscal year 2008:
<tr>
<th>Cost of sales</th>
<td>21,334</td>
<td>15,852</td>
<td>13,717</td>
</tr>

This table could look like this:

<table>
<thead>
<tr>
<th></th>
<th>2008</th>
<th>2007</th>
<th>2006</th>
</tr>
</thead>
<tbody>
<tr>
<td>Net sales</td>
<td>$32,479</td>
<td>$24,006</td>
<td>$19,315</td>
</tr>
<tr>
<td>Cost of sales</td>
<td>$21,334</td>
<td>$15,852</td>
<td>$13,717</td>
</tr>
<tr>
<td>Gross margin</td>
<td>$11,145</td>
<td>$8,154</td>
<td>$5,598</td>
</tr>
<tr>
<td>Gross margin percentage</td>
<td>34.3%</td>
<td>34.0%</td>
<td>29.0%</td>
</tr>
</tbody>
</table>

The following shows how one might mark up the operating expenses table from lower on the same page of that document:

This table could look like this:

<table>
<thead>
<tr>
<th></th>
<th>2008</th>
<th>2007</th>
<th>2006</th>
</tr>
</thead>
<tbody>
<tr>
<td>Research and development</td>
<td>$1,109</td>
<td>$782</td>
<td>$712</td>
</tr>
<tr>
<td>Percentage of net sales</td>
<td>3.4%</td>
<td>3.3%</td>
<td>3.7%</td>
</tr>
<tr>
<td>Selling, general, and administrative</td>
<td>$3,761</td>
<td>$2,963</td>
<td>$2,433</td>
</tr>
<tr>
<td>Percentage of net sales</td>
<td>11.6%</td>
<td>12.3%</td>
<td>12.6%</td>
</tr>
</tbody>
</table>

4.10 Forms

4.10.1 Introduction

This section is non-normative.
A form is a component of a Web page that has form controls, such as text, buttons, checkboxes, range, or color picker controls. A user can interact with such a form, providing data that can then be sent to the server for further processing (e.g. returning the results of a search or calculation). No client-side scripting is needed in many cases, though an API is available so that scripts can augment the user experience or use forms for purposes other than submitting data to a server.

Writing a form consists of several steps, which can be performed in any order: writing the user interface, implementing the server-side processing, and configuring the user interface to communicate with the server. 

4.10.1.1 Writing a form's user interface

This section is non-normative.

For the purposes of this brief introduction, we will create a pizza ordering form.

Any form starts with a form element, inside which are placed the controls. Most controls are represented by the input element, which by default provides a text control. To label a control, the label element is used; the label text and the control itself go inside the label element. Each part of a form is considered a paragraph, and is typically separated from other parts using p elements. Putting this together, here is how one might ask for the customer's name:

```html
<form>
  <p><label>Customer name: <input></label></p>
</form>
```

To let the user select the size of the pizza, we can use a set of radio buttons. Radio buttons also use the input element, this time with a type attribute with the value radio. To make the radio buttons work as a group, they are given a common name using the name attribute. To group a batch of controls together, such as, in this case, the radio buttons, one can use the fieldset element. The title of such a group of controls is given by the first element in the fieldset, which has to be a legend element.

```html
<form>
  <p><label>Customer name: <input></label></p>
</form>
```

```html
<fieldset>
  <legend>Pizza Size</legend>
  <p><label><input type=radio name=size> Small</label></p>
  <p><label><input type=radio name=size> Medium</label></p>
  <p><label><input type=radio name=size> Large</label></p>
</fieldset>
```

Note

Changes from the previous step are highlighted.

To pick toppings, we can use checkboxes. These use the input element with a type attribute with the value checkbox:

```html
<form>
  <p><label>Customer name: <input></label></p>
</form>
```

```html
<fieldset>
  <legend>Pizza Size</legend>
  <p><label><input type=radio name=size> Small</label></p>
  <p><label><input type=radio name=size> Medium</label></p>
  <p><label><input type=radio name=size> Large</label></p>
</fieldset>
```

```html
<fieldset>
  <legend>Pizza Toppings</legend>
  <p><label><input type=checkbox> Bacon</label></p>
  <p><label><input type=checkbox> Extra Cheese</label></p>
  <p><label><input type=checkbox> Onion</label></p>
  <p><label><input type=checkbox> Mushroom</label></p>
</fieldset>
```
The pizzeria for which this form is being written is always making mistakes, so it needs a way to contact the customer. For this purpose, we can use form controls specifically for telephone numbers (input elements with their type attribute set to tel) and e-mail addresses (input elements with their type attribute set to email):

```html
<form>
  <p><label>Customer name: <input></label></p>
  <p><label>Telephone: <input type=tel></label></p>
  <p><label>E-mail address: <input type=email></label></p>
</form>
```

We can use an input element with its type attribute set to time to ask for a delivery time. Many of these form controls have attributes to control exactly what values can be specified; in this case, three attributes of particular interest are min, max, and step. These set the minimum time, the maximum time, and the interval between allowed values (in seconds). This pizzeria only delivers between 11am and 9pm, and doesn't promise anything better than 15 minute increments, which we can mark up as follows:

```html
<form>
  <p><label>Customer name: <input></label></p>
  <p><label>Telephone: <input type=tel></label></p>
  <p><label>E-mail address: <input type=email></label></p>
</form>
```

The textarea element can be used to provide a multiline text control. In this instance, we are going to use it to provide a space for the customer to give delivery instructions:
<fieldset>
  <legend>Pizza Toppings</legend>
  <p><label><input type=checkbox> Bacon</label></p>
  <p><label><input type=checkbox> Extra Cheese</label></p>
  <p><label><input type=checkbox> Onion</label></p>
  <p><label><input type=checkbox> Mushroom</label></p>
</fieldset>

<p>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"></p>
<p>Delivery instructions: <textarea></textarea></p>

Finally, to make the form submittable we use the <code>button</code> element:

<form>
  <p><label>Customer name: <input></label></p>
  <p><label>Telephone: <input type=tel></label></p>
  <p><label>E-mail address: <input type=email></label></p>

  <fieldset>
    <legend>Pizza Size</legend>
    <p><label><input type=radio name=size checked> Small</label></p>
    <p><label><input type=radio name=size> Medium</label></p>
    <p><label><input type=radio name=size> Large</label></p>
  </fieldset>

  <fieldset>
    <legend>Pizza Toppings</legend>
    <p><label><input type=checkbox> Bacon</label></p>
    <p><label><input type=checkbox> Extra Cheese</label></p>
    <p><label><input type=checkbox> Onion</label></p>
    <p><label><input type=checkbox> Mushroom</label></p>
  </fieldset>

  <p>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"></p>
  <p>Delivery instructions: <textarea></textarea></p>
  <p><button>Submit order</button></p>
</form>

4.10.1.2 Implementing the server-side processing for a form

This section is non-normative.

The exact details for writing a server-side processor are out of scope for this specification. For the purposes of this introduction, we will assume that the script at https://pizza.example.com/order.cgi is configured to accept submissions using the <code>application/x-www-form-urlencoded</code> format, expecting the following parameters sent in an HTTP POST body:

custname
  Customer's name
custtel
  Customer's telephone number
custemail
  Customer's e-mail address
size
  The pizza size, either small, medium, or large
topping
  A topping, specified once for each selected topping, with the allowed values being bacon, cheese, onion, and mushroom
delivery
  The requested delivery time
4.10.1.3 Configuring a form to communicate with a server

This section is non-normative.

Form submissions are exposed to servers in a variety of ways, most commonly as HTTP GET or POST requests. To specify the exact method used, the `method` attribute is specified on the `form` element. This doesn't specify how the form data is encoded, though; to specify that, you use the `enctype` attribute. You also have to specify the `URL` of the service that will handle the submitted data, using the `action` attribute.

For each form control you want submitted, you then have to give a name that will be used to refer to the data in the submission. We already specified the name for the group of radio buttons; the same attribute (name) also specifies the submission name. Radio buttons can be distinguished from each other in the submission by giving them different values, using the `value` attribute.

Multiple controls can have the same name; for example, here we give all the checkboxes the same name, and the server distinguishes which checkbox was checked by seeing which values are submitted with that name — like the radio buttons, they are also given unique values with the `value` attribute.

Given the settings in the previous section, this all becomes:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
  <p><label>Customer name: <input name="custname"></label></p>
  <p><label>Telephone: <input type="tel" name="custtel"></label></p>
  <p><label>E-mail address: <input type="email" name="custemail"></label></p>
  <fieldset>
    <legend>Pizza Size</legend>
    <p><label><input type="radio" name="size" value="small"> Small</label></p>
    <p><label><input type="radio" name="size" value="medium"> Medium</label></p>
    <p><label><input type="radio" name="size" value="large"> Large</label></p>
  </fieldset>
  <fieldset>
    <legend>Pizza Toppings</legend>
    <p><label><input type="checkbox" name="topping" value="bacon"> Bacon</label></p>
    <p><label><input type="checkbox" name="topping" value="cheese"> Extra Cheese</label></p>
    <p><label><input type="checkbox" name="topping" value="onion"> Onion</label></p>
    <p><label><input type="checkbox" name="topping" value="mushroom"> Mushroom</label></p>
  </fieldset>
  <p><label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="900" name="delivery"></label></p>
  <p><label>Delivery instructions: <textarea name="comments"></textarea></label></p>
  <p><button>Submit order</button></p>
</form>
```

Note

There is no particular significance to the way some of the attributes have their values quoted and others don't. The HTML syntax allows a variety of equally valid ways to specify attributes, as discussed in the syntax section.

For example, if the customer entered "Denise Lawrence" as their name, "555-321-8642" as their telephone number, did not specify an e-mail address, asked for a medium-sized pizza, selected the Extra Cheese and Mushroom toppings, entered a delivery time of 7pm, and left the delivery instructions text control blank, the user agent would submit the following to the online Web service:

```
custname=Denise+Lawrence&custtel=555-321-8642&custemail=&size=medium&topping=cheese&topping=mushroom&delivery=19%3A00&comments=
```
4.10.1.4 Client-side form validation

This section is non-normative.

Forms can be annotated in such a way that the user agent will check the user's input before the form is submitted. The server still has to verify the input is valid (since hostile users can easily bypass the form validation), but it allows the user to avoid the wait incurred by having the server be the sole checker of the user's input.

The simplest annotation is the required attribute, which can be specified on input elements to indicate that the form is not to be submitted until a value is given. By adding this attribute to the customer name, pizza size, and delivery time fields, we allow the user agent to notify the user when the user submits the form without filling in those fields:

```
<form method="post"
  enctype="application/x-www-form-urlencoded"
  action="https://pizza.example.com/order.cgi">
<p><label>Customer name: <input name="custname" required>
</label></p>
<p><label>Telephone: <input type="tel" name="custtel"></label></p>
<p><label>E-mail address: <input type="email" name="custemail"></label></p>
</form>
```

It is also possible to limit the length of the input, using the maxlength attribute. By adding this to the textarea element, we can limit users to 1000 characters, preventing them from writing huge essays to the busy delivery drivers instead of staying focused and to the point:

```
<form method="post"
  enctype="application/x-www-form-urlencoded"
  action="https://pizza.example.com/order.cgi">
<p><label>Customer name: <input name="custname" required></label></p>
<p><label>Telephone: <input type="tel" name="custtel"></label></p>
<p><label>E-mail address: <input type="email" name="custemail"></label></p>
</form>
```
4.10.1.5 Enabling client-side automatic filling of form controls

This section is non-normative.

Some browsers attempt to aid the user by automatically filling form controls rather than having the user reenter their information each time. For example, a field asking for the user's telephone number can be automatically filled with the user's phone number.

To help the user agent with this, the `autocomplete` attribute can be used to describe the field's purpose. In the case of this form, we have three fields that can be usefully annotated in this way: the information about who the pizza is to be delivered to. Adding this information looks like this:

```html
<form method="post"
  enctype="application/x-www-form-urlencoded"
  action="https://pizza.example.com/order.cgi">
  <p><label>Customer name: <input name="custname" required autocomplete="shipping name"/></label></p>
  <p><label>Telephone: <input type="tel" name="custtel" autocomplete="shipping tel"/></label></p>
  <p><label>E-mail address: <input type="email" name="custemail" autocomplete="shipping email"/></label></p>
  <fieldset>
    <legend>Pizza Size</legend>
    <p><label><input type="radio" name="size" required value="small"> Small</label></p>
    <p><label><input type="radio" name="size" required value="medium"> Medium</label></p>
    <p><label><input type="radio" name="size" required value="large"> Large</label></p>
  </fieldset>
  <fieldset>
    <legend>Pizza Toppings</legend>
    <p><label><input type="checkbox" name="topping" value="bacon"> Bacon</label></p>
    <p><label><input type="checkbox" name="topping" value="cheese"> Extra Cheese</label></p>
    <p><label><input type="checkbox" name="topping" value="onion"> Onion</label></p>
    <p><label><input type="checkbox" name="topping" value="mushroom"> Mushroom</label></p>
  </fieldset>
  <p><label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="900" name="delivery" required/></label></p>
  <p><label>Delivery instructions: <textarea name="comments" maxlength="1000"></textarea></label></p>
  <p><button>Submit order</button></p>
</form>

4.10.1.6 Improving the user experience on mobile devices

This section is non-normative.

Some devices, in particular those with virtual keyboards can provide the user with multiple input modalities. For example, when typing in a credit card number the user may wish to only see keys for digits 0-9, while when typing in their name they may wish to see a form field that by default capitalizes each word.

Using the `inputmode` attribute we can select appropriate input modalities:

```html
<form method="post"
  enctype="application/x-www-form-urlencoded">
  <p><label>Customer name: <input name="custname" required autocomplete="shipping name"/></label></p>
  <p><label>Telephone: <input type="tel" name="custtel" autocomplete="shipping tel"/></label></p>
  <p><label>E-mail address: <input type="email" name="custemail" autocomplete="shipping email"/></label></p>
  <fieldset>
    <legend>Pizza Size</legend>
    <p><label><input type="radio" name="size" required value="small"> Small</label></p>
    <p><label><input type="radio" name="size" required value="medium"> Medium</label></p>
    <p><label><input type="radio" name="size" required value="large"> Large</label></p>
  </fieldset>
  <fieldset>
    <legend>Pizza Toppings</legend>
    <p><label><input type="checkbox" name="topping" value="bacon"> Bacon</label></p>
    <p><label><input type="checkbox" name="topping" value="cheese"> Extra Cheese</label></p>
    <p><label><input type="checkbox" name="topping" value="onion"> Onion</label></p>
    <p><label><input type="checkbox" name="topping" value="mushroom"> Mushroom</label></p>
  </fieldset>
  <p><label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="900" name="delivery" required/></label></p>
  <p><label>Delivery instructions: <textarea name="comments" maxlength="1000"></textarea></label></p>
  <p><button>Submit order</button></p>
</form>

---

Note

When a form is submitted, `invalid` events are fired at each form control that is invalid, and then at the `form` element itself. This can be useful for displaying a summary of the problems with the form, since typically the browser itself will only report one problem at a time.
4.10.1.7 The difference between the field type, the autofill field name, and the input modality

This section is non-normative.

The type, autocomplete, and inputmode attributes can seem confusingly similar. For instance, in all three cases, the string "email" is a valid value. This section attempts to illustrate the difference between the three attributes and provides advice suggesting how to use them.

The type attribute on input elements decides what kind of control the user agent will use to expose the field. Choosing between different values of this attribute is the same choice as choosing whether to use an input element, a textarea element, a select element, etc.

The autocomplete attribute, in contrast, describes what the value that the user will enter actually represents. Choosing between different values of this attribute is the same choice as choosing what the label for the element will be.

First, consider telephone numbers. If a page is asking for a telephone number from the user, the right form control to use is type=tel. However, which autocomplete value to use depends on which phone number the page is asking for, whether they expect a telephone number in the international format or just the local format, and so forth.

For example, a page that forms part of a checkout process on an e-commerce site for a customer buying a gift to be shipped to a friend might need both the buyer’s telephone number (in case of payment issues) and the friend’s telephone number (in case of delivery issues). If the site expects international phone numbers (with the country code prefix), this could thus look like this:

<code>
<p>Customer name: <input type="text" name="custname" required autocomplete="shipping name"></p>
<p>Telephone: <input type=tel name="custtel" autocomplete="shipping tel"></p>
<p>Buzzer code: <input type=tel name="custbuzz" inputmode="number"></p>
<p>Email address: <input type=email name="custemail" autocomplete="shipping email"></p>
</form>
</code>

But if the site only supports British customers and recipients, it might instead look like this (notice the use of tel-national rather than tel):

<code>
<p>Your phone number: <input type=tel name="custtel" autocomplete="billing tel"></p>
<p>Recipient's phone number: <input type=tel name="shiptel" autocomplete="shipping tel"></p>
<p>Please enter complete phone numbers including the country code prefix, as in "+1 555 123 4567".
</p>
</code>

<code>
<p>Your phone number: <input type=tel name="custtel" autocomplete="billing tel-national"></p>
<p>Recipient's phone number: <input type=tel name="shiptel" autocomplete="shipping tel-national"></p>
<p>Please enter complete UK phone numbers, as in "+(01632) 960 123".
</p>
</code>
Now, consider a person’s preferred languages. The right autocomplete value is language. However, there could be a number of different form controls used for the purpose: a text control (<input type=text>), a drop-down list (<select>), radio buttons (<input type=radio>), etc. It only depends on what kind of interface is desired.

Finally, consider names. If a page just wants one name from the user, then the relevant control is <input type=text>. If the page is asking for the user’s full name, then the relevant autocomplete value is name.

```html
<p><label>Japanese name: <input name="j" type="text" autocomplete="section-jp name"></label>
<label>Romanized name: <input name="e" type="text" autocomplete="section-en name"></label>
</p>
```

In this example, the "section-*" keywords in the autocomplete attributes’ values tell the user agent that the two fields expect different names. Without them, the user agent could automatically fill the second field with the value given in the first field when the user gave a value to the first field.

**Note**
The "-jp" and "-en" parts of the keywords are opaque to the user agent; the user agent cannot guess, from those, that the two names are expected to be in Japanese and English respectively.

Separate from the choices regarding type and autocomplete, the inputmode attribute decides what kind of input modality (e.g., virtual keyboard) to use, when the control is a text control.

Consider credit card numbers. The appropriate input type is not <input type=number>, as explained below; it is instead <input type=text>. To encourage the user agent to use a numeric input modality anyway (e.g., a virtual keyboard displaying only digits), the page would use

```html
<p><label>Credit card number: <input name="cc" type="text" inputmode="numeric" pattern="[0-9]{8,19}" autocomplete="cc-number"></label>
</p>
```

4.10.8 Date, time, and number formats

This section is non-normative.

In this pizza delivery example, the times are specified in the format "HH:MM": two digits for the hour, in 24-hour format, and two digits for the time. (Seconds could also be specified, though they are not necessary in this example.)

In some locales, however, times are often expressed differently when presented to users. For example, in the United States, it is still common to use the 12-hour clock with an am/pm indicator, as in "2pm". In France, it is common to separate the hours from the minutes using an "h" character, as in "14h00".

Similar issues exist with dates, with the added complication that even the order of the components is not always consistent — for example, in Cyprus the first of February 2003 would typically be written "1/2/03", while that same date in Japan would typically be written as "2003年02月01日" — and even with numbers, where locales differ, for example, in what punctuation is used as the decimal separator and the thousands separator.

It is therefore important to distinguish the time, date, and number formats used in HTML and in form submissions, which are always the formats defined in this specification (and based on the well-established ISO 8601 standard for computer-readable date and time formats), from the time, date, and number formats presented to the user by the browser and accepted as input from the user by the browser.

The format used "on the wire", i.e. in HTML markup and in form submissions, is intended to be computer-readable and consistent irrespective of the user’s locale. Dates, for instance, are always written in the format "YYYY-MM-DD", as in "2003-02-01". Users are not expected to ever see this format.

The time, date, or number given by the page in the wire format is then translated to the user’s preferred presentation (based on user preferences or on the locale of the page itself), before being displayed to the user. Similarly, after the user inputs a time, date, or number using their preferred format, the user agent converts it back to the wire format before putting it in the DOM or submitting it.

This allows scripts in pages and on servers to process times, dates, and numbers in a consistent manner without needing to support dozens of different formats, while still supporting the users’ needs.
Mostly for historical reasons, elements in this section fall into several overlapping (but subtly different) categories in addition to the usual ones like flow content, phrasing content, and interactive content.

A number of the elements are form-associated elements, which means they can have a form owner.

⇒ button, fieldset, input, object, output, select, textarea, img

The form-associated elements fall into several subcategories:

Listed elements
Denotes elements that are listed in the form.elements and fieldset.elements APIs. These elements also have a form content attribute, and a matching form IDL attribute, that allow authors to specify an explicit form owner.

⇒ button, fieldset, input, object, output, select, textarea

Submittable elements
Denotes elements that can be used for constructing the entry list when a form element is submitted.

⇒ button, input, object, select, textarea

Some submittable elements can be, depending on their attributes, buttons. The prose below defines when an element is a button. Some buttons are specifically submit buttons.

Resettable elements
Denotes elements that can be affected when a form element is reset.

⇒ input, output, select, textarea

Autocapitalize-inheriting elements
Denotes elements that inherit the autocapitalize attribute from their form owner.

⇒ button, fieldset, input, output, select, textarea

Some elements, not all of them form-associated, are categorized as labelable elements. These are elements that can be associated with a label element.

⇒ button (if the type attribute is not in the Hidden state), select, textarea

4.10.3 The form element

Categories:
Flow content
Palpable content

Contexts in which this element can be used:
Where flow content is expected.

Content model:
Flow content, but with no form element descendants.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
Global attributes
accept-charset — Character encodings to use for form submission
action — URL to use for form submission

See also the implementation notes regarding localization of form controls.
The **form** element represents a collection of form-associated elements, some of which can represent editable values that can be submitted to a server for processing.

The **accept-charset** attribute gives the character encodings that are to be used for the submission. If specified, the value must be an ordered set of unique space-separated tokens that are ASCII case-insensitive, and each token must be an ASCII case-insensitive match for one of the labels of an ASCII-compatible encoding. The **name** attribute represents the form's name within the forms collection. The value must not be the empty string, and the value must be unique amongst the form elements in the forms collection that it is in, if any.

The **autocomplete** attribute is an enumerated attribute. The attribute has two states. The **on** keyword maps to the **on** state, and the **off** keyword maps to the **off** state. The attribute may also be omitted. The missing value default and the invalid value default are the **on** state. The **off** state indicates that by default, form controls in the form will have their autofill field name set to "off"; the **on** state indicates that by default, form controls in the form will have their autofill field name set to "on".

The **action**, **enctype**, **method**, **novalidate**, and **target** attributes are attributes for form submission.

### For web developers (non-normative)

**form.elements**

Returns an `HTMLFormControlsCollection` of the form controls in the form (excluding image buttons for historical reasons).

**form.length**

Returns the number of form controls in the form (excluding image buttons for historical reasons).
The **autocomplete** IDL attribute must **reflect** the content attribute of the same name, **limited to only known values**.

The **name** IDL attribute must **reflect** the content attribute of the same name.

The **acceptCharset** IDL attribute must **reflect** the **accept-charset** content attribute.

The **elements** IDL attribute must return a **HTMLFormControlsCollection** rooted at the **form** element's **root**, whose filter matches **listed elements** whose **form owner** is the **form** element, with the exception of **input** elements whose **type** attribute is in the **Image Button** state, which must, for historical reasons, be excluded from this particular collection.

The **length** IDL attribute must return the number of nodes **represented** by the **elements** collection.

The **supported property indices** at any instant are the indices supported by the object returned by the **elements** attribute at that instant.

To determine the value of an indexed property for a **form** element, the user agent must return the value returned by the **item** method on the **elements** collection, when invoked with the given index as its argument.

Each **form** element has a mapping of names to elements called the **past names map**. It is used to persist names of controls even when they change names.

The **supported property names** consist of the names obtained from the following algorithm, in the order obtained from this algorithm:

1. Let **sourced names** be an initially empty ordered list of tuples consisting of a string, an element, a source, where the source is either **id**, **name**, or **past**, and, if the source is **past**, an age.

2. For each **listed element** **candidate** whose **form owner** is the **form** element, with the exception of any **input** elements whose **type** attribute is in the **Image Button** state:
   1. If **candidate** has an **id** attribute, add an entry to **sourced names** with that **id** attribute's value as the string, **candidate** as the element, and **id** as the source.
   2. If **candidate** has a **name** attribute, add an entry to **sourced names** with that **name** attribute's value as the string, **candidate** as the element, and **name** as the source.
For each `img` element candidate whose `form owner` is the `form` element:

1. If `candidate` has an `id` attribute, add an entry to `sourced names` with that `id` attribute's value as the string, `candidate` as the element, and `id` as the source.
2. If `candidate` has a `name` attribute, add an entry to `sourced names` with that `name` attribute's value as the string, `candidate` as the element, and `name` as the source.

For each entry past entry in the `past names map` add an entry to `sourced names` with the past entry's name as the string, past entry's element as the element, `past` as the source, and the length of time past entry has been in the `past names map` as the age.

Sort `sourced names` by `tree order` of the element entry of each tuple, sorting entries with the same element by putting entries whose source is `id` first, then entries whose source is `name`, and finally entries whose source is `past`, and sorting entries with the same element and source by their age, oldest first.

Remove any entries in `sourced names` that have the empty string as their name.

Remove any entries in `sourced names` that have the same name as an earlier entry in the map.

Return the list of names from `sourced names`, maintaining their relative order.

To determine the value of a named property `name` for a `form` element, the user agent must run the following steps:

1. Let `candidates` be a `live` `RadioNodeList` object containing all the `listed elements`, whose `form owner` is the `form` element, that have either an `id` attribute or a `name` attribute equal to `name`, with the exception of `input` elements whose `type` attribute is in the `Image Button` state, in `tree order`.
2. If `candidates` is empty, let `candidates` be a `live` `RadioNodeList` object containing all the `img` elements, whose `form owner` is the `form` element, that have either an `id` attribute or a `name` attribute equal to `name`, in `tree order`.
3. If `candidates` is empty, `name` is the name of one of the entries in the `form` element's `past names map`.

If an element listed in a `form` element's `past names map` changes `form owner`, then its entries must be removed from that map.

The `submit()` method, when invoked, must `submit` the `form` element from the `form` element itself, with the submitted from `submit()` method flag set.

The `reset()` method, when invoked, must run the following steps:

1. If the `form` element is marked as `locked for reset`, then return.
2. Mark the `form` element as `locked for reset`.
3. `Reset` the `form` element.
4. Unmark the `form` element as `locked for reset`.

If the `checkValidity()` method is invoked, the user agent must `statically validate the constraints` of the `form` element, and return true if the constraint validation return a `positive` result, and false if it returned a `negative` result.

If the `reportValidity()` method is invoked, the user agent must `interactively validate the constraints` of the `form` element, and return true if the constraint validation return a `positive` result, and false if it returned a `negative` result.

Example

This example shows two search forms:
4.10.4 The label element

**Categories**

- Flow content
- Phrasing content
- Interactive content
- Palpable content

**Contexts in which this element can be used**:

Where phrasing content is expected.

**Content model**

Phrasing content, but with no descendant labelable elements unless it is the element's labeled control, and no descendant label elements.

**Tag omission in text/html**

Neither tag is omissible.

**Content attributes**

- Global attributes
  - for — Associate the label with form control

**DOM interface**

```
IDL

[Exposed=Window, HTMLConstructor]
interface HTMLLabelElement : HTMLElement {
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute DOMString htmlFor;
  readonly attribute HTMLElement? control;
};
```

The label element represents a caption in a user interface. The caption can be associated with a specific form control, known as the label element's labeled control, either using the for attribute, or by putting the form control inside the label element itself.

Except where otherwise specified by the following rules, a label element has no labeled control.

The for attribute may be specified to indicate a form control with which the caption is to be associated. If the attribute is specified, the attribute's value must be the ID of a labelable element in the same tree as the label element. If the attribute is specified and there is an element in the tree whose ID is equal to the value of the for attribute, and the first such element in tree order is a labelable element, then that element is the label element's labeled control.

If the for attribute is not specified, but the label element has a labelable element descendant, then the first such descendant in tree order is the label element's labeled control.

The label element's exact default presentation and behavior, in particular what its activation behavior might be, if anything, should match the platform's label behavior. The activation behavior of a label element for events targeted at interactive content descendants of a label element, and any descendants of those interactive content descendants, must be to do nothing.
For example, on platforms where clicking a checkbox label checks the checkbox, clicking the label in the following snippet could trigger the user agent to fire a click event at the input element, as if the element itself had been triggered by the user:

```html
<label><input type=checkbox name=lost> Lost</label>
```

On other platforms, the behavior might be just to focus the control, or do nothing.

Example

The following example shows three form controls each with a label, two of which have small text showing the right format for users to use.

```html
<p><label>Full name: <input name=fn> <small>Format: First Last</small></label></p>
<p><label>Age: <input name=age type=number min=0></label></p>
<p><label>Post code: <input name=pc> <small>Format: AB12 3CD</small></label></p>
```

For web developers (non-normative)

**`label . control`**

Returns the form control that is associated with this element.

**`label . form`**

Returns the form owner of the form control that is associated with this element.

Returns null if there isn't one.

The `htmlFor` IDL attribute must reflect the `form` content attribute.

The `control` IDL attribute must return the `label` element's `labeled control`, if any, or null if there isn't one.

The `form` IDL attribute must run the following steps:

1. If the `label` element has no `labeled control`, then return null.
2. If the `label` element's `labeled control` is not a `form-associated element`, then return null.
3. Return the `label` element's `labeled control`'s `form owner` (which can still be null).

Note

The `form` IDL attribute on the `label` element is different from the `form` IDL attribute on listed, form-associated elements, and the `label` element does not have a `form content` attribute.

For web developers (non-normative)

**`control . labels`**

Returns a NodeList of all the `label` elements that the form control is associated with.

Labelable elements and all `input` elements have a `live` object associated with them that represents the list of `label` elements, in tree order, whose `labeled control` is the element in question. The `labels` IDL attribute of labelable elements and `input` elements, on getting, must return that `NodeList` object, and that same value must always be returned, unless this element is an `input` element whose `type` attribute is in the `Hidden` state, in which case it must instead return null.

Example
This (non-conforming) example shows what happens to the `NodeList` and what `labels` returns when an `input` element has its `type` attribute changed.

```html
<!doctype html>
<p><label><input></label></p>
<script>
const input = document.querySelector('input');
const labels = input.labels;
console.assert(labels.length === 1);

input.type = 'hidden';
console.assert(labels.length === 0); // the input is no longer the label's labeled control
console.assert(input.labels === null);

input.type = 'checkbox';
console.assert(labels.length === 1); // the input is once again the label's labeled control
console.assert(input.labels === labels); // same value as returned originally
</script>

4.10.5 The `input` element

Categories:
- Flow content
- Phrasing content

If the `type` attribute is not in the `Hidden` state: Interactive content
If the `type` attribute is not in the `Hidden` state: Listed, labelable, submittable, ressettable, and autocapitalize-inheriting form-associated element.
If the `type` attribute is in the `Hidden` state: Listed, submittable, ressettable, and autocapitalize-inheriting form-associated element.
If the `type` attribute is not in the `Hidden` state: Palpable content.

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
- Nothing

Tag omission in text/html:
- No end tag

Content attributes:
- Global attributes
  - `accept` — Hint for expected file type in file upload controls
  - `alt` — Replacement text for use when images are not available
  - `autocomplete` — Hint for form autofill feature
  - `autofocus` — Automatically focus the form control when the page is loaded
  - `checked` — Whether the control is checked
  - `dirname` — Name of form control to use for sending the element's directionality in form submission
  - `disabled` — Whether the form control is disabled
  - `form` — Associates the control with a form element
  - `formaction` — URL to use for form submission
  - `formenctype` — Variant to use for form submission
  - `formnovalidate` — Bypass form control validation for form submission
  - `formtarget` — Browsing context for form submission
  - `height` — Vertical dimension
  - `list` — List of autocomplete options
  - `max` — Maximum value
maxlength — Maximum length of value
min — Minimum value
minlength — Minimum length of value
multiple — Whether to allow multiple values
name — Name of form control to use for form submission and in the form.elements API
pattern — Pattern to be matched by the form control’s value
placeholder — User-visible label to be placed within the form control
readonly — Whether to allow the value to be edited by the user
required — Whether the control is required for form submission
size — Size of the control
src — Address of the resource
step — Granularity to be matched by the form control’s value
type — Type of form control
value — Value of the form control
width — Horizontal dimension

Also, the title attribute has special semantics on this element: Description of pattern (when used with pattern attribute).

DOM Interface:

```idl
[Exposed=Window,
HTMLConstructor]
interface HTMLInputElement : HTMLElement {
  [CEReactions] attribute DOMString accept;
  [CEReactions] attribute DOMString alt;
  [CEReactions] attribute DOMString autocomplete;
  [CEReactions] attribute boolean autofocus;
  [CEReactions] attribute boolean defaultChecked;
  attribute boolean checked;
  [CEReactions] attribute DOMString dirName;
  [CEReactions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  attribute FileList? files;
  [CEReactions] attribute USVString formAction;
  [CEReactions] attribute DOMString formEnctype;
  [CEReactions] attribute DOMString formMethod;
  [CEReactions] attribute boolean formNoValidate;
  [CEReactions] attribute DOMString formTarget;
  [CEReactions] attribute unsigned long height;
  attribute boolean indeterminate;
  readonly attribute HTMLInputElement? list;
  [CEReactions] attribute DOMString max;
  [CEReactions] attribute long maxLength;
  [CEReactions] attribute DOMString min;
  [CEReactions] attribute long minLength;
  [CEReactions] attribute boolean multiple;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString pattern;
  [CEReactions] attribute DOMString placeholder;
  [CEReactions] attribute boolean readOnly;
  [CEReactions] attribute boolean required;
  [CEReactions] attribute unsigned long size;
  [CEReactions] attribute USVString src;
  [CEReactions] attribute DOMString step;
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute DOMString defaultValue;
  [CEReactions] attribute [TreatNullAs=EmptyString] DOMString value;
  attribute object? valueAsDate;
  attribute unrestricted double valueAsNumber;
  [CEReactions] attribute unsigned long width;
```
The `input` element represents a typed data field, usually with a form control to allow the user to edit the data.

The `type` attribute controls the data type (and associated control) of the element. It is an enumerated attribute. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
<th>Data type</th>
<th>Control type</th>
</tr>
</thead>
<tbody>
<tr>
<td>hidden</td>
<td>Hidden</td>
<td>An arbitrary string</td>
<td>n/a</td>

</table>
The **missing value default** and the **invalid value default** are the Text state.

Which of the accept, alt, **autocomplete**, checked, dirname, formation, formencodetype, formmethod, formvalidate, formtarget, height, list, max, maxlength, min, minlength, multiple, pattern, placeholder, readonly, required, size, src, step, and width content attributes, the checked, files, valueAsDate, valueAsNumber, and list IDL attributes, the select method, the selectionStart, selectionEnd, and selectionDirection, IDL attributes, the setRangeText and setSelectionRange methods, the **stepUp** and **stepDown** methods, and the input and change events apply to an input element depends on the state of its type attribute. The subsections that define each type also clearly define in normative "bookkeeping" sections which of these feature apply, and which do not apply, to each type. The behavior of these features depends on whether they apply or not, as defined in their various sections (q.v. for content attributes, for APIs, and for events).

The following table is non-normative and summarizes which of those content attributes, IDL attributes, methods, and events apply to each state:

<table>
<thead>
<tr>
<th>Hidden</th>
<th>Text, Search</th>
<th>URL, Telephone</th>
<th>E-mail</th>

† If the control has no selectable text, the `select()` method results in a no-op, with no `InvalidStateError` `DOMException`.

Some states of the `type` attribute define a value sanitization algorithm.

Each `input` element has a `value` which is exposed by the `value` IDL attribute. Some states define an algorithm to convert a string to a number, an algorithm to convert a number to a string, an algorithm to convert a string to a `Date` object, and an algorithm to convert a `Date` object to a string, which are used by `max`, `min`, `step`, `valueAsDate`, `valueAsNumber`, and `stepUp()`.

An `input` element's `dirty value flag` must be set to true whenever the user interacts with the control in a way that changes the `value`. (It is also set to true when the value is programmatically changed, as described in the definition of the `value` IDL attribute.)

The `value` content attribute gives the default `value`, of the `input` element. When the `value` content attribute is added, set, or removed, if the control's `dirty value flag` is false, the user agent must set the `value` of the element to the value of the `value` content attribute, if there is one, or the empty string otherwise, and then run the current value sanitization algorithm, if one is defined.

Each `input` element has a `checkedness`, which is exposed by the `checked` IDL attribute.

Each `input` element has a boolean `dirty checkedness flag`. When it is true, the element is said to have a dirty checkedness. The `dirty checkedness flag` must be initially set to false when the element is created, and must be set to true whenever the user interacts with the control in a way that changes the `checkedness`.

The `checked` content attribute is a boolean attribute that gives the default `checkedness` of the `input` element. When the `checked` content attribute is added, set, or removed, if the control's `dirty checkedness flag` is false, the user agent must set the `checkedness` of the element to true; when the `checked` content attribute is removed, if the control does not have `dirty checkedness`, the user agent must set the `checkedness`, of the element to false.

The `reset algorithm` for `input` elements is to set the `dirty value flag` and `dirty checkedness flag` back to false, set the `value` of the element to the value of the `value` content attribute, if there is one, or the empty string otherwise, set the `checkedness` of the element to true if the element has a `checkedness` content attribute and false if it does not, empty the list of `selected files`, and then invoke the value sanitization algorithm, if the `type` attribute's current state defines one.

Each `input` element can be `mutable`. Except where otherwise specified, an `input` element is always `mutable`. Similarly, except where otherwise specified, the user agent should not allow the user to modify the element's `value` or `checkedness`.

When an `input` element is `disabled`, it is not `mutable`.

The `readonly` attribute can also in some cases (e.g. for the `Date` state, but not the `Checkbox` state) stop an `input` element from being `mutable`.

The cloning steps for `input` elements must propagate the `value`, `dirty value flag`, `checkedness`, and `dirty checkedness flag` from the node being cloned to the copy.

The activation behavior for `input` elements are these steps:

1. If this element is not `mutable`, then return.
2. Run this element's input activation behavior, if any, and do nothing otherwise.

The legacy-pre-activation behavior for `input` elements are these steps:
1. If this element is not `mutable`\(^{548}\), then return.

2. If this element's `type`\(^{478}\) attribute is in the Checkbox state\(^{496}\), then set this element's `checkedness`\(^{547}\) to its opposite value (i.e. true if it is false, false if it is true) and set this element's `indeterminate`\(^{461}\) IDL attribute to false.

3. If this element's `type`\(^{478}\) attribute is in the Radio Button state\(^{497}\), then get a reference to the element in this element's radio button group\(^{497}\) that has its `checkedness`\(^{544}\) set to true, if any, and then set this element's `checkedness`\(^{544}\) to true.

The legacy-canceled-activation behavior for `input`\(^{476}\) elements are these steps:

1. If the element is not `mutable`\(^{548}\), then return.

2. If the element's `type`\(^{478}\) attribute is in the Checkbox state\(^{496}\), then set the element's `checkedness`\(^{547}\) and the element's `indeterminate`\(^{461}\) IDL attribute back to the values they had before the legacy-pre-activation behavior was run.

3. If this element's `type`\(^{478}\) attribute is in the Radio Button state\(^{497}\), then if the element to which a reference was obtained in the legacy-pre-activation behavior, if any, is still in what is now this element's radio button group\(^{497}\), if it still has one, and if so, then set the element's `checkedness`\(^{547}\) to true; or else, if there was no such element, or that element is no longer in this element's radio button group\(^{497}\), or if this element no longer has a radio button group\(^{497}\), setting this element's `checkedness`\(^{544}\) to false.

When an `input`\(^{476}\) element is first created, the element's rendering and behavior must be set to the rendering and behavior defined for the `type`\(^{478}\) attribute's state, and the value sanitization algorithm\(^{480}\), if one is defined for the `type`\(^{478}\) attribute's state, must be invoked.

When an `input`\(^{476}\) element's `type`\(^{478}\) attribute changes state, the user agent must run the following steps:

1. If the previous state of the element's `type`\(^{478}\) attribute put the `value`\(^{514}\) IDL attribute in the `value`\(^{514}\) mode, and the element's `value`\(^{547}\) is not the empty string, and the new state of the element's `type`\(^{478}\) attribute puts the `value`\(^{514}\) IDL attribute in either the `default`\(^{514}\) mode or the `default/on`\(^{514}\) mode, then set the element's `value`\(^{548}\) content attribute to the element's `value`\(^{547}\).

2. Otherwise, if the previous state of the element's `type`\(^{478}\) attribute put the `value`\(^{514}\) IDL attribute in any mode other than the `value`\(^{514}\) mode, and the new state of the element's `type`\(^{478}\) attribute puts the `value`\(^{514}\) IDL attribute in the `value`\(^{514}\) mode, then set the `value`\(^{547}\) of the element to the value of the `value`\(^{548}\) content attribute, if there is one, or the empty string otherwise, and then set the control's `dirty value flag`\(^{547}\) to false.

3. Otherwise, if the previous state of the element's `type`\(^{478}\) attribute put the `value`\(^{514}\) IDL attribute in any mode other than the `filename`\(^{514}\) mode, and the new state of the element's `type`\(^{478}\) attribute puts the `value`\(^{514}\) IDL attribute in the `filename`\(^{521}\) mode, then set the `value`\(^{547}\) of the element to the empty string.

4. Update the element's rendering and behavior to the new state's.

5. **Signal a type change** for the element. (The Radio Button\(^{497}\) state uses this, in particular.)

6. Invoke the value sanitization algorithm\(^{480}\), if one is defined for the `type`\(^{478}\) attribute's new state.

7. Let previouslySelectable be true if `setRangeText()`\(^{571}\) previously applied\(^{479}\) to the element, and false otherwise.

8. Let nowSelectable be true if `setRangeText()`\(^{571}\) now applies\(^{479}\) to the element, and false otherwise.

9. If previouslySelectable is false and nowSelectable is true, set the element's `text entry cursor position`\(^{568}\) to the beginning of the text control, and set its selection direction\(^{569}\) to "none".

The `name`\(^{549}\) attribute represents the element's name. The `dirName`\(^{555}\) attribute controls how the element's `directionality`\(^{513}\) is submitted. The `disabled`\(^{551}\) attribute is used to make the control non-interactive and to prevent its value from being submitted. The `form`\(^{554}\) attribute is used to explicitly associate the `input`\(^{476}\) element with its `form owner`\(^{548}\). The `autofocus`\(^{554}\) attribute controls focus. The `autocomplete`\(^{555}\) attribute controls how the user agent provides autofill behavior.

The `indeterminate` IDL attribute must initially be set to false. On setting, it must return the last value it was set to. On setting, it must be set to the new value. It has no effect except for changing the appearance of `checkbox`\(^{496}\) controls.

The `accept`, `alt`, `max`, `min`, `multiple`, `pattern`, `placeholder`, `required`, `size`, `src`, and `step` IDL attributes must `reflect`\(^{500}\) the respective content attributes of the same name. The `dirName` IDL attribute must `reflect`\(^{500}\) the `dirName`\(^{555}\) content attribute. The
readOnly IDL attribute must reflect the readonly content attribute. The defaultChecked IDL attribute must reflect the checked content attribute. The defaultValue IDL attribute must reflect the value content attribute.

The type IDL attribute must reflect the respective content attribute of the same name, limited to only known values. The maxLength IDL attribute must reflect the max-length content attribute, limited to only non-negative numbers. The minLength IDL attribute must reflect the min-length content attribute, limited to only non-negative numbers.

The IDL attributes width and height must return the rendered width and height of the image, in CSS pixels, if an image is being rendered, and is being rendered to a visual medium; or else the intrinsic width and height of the image, in CSS pixels, if an image is available, but not being rendered to a visual medium; or else 0, if no image is available. When the input element's type attribute is not in the Image Button state, then no image is available. [CSS]

On setting, they must act as if they reflected, the respective content attributes of the same name.

The willValidate, validity, and validationMessage IDL attributes, and the checkValidity(), reportValidity(), and setCustomValidity() methods, are part of the constraint validation API. The labels IDL attribute provides a list of the element's label's. The select(), selectionStart, selectionEnd, selectionDirection, setRangeText(), and setSelectionRange() methods and IDL attributes expose the element's text selection. The autofocus, disabled, form, and name IDL attributes are part of the element's forms API.

### 4.10.5.1 States of the type attribute

#### 4.10.5.1.1 Hidden state (type=hidden)

When an input element's type attribute is in the Hidden state, the rules in this section apply.

The input element represents a value that is not intended to be examined or manipulated by the user.

Constraint validation: If an input element's type attribute is in the Hidden state, it is barred from constraint validation.

If the name attribute is present and has a value that is a case-sensitive match for the string _charset_, then the element’s value attribute must be omitted.

**Bookkeeping details**

- The autocomplete content attribute applies to this element.
- The value IDL attribute applies to this element and is in mode default.
- The following content attributes must not be specified and do not apply to the element: accept, alt, checked, dirname, formaction, formmethod, formnovalidate, formtarget, height, list, max, min, max-length, min-length, bin-length, multiple, pattern, placeholder, required, size, src, step, and width.
- The following IDL attributes and methods do not apply to the element: checked, files, list, selectionStart, selectionEnd, selectionDirection, valueAsDate, and valueAsNumber. IDL attributes; select, setRangeText(), setSelectionRange(), stepDown, and stepUp methods.
- The input and change events do not apply.

### 4.10.5.2 Text (type=text) and Search state (type=search)

When an input element's type attribute is in the Text state or the Search state, the rules in this section apply.

The input element represents a one line plain text edit control for the element's value.

#### Note

The difference between the Text state and the Search state is primarily stylistic: on platforms where search controls are distinguished from regular text controls, the Search state might result in an appearance consistent with the platform's search controls rather than appearing like a regular text control.

If the element is mutable, its value should be editable by the user. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the element’s value.

If the element is mutable, the user agent should allow the user to change the writing direction of the element, setting it either to a left-to-right writing direction or a right-to-left writing direction. If the user does so, the user agent must then run the following steps:
1. Set the element’s `dir` attribute to "ltr" if the user selected a left-to-right writing direction, and "rtl" if the user selected a right-to-left writing direction.

2. Queue a task to fire an event named `input` at the `input` element, with the `bubbles` attribute initialized to true.

The `value` attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

**The value sanitization algorithm** is as follows: Strip newlines from the `value`.

**Bookkeeping details**

- The following common `input` element content attributes, IDL attributes, and methods apply to the element: `autocomplete`, `dirname`, `list`, `maxlength`, `minlength`, `pattern`, `placeholder`, `readonly`, `required`, and `size`. Content attributes; `list`, `selectionStart`, `selectionDirection`, and `value` IDL attributes; `select()`, `setRangeText()`, and `setSelectionRange()` methods.

- The `value` IDL attribute is in mode `value`.

- The `input` and `change` events apply.

- The following content attributes must not be specified and `do not apply` to the element: `accept`, `alt`, `checked`, `form`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `max`, `min`, `multiple`, `src`, `step`, and `width`.

- The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `valueAsDate`, and `valueAsNumber` IDL attributes; `stepDown()` and `stepUp()` methods.

4.10.5.1.3 **Telephone state (type=tel)**

When an `input` element's `type` attribute is in the `Telephone` state, the rules in this section apply.

The `input` element represents a control for editing a telephone number given in the element's `value`.

If the element is `mutable`, its `value` should be editable by the user. User agents may change the spacing and, with care, the punctuation of `value` that the user enters. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the element's `value`.

The `value` attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

**The value sanitization algorithm** is as follows: Strip newlines from the `value`.

**Bookkeeping details**

- The following common `input` element content attributes, IDL attributes, and methods apply to the element: `autocomplete`, `dirname`, `list`, `maxlength`, `minlength`, `pattern`, `placeholder`, `readonly`, `required`, and `size`. Content attributes; `list`, `selectionStart`, `selectionDirection`, and `value` IDL attributes; `select()`, `setRangeText()`, and `setSelectionRange()` methods.

- The `value` IDL attribute is in mode `value`.

- The `input` and `change` events apply.

- The following content attributes must not be specified and `do not apply` to the element: `accept`, `alt`, `checked`, `form`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `max`, `min`, `multiple`, `src`, `step`, and `width`.

- The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `valueAsDate`, and `valueAsNumber` IDL attributes; `stepDown()` and `stepUp()` methods.

4.10.5.1.4 **URL state (type=url)**

When an `input` element's `type` attribute is in the `URL` state, the rules in this section apply.

The `input` element represents a control for editing a single **absolute URL** given in the element's `value`.

If the element is `mutable`, the user agent should allow the user to change the URL represented by its `value`. User agents may allow the user to set the `value` to a string that is not a valid absolute URL, but may also or instead automatically escape characters.
entered by the user so that the value is always a valid absolute URL (even if that isn’t the actual value seen and edited by the user in the interface). User agents should allow the user to set the value to the empty string. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the value.

The value attribute, if specified and not empty, must have a value that is a valid URL potentially surrounded by spaces that is also an absolute URL.

The value sanitization algorithm is as follows: Strip newlines from the value, then strip leading and trailing ASCII whitespace from the value.

Constraint validation: While the value of the element is neither the empty string nor a valid absolute URL, the element is suffering from a type mismatch.

Bookkeeping details

The following common input element content attributes, IDL attributes, and methods apply to the element: autocomplete, list, maxlength, minlength, pattern, placeholder, readonly, required, and size content attributes; list, selectionStart, selectionEnd, selectionDirection, and value IDL attributes; select, setRangeText, and setSelectionRange methods.

The value IDL attribute is in mode value.

The input and change events apply.

The following content attributes must be specified and do not apply to the element: accept, alt, checked, dirname, formaction, formmethod, formnovalidate, formtarget, height, max, min, multiple, src, step, and width.

The following IDL attributes and methods do not apply to the element: checked, files, valueAsDate, and valueAsNumber IDL attributes; stepDown and stepUp methods.

Example

If a document contained the following markup:

```html
<input type="url" name="location" list="urls">
<datalist id="urls">
  <option label="MIME: Format of Internet Message Bodies" value="https://tools.ietf.org/html/rfc2045">
  <option label="HTML" value="https://html.spec.whatwg.org/">
  <option label="DOM" value="https://dom.spec.whatwg.org/">
  <option label="Fullscreen" value="https://fullscreen.spec.whatwg.org/">
  <option label="Media Session" value="https://media_session.spec.whatwg.org/">
</datalist>
```

...and the user had typed "spec.w", and the user agent had also found that the user had visited https://url.spec.whatwg.org/#url-parsing and https://streams.spec.whatwg.org/ in the recent past, then the rendering might look like this:

<table>
<thead>
<tr>
<th>spec.w</th>
<th>HTML</th>
<th>Media Session</th>
<th>Fullscreen</th>
<th>DOM</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="https://fullscreen.spec.whatwg.org/">https://fullscreen.spec.whatwg.org/</a></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The first four URLs in this sample consist of the four URLs in the author-specified list that match the text the user has entered, sorted in some UA-defined manner (maybe by how frequently the user refers to those URLs). Note how the UA is using the knowledge that the values are URLs to allow the user to omit the scheme part and perform intelligent matching on the domain name.

The last two URLs (and probably many more, given the scrollbar’s indications of more values being available) are the matches from the user agent’s session history data. This data is not made available to the page DOM. In this particular case, the UA has no titles for those values.
When an `input` element's `type` attribute is in the `E-mail` state, the rules in this section apply.

How the `E-mail` state operates depends on whether the `multiple` attribute is specified or not.

**When the `multiple` attribute is not specified on the element**

The `input` element represents a control for editing an e-mail address given in the element's `value`.

If the element is `mutable`, the user agent should allow the user to change the e-mail address represented by its `value`. User agents may allow the user to set the `value` to a string that is not a valid e-mail address. The user agent should act in a manner consistent with expecting the user to provide a single e-mail address. User agents should allow the user to set the `value` to the empty string. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the `value`. User agents may transform the `value` for display and editing; in particular, user agents should convert punycode in the domain labels of the `value` to IDN in the display and vice versa.

**Constraint validation**: While the user interface is representing input that the user agent cannot convert to punycode, the control is suffering from bad input.

The `value` attribute, if specified and not empty, must have a value that is a single valid e-mail address.

The `value sanitization algorithm` is as follows: Strip newlines from the `value`, then strip leading and trailing ASCII whitespace from the `value`.

**Constraint validation**: While the `value` of the element is neither the empty string nor a single valid e-mail address, the element is suffering from a type mismatch.

**When the `multiple` attribute is specified on the element**

The `input` element represents a control for adding, removing, and editing the e-mail addresses given in the element's `values`.

If the element is `mutable`, the user agent should allow the user to add, remove, and edit the e-mail addresses represented by its `values`. User agents may allow the user to set any individual value in the list of `values` to a string that is not a valid e-mail address, but must not allow users to set any individual value to a string containing U+002C COMMA (,), U+000A LINE FEED (LF), or U+000D CARRIAGE RETURN (CR) characters in the `values`. User agents may transform the `values` for display and editing; in particular, user agents should convert punycode in the domain labels of the `value` to IDN in the display and vice versa.

**Constraint validation**: While the user interface describes a situation where an individual value contains a U+002C COMMA (,), or is representing input that the user agent cannot convert to punycode, the control is suffering from bad input.

Whenever the user changes the element's `values`, the user agent must run the following steps:

1. Let `latest values` be a copy of the element's `values`.
2. Strip leading and trailing ASCII whitespace from each value in `latest values`.
3. Let the element's `value` be the result of concatenating all the values in `latest values`, separating each value from the next by a single U+002C COMMA character (,), maintaining the list's order.

The `value` attribute, if specified, must have a value that is a valid e-mail address list.

The `value sanitization algorithm` is as follows:

1. Split on commas the element's `value`, strip leading and trailing ASCII whitespace from each resulting token, if any, and let the element's `values` be the (possibly empty) resulting list of (possibly empty) tokens, maintaining the original order.
2. Let the element's `value` be the result of concatenating the element's `values`, separating each value from the next by a single U+002C COMMA character (,), maintaining the list's order.

**Constraint validation**: While the `value` of the element is not a valid e-mail address list, the element is suffering from a type mismatch.

When the `multiple` attribute is set or removed, the user agent must run the `value sanitization algorithm`.
A valid e-mail address is a string that matches the email production of the following ABNF, the character set for which is Unicode.

### Bookkeeping details
- The following common `input` element content attributes, IDL attributes, and methods apply\(511\) to the element: `autocomplete\(555\)`, `list\(555\)`, `maxlength\(554\)`, `minlength\(554\)`, `multiple\(556\)`, `pattern\(556\)`, `placeholder\(553\)`, `readonly\(555\)`, `required\(556\)`, and `size\(556\)` content attributes; `list\(556\)` and `value\(555\)` IDL attributes; `select()\(508\)` method.
- The `value\(551\)` IDL attribute is in mode `value\(554\)`.
- The `input\(517\)` and `change\(512\)` events apply\(479\).
- The following common `input` content attributes must not be specified and do not apply\(479\) to the element: `accept\(486\)`, `alt\(486\)`, `checked\(486\)`, `dirname\(550\)`, `formaction\(511\)`, `formenctype\(486\)`, `formmethod\(511\)`, `formnovalidate\(514\)`, `formtarget\(514\)`, `height\(519\)`, `max\(486\)`, `min\(486\)`, `src\(486\)`, `step\(515\)`, and `width\(514\)`.
- The following common `input` attributes and methods do not apply\(479\) to the element: `checked\(486\)`, `files\(515\)` selectionStart\(515\) selectionEnd\(515\) selectionDirection\(515\) valueAsDate\(515\) and valueAsNumber\(515\) IDL attributes; `setRangeText()\(515\)` `setSelectionRange()\(515\)` `stepDown()\(515\)` and `stepUp()\(515\)` methods.

### 4.10.5.1.6 Password state (type=password)\(546\)

When an `input\(546\)` element's `type\(546\)` attribute is in the Password\(546\)` state, the rules in this section apply.

The `input\(546\)` element represents\(520\) a one line plain text edit control for the element's `value\(547\)` The user agent should obscure the value so that people other than the user cannot see it.

If the element is mutable\(546\), its `value\(547\)` should be editable by the user. User agents must not allow users to insert U+00A LINE FEED (LF) or U+00D CARRIAGE RETURN (CR) characters into the `value\(547\)`.

The `value\(546\)` attribute, if specified, must have a value that contains no U+00A LINE FEED (LF) or U+00D CARRIAGE RETURN (CR) characters.

The value sanitization algorithm\(488\) is as follows: Strip newlines from the `value\(547\)`.

### Bookkeeping details
- The following common `input\(546\)` element content attributes, IDL attributes, and methods apply\(546\) to the element: `autocomplete\(555\)`, `maxlength\(554\)`, `minlength\(554\)` `pattern\(556\)` `placeholder\(553\)` `readonly\(555\)` `required\(556\)` and `size\(556\)` content attributes; `selectionStart\(515\)` `selectionEnd\(515\)` and `value\(551\)` IDL attributes; `select()\(508\)` `setRangeText()\(515\)` `setSelectionRange()\(515\)` `stepDown()\(515\)` and `stepUp()\(515\)` methods.
- The `value\(551\)` IDL attribute is in mode `value\(554\)`.
- The `input\(517\)` and `change\(512\)` events apply\(479\).
- The following common `input` content attributes must not be specified and do not apply\(479\) to the element: `accept\(486\)`, `alt\(486\)` `checked\(486\)` `dirname\(550\)` `formaction\(511\)` `formenctype\(486\)` `formmethod\(511\)` `formnovalidate\(514\)` `formtarget\(514\)` `height\(519\)` `max\(486\)` `min\(486\)` `multiple\(556\)` `src\(486\)` `step\(515\)` and `width\(514\)`.
- The following common `input` attributes and methods do not apply\(479\) to the element: `checked\(486\)` `files\(515\)` `selectionStart\(515\)` `selectionEnd\(515\)` `selectionDirection\(515\)` `valueAsDate\(515\)` and `valueAsNumber\(515\)` IDL attributes; `setRangeText()\(515\)` `setSelectionRange()\(515\)` `stepDown()\(515\)` and `stepUp()\(515\)` methods.
4.10.5.1.7 Date state (type=date) p487

When an input element's type attribute is in the Date state, the rules in this section apply.

The input element represents a control for setting the element's value to a string representing a specific date.

If the element is mutable, the user agent should allow the user to change the date represented by its value, as obtained by parsing a date from it. User agents must not allow the user to set the value to a non-empty string that is not a valid date string. If the user agent provides a user interface for selecting a date, then the value must be set to a valid date string representing the user's selection. User agents should allow the user to set the value, to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a valid date string, the control is suffering from bad input.

**Note**

See the introduction section for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes regarding localization of form controls.

The value attribute, if specified and not empty, must have a value that is a valid date string.

**The value sanitization algorithm** is as follows: If the value of the element is not a valid date string, then set it to the empty string instead.

The min attribute, if specified, must have a value that is a valid date string. The max attribute, if specified, must have a value that is a valid date string.

The step attribute is expressed in days. The step scale factor is 86,400,000 (which converts the days to milliseconds, as used in the other algorithms). The default step is 1 day.

When the element is suffering from a step mismatch, the user agent may round the element's value to the nearest date for which the element would not suffer from a step mismatch.

**The algorithm to convert a string to a number**, given a string input, is as follows: If parsing a date from input results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z") to midnight UTC on the morning of the parsed date, ignoring leap seconds.

The algorithm to convert a number to a string, given a number input, is as follows: Return a valid date string that represents the date that, in UTC, is current input milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z").

The algorithm to convert a string to a Date object, given a string input, is as follows: If parsing a date from input results in an error, then return an error; otherwise, return a new Date object representing midnight UTC on the morning of the parsed date.

The algorithm to convert a Date object to a string, given a Date object input, is as follows: Return a valid date string that represents the date current at the time represented by input in the UTC time zone.

**Note**

The Date state (and other date- and time-related states described in subsequent sections) is not intended for the entry of values for which a precise date and time relative to the contemporary calendar cannot be established. For example, it would be inappropriate for the entry of times like "one millisecond after the big bang", "the early part of the Jurassic period", or "a winter around 250 BCE".

For the input of dates before the introduction of the Gregorian calendar, authors are encouraged to not use the Date state (and the other date- and time-related states described in subsequent sections), as user agents are not required to support converting dates and times from earlier periods to the Gregorian calendar, and asking users to do so manually puts an undue burden on users. (This is complicated by the manner in which the Gregorian calendar was phased in, which occurred at different times in different countries, ranging from 1752 in France to 1923 in Saudi Arabia.) Instead, authors are encouraged to provide fine-grained input controls using the select element and input elements with the Number state.

**Bookkeeping details**
4.10.5.1.8 Month state (type=month) 

When an `input` element's `type` attribute is in the `Month` state, the rules in this section apply.

The `input` element represents a control for setting the element's `value` to a string representing a specific `month`.

If the element is `mutable`, the user agent should allow the user to change the `month` represented by its `value`, as obtained by parsing a month from it. User agents must not allow the user to set the `value` to a non-empty string that is not a `valid month string`. If the user agent provides a user interface for selecting a `month`, then the `value` must be set to a `valid month string` representing the user's selection. User agents should allow the user to set the `value` to the empty string.

Constraint validation: When the user interface describes input that the user agent cannot convert to a `valid month string`, the control is suffering from bad input.

**Note**: See the introduction section for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes regarding localization of form controls.

The `value` attribute, if specified and not empty, must have a value that is a `valid month string`.

The **value sanitization algorithm** is as follows: If the `value` of the element is not a `valid month string`, then set it to the empty string instead.

The `min` attribute, if specified, must have a value that is a `valid month string`. The `max` attribute, if specified, must have a value that is a `valid month string`.

The `step` attribute is expressed in months. The `step scale factor` is 1 (there is no conversion needed as the algorithms use months). The default `step` is 1 month.

When the element is suffering from a step mismatch, the user agent may round the element's `value` to the nearest `month` for which the element would not suffer from a step mismatch.

The **algorithm to convert a string to a number**, given a string `input`, is as follows: If parsing a month from input results in an error, then return an error; otherwise, return the number of months between January 1970 and the parsed `month` for which the element would not suffer from a step mismatch.

The **algorithm to convert a number to a string**, given a number `input`, is as follows: Return a `valid month string` that represents the `month` that has input months between it and January 1970.

The **algorithm to convert a string to a Date object**, given a string `input`, is as follows: If parsing a month from input results in an error, then return an error; otherwise, return a new `Date object` representing midnight UTC on the morning of the first day of the parsed `month`.

The **algorithm to convert a Date object to a string**, given a `Date object input`, is as follows: Return a `valid month string` that represents the `month` current at the time represented by input in the UTC time zone.

**Bookkeeping details**

- The following common `input` element content attributes, IDL attributes, and methods apply to the element: `autocomplete`, `list`, `max`, `min`, `readonly`, `required`, and `step` content attributes; `list`, `value`, `valueAsDate`, and `valueAsNumber` IDL attributes; `select` methods, `stepDown()`, and `stepUp()` methods.
- The `value` IDL attribute is in mode `value`.
- The `input` and `change` events apply.
- The following content attributes must not be specified and do not apply to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `size`, `src`, and `width`.
- The following IDL attributes and methods do not apply to the element: `checked`, `selectionStart`, `selectionEnd`, and `selectionDirection` IDL attributes; `setRangeText()`, and `setSelectionRange()` methods.
The following IDL attributes and methods do not apply to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, and `selectionDirection` IDL attributes; `setRangeText()` and `setSelectionRange()` methods.

### 4.10.5.1.9 Week state (type=week)

When an `input` element's `type=week` attribute is in the `Week` state, the rules in this section apply.

The `input` element represents a control for setting the element's `value` to a string representing a specific `week`.

If the element is `mutable`, the user agent should allow the user to change the `week` represented by its `value`, as obtained by parsing a week from it. User agents must not allow the user to set the `value` to a non-empty string that is not a `valid week string`. If the user agent provides a user interface for selecting a `week`, then the `value` must be set to a `valid week string` representing the user’s selection. User agents should allow the user to set the `value` to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a `valid week string`, the control is suffering from bad input.

The `value` attribute, if specified and not empty, must have a value that is a `valid week string`.

**The value sanitization algorithm** is as follows: If the `value` of the element is not a `valid week string`, then set it to the empty string instead.

The `min` attribute, if specified, must have a value that is a `valid week string`. The `max` attribute, if specified, must have a value that is a `valid week string`.

The `step` attribute is expressed in weeks. The `step scale factor` is 604,800,000 (which converts the weeks to milliseconds, as used in the other algorithms). The `default step` is 1 week. The `default step base` is −259,200,000 (the start of week 1970-W01).

When the element is suffering from a step mismatch, the user agent may round the element’s `value` to the nearest `week` for which the element would not suffer from a step mismatch.

The **algorithm to convert a string to a number**, given a string `input`, is as follows: If parsing a `week` from `input` results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z") to midnight UTC on the Monday of the parsed `week`, ignoring leap seconds.

The **algorithm to convert a number to a string**, given a number `input`, is as follows: Return a `valid week string` that represents the `week` that, in UTC, is current input milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z").

The **algorithm to convert a string to a Date object**, given a string `input`, is as follows: If parsing a `week` from `input` results in an error, then return an error; otherwise, return a new `Date object` representing midnight UTC on the morning of the Monday of the parsed `week`.

The **algorithm to convert a Date object to a string**, given a `Date object input`, is as follows: Return a `valid week string` that represents the `week` current at the time represented by `input` in the UTC time zone.

**Bookkeeping details**

- The following common `input` element content attributes, IDL attributes, and methods apply to the element: `autocomplete`, `list`, `max`, `min`, `readonly`, `required`, and `step` content attributes; `list`, `value`, `valueAsDate`, and `valueAsNumber` IDL attributes; `select()`, `stepDown()`, and `stepUp()` methods.
- The `value` IDL attribute is in mode `value`
- The `input` and `change` events apply.
- The following content attributes must not be specified and do not apply to the element: `accept`, `autocomplete`, `checked`, `dir`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `maxlength`, `minlength`, `multiple`, `pattern`, `placeholder`, `size`, `src`, and `width`.
- The following IDL attributes and methods do not apply to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, and...
4.10.5.1.10 Time state (type=time)

When an input element's type attribute is in the Time state, the rules in this section apply.

The input element represents a control for setting the element's value to a string representing a specific time.

If the element is mutable, the user agent should allow the user to change the time represented by its value, as obtained by parsing a time from it. User agents must not allow the user to set the value to a non-empty string that is not a valid time string. If the user agent provides a user interface for selecting a time, then the value must be set to a valid time string representing the user's selection. User agents should allow the user to set the value to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid time string, the control is suffering from bad input.

Note: See the introduction section for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes regarding localization of form controls.

The value attribute, if specified and not empty, must have a value that is a valid time string.

The value sanitization algorithm is as follows: If the value of the element is not a valid time string, then set it to the empty string instead.

The form control has a periodic domain.

The min attribute, if specified, must have a value that is a valid time string. The max attribute, if specified, must have a value that is a valid time string.

The step attribute is expressed in seconds. The step scale factor is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The default step is 60 seconds.

When the element is suffering from a step mismatch, the user agent may round the element's value to the nearest time for which the element would not suffer from a step mismatch.

The algorithm to convert a string to a number, given a string input, is as follows: If parsing a time from input results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight to the parsed time on a day with no time changes.

The algorithm to convert a number to a string, given a number input, is as follows: Return a valid time string that represents the time, that is input milliseconds after midnight on a day with no time changes.

The algorithm to convert a string to a Date object, given a string input, is as follows: If parsing a time from input results in an error, then return an error; otherwise, return a new Date representing the parsed time in UTC on 1970-01-01.

The algorithm to convert a Date object to a string, given a Date object input, is as follows: Return a valid time string that represents the UTC component that is represented by input.

Bookkeeping details
- The following common input element content attributes, IDL attributes, and methods apply to the element: autocapitalize, list, max, min, readonly, required, and step content attributes; list, value, valueAsDate, and valueAsNumber IDL attributes; select, stepDown, stepUp, and stepUp methods.
- The IDL attribute is in mode.
- The input and change events apply.
- The following content attributes must not be specified and do not apply to the element: accept, alt, dir, form, formenctype, formmethod, formnovalidate, formtarget, height, maxlength, minlength, multiple, pattern, placeholder, size, src, and width.
- The following IDL attributes and methods do not apply to the element: checked, files, selectionStart, selectionEnd, and selectionDirection IDL attributes; setRangeText, and setSelectionRange methods.
When an input element's type attribute is in the Local Date and Time state, the rules in this section apply.

The input element represents a control for setting the element's value to a string representing a local date and time, with no time-zone offset information.

If the element is mutable, the user agent should allow the user to change the date and time represented by its value, as obtained by parsing a date and time from it. User agents must not allow the user to set the value to a non-empty string that is not a valid normalized local date and time string. If the user agent provides a user interface for selecting a local date and time, then the value must be set to a valid normalized local date and time string representing the user's selection. User agents should allow the user to set the value to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid normalized local date and time string, the control is suffering from bad input.

The value attribute, if specified and not empty, must have a value that is a valid local date and time string.

The value sanitization algorithm is as follows: If the value of the element is a valid local date and time string, then set it to a valid normalized local date and time string representing the same date and time; otherwise, set it to the empty string instead.

The min attribute, if specified, must have a value that is a valid local date and time string. The max attribute, if specified, must have a value that is a valid local date and time string.

The step attribute is expressed in seconds. The step scale factor is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The default step is 60 seconds.

When the element is suffering from a step mismatch, the user agent may round the element's value to the nearest local date and time for which the element would not suffer from a step mismatch.

The algorithm to convert a string to a number, given a string input, is as follows: If parsing a date and time from input results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0") to the parsed local date and time, ignoring leap seconds.

The algorithm to convert a number to a string, given a number input, is as follows: Return a valid normalized local date and time string that represents the date and time that is input milliseconds after midnight on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0").

See the note on historical dates in the Date state section.

Note See the introduction section for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes regarding localization of form controls.

The following common input element content attributes, IDL attributes, and methods apply to the element: autocomplete, list, max, min, readonly, required, and step content attributes; list, value, and valueAsNumber IDL attributes; select(), stepDown(), and stepUp() methods.

The value attribute is in mode value.

The input and change events apply.

The following content attributes must not be specified and do not apply to the element: accept, alt, checked, dirname, formaction, formenctype, formmethod, formnovalidate, formtarget, height, maxlength, minlength, multiple, pattern, placeholder, size, src, and width.

The following IDL attributes and methods do not apply to the element: checked, files, selectionStart, selectionEnd, selectionDirection, and valueAsDate IDL attributes; setRangeText(), and setSelectionRange() methods.

Example

The following example shows part of a flight booking application. The application uses an input element with its type attribute set to datetime-local, and it then interprets the given date and time in the time zone of the selected airport.
When an input element’s type attribute is in the `Number` state, the rules in this section apply.

The input element represents a control for setting the element’s value to a string representing a number.

If the element is mutable, the user agent should allow the user to change the number represented by its value, as obtained from applying the rules for parsing floating-point number values to it. User agents must not allow the user to set the value to a non-empty string that is not a valid floating-point number. If the user agent provides a user interface for selecting a number, then the value must be set to the best representation of the number representing the user’s selection as a floating-point number. User agents should allow the user to set the value to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid floating-point number, the control is suffering from bad input.

This specification does not define what user interface user agents are to use; user agent vendors are encouraged to consider what would best serve their users’ needs. For example, a user agent in Persian or Arabic markets might support Persian and Arabic numeric input (converting it to the format required for submission as described above). Similarly, a user agent designed for Romans might display the value in Roman numerals rather than in decimal; or (more realistically) a user agent designed for the French market might display the value with apostrophes between thousands and commas before the decimals, and allow the user to enter a value in that manner, internally converting it to the submission format described above.

The value attribute, if specified and not empty, must have a value that is a valid floating-point number.

The value sanitization algorithm is as follows: If the value of the element is not a valid floating-point number, then set it to the empty string instead.

The min attribute, if specified, must have a value that is a valid floating-point number. The max attribute, if specified, must have a value that is a valid floating-point number.

The step scale factor is 1. The default step is 1 (allowing only integers to be selected by the user, unless the step base has a non-integer value).

When the element is suffering from a step mismatch, the user agent may round the element’s value to the nearest number for which the element would not suffer from a step mismatch. If there are two such numbers, user agents are encouraged to pick the one nearest positive infinity.

The algorithm to convert a string to a number, given a string input, is as follows: If applying the rules for parsing floating-point number values results in an error, then return an error; otherwise, return the resulting number.

The algorithm to convert a number to a string, given a number input, is as follows: Return a valid floating-point number that represents input.

Bookkeeping details

The following common input element content attributes, IDL attributes, and methods apply to the element: `autocomplete`, `list`, `max`, `min`.
placeholders, readonly, required, and step content attributes; list, value, and valueAsNumber IDL attributes; select, stepDown, and stepUp methods.

The value IDL attribute is in mode.

The input and change events apply.

The following content attributes must not be specified and do not apply to the element: accept, alt, checked, dirname, formaction, formmethod, formnovalidate, formattarget, height, axlength, minlength, multiple, pattern, size, src, and width.

The following IDL attributes and methods do not apply to the element: checked, files, selectionStart, selectionEnd, selectionDirection, and valueAsDate IDL attributes; setRangeText, and setSelectionRange methods.

Example

Here is an example of using a numeric input control:

```html
<p>How much do you want to charge? $<input type=number min=0 step=0.01 name=price></p>
```

As described above, a user agent might support numeric input in the user's local format, converting it to the format required for submission as described above. This might include handling grouping separators (as in "872,000,000,000") and various decimal separators (such as "3,99" vs "3.99") or using local digits (such as those in Arabic, Devanagari, Persian, and Thai).

4.10.5.1.13 Range state (type=range)

When an input element's type attribute is in the Range state, the rules in this section apply.

The input element represents a control for setting the element's value to a string representing a number, but with the caveat that the exact value is not important, letting UAs provide a simpler interface than they do for the Number state.

If the element is mutable, the user agent should allow the user to change the number represented by its value, as obtained from applying the rules for parsing floating-point number values to it. User agents must not allow the user to set the value to a string that is not a valid floating-point number. If the user agent provides a user interface for selecting a number, then the value must be set to a best representation of the number representing the user's selection as a floating-point number.

User agents must not allow the user to set the value to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid floating-point number, the control is suffering from bad input.

The value attribute, if specified, must have a value that is a valid floating-point number.

The value sanitation algorithm is as follows: If the value of the element is not a valid floating-point number, then set it to the best representation, as a floating-point number, of the default value.

The default value is the minimum plus half the difference between the minimum and the maximum, unless the maximum is less than the minimum, in which case the default value is the minimum.

When the element is suffering from an underflow, the user agent must set the element's value to the best representation, as a floating-point number, of the minimum.

When the element is suffering from an overflow, if the maximum is not less than the minimum, the user agent must set the element's value to a valid floating-point number that represents the maximum.

When the element is suffering from a step mismatch, the user agent must round the element's value to the nearest number for which the element would not suffer from a step mismatch, and which is greater than or equal to the minimum, and, if the
maximum is not less than the minimum, which is less than or equal to the maximum, if there is a number that matches these constraints. If two numbers match these constraints, then user agents must use the one nearest to positive infinity.

Example

For example, the markup `<input type="range" min=0 max=100 step=20 value=50>` results in a range control whose initial value is 60.

Example

Here is an example of a range control using an autocomplete list with the `list` attribute. This could be useful if there are values along the full range of the control that are especially important, such as preconfigured light levels or typical speed limits in a range control used as a speed control. The following markup fragment:

```html
<input type="range" min="-100" max="100" value="0" step="10" name="power" list="powers">
<datalist id="powers">
  <option value="0">
  <option value="-30">
  <option value="30">
  <option value="++50">
</datalist>
```

...with the following style sheet applied:

```css
input { height: 75px; width: 49px; background: #D5CCBB; color: black; }
```

...might render as:

![Range control with autocomplete list](image)

Note how the UA determined the orientation of the control from the ratio of the style-sheet-specified height and width properties. The colors were similarly derived from the style sheet. The tick marks, however, were derived from the markup. In particular, the `step` attribute has not affected the placement of tick marks, the UA deciding to only use the author-specified completion values and then adding longer tick marks at the extremes.

Note also how the invalid value `++50` was completely ignored.

Example

For another example, consider the following markup fragment:

```html
<input name=x type="range" min="100" max="700" step="9.09090909" value="509.09090909">
```

A user agent could display in a variety of ways, for instance:

![Range control](image)

Or, alternatively, for instance:
The user agent could pick which one to display based on the dimensions given in the style sheet. This would allow it to maintain the same resolution for the tick marks, despite the differences in width.

**Example**

Finally, here is an example of a range control with two labeled values:

```html
<input type="range" name="a" list="a-values">
<datalist id="a-values">
  <option value="10" label="Low">
  <option value="90" label="High">
</datalist>
```

With styles that make the control draw vertically, it might look as follows:

![Vertical range control](image)

**Note**

*In this state, the range and step constraints are enforced even during user input, and there is no way to set the value to the empty string.*

The `min` attribute, if specified, must have a value that is a valid floating-point number. The default minimum is 0. The `max` attribute, if specified, must have a value that is a valid floating-point number. The default maximum is 100.

The `step` scale factor is 1. The default step is 1 (allowing only integers, unless the `min` attribute has a non-integer value).

**The algorithm to convert a string to a number**, given a string `input`, is as follows: If applying the rules for parsing floating-point number values to `input` results in an error, then return an error; otherwise, return the resulting number.

**The algorithm to convert a number to a string**, given a number `input`, is as follows: Return the best representation, as a floating-point number, of `input`.

**Bookkeeping details**

- The following common `input` element content attributes, IDL attributes, and methods do not apply to the element: `autocomplete`, `list`, `max`, `min`, and `step` content attributes; `list`, `valueAsNumber`, and `valueAsDate` IDL attributes; `stepDown()` and `stepUp()` methods.
- The `value` IDL attribute is in mode `value`.
- The `input` element and `change` events do not apply.
- The following content attributes must not be specified and do not apply to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `size`, `src`, and `width`.
- The following IDL attributes and methods do not apply to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, `selectionDirection`, and `valueAsDate` IDL attributes; `select()`, `setRangeText()`, and `setSelectionRange()` methods.

### 4.10.5.1.14 Color state (type=color)

When an `input` element's `type` attribute is in the Color state, the rules in this section apply.
The **input** element represents a well control, for setting the element’s **value** to a string representing a **simple color**.

**Note**

In this state, there is always a color picked, and there is no way to set the value to the empty string.

If the element is **mutable**, the user agent should allow the user to change the color represented by its **value**, as obtained from applying the rules for parsing simple color values to it. User agents must not allow the user to set the **value** to a string that is not a **valid lowercase simple color**. If the user agent provides a user interface for selecting a color, then the **value** must be set to the result of using the rules for serializing simple color values to the user’s selection. User agents must not allow the user to set the **value** to the empty string.

**Constraint validation**: While the user interface describes input that the user agent cannot convert to a **valid lowercase simple color**, the control is suffering from bad input.

The **value** attribute, if specified and not empty, must have a value that is a **valid simple color**.

The **value sanitization algorithm** is as follows: If the **value** of the element is a **valid simple color**, then set it to the **value** of the element converted to ASCII lowercase; otherwise, set it to the string "#000000".

**Bookkeeping details**

- The following common **input** element content attributes and IDL attributes apply to the element: **autocomplete** and **list** content attributes; **list** and **value** IDL attributes; **select()** method.
- The **value** IDL attribute is in mode **value**.
- The **input** and **change** events apply.
- The following content attributes must not be specified and do not apply to the element: **accept**; **alt**; **checked**; **dirname**; **formaction**; **formenctype**; **formmethod**; **formmove**; **formname**; **formnovalidate**; **formtarget**; **formSelectionDirection**; **formSelectionEnd**; **formSelectionStart**; **formtarget**; **formSelectionValue**; **formValueAsNumber**; **list** attributes; **setRangeText()**, **setSelectionRange()**, **stepDown()**, and **stepUp()** methods.

### 4.10.5.1.15 Checkbox state (type=checkbox)

When an **input** element’s **type** attribute is in the **Checkbox** state, the rules in this section apply.

The **input** element represents a two-state control that represents the element’s checkedness state. If the element’s checkedness state is true, the control represents a positive selection, and if it is false, a negative selection. If the element’s indeterminate IDL attribute is set to true, then the control’s selection should be obscured as if the control was in a third, indeterminate, state.

**Note**

The control is never a true tri-state control, even if the element’s **indeterminate** IDL attribute is set to true. The **indeterminate** IDL attribute only gives the appearance of a third state.

The **input activation behavior** is to fire an event named **input** at the element, with the **bubbles** attribute initialized to true, and then fire an event named **change** at the element, with the **bubbles** attribute initialized to true.

**Constraint validation**: If the element is **required** and its checkedness is false, then the element is suffering from being missing.

**For web developers (non-normative)**

```
input . indeterminate [ = value ]
```

When set, overrides the rendering of checkbox controls so that the current value is not visible.

**Bookkeeping details**

- The following common **input** element content attributes and IDL attributes apply to the element: **checked** and **required** content attributes; **checked** and **value** IDL attributes.
- The **value** IDL attribute is in mode **default**.
- The **input** and **change** events apply.
4.10.5.1.16 Radio button state (type=radio)  

When an input's type attribute is in the Radio Button state, the rules in this section apply.

The input element represents a control that, when used in conjunction with other input elements, forms a radio button group in which only one control can have its checkedness state set to true. If the element's checkedness state is true, the control represents the selected control in the group, and if it is false, it indicates a control in the group that is not selected.

The radio button group that contains an input element a also contains all the other input elements b that fulfill all of the following conditions:

- The input element b's type attribute is in the Radio Button state.
- Either a and b have the same form owner, or they both have no form owner.
- Both a and b are in the same tree.
- They both have a name attribute, their name attributes are not empty, and the value of a's name attribute equals the value of b's name attribute.

A tree must not contain an input element whose radio button group contains only that element.

When any of the following phenomena occur, if the element's checkedness state is true after the occurrence, the checkedness state of all the other elements in the same radio button group must be set to false:

- The element's checkedness state is set to true (for whatever reason).
- The element's name attribute is set, changed, or removed.
- The element's form owner changes.
- A type change is signalled for the element.

The input activation behavior is to fire an event named input at the element, with the bubbles attribute initialized to true, and then fire an event named change at the element, with the bubbles attribute initialized to true.

Constraint validation: If an element in the radio button group is required, and all of the input elements in the radio button group have a checkedness that is false, then the element is suffering from being missing.

Example

The following example, for some reason, has specified that Pupperers are both required and disabled:

```
<form>
  <p><label><input type="radio" name="dog-type" value="pupper" required disabled> Pupper</label></p>
  <p><label><input type="radio" name="dog-type" value="doggo"> Doggo</label></p>
  <p><button>Make your choice</button></p>
</form>
```

If the user tries to submit this form without first selecting "Doggo", then both input elements will be suffering from being missing, since an element in the radio button group is required (viz. the first element), and both of the elements in the radio button group have a false checkedness.

On the other hand, if the user selects "Doggo" and then submits the form, then neither input element will be suffering from being missing, since while one of them is required, not all of them have a false checkedness.
If none of the radio buttons in a radio button group are checked, then they will all be initially unchecked in the interface, until such time as one of them is checked (either by the user or by script).

**Bookkeeping details**

- The following common `input` element content attributes and IDL attributes, apply to the element: `checked` and `required` content attributes; `checked` and `value` IDL attributes.
- The `value` IDL attribute is in mode `default/on`.
- The `input` and `change` events apply.
- The following content attributes must not be specified and do not apply to the element: `accept`, `alt`, `autocomplete`, `dir`, `dirname`, `formaction`, `form enctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `max`, `maxlength`, `min`, `multiple`, `pattern`, `placeholder`, `readonly`, `size`, `src`, `step`, and `width`.
- The following IDL attributes and methods do not apply to the element: `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsNumber` IDL attributes; `select`, `setRangeText`, `setSelectionRange`, `stepDown`, and `stepUp` methods.

### 4.10.5.17 File Upload state (type=file) §p49

When an `input` element's `type` attribute is in the File Upload state, the rules in this section apply.

The `input` element represents a list of selected files, each file consisting of a file name, a file type, and a file body (the contents of the file).

File names must not contain path components, even in the case that a user has selected an entire directory hierarchy or multiple files with the same name from different directories. Path components, for the purposes of the File Upload state, are those parts of file names that are separated by U+005C REVERSE SOLIDUS character (\) characters.

Unless the `multiple` attribute is set, there must be no more than one file in the list of selected files.

The element's `input activation behavior` is to run the following steps:

1. If the algorithm is not triggered by user activation, then return without doing anything else.
2. Run these steps in parallel:
   1. Optionally, wait until any prior execution of this algorithm has terminated.
   2. Display a prompt to the user requesting that the user specify some files. If the `multiple` attribute is not set, there must be no more than one file selected; otherwise, any number may be selected. Files can be from the filesystem or created on the fly, e.g., a picture taken from a camera connected to the user's device.
   3. Wait for the user to have made their selection.
   4. Queue a task to first update the element's selected files so that it represents the user's selection, then fire an event named `input` at the `input` element, with the `bubbles` attribute initialized to true, and finally fire an event named `change` at the `input` element, with the `bubbles` attribute initialized to true.

If the element is `mutable`, the user agent should allow the user to change the files on the list in other ways also, e.g. adding or removing files by drag-and-drop. When the user does so, the user agent must queue a task to first update the element's selected files so that it represents the user's new selection, then fire an event named `input` at the `input` element, with the `bubbles` attribute initialized to true, and finally fire an event named `change` at the `input` element, with the `bubbles` attribute initialized to true.

If the element is not `mutable`, the user agent must not allow the user to change the element's selection.

**Constraint validation:** If the element is `required` and the list of selected files is empty, then the element is suffering from being missing.

The `accept` attribute may be specified to provide user agents with a hint of what file types will be accepted.

If specified, the attribute must consist of a set of comma-separated tokens, each of which must be an ASCII case insensitive match for one of the following:
The string "audio/*"
Indicates that sound files are accepted.

The string "video/*"
Indicates that video files are accepted.

The string "image/*"
Indicates that image files are accepted.

A valid MIME type string with no parameters
Indicates that files of the specified type are accepted.

A string whose first character is a U+002E FULL STOP character (.)
Indicates that files with the specified file extension are accepted.

The tokens must not be ASCII case-insensitive matches for any of the other tokens (i.e. duplicates are not allowed). To obtain the list of tokens from the attribute, the user agent must split the attribute value on commas.

User agents may use the value of this attribute to display a more appropriate user interface than a generic file picker. For instance, given the value image/*, a user agent could offer the user the option of using a local camera or selecting a photograph from their photo collection; given the value audio/*, a user agent could offer the user the option of recording a clip using a headset microphone.

User agents should prevent the user from selecting files that are not accepted by one (or more) of these tokens.

Note
Authors are encouraged to specify both any MIME types and any corresponding extensions when looking for data in a specific format.

Example
For example, consider an application that converts Microsoft Word documents to Open Document Format files. Since Microsoft Word documents are described with a wide variety of MIME types and extensions, the site can list several, as follows:

<input type="file" accept=".doc,.docx,.xml,application/msword,application/vnd.openxmlformats-officedocument.wordprocessingml.document">

On platforms that only use file extensions to describe file types, the extensions listed here can be used to filter the allowed documents, while the MIME types can be used with the system’s type registration table (mapping MIME types to extensions used by the system), if any, to determine any other extensions to allow. Similarly, on a system that does not have file names or extensions but labels documents with MIME types internally, the MIME types can be used to pick the allowed files, while the extensions can be used if the system has an extension registration table that maps known extensions to MIME types used by the system.

⚠️ Warning!
Extensions tend to be ambiguous (e.g. there are an untold number of formats that use the ".*dat" extension, and users can typically quite easily rename their files to have a ".*doc" extension even if they are not Microsoft Word documents), and MIME types tend to be unreliable (e.g. many formats have no formally registered types, and many formats are in practice labeled using a number of different MIME types). Authors are reminded that, as usual, data received from a client should be treated with caution, as it may not be in an expected format even if the user is not hostile and the user agent fully obeyed the accept attribute's requirements.

Example
For historical reasons, the valueIDL attribute prefixes the file name with the string "C:\fakepath\". Some legacy user agents actually included the full path (which was a security vulnerability). As a result of this, obtaining the file name from the valueIDL attribute in a backwards-compatible way is non-trivial. The following function extracts the file name in a suitably compatible manner:

```javascript
function extractFilename(path) {
    if (path.substr(0, 12) == "C:\fakepath\")
        return path.substr(12); // modern browser
    var x;
```
```
x = path.lastIndexOf('/');
if (x >= 0) // Unix-based path
    return path.substr(x+1);
else
    x = path.lastIndexOf('\');
if (x >= 0) // Windows-based path
    return path.substr(x+1);
return path; // just the file name
```

This can be used as follows:

```html
<p><input type=file name=image onchange="updateFilename(this.value)"/>
<p>The name of the file you picked is: <span id="filename">(none)</span></p>
<script>
function updateFilename(path) {
    var name = extractFilename(path);
    document.getElementById('filename').textContent = name;
}
</script>
```

**Bookkeeping details**
- The following common `input` element content attributes and IDL attributes apply to the element: `accept`, `multiple`, and `required` content attributes; `files` and `value` IDL attributes; `select()` method.
- The `value` IDL attribute is in mode `filename`.
- The `input` and `change` events apply.
- The following content attributes must not be specified and `do not apply` to the element: `autocomplete`, `dir`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `size`, `src`, `step`, and `width`.
- The element's `value` attribute must be omitted.
- The following IDL attributes and methods `do not apply` to the element: `checked`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsNumber` IDL attributes; `setRangeText()`, `setSelectionRange()`, `stepUp()`, and `stepDown()` methods.

### 4.10.5.1.18 Submit Button state (type=submit)

When an `input` element's `type` attribute is in the `Submit Button` state, the rules in this section apply.

The `input` element represents a button that, when activated, submits the form. If the element has a `value` attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Submit" or some such. The element is a button, specifically a `submit button`.

**Note**
Since the default label is implementation-defined, and the width of the button typically depends on the button's label, the button's width can leak a few bits of fingerprintable information. These bits are likely to be strongly correlated to the identity of the user agent and the user's locale.

The element's `input activation behavior` is as follows: if the element has a `form owner`, and the element's `node document` is fully active, the `submit` the `form owner` from the `input` element; otherwise, do nothing.

The `formaction`, `formenctype`, `formmethod`, `formnovalidate`, and `formtarget` attributes are `attributes for form submission`.

**Note**
The `formnovalidate` attribute can be used to make submit buttons that do not trigger the constraint validation.

**Bookkeeping details**
- The following common `input` element content attributes and IDL attributes apply to the element: `formaction`, `formenctype`, `formmethod`.
The `value` IDL attribute is in mode `default`.

The following content attributes must not be specified and `do not apply` to the element: accept, alt, autocomplete, checked, dirname, height, list, max, maxlength, min, minlength, multiple, pattern, placeholder, readonly, required, size, src, step, width.

The following IDL attributes and methods `do not apply` to the element: checked, files, list, selectionStart, selectionEnd, selectionDirection, valueAsDate, and valueAsNumber IDL attributes; select, setRangeText, setSelectionRange, stepUp, and stepDown methods.

The `input` and `change` events `do not apply`.

---

### 4.10.5.1.19 Image Button state (type=image)

When an `input` element's `type` attribute is in the Image Button state, the rules in this section apply.

The `input` element represents either an image from which a user can select a coordinate and submit the form, or alternatively a button from which the user can submit the form. The element is a `button`, specifically a submit button.

---

**Note**

The coordinate is sent to the server during form submission by sending two entries for the element, derived from the name of the control but with ".x" and ".y" appended to the name with the x and y components of the coordinate respectively.

---

The image is given by the `src` attribute. The `src` attribute must be present, and must contain a valid non-empty URL potentially surrounded by spaces referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.

When any of these events occur

- the `input` element's `type` attribute is first set to the Image Button state (possibly when the element is first created), and the `src` attribute is present
- the `input` element's `type` attribute is changed back to the Image Button state, and the `src` attribute is present, and its value has changed since the last time the `type` attribute was in the Image Button state
- the `input` element's `type` attribute is in the Image Button state, and the `src` attribute is set or changed then unless the user agent cannot support images, or its support for images has been disabled, or the user agent only fetches images on demand, or the `src` attribute's value is the empty string, the user agent must `parse` the value of the `src` attribute, relative to the element's `node document`, and if that is successful, then:

  1. Let request be a new request whose `url` is the resulting URL record, `client` is the element's relevant settings object, `destination` is "image", `credentials mode` is "include", and whose `use-URL-credentials` flag is set.
  2. Fetch request.

Fetching the image must delay the load event of the element's `node document` until the `task` that is queued by the networking task source once the resource has been fetched (defined below) has been run.

If the image was successfully obtained, with no network errors, and the image's type is a supported image type, and the image is a valid image of that type, then the image is said to be available. If this is true before the image is completely downloaded, each `task` that is queued by the networking task source, while the image is being fetched must update the presentation of the image appropriately.

The user agent should apply the image sniffing rules to determine the type of the image, with the image's associated Content-Type headers giving the official type. If these rules are not applied, then the type of the image must be the type given by the image's associated Content-Type headers.

User agents must not support non-image resources with the `input` element. User agents must not run executable code embedded in the image resource. User agents must only display the first page of a multipage resource. User agents must not allow the resource to act in an interactive fashion, but should honor any animation in the resource.

The `task` that is queued by the networking task source once the resource has been fetched, must, if the download was successful and the image is available, queue a task to fire an event named `load` at the `input` element; and otherwise, if the fetching process fails without a response from the remote server, or completes but the image is not a valid or supported image,
queue a task\textsuperscript{4693} to fire an event named \textbf{error}\textsuperscript{4177} on the \textbf{input}\textsuperscript{4476} element.

The \textbf{alt} attribute provides the textual label for the button for users and user agents who cannot use the image. The \textbf{alt}\textsuperscript{4502} attribute must be present, and must contain a non-empty string giving the label that would be appropriate for an equivalent button if the image was unavailable.

The \textbf{input}\textsuperscript{4476} element supports \textbf{dimension attributes}\textsuperscript{434}.

If the \textbf{src}\textsuperscript{501} attribute is set, and the image is \textbf{available}\textsuperscript{502} and the user agent is configured to display that image, then: The element \textbf{represents}\textsuperscript{5126} a control for selecting a \textbf{coordinate}\textsuperscript{5065} from the image specified by the \textbf{src}\textsuperscript{501} attribute; if the element is \textbf{mutable}\textsuperscript{5468}, the user agent should allow the user to select this \textbf{coordinate}\textsuperscript{5065}, and the element's \textbf{input activation behavior}\textsuperscript{5460} is as follows: if the element has a \textbf{form owner}\textsuperscript{548}, and the element's \textbf{node document} is \textbf{fully active}\textsuperscript{5782}, take the user's selected \textbf{coordinate}\textsuperscript{5065}, and \textbf{submit}\textsuperscript{578} the \textbf{input}\textsuperscript{4476} element's \textbf{form owner}\textsuperscript{554} from the \textbf{input}\textsuperscript{4476} element. If the user activates the control without explicitly selecting a coordinate, then the coordinate (0,0) must be assumed.

Otherwise, the element \textbf{represents}\textsuperscript{5120} a submit button whose label is given by the value of the \textbf{alt}\textsuperscript{4502} attribute; the element's \textbf{input activation behavior}\textsuperscript{4480} is as follows: if the element has a \textbf{form owner}\textsuperscript{548}, and the element's \textbf{node document} is \textbf{fully active}\textsuperscript{5782}, set the \textbf{selected coordinate}\textsuperscript{5202} to (0,0), and \textbf{submit}\textsuperscript{578} the \textbf{input}\textsuperscript{4476} element's \textbf{form owner}\textsuperscript{554} from the \textbf{input}\textsuperscript{4476} element.

In either case, if the element has no \textbf{form owner}\textsuperscript{548} or the element's \textbf{node document} is not \textbf{fully active}\textsuperscript{5782}, then its \textbf{input activation behavior}\textsuperscript{4480} must be to do nothing.

The \textbf{selected coordinate} must consist of an x-component and a y-component. The coordinates represent the position relative to the edge of the image, with the coordinate space having the positive x direction to the right, and the positive y direction downwards.

The x-component must be a \textbf{valid integer}\textsuperscript{466} representing a number x in the range \(−(\text{borderleft}+\text{paddingleft}) \leq x \leq \text{width}+\text{borderright}+\text{paddingright}\), where \text{width} is the rendered width of the image, \text{borderleft} is the width of the border on the left of the image, \text{paddingleft} is the width of the padding on the left of the image, \text{borderright} is the width of the border on the right of the image, and \text{paddingright} is the width of the padding on the right of the image, with all dimensions given in CSS pixels.

The y-component must be a \textbf{valid integer}\textsuperscript{466} representing a number y in the range \(−(\text{borderbottom}+\text{paddingbottom}) \leq y \leq \text{height}+\text{borderbottom}+\text{paddingbottom}\), where \text{height} is the rendered height of the image, \text{borderbottom} is the width of the border above the image, \text{paddingbottom} is the width of the padding above the image, \text{borderbottom} is the width of the border below the image, and \text{paddingbottom} is the width of the padding below the image, with all dimensions given in CSS pixels.

Where a border or padding is missing, its width is zero CSS pixels.

The \textbf{formaction}\textsuperscript{552}, \textbf{formenctype}\textsuperscript{553}, \textbf{formmethod}\textsuperscript{552}, \textbf{formnovalidate}\textsuperscript{553}, and \textbf{formtarget}\textsuperscript{553} attributes are \textbf{attributes for form submission}\textsuperscript{553}.

For web developers (non-normative)

\begin{verbatim}
image . width\textsuperscript{462} [ = value ]
image . height\textsuperscript{462} [ = value ]
\end{verbatim}

These attributes return the actual rendered dimensions of the image, or zero if the dimensions are not known.

They can be set, to change the corresponding content attributes.

**Bookkeeping details**

- The following common \textbf{input}\textsuperscript{4476} element content attributes and IDL attributes \textbf{apply}\textsuperscript{4479} to the element: \textbf{alt}\textsuperscript{551}, \textbf{formaction}\textsuperscript{4352}, \textbf{formenctype}\textsuperscript{553}, \textbf{formmethod}\textsuperscript{552}, \textbf{formnovalidate}\textsuperscript{553}, \textbf{formtarget}\textsuperscript{553}, \textbf{height}\textsuperscript{564}, \textbf{src}\textsuperscript{501}, and \textbf{width}\textsuperscript{596} content attributes; \textbf{value}\textsuperscript{511} IDL attribute.
- The \textbf{value}\textsuperscript{511} IDL attribute is in mode \textbf{default}\textsuperscript{514}.
- The following content attributes must not be specified and \textbf{do not apply}\textsuperscript{4178} to the element: \textbf{accept}\textsuperscript{498}, \textbf{autocomplete}\textsuperscript{555}, \textbf{checked}\textsuperscript{498}, \textbf{dirname}\textsuperscript{456}, \textbf{list}\textsuperscript{518}, \textbf{max}\textsuperscript{518}, \textbf{maxlength}\textsuperscript{518}, \textbf{min}\textsuperscript{518}, \textbf{ minlength}\textsuperscript{518}, \textbf{multiple}\textsuperscript{518}, \textbf{pattern}\textsuperscript{451}, \textbf{placeholder}\textsuperscript{451}, \textbf{readonly}\textsuperscript{451}, \textbf{required}\textsuperscript{451}, \textbf{size}\textsuperscript{451}, and \textbf{step}\textsuperscript{451}.
- The element's \textbf{value}\textsuperscript{511} attribute must be omitted.
- The following IDL attributes and methods \textbf{do not apply}\textsuperscript{4178} to the element: \textbf{checked}\textsuperscript{511}, \textbf{files}\textsuperscript{435}, \textbf{list}\textsuperscript{515}, \textbf{selectionStart}\textsuperscript{505}, \textbf{selectionEnd}\textsuperscript{505}, \textbf{selectionDirection}\textsuperscript{505}, \textbf{valueAsNumber}\textsuperscript{405}, and \textbf{valueAsDate}\textsuperscript{405}, and \textbf{valueAsNumber}\textsuperscript{405}, \textbf{setRangeText()}\textsuperscript{405}, \textbf{setSelectionRange()}\textsuperscript{405}, \textbf{stepDown()}\textsuperscript{405}, and \textbf{stepUp()}\textsuperscript{405} methods.
- The \textbf{input}\textsuperscript{4177} and \textbf{change}\textsuperscript{4152} events \textbf{do not apply}\textsuperscript{4178}.
When an input element's type attribute is in the Reset Button state, the rules in this section apply.

The input element represents a button that, when activated, resets the form. If the element has a value attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Reset" or some such. The element is a button.

The element's input activation behavior, if the element has a form owner and the element's node document is fully active, is to reset the form owner; otherwise, it is to do nothing.

Constraint validation: The element is barred from constraint validation.

Bookkeeping details:
- The value IDL attribute applies to this element and is in mode default.
- The following content attributes must not be specified and do not apply to the element: accept, alt, autocomplete, checked, dirname, formaction, formmethod, formnovalidate, formtarget, height, list, max, maxlength, min, minlength, multiple, pattern, placeholder, readonly, required, size, src, step, and width.
- The following IDL attributes and methods do not apply to the element: checked, files, list, selectionStart, selectionEnd, selectionDirection, valueAsDate, and valueAsNumber IDL attributes; select, setRangeText, setSelectionRange, stepDown, and stepUp methods.
- The input and change events do not apply.

4.10.5.1.20 Reset Button state (type=reset)§

When an input element's type attribute is in the Reset Button state, the rules in this section apply.

The input element represents a button that, when activated, resets the form. If the element has a value attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Reset" or some such. The element is a button.

The element's input activation behavior, if the element has a form owner and the element's node document is fully active, is to reset the form owner; otherwise, it is to do nothing.

Constraint validation: The element is barred from constraint validation.

Example

Take the following form:

```html
<form action="process.cgi">
  <input type=image src=map.png name=where alt="Show location list">
</form>
```

If the user clicked on the image at coordinate (127,40) then the URL used to submit the form would be "process.cgi?where.x=127&where.y=40".

(In this example, it's assumed that for users who don't see the map, and who instead just see a button labeled "Show location list", clicking the button will cause the server to show a list of locations to pick from instead of the map.)

4.10.5.1.21 Button state (type=button)§

When an input element's type attribute is in the Button state, the rules in this section apply.

The input element represents a button with no default behavior. A label for the button must be provided in the value attribute, though it may be the empty string. If the element has a value attribute, the button's label must be the value of that attribute; otherwise, it must be the empty string. The element is a button.

The element has no input activation behavior.

Constraint validation: The element is barred from constraint validation.
4.10.5.2 Implementation notes regarding localization of form controls

This section is non-normative.

The formats shown to the user in date, time, and number controls is independent of the format used for form submission. Browsers are encouraged to use user interfaces that present dates, times, and numbers according to the conventions of either the locale implied by the page-provided data. If the browser, configured to use the British English locale, only showed the date 03/02 in the ticket purchase showing on 02/03, then there's only so much that can be done about such cultural differences...

Example

For example, it would be confusing to users if an American English page claimed that a Cirque De Soleil show was going to be forcing any conversation through this medium to be terse and discouraging intelligent discourse.

```html
<label>What are you doing? <input name=status maxlength=140></label>
```

Example

Here, a password is given a minimum length:

```html
<p><label>Username: <input name=u required></label></p>
<p><label>Password: <input name=p required minlength=12></label></p>
```
4.10.5.3.2 The `size` attribute\(^{661}\)

The `size` attribute gives the number of characters that, in a visual rendering, the user agent is to allow the user to see while editing the element's `value`\(^{657}\).

The `size`\(^{665}\) attribute, if specified, must have a value that is a valid non-negative integer\(^{666}\) greater than zero.

If the attribute is present, then its value must be parsed using the rules for parsing non-negative integers\(^{666}\), and if the result is a number greater than zero, then the user agent should ensure that at least that many characters are visible.

The `size`\(^{661}\) IDL attribute is limited to only non-negative numbers greater than zero\(^{691}\) and has a default value of 20.

4.10.5.3.3 The `readonly` attribute\(^{665}\)

The `readonly` attribute is a boolean attribute\(^{665}\) that controls whether or not the user can edit the form control. When specified, the element is not mutable\(^{548}\).

**Constraint validation:** If the `readonly`\(^{665}\) attribute is specified on an `input`\(^{647}\) element, the element is barred from constraint validation\(^{572}\).

**Note**

The difference between `disabled`\(^{651}\) and `readonly`\(^{665}\) is that read-only controls can still function, whereas disabled controls generally do not function as controls until they are enabled. This is spelled out in more detail elsewhere in this specification with normative requirements that refer to the `disabled`\(^{652}\) concept (for example, the element's activation behavior, whether or not it is a focusable area\(^{744}\), or when constructing the entry list\(^{641}\)). Any other behavior related to user interaction with disabled controls, such as whether text can be selected or copied, is not defined in this standard.

*Only text controls can be made read-only, since for other controls (such as checkboxes and buttons) there is no useful distinction between being read-only and being disabled, so the `readonly`\(^{665}\) attribute does not apply\(^{679}\).*

**Example**

In the following example, the existing product identifiers cannot be modified, but they are still displayed as part of the form, for consistency with the row representing a new product (where the identifier is not yet filled in).

```html
<form action="products.cgi" method="post" enctype="multipart/form-data">
<table>
<tr><th>Product ID</th><th>Product name</th><th>Price</th><th>Action</th></tr>
<tr><td><input readonly="readonly" name="1.pid" value="H412"></td><td><input required="required" name="1.pname" value="Floor lamp Ulke"></td><td><$input required="required" type="number" min="0" step="0.01" name="1.pprice" value="49.99"></td><td><button formnovalidate="formnovalidate" name="action" value="delete:1">Delete</button></td></tr>
<tr><td><input readonly="readonly" name="2.pid" value="FG28"></td><td><input required="required" name="2.pname" value="Table lamp Ulke"></td><td><$input required="required" type="number" min="0" step="0.01" name="2.pprice" value="24.99"></td><td><button formnovalidate="formnovalidate" name="action" value="delete:2">Delete</button></td></tr>
<tr><td><input required="required" name="3.pid" value="" pattern="[A-Z0-9]+"></td><td><input required="required" name="3.pname" value=""></td><td><$input required="required" type="number" min="0" step="0.01" name="3.pprice" value=""></td><td><button formnovalidate="formnovalidate" name="action" value="delete:3">Delete</button></td></tr>
</table>

<p><button formnovalidate="formnovalidate" name="action" value="add">Add</button></p>
<p><button name="action" value="update">Save</button></p>
</form>
```
4.10.5.3.4 The `required` attribute

The `required` attribute is a boolean attribute. When specified, the element is `required`.

Constraint validation: If the element is `required`, and its `value` IDL attribute applies and is in the mode `value`, and the element is `mutable`, and the element's `value` is the empty string, then the element is suffering from being missing.

Example

The following form has two required fields, one for an e-mail address and one for a password. It also has a third field that is only considered valid if the user types the same password in the password field and this third field.

```html
<h1>Create new account</h1>
<form action="/newaccount" method=post>
  <p oninput="up2.setCustomValidity(up2.value != up.value ? 'Passwords do not match.' : '')">
  </p>
  <label for="username">E-mail address:</label>
  <input id="username" type=email required name="un">
  <label for="password1">Password:</label>
  <input id="password1" type=password required name="up">
  <label for="password2">Confirm password:</label>
  <input id="password2" type=password name="up2">
  <input type=submit value="Create account">
</form>
```

Example

For radio buttons, the `required` attribute is satisfied if any of the radio buttons in the group is selected. Thus, in the following example, any of the radio buttons can be checked, not just the one marked as required:

```html
<fieldset>
  <legend>Did the movie pass the Bechdel test?</legend>
  <p><label><input type="radio" name="bechdel" value="no-characters"> No, there are not even two female characters in the movie. </label></p>
  <p><label><input type="radio" name="bechdel" value="no-names"> No, the female characters never talk to each other. </label></p>
  <p><label><input type="radio" name="bechdel" value="no-topic"> No, when female characters talk to each other it's always about a male character. </label></p>
  <p><label><input type="radio" name="bechdel" value="yes" required> Yes. </label></p>
  <p><label><input type="radio" name="bechdel" value="unknown"> I don't know. </label></p>
</fieldset>
```

To avoid confusion as to whether a radio button group is required or not, authors are encouraged to specify the attribute on all the radio buttons in a group. Indeed, in general, authors are encouraged to avoid having radio button groups that do not have any initially checked controls in the first place, as this is a state that the user cannot return to, and is therefore generally considered a poor user interface.

4.10.5.3.5 The `multiple` attribute

The `multiple` attribute is a boolean attribute that indicates whether the user is to be allowed to specify more than one value.

Example

The following extract shows how an e-mail client's "To" field could accept multiple e-mail addresses.
The pattern attribute specifies a regular expression against which the control's value, or, when the multiple attribute applies and is set, the control's values, are to be checked. If specified, the attribute's value must match the JavaScript Pattern production.

If an input element has a pattern attribute specified, and the attribute's value, when compiled as a JavaScript regular expression with only the "u" flag specified, compiles successfully, then the resulting regular expression is the element's compiled pattern regular expression. If the element has no such attribute, or if the value doesn't compile successfully, then the element has no compiled pattern regular expression. [JAVASCRIPT]
Constraint validation: If the element’s `value` is not the empty string, and either the element’s `multiple` attribute is not specified or it does not apply to the `input` element given its `type` attribute’s current state, and the element has a compiled pattern regular expression but that regular expression does not match the entirety of the element’s `value`, then the element is suffering from a pattern mismatch.

Constraint validation: If the element’s `value` is not the empty string, and the element’s `multiple` attribute is specified and applies to the `input` element, and the element has a compiled pattern regular expression but that regular expression does not match the entirety of each of the element’s `values`, then the element is suffering from a pattern mismatch.

The compiled pattern regular expression, when matched against a string, must have its start anchored to the start of the string and its end anchored to the end of the string.

Note: This implies that the regular expression language used for this attribute is the same as that used in JavaScript, except that the `pattern` attribute is matched against the entire value, not just any subset (somewhat as if it implied a `^` at the start of the pattern and a `$` at the end).

When an `input` element has a `pattern` attribute specified, authors should include a `title` attribute to give a description of the pattern. User agents may use the contents of this attribute, if it is present, when informing the user that the pattern is not matched, or at any other suitable time, such as in a tooltip or read out by assistive technology when the control gains focus.

Example

For example, the following snippet:

```html
<label> Part number: 
<input pattern="[0-9][A-Z]{3}" name="part" 
title="A part number is a digit followed by three uppercase letters."/>
</label>
```

...could cause the UA to display an alert such as:

A part number is a digit followed by three uppercase letters.
You cannot submit this form when the field is incorrect.

When a control has a `pattern` attribute, the `title` attribute, if used, must describe the pattern. Additional information could also be included, so long as it assists the user in filling in the control. Otherwise, assistive technology would be impaired.

Example

For instance, if the title attribute contained the caption of the control, assistive technology could end up saying something like The text you have entered does not match the required pattern. Birthday, which is not useful.

UAs may still show the `title` in non-error situations (for example, as a tooltip when hovering over the control), so authors should be careful not to word `title`s as if an error has necessarily occurred.

4.10.5.3.7 The `min` and `max` attributes

Some form controls can have explicit constraints applied limiting the allowed range of values that the user can provide. Normally, such a range would be linear and continuous. A form control can have a periodic domain, however, in which case the form control’s broadest possible range is finite, and authors can specify explicit ranges within it that span the boundaries.

Example

Specifically, the broadest range of a `type=time` control is midnight to midnight (24 hours), and authors can set both continuous linear ranges (such as 9pm to 11pm) and discontinuous ranges spanning midnight (such as 11pm to 1am).

The `min` and `max` attributes indicate the allowed range of values for the element.
Their syntax is defined by the section that defines the type attribute's current state.

If the element has a min attribute, and the result of applying the algorithm to convert a string to a number to the value of the min attribute is a number, then that number is the element's minimum; otherwise, if the type attribute's current state defines a default minimum, then that is the minimum; otherwise, the element has no minimum.

The min attribute also defines the step base.

If the element has a max attribute, and the result of applying the algorithm to convert a string to a number to the value of the max attribute is a number, then that number is the element's maximum; otherwise, if the type attribute's current state defines a default maximum, then that is the maximum; otherwise, the element has no maximum.

If the element does not have a periodic domain, the max attribute's value (the maximum) must not be less than the min attribute's value (its minimum).

An element has a reversed range if it has a periodic domain and its maximum is less than its minimum.

An element has range limitations if it has a defined minimum or a defined maximum.

Constraint validation: When the element has a minimum and does not have a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is less than the minimum, the element is suffering from an underflow.

Constraint validation: When the element has a maximum and does not have a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is more than the maximum, the element is suffering from an overflow.

Constraint validation: When an element has a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is more than the maximum and less than the minimum, the element is simultaneously suffering from an underflow and suffering from an overflow.

The step attribute indicates the granularity that is expected (and required) of the value or values, by limiting the allowed values. The section that defines the type attribute's current state also defines the default step, the step scale factor, and in

---

Note

If an element that does not have a periodic domain has a maximum that is less than its minimum, then so long as the element has a value, it will either be suffering from an underflow or suffering from an overflow.

An element has a reversed range if it has a periodic domain, and its maximum is less than its minimum.

An element has range limitations if it has a defined minimum or a defined maximum.

Constraint validation: When the element has a minimum and does not have a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is less than the minimum, the element is suffering from an underflow.

Constraint validation: When the element has a maximum and does not have a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is more than the maximum, the element is suffering from an overflow.

Constraint validation: When an element has a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is more than the maximum and less than the minimum, the element is simultaneously suffering from an underflow and suffering from an overflow.

Example

The following date control limits input to dates that are before the 1980s:

```html
<input name=bday type=date max="1979-12-31">
```

Example

The following number control limits input to whole numbers greater than zero:

```html
<input name=quantity required="" type="number" min="1" value="1">
```

Example

The following time control limits input to those minutes that occur between 9pm and 6am, defaulting to midnight:

```html
<input name=sleepStart type=time min="21:00" max="06:00" step="60" value="00:00">
```

4.10.5.3.8 The step attribute

The step attribute indicates the granularity that is expected (and required) of the value or values, by limiting the allowed values. The section that defines the type attribute's current state also defines the default step, the step scale factor, and in
some cases the **default step base**, which are used in processing the attribute as described below.

The **step** \(^{509}\) attribute, if specified, must either have a value that is a **valid floating-point number** \(^{566}\) that **parses** \(^{567}\) to a number that is greater than zero, or must have a value that is an **ASCII case-insensitive** match for the string “any”.

The attribute provides the **allowed value step** for the element, as follows:

1. If the attribute is absent, then the **allowed value step** \(^{510}\) is the **default step** \(^{509}\) multiplied by the **step scale factor** \(^{509}\).
2. Otherwise, if the attribute's value is an **ASCII case-insensitive** match for the string “any”, then there is no **allowed value step** \(^{510}\).
3. Otherwise, if the **rules for parsing floating-point number values** \(^{567}\), when they are applied to the attribute's value, return an error, zero, or a number less than zero, then the **allowed value step** \(^{510}\) is the **default step** \(^{509}\) multiplied by the **step scale factor** \(^{509}\).
4. Otherwise, the **allowed value step** \(^{510}\) is the number returned by the **rules for parsing floating-point number values** \(^{567}\) when they are applied to the attribute's value, multiplied by the **step scale factor** \(^{509}\).

The **step base** is the value returned by the following algorithm:

1. If the element has a **min** \(^{508}\) content attribute, and the result of applying the **algorithm to convert a string to a number** \(^{5480}\) to the value of the **min** \(^{508}\) content attribute is not an error, then return that result.
2. If the element has a **value** \(^{5488}\) content attribute, and the result of applying the **algorithm to convert a string to a number** \(^{5480}\) to the value of the **value** \(^{5488}\) content attribute is not an error, then return that result.
3. If a **default step base** \(^{510}\) is defined for this element given its **type** \(^{478}\) attribute's state, then return it.
4. Return zero.

**Constraint validation:** When the element has an **allowed value step** \(^{510}\), and the result of applying the **algorithm to convert a string to a number** \(^{5480}\) to the string given by the element's **value** \(^{547}\) is a number, and that number subtracted from the **step base** \(^{510}\) is not an integral multiple of the **allowed value step** \(^{510}\), the element is **suffering from a step mismatch** \(^{573}\).

Example

The following range control only accepts values in the range 0..1, and allows 256 steps in that range:

```
<input name=opacity type=range min=0 max=1 step=0.00392156863>
```

Example

The following control allows any time in the day to be selected, with any accuracy (e.g. thousandth-of-a-second accuracy or more):

```
<input name=favtime type=time step=any>
```

Normally, time controls are limited to an accuracy of one minute.

4.10.5.3.9 The **list** \(^{510}\) attribute

The **list** attribute is used to identify an element that lists predefined options suggested to the user.

If present, its value must be the **ID** of a **datalist** \(^{525}\) element in the same **tree**.

The **suggestions source element** is the first element in the **tree** in **tree order** to have an **ID** equal to the value of the **list** \(^{510}\) attribute, if that element is a **datalist** \(^{525}\) element. If there is no **list** \(^{510}\) attribute, or if there is no element with that **ID**, or if the first element with that **ID** is not a **datalist** \(^{525}\) element, then there is no **suggestions source element** \(^{510}\).

If there is a **suggestions source element** \(^{510}\), then, when the user agent is allowing the user to edit the **input** \(^{547}\) element's **value** \(^{547}\), the user agent should offer the suggestions represented by the **suggestions source element** \(^{510}\) to the user in a manner suitable for the
type of control used. If appropriate, the user agent should use the suggestion's label and value to identify the suggestion to the user.

User agents are encouraged to filter the suggestions represented by the suggestions source element when the number of suggestions is large, including only the most relevant ones (e.g. based on the user's input so far). No precise threshold is defined, but capping the list at four to seven values is reasonable. If filtering based on the user's input, user agents should use substring matching against both the suggestions' label and value.

How user selections of suggestions are handled depends on whether the element is a control accepting a single value only, or whether it accepts multiple values:

↪ If the element does not have a multiple attribute specified or if the multiple attribute does not apply, When the user selects a suggestion, the input element's value must be set to the selected suggestion's value, as if the user had written that value themself.

↪ If the element's type attribute is in the Email state and the element has a multiple attribute specified, When the user selects a suggestion, the user agent must either add a new entry to the input element's values, whose value is the selected suggestion's value, or change an existing entry in the input element's values to have the value given by the selected suggestion's value, as if the user had themself added an entry with that value, or edited an existing entry to be that value. Which behavior is to be applied depends on the user interface in a user-agent-defined manner.

If the list attribute does not apply, there is no suggestions source element.

Example

This text field allows you to choose a type of JavaScript function.

```
<input type="text" list="function-types">
<datalist id="function-types">
  <option value="function">function
  <option value="async function">async function
  <option value="function*">generator function
  <option value="=>">arrow function
  <option value="async =>">async arrow function
  <option value="async function*">async generator function
</datalist>
```

For user agents that follow the above suggestions, both the label and value would be shown:

```
function
async function
function*
=>
async =>
async function*
```

Then, typing "arrow" or "=>" would filter the list to the entries with labels "arrow function" and "async arrow function". Typing "generator" or "*" would filter the list to the entries with labels "generator function" and "async generator function".

Example

As always, user agents are free to make user interface decisions which are appropriate for their particular requirements and for the user's particular circumstances. However, this has historically been an area of confusion for implementers, web developers, and users alike, so we've given some "should" suggestions above.

How user selections of suggestions are handled depends on whether the element is a control accepting a single value only, or whether it accepts multiple values:

↪ If the element does not have a multiple attribute specified or if the multiple attribute does not apply, When the user selects a suggestion, the input element's value must be set to the selected suggestion's value, as if the user had written that value themself.

↪ If the element's type attribute is in the Email state and the element has a multiple attribute specified, When the user selects a suggestion, the user agent must either add a new entry to the input element's values, whose value is the selected suggestion's value, or change an existing entry in the input element's values to have the value given by the selected suggestion's value, as if the user had themself added an entry with that value, or edited an existing entry to be that value. Which behavior is to be applied depends on the user interface in a user-agent-defined manner.

If the list attribute does not apply, there is no suggestions source element.
This URL field offers some suggestions.

```html
<label>Homepage: <input name=hp type=url list=hpurls></label>
<datalist id=hpurls>
  <option value="https://www.google.com/" label="Google">
  <option value="https://www.reddit.com/" label="Reddit">
</datalist>
```

Other URLs from the user’s history might show also; this is up to the user agent.

Example

This example demonstrates how to design a form that uses the autocompletion list feature while still degrading usefully in legacy user agents.

If the autocompletion list is merely an aid, and is not important to the content, then simply using a `datalist` element with children `option` elements is enough. To prevent the values from being rendered in legacy user agents, they need to be placed inside the `value` attribute instead of inline.

```html
<p>
  <label>
    Enter a breed:
    <input type=text name=breed list=breeds>
  </label>
  <datalist id=breeds>
  
  </datalist>
</p>
```

However, if the values need to be shown in legacy UAs, then fallback content can be placed inside the `datalist` element, as follows:

```html
<p>
  <label>
    Enter a breed:
    <input type=text name=breed list=breeds>
  </label>
  <datalist id=breeds>
    <label>
      or select one from the list:
      <select name=breed>
        <option value="">(none selected)
        <option>Abyssinian
        <option>Alpaca
      <!-- ... -->
    </select>
  </label>
</datalist>
</p>
```

The fallback content will only be shown in UAs that don’t support `datalist`. The options, on the other hand, will be detected by all UAs, even though they are not children of the `datalist` element.

Note that if an `option` element used in a `datalist` is `selected`, it will be selected by default by legacy UAs (because it affects the `select` element, but it will not have any effect on the `input` element in UAs that support `datalist`.)
4.10.5.3.10 The `placeholder` attribute.

The `placeholder` attribute represents a short hint (a word or short phrase) intended to aid the user with data entry when the control has no value. A hint could be a sample value or a brief description of the expected format. The attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The `placeholder` attribute should not be used as an alternative to a `label`. For a longer hint or other advisory text, the `title` attribute is more appropriate.

User agents should present this hint to the user, after having stripped newlines from it, when the element’s `value` is the empty string, especially if the control is not focused.

If a user agent normally doesn’t show this hint to the user when the control is focused, then the user agent should nonetheless show the hint for the control if it was focused as a result of the `autofocus` attribute, since in that case the user will not have had an opportunity to examine the control before focusing it.

Example

Here is an example of a mail configuration user interface that uses the `placeholder` attribute:

```html
<fieldset>
  <legend>Mail Account</legend>
  <p><label>Name: <input type="text" name="fullname" placeholder="John Ratzenberger"></label></p>
  <p><label>Address: <input type="email" name="address" placeholder="john@example.net"></label></p>
  <p><label>Password: <input type="password" name="password"></label></p>
  <p><label>Description: <input type="text" name="desc" placeholder="My Email Account"></label></p>
</fieldset>
```

Example

In situations where the control's content has one directionality but the placeholder needs to have a different directionality, Unicode's bidirectional-algorithm-formating characters can be used in the attribute value:

```html
<input name=t1 type=tel placeholder="\u0643\u0627\u0631\u0628\u0646 1 رقم الهاتف"/>
<input name=t2 type=tel placeholder="\u0643\u0627\u0631\u0628\u0646 2 رقم الهاتف"/>
```

For slightly more clarity, here’s the same example using numeric character references instead of inline Arabic:

```html
<input name=t1 type=tel placeholder="\#x202B;\#x1585;\#1602;\#1605;\#1575;\#1604;\#1607;\#1575;\#1578;\#1601;1\#x202E;"/>
<input name=t2 type=tel placeholder="\#x202B;\#x1585;\#1602;\#1605;\#1575;\#1604;\#1607;\#1575;\#1578;\#1601;2\#x202E;"/>
```

4.10.5.4 Common `input` element APIs

```javascript
input .value [ = value ]
```

Returns the current `value` of the form control. Can be set, to change the value. Throws an `InvalidStateError` `DOMException` if it is set to any value other than the empty string when the control is a file upload control.
The value IDL attribute allows scripts to manipulate the value of an `input` element. The attribute is in one of the following modes, which define its behavior:

**value**

On getting, return the current value of the element.

On setting:

1. Let oldValue be the element's value.
2. Set the element's value to the new value.
3. Set the element's dirty value flag to true.
4. Invoke the value sanitization algorithm, if the element's type attribute's current state defines one.
5. If the element's value (after applying the value sanitization algorithm) is different from oldValue, and the element has a text entry cursor position, move the text entry cursor position to the end of the text control, unselecting any selected text and resetting the selection direction to "none".

**default**

On getting, if the element has a value content attribute, return that attribute's value; otherwise, return the empty string.

On setting, set the value of the element's value content attribute to the new value.

**default/on**

On getting, if the element has a value content attribute, return that attribute's value; otherwise, return the string "on".

On setting, set the value of the element's value content attribute to the new value.
On getting, return the string "C:\fakepath\" followed by the name of the first file in the list of selected files, if any, or the empty string if the list is empty.

On setting, if the new value is the empty string, empty the list of selected files; otherwise, throw an "InvalidStateError" DOMException.

**Note**

This "fakepath" requirement is a sad accident of history. See the example in the File Upload state section for more information.

**Note**

Since path components are not permitted in file names in the list of selected files, the "(fakepath)" cannot be mistaken for a path component.

The checked IDL attribute allows scripts to manipulate the checkedness of an input element. On getting, it must return the current checkedness of the element; and on setting, it must set the element's checkedness to the new value and set the element's dirty checkedness flag to true.

The files IDL attribute allows scripts to access the element's selected files.

On getting, if the IDL attribute applies, it must return a FileList object that represents the current selected files. The same object must be returned until the list of selected files changes. If the IDL attribute does not apply, then it must instead return null.

On setting, it must run these steps:

1. If the IDL attribute does not apply or the given value is null, then return.
2. Replace the element's selected files with the given value.

The valueAsDate IDL attribute represents the value of the element, interpreted as a date.

On getting, if the valueAsDate attribute does not apply, as defined for the input element's type attribute's current state, then return null. Otherwise, run the algorithm to convert a string to a Date object, defined for that state to the element's value; if the algorithm returned a Date object, then return it, otherwise, return null.

On setting, if the new value is infinite, then throw a TypeError exception. Otherwise, if the valueAsDate attribute does not apply, as defined for the input element's type attribute's current state, then throw an "InvalidStateError" DOMException; otherwise, if the new value is not null and not a Date object throw a TypeError exception; otherwise if the new value is null or a Date object representing the NaN time value, then set the value of the element to the empty string; otherwise, run the algorithm to convert a Date object to a string, as defined for that state, on the new value, and set the value of the element to the resulting string.

The valueAsNumber IDL attribute represents the value of the element, interpreted as a number.

On getting, if the valueAsNumber attribute does not apply, as defined for the input element's type attribute's current state, then return a Not-a-Number (NaN) value. Otherwise, run the algorithm to convert a string to a number, defined for that state to the element's value; if the algorithm returned a number, then return it, otherwise, return a Not-a-Number (NaN) value.

On setting, if the new value is infinite, then throw a TypeError exception. Otherwise, if the valueAsNumber attribute does not apply, as defined for the input element's type attribute's current state, then throw an "InvalidStateError" DOMException. Otherwise, if the new value is a Not-a-Number (NaN) value, then set the value of the element to the empty string. Otherwise, run the algorithm to convert a number to a string, as defined for that state, on the new value, and set the value of the element to the resulting string.

The stepDown(n) and stepUp(n) methods, when invoked, must run the following algorithm:

1. If the stepDown() and stepUp() methods do not apply, as defined for the input element's type attribute's...
current state, then throw an "InvalidStateError" DOMException.

2. If the element has no allowed value step\(^{510}\), then throw an "InvalidStateError" DOMException.

3. If the element has a minimum\(^{509}\) and a maximum\(^{509}\) and the minimum\(^{509}\) is greater than the maximum\(^{509}\), then return.

4. If the element has a minimum\(^{509}\) and a maximum\(^{509}\) and there is no value greater than or equal to the element’s minimum\(^{509}\) and less than or equal to the element’s maximum\(^{509}\) that, when subtracted from the step base\(^{510}\), is an integral multiple of the allowed value step\(^{516}\), then return.

5. If applying the algorithm to convert a string to a number\(^{480}\) to the string given by the element’s value\(^{547}\) does not result in an error, then let value be the result of that algorithm. Otherwise, let value be zero.

6. Let valueBeforeStepping be value.

7. If value subtracted from the step base\(^{510}\) is not an integral multiple of the allowed value step\(^{510}\), then set value to the nearest value that, when subtracted from the step base\(^{510}\), is an integral multiple of the allowed value step\(^{510}\), and that is less than value if the method invoked was the stepDown()\(^{515}\) method, and more than value otherwise. Otherwise (value subtracted from the step base\(^{510}\) is an integral multiple of the allowed value step\(^{516}\)):
   1. Let n be the argument.
   2. Let delta be the allowed value step\(^{510}\) multiplied by n.
   3. If the method invoked was the stepDown()\(^{515}\) method, negate delta.
   4. Let value be the result of adding delta to value.

8. If the element has a minimum\(^{509}\), and value is less than that minimum\(^{509}\), then set value to the smallest value that, when subtracted from the step base\(^{510}\), is an integral multiple of the allowed value step\(^{510}\), and that is more than or equal to minimum.

9. If the element has a maximum\(^{509}\) and value is greater than that maximum\(^{509}\), then set value to the largest value that, when subtracted from the step base\(^{510}\), is an integral multiple of the allowed value step\(^{510}\), and that is less than or equal to maximum.

10. If either the method invoked was the stepDown()\(^{515}\) method and value is greater than valueBeforeStepping, or the method invoked was the stepUp()\(^{515}\) method and value is less than valueBeforeStepping, then return.

**Example**

This ensures that invoking the stepUp()\(^{515}\) method on the input\(^{476}\) element in the following example does not change the value\(^{547}\) of that element:

```html
<input type="number" value="1" max="0">
```

11. Let value as string be the result of running the algorithm to convert a number to a string\(^{480}\), as defined for the input\(^{476}\) element’s type\(^{478}\) attribute’s current state, on value.

12. Set the value\(^{547}\) of the element to value as string.

The list IDL attribute must return the current suggestions source element\(^{510}\), if any, or null otherwise.

### 4.10.5.5 Common event behaviors\(^5^{61}\)

When the input\(^{41217}\) and change\(^{41216}\) events apply\(^{479}\) (which is the case for all input\(^{476}\) controls other than buttons\(^{478}\) and those with the type\(^{479}\) attribute in the Hidden\(^{482}\) state), the events are fired to indicate that the user has interacted with the control. The input\(^{41217}\) event fires whenever the user has modified the data of the control. The change\(^{41216}\) event fires when the value is committed, if that makes sense for the control, or else when the control loses focus\(^{749}\). In all cases, the input\(^{41217}\) event comes before the corresponding change\(^{41216}\) event (if any).

When an input\(^{476}\) element has a defined input activation behavior\(^{480}\), the rules for dispatching these events, if they apply\(^{479}\), are
given in the section above that defines the `type` attribute's state. (This is the case for all `input` controls with the `type` attribute in the `Checkbox` state, the `Radio Button` state, or the `File Upload` state.)

For `input` elements without a defined `input activation behavior`, but to which these events apply, and for which the user interface involves both interactive manipulation and an explicit commit action, then when the user changes the element's `value`, the user agent must `queue a task` to fire an event named `input` at the `input` element, with the `bubbles` attribute initialized to true, and any time the user commits the change, the user agent must `queue a task` to fire an event named `change` at the `input` element, with the `bubbles` attribute initialized to true.

Example

An example of a user interface involving both interactive manipulation and a commit action would be a `Range` controls that use a slider, when manipulated using a pointing device. While the user is dragging the control's knob, `input` events would fire whenever the position changed, whereas the `change` event would only fire when the user let go of the knob, committing to a specific value.

For `input` elements without a defined `input activation behavior`, but to which these events apply, and for which the user interface involves an explicit commit action but no intermediate manipulation, then any time the user commits a change to the element's `value`, the user agent must `queue a task` to fire an event named `input` at the `input` element, with the `bubbles` attribute initialized to true, and then fire an event named `change` at the `input` element, with the `bubbles` attribute initialized to true.

Example

An example of a user interface with a commit action would be a `Color` control that consists of a single button that brings up a color wheel: if the `value` only changes when the dialog is closed, then that would be the explicit commit action. On the other hand, if manipulating the control changes the color interactively, then there might be no commit action.

Example

Another example of a user interface with a commit action would be a `Date` control that allows both text-based user input and user selection from a drop-down calendar: while text input might not have an explicit commit step, selecting a date from the drop down calendar and then dismissing the drop down would be a commit action.

For `input` elements without a defined `input activation behavior`, but to which these events apply, any time the user causes the element's `value` to change without an explicit commit action, the user agent must `queue a task` to fire an event named `input` at the `input` element, with the `bubbles` attribute initialized to true. The corresponding `change` event, if any, will be fired when the control loses focus.

Example

Examples of a user changing the element's `value` would include the user typing into a text control, pasting a new value into the control, or undoing an edit in that control. Some user interactions do not cause changes to the value, e.g., hitting the "delete" key in an empty text control, or replacing some text in the control with text from the clipboard that happens to be exactly the same text.

Example

A `Range` control in the form of a slider that the user has focused and is interacting with using a keyboard would be another example of the user changing the element's `value` without a commit step.

In the case of `task` that just fire an `input` event, user agents may wait for a suitable break in the user's interaction before `queueing` the tasks; for example, a user agent could wait for the user to have not hit a key for 100ms, so as to only fire the event when the user pauses, instead of continuously for each keystroke.

When the user agent is to change an `input` element's `value` on behalf of the user (e.g. as part of a form prefilling feature), the user agent must `queue a task` to first update the `value` accordingly, then fire an event named `input` at the `input` element, with the `bubbles` attribute initialized to true, then fire an event named `change` at the `input` element, with the `bubbles` attribute initialized to true.

Note

These events are not fired in response to changes made to the values of form controls by scripts. (This is to make it easier to update the values of form controls in response to the user manipulating the controls, without having to then filter out the script's own changes to avoid an infinite loop.)

The `task source` for these `task` is the `user interaction task source`.
4.10.6 The `button` element

**Categories**
- Flow content
- Phrasing content
- Interactive content
- Listed
- labelable
- submittable
- autocapitalize-inheriting
- form-associated element
- Palpable content

**Contexts in which this element can be used**: Where phrasing content is expected.

**Content model**: Phrasing content, but there must be no interactive content descendant.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**:
- Global attributes
  - autofocus — Automatically focus the form control when the page is loaded
  - disabled — Whether the form control is disabled
  - form — Associates the control with a form element
  - formaction — URL to use for form submission
  - formenctype — Entry list encoding type to use for form submission
  - formmethod — Variant to use for form submission
  - formnovalidate — Bypass form control validation for form submission
  - formtarget — Browsing context for form submission
  - name — Name of form control to use for form submission and in the form.elements API
  - type — Type of button
  - value — Value to be used for form submission

**DOM interface**:

```
IDL {Exposed=Window, HTMLConstructor}
interface HTMLButtonElement : HTMLElement {

  [CEReactions] attribute boolean autofocus;
  [CEReactions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute USVString formAction;
  [CEReactions] attribute DOMString formEncType;
  [CEReactions] attribute DOMString formMethod;
  [CEReactions] attribute boolean formNoValidate;
  [CEReactions] attribute DOMString formTarget;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute DOMString value;

  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  void setCustomValidity(DOMString error);

  readonly attribute ModelList labels;
};
```

The `button` element represents a button labeled by its contents.

The element is a `button`.

The `type` attribute controls the behavior of the button when it is activated. It is an enumerated attribute. The following table lists the
keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
<th>Brief description</th>
</tr>
</thead>
<tbody>
<tr>
<td>submit</td>
<td>Submit Button</td>
<td>Submits the form.</td>
</tr>
<tr>
<td>reset</td>
<td>Reset Button</td>
<td>Resets the form.</td>
</tr>
<tr>
<td>button</td>
<td>Button</td>
<td>Does nothing.</td>
</tr>
</tbody>
</table>

The missing value default and invalid value default are the Submit Button state.

If the type attribute is in the Submit Button state, the element is specifically a submit button.

**Constraint validation:** If the type attribute is in the Reset Button state or the Button state, the element is barred from constraint validation.

A button element's activation behavior is to run the steps defined in the following list for the current state of this element's type attribute, if this element is not disabled, and do nothing otherwise:

**Submit Button**
- If the element has a form owner and the element's node document is fully active, the element must submit the form owner from the button element.

**Reset Button**
- If the element has a form owner and the element's node document is fully active, the element must reset the form owner.

**Button**
- Do nothing.

The form attribute is used to explicitly associate the button element with its form owner. The name attribute represents the element's name. The disabled attribute is used to make the control non-interactive and to prevent its value from being submitted. The autofocus attribute controls focus. The formaction, formenctype, formmethod, formnovalidate, and formtarget attributes are attributes for form submission.

**Note**
- The formnovalidate attribute can be used to make submit buttons that do not trigger the constraint validation.

The formaction, formenctype, formmethod, formnovalidate, and formtarget attributes must not be specified if the element's type attribute is not in the Submit Button state.

The value attribute gives the element's value for the purposes of form submission. The element's value is the value of the element's value attribute, if there is one, or the empty string otherwise.

**Note**
- A button (and its value) is only included in the form submission if the button itself was used to initiate the form submission.

The value IDL attribute must reflect the content attribute of the same name.

The type IDL attribute must reflect the content attribute of the same name, limited to only known values.

The willValidate, validity, and validationMessage IDL attributes, and the checkValidity(), reportValidity(), and setCustomValidity() methods, are part of the constraint validation API. The labels IDL attribute provides a list of the element's label's. The autofocus, disabled, form, and name IDL attributes are part of the element's forms API.

**Example**
- The following button is labeled “Show hint” and pops up a dialog box when activated:

  ```html
  <button type=button
              onclick="alert('This 15-20 minute piece was composed by George Gershwin.')">
  ```
4.10.7 The `select` element

**Categories**
- Flow content
- Phrasing content
- Interactive content
- Listed, labelable, submittable, resettable, and autocapitalize-inheriting form-associated element.

**Contexts in which this element can be used**:
Where phrasing content is expected.

**Content model**
Zero or more `option`, `optgroup`, and script-supporting elements.

**Tag omission in text/html**
Neither tag is omissible.

**Content attributes**
- `autocomplete` — Hint for form autofill feature
- `autofocus` — Automatically focus the form control when the page is loaded
- `disabled` — Whether the form control is disabled
- `form` — Associates the control with a form element
- `multiple` — Whether to allow multiple values
- `name` — Name of form control to use for form submission and in the `form.elements` API
- `required` — Whether the control is required for form submission
- `size` — Size of the control

**DOM interface**

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLSelectElement : HTMLElement {
  [CEReactions] attribute DOMString autocomplete;
  [CEReactions] attribute boolean autofocus;
  [CEReactions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute boolean multiple;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute boolean required;
  [CEReactions] attribute unsigned long size;
  readonly attribute DOMString type;
  [SameObject] readonly attribute HTMLOptionsCollection options;
  [CEReactions] attribute unsigned long length;
  getter Element? item(unsigned long index);
  HTMLOptionElement? namedItem(DOMString name);
  [CEReactions] void add((HTMLOptionElement or HTMLOptGroupElement) element, optional (HTMLElement or long)? before = null);
  [CEReactions] void remove(); // ChildNode overload
  [CEReactions] void remove(long index);
  [CEReactions] setter void (unsigned long index, HTMLOptionElement? option);
```
```html
[SameObject] readonly attribute HTMLCollection selectedOptions;
attribute long selectedIndex;
attribute DOMString value;

readonly attribute boolean willValidate;
readonly attribute ValidityState validity;
readonly attribute DOMString validationMessage;
boolean checkValidity();
boolean reportValidity();
void setCustomValidity(DOMString error);

readonly attribute Modelist labels;
```

The `select` element represents a control for selecting amongst a set of options.

The `multiple` attribute is a boolean attribute<sup>66</sup>. If the attribute is present, then the `select` element represents<sup>629</sup> a control for selecting zero or more options from the list of options<sup>621</sup>. If the attribute is absent, then the `select` element represents<sup>620</sup> a control for selecting a single option from the list of options<sup>621</sup>.

The `size` attribute gives the number of options to show to the user. The `size` attribute, if specified, must have a value that is a valid non-negative integer<sup>446</sup> greater than zero.

The display size of a `select` element is the result of applying the rules for parsing non-negative integers<sup>66</sup> to the value of element's `size` attribute, if it has one and parsing it is successful. If applying those rules to the attribute's value is not successful, or if the `size` attribute is absent, then the element's display size<sup>621</sup> is 4 if the element's `multiple` content attribute is present, and 1 otherwise.

The list of options for a `select` element consists of all the `option` element children of the `select` element, and all the `option` element children of all the `optgroup` element children of the `select` element, in tree order.

The `required` attribute is a boolean attribute<sup>66</sup>. When specified, the user will be required to select a value before submitting the form.

If a `select` element has a `required` attribute specified, does not have a `multiple` attribute specified, and has a display size of 1; and if the `value` of the first `option` element in the `select` element's list of options (if any) is the empty string, and that `option` element's parent node is the `select` element (and not an `optgroup` element), then that `option` is the `select` element's placeholder label option.

If a `select` element has a `required` attribute specified, does not have a `multiple` attribute specified, and has a display size of 1, then the `select` element must have a placeholder label option.<sup>621</sup>

**Note**

In practice, the requirement stated in the paragraph above can only apply when a `select` element does not have a `size` attribute with a value greater than 1.

**Constraint validation:** If the element has its `required` attribute specified, and either none of the `option` elements in the `select` element's list of options have their `selectedness` set to true, or the only `option` element in the `select` element's list of options, with its `selectedness` set to true is the placeholder label option, then the element is suffering from being missing<sup>652</sup>.

If the `multiple` attribute is absent, and the element is not disabled<sup>652</sup>, then the user agent should allow the user to pick an `option` element in its list of options that is itself not disabled<sup>652</sup>. Upon this `option` element being picked (either through a click, or through unfocusing the element after changing its value), or through a menu command, or through any other mechanism), and before the relevant user interaction event is queued (e.g. before the click event), the user agent must set the selectedness of the picked `option` element to true, set its `dirtiness` to true, and then send select update notifications<sup>622</sup>.

If the `multiple` attribute is absent, whenever an `option` element in the `select` element's list of options has its selectedness set to true, and whenever an `option` element with its selectedness set to true is added to the `select` element's list of options, the user agent must set the selectedness of all the other `option` elements in its list of options to false.
If the `multiple` attribute is absent and the element's `display size` is greater than 1, then the user agent should also allow the user to request that the `option` whose `selectedness` is true, if any, be unselected. Upon this request being conveyed to the user agent, and before the relevant user interaction event is queued (e.g. before the `click` event), the user agent must set the `selectedness` of that `option` element to false, set its `dirtiness` to true, and then send `select update notifications`.

If nodes are inserted or nodes are removed causing the `list of options` to gain or lose one or more `option` elements, or if an `option` element in the `list of options` asks for a reset, then, if the `select` element's `multiple` attribute is absent, the user agent must run the first applicable set of steps from the following list:

- If the `select` element's `display size` is 1, and no `option` elements in the `select` element's `list of options` have their `selectedness` set to true
  - Set the `selectedness` of the first `option` element in the `list of options` in `tree order` that is not `disabled`, if any, to true.

- If two or more `option` elements in the `select` element's `list of options` have their `selectedness` set to true
  - Set the `selectedness` of all but the last `option` element with its `selectedness` set to true in the `list of options` in `tree order` to false.

If the `multiple` attribute is present, and the element is not `disabled`, then the user agent should allow the user to `toggle` the `selectedness` of the `option` elements in its `list of options` that are themselves not `disabled`. Upon such an element being `toggled` (either through a `click`, or through a `menu command`, or any other mechanism), and before the relevant user interaction event is queued (e.g. before a related `click` event), the `selectedness` of the `option` element must be changed (from true to false or false to true), the `dirtiness` of the element to true, and the user agent must `send select update notifications`.

When the user agent is to `send select update notifications`, `queue a task`, using the `user interaction task source`, to run these steps:

1. Fire an event named `input` at the `select` element, with the `bubbles` attribute initialized to true.
2. Fire an event named `change` at the `select` element, with the `bubbles` attribute initialized to true.

The `reset algorithm` for `select` elements is to go through all the `option` elements in the element's `list of options`, set their `selectedness` to true if the `option` element has a `selected` attribute, and false otherwise, set their `dirtiness` to false, and then have the `option` elements `ask for a reset`.

The `form` attribute is used to explicitly associate the `select` element with its `form owner`. The `name` attribute represents the element's name. The `disabled` attribute is used to make the control non-interactive and to prevent its value from being submitted. The `autofocus` attribute controls focus. The `autocomplete` attribute controls how the user agent provides autofill behavior.

A `select` element that is not `disabled` is `mutable`.

For web developers (non-normative)

```plaintext
select . type
Returns "select-multiple" if the element has a `multiple` attribute, and "select-one" otherwise.

select . options
Returns an `HTMLOptionsCollection` of the `list of options`.

select . length [ = value ]
Returns the number of elements in the `list of options`.
When set to a smaller number, truncates the number of `option` elements in the `select`.
When set to a greater number, adds new blank `option` elements to the `select`.

element = select . item (index)
select[index]
Returns the item with index `index` from the `list of options`. The items are sorted in `tree order`.
```
The type IDL attribute, on getting, must return the string "select-one" if the multiple attribute is absent, and the string "select-multiple" if the multiple attribute is present.

The options IDL attribute must return an HTMLSelectElement object. The supported property indices at any instant are the indices supported by the object returned by the options attribute at that instant.

The length IDL attribute must return the number of nodes represented by the options collection. On setting, it must act like the attribute of the same name on the options collection.

The item(index) method must return the value returned by the method of the same name on the options collection, when invoked with the same argument.

The namedItem(name) method must return the value returned by the method of the same name on the options collection, when invoked with the same argument.

When the user agent is to set the value of a new indexed property or set the value of an existing indexed property for a select element, it must instead run the corresponding algorithm on the select element's options collection.

Similarly, the add() method must act like its namesake method on that same options collection.

The remove() method must act like its namesake method on that same options collection when it has arguments, and like its namesake method on the ChildNode interface implemented by the HTMLSelectElement ancestor interface Element when it has no arguments.

The selectedOptions IDL attribute must return an HTMLCollection of the list of options that have their selectedness set to true.

The selectedIndex IDL attribute, on getting, must return the index of the first selected item, if any, or −1 if there is no selected item. Can be set, to change the selection.

The selectedOptions collection is also mirrored on the HTMLSelectElement object. The supported property indices at any instant are the indices supported by the object returned by the options attribute at that instant.

The length IDL attribute must return the number of nodes represented by the options collection. On setting, it must act like the attribute of the same name on the options collection.

The item(index) method must return the value returned by the method of the same name on the options collection, when invoked with the same argument.

The namedItem(name) method must return the value returned by the method of the same name on the options collection, when invoked with the same argument.

When the user agent is to set the value of a new indexed property or set the value of an existing indexed property for a select element, it must instead run the corresponding algorithm on the select element's options collection.

Similarly, the add() method must act like its namesake method on that same options collection.

The remove() method must act like its namesake method on that same options collection when it has arguments, and like its namesake method on the ChildNode interface implemented by the HTMLSelectElement ancestor interface Element when it has no arguments.

The selectedOptions IDL attribute must return an HTMLCollection of the list of options that have their selectedness set to true.

The selectedIndex IDL attribute, on getting, must return the index of the first selected item, if any, or −1 if there is no selected item. Can be set, to change the selection.
selectedness\textsuperscript{p529} set to true and its dirtiness\textsuperscript{p539} set to true.

**Note**

This can result in no element having a selectedness\textsuperscript{p529} set to true even in the case of the select\textsuperscript{p520} element having no multiple\textsuperscript{p521} attribute and a display size\textsuperscript{p521} of 1.

The value IDL attribute, on getting, must return the value\textsuperscript{p529} of the first option\textsuperscript{p528} element in the list of options\textsuperscript{p521} in tree order that has its selectedness\textsuperscript{p529} set to true, if any. If there isn't one, then it must return the empty string.

On setting, the value\textsuperscript{p524} attribute must set the selectedness\textsuperscript{p529} of all the option\textsuperscript{p528} elements in the list of options\textsuperscript{p521} to false, and then the first option\textsuperscript{p528} element in the list of options\textsuperscript{p521}, in tree order, whose value\textsuperscript{p529} is equal to the given new value, if any, must have its selectedness\textsuperscript{p529} set to true and its dirtiness\textsuperscript{p529} set to true.

**Note**

This can result in no element having a selectedness\textsuperscript{p529} set to true even in the case of the select\textsuperscript{p520} element having no multiple\textsuperscript{p521} attribute and a display size\textsuperscript{p521} of 1.

The multiple, required, and size IDL attributes must reflect\textsuperscript{p90} the respective content attributes of the same name. The size\textsuperscript{p524} IDL attribute has a default value of zero.

**Note**

For historical reasons, the default value of the size\textsuperscript{p524} IDL attribute does not return the actual size used, which, in the absence of the size\textsuperscript{p521} content attribute, is either 1 or 4 depending on the presence of the multiple\textsuperscript{p521} attribute.

The willValidate\textsuperscript{p575}, validity\textsuperscript{p575}, and validationMessage\textsuperscript{p577} IDL attributes, and the checkValidity()\textsuperscript{p576}, reportValidity()\textsuperscript{p576} and setCustomValidity()\textsuperscript{p577} methods, are part of the constraint validation API\textsuperscript{p574}. The label\textsuperscript{p475} IDL attribute provides a list of the element's label\textsuperscript{p475}s. The autofocus\textsuperscript{p555}, disabled\textsuperscript{p552}, form\textsuperscript{p549}, and name\textsuperscript{p550} IDL attributes are part of the element's forms API.

**Example**

The following example shows how a select\textsuperscript{p528} element can be used to offer the user with a set of options from which the user can select a single option. The default option is preselected.

```html
<p>
  <label for="unittype">Select unit type:</label>
  <select id="unittype" name="unittype">
    <option value="1">Miner</option>
    <option value="2">Puffer</option>
    <option value="3" selected>Snipey</option>
    <option value="4">Max</option>
    <option value="5">Firebot</option>
  </select>
</p>
```

When there is no default option, a placeholder can be used instead:

```html
<select name="unittype" required>
  <option value="">Select unit type</option>
  <option value="1">Miner</option>
  <option value="2">Puffer</option>
  <option value="3">Snipey</option>
  <option value="4">Max</option>
  <option value="5">Firebot</option>
</select>
```

**Example**

Here, the user is offered a set of options from which they can select any number. By default, all five options are selected.

```html
<p>
</p>
```
<label for="allowedunits">Select unit types to enable on this map:</label>
<select id="allowedunits" name="allowedunits" multiple>
  <option value="1" selected> Miner </option>
  <option value="2" selected> Puffer </option>
  <option value="3" selected> Snipey </option>
  <option value="4" selected> Max </option>
  <option value="5" selected> Firebot </option>
</select>

Sometimes, a user has to select one or more items. This example shows such an interface.

<label>
  Select the songs from that you would like on your Act II Mix Tape:
  <select multiple required name="act2">
    <option value="s1">It Sucks to Be Me (Reprise)</option>
    <option value="s2">There is Life Outside Your Apartment</option>
    <option value="s3">The More You Ruv Someone</option>
    <option value="s4">Schadenfreude</option>
    <option value="s5">I Wish I Could Go Back to College</option>
    <option value="s6">The Money Song</option>
    <option value="s7">School for Monsters</option>
    <option value="s8">The Money Song (Reprise)</option>
    <option value="s9">There's a Fine, Fine Line (Reprise)</option>
    <option value="s10">What Do You Do With a B.A. in English? (Reprise)</option>
    <option value="s11">For Now</option>
  </select>
</label>

### 4.10.8 The `datalist` element

**Categories**

- Flow content
- Phrasing content

**Contexts in which this element can be used:**

Where phrasing content is expected.

**Content model:**

Either: phrasing content.

Or: Zero or more option and script-supporting elements.

**Tag omission in text/html:**

Neither tag is omissible.

**Content attributes:**

Global attributes

**DOM interface:**

```javascript
IDL
[Exposed=Window, HTMLConstructor]
interface HTMLDataListElement : HTMLElement {
  [SameObject] readonly attribute HTMLCollection options;
};
```
The `datalist` element represents a set of `option` elements that represent predefined options for other controls. In the rendering, the `datalist` element represents nothing and it, along with its children, should be hidden.

The `datalist` element can be used in two ways. In the simplest case, the `datalist` element has just `option` children.

In the more elaborate case, the `datalist` element can be given contents that are to be displayed for down-level clients that don't support `datalist`. In this case, the `option` elements are provided inside a `select` element inside the `datalist` element.

The `datalist` element is hooked up to an `input` element using the `list` attribute on the `input` element. Each `option` element that is a descendant of the `datalist` element, that is not disabled, and whose `value` is a string that isn't the empty string, represents a suggestion. Each suggestion has a `value` and a `label`.

**For web developers (non-normative)**

```
<datalist id=sexes>
  <option value="Female">Female</option>
  <option value="Male">Male</option>
</datalist>
```

The `options` IDL attribute must return an `HTMLCollection` rooted at the `datalist node`, whose filter matches `option` elements.

**Constraint validation**: If an element has a `datalist` element ancestor, it is barred from constraint validation.

---

4.10.9 The `optgroup` element

**Categories**: None.

**Contexts in which this element can be used**: As a child of a `select` element.
Content model:
Zero or more option and script-supporting elements.

Tag omission in text/html:
An optgroup element's end tag can be omitted if the optgroup element is immediately followed by another optgroup element, or if there is no more content in the parent element.

Content attributes:
- Global attributes: disabled — Whether the form control is disabled
  label — User-visible label

DOM interface:

```idl
[Exposed=Window,
  HTMLConstructor]
interface HTMLOptGroupElement : HTMLElement {
  [CEReactions] attribute boolean disabled;
  [CEReactions] attribute DOMString label;
};
```

The optgroup element represents a group of option elements with a common label.

The element's group of option elements consists of the option elements that are children of the optgroup element.

When showing option elements in select elements, user agents should show the option elements of such groups as being related to each other and separate from other option elements.

The disabled attribute is a boolean attribute and can be used to disable a group of option elements together.

The label attribute must be specified. Its value gives the name of the group, for the purposes of the user interface. User agents should use this attribute's value when labeling the group of option elements in a select element.

The disabled and label attributes must reflect the respective content attributes of the same name.

Note:
There is no way to select an optgroup element. Only option elements can be selected. An optgroup element merely provides a label for a group of option elements.

Example:
The following snippet shows how a set of lessons from three courses could be offered in a select drop-down widget:

```html
<form action="courseselector.dll" method="get">
  <p>Which course would you like to watch today?</p>
  <label>Course:
    <select name="c">
      <optgroup label="8.01 Physics I: Classical Mechanics">
        <option value="8.01.1">Lecture 01: Powers of Ten</option>
        <option value="8.01.2">Lecture 02: 1D Kinematics</option>
        <option value="8.01.3">Lecture 03: Vectors</option>
      </optgroup>
      <optgroup label="8.02 Electricity and Magnetism">
        <option value="8.02.1">Lecture 01: What holds our world together?</option>
        <option value="8.02.2">Lecture 02: Electric Field</option>
        <option value="8.02.3">Lecture 03: Electric Flux</option>
      </optgroup>
      <optgroup label="8.03 Physics III: Vibrations and Waves">
        <option value="8.03.1">Lecture 01: Periodic Phenomenon</option>
        <option value="8.03.2">Lecture 02: Beats</option>
        <option value="8.03.3">Lecture 03: Forced Oscillations with Damping</option>
      </optgroup>
    </select>
  </label>
</form>
```
4.10.10 The option element

**Categories**
None.

**Contexts in which this element can be used**
- As a child of a select element.
- As a child of a datalist element.
- As a child of an optgroup element.

**Content model**
- If the element has a label attribute and a value attribute: Nothing.
- If the element has a label attribute but no value attribute: Text.
- If the element has no label attribute and is not a child of a datalist element: Text that is not inter-element whitespace.
- If the element has no label attribute and is a child of a datalist element: Text.

**Tag omission in text/html**
An option element's end tag can be omitted if the option element is immediately followed by another option element, or if it is immediately followed by an optgroup element, or if there is no more content in the parent element.

**Content attributes**
- **disabled** — Whether the form control is disabled
- **label** — User-visible label
- **selected** — Whether the option is selected by default
- **value** — Value to be used for form submission

**DOM interface**:

```html
IDL
[Exposed=Window, HTMLConstructor,
NamedConstructor=Option(optional DOMString text = "", optional DOMString value, optional boolean defaultSelected = false, optional boolean selected = false)]
interface HTMLOptionElement : HTMLElement {
[CFReactions] attribute boolean disabled;
readonly attribute HTMLFormElement? form;
[CFReactions] attribute DOMString label;
[CFReactions] attribute boolean defaultSelected;
attribute boolean selected;
[CFReactions] attribute DOMString value;

[CFReactions] attribute DOMString text;
readonly attribute long index;
};
```

The option element represents an option in a select element or as part of a list of suggestions in a datalist element.

In certain circumstances described in the definition of the select element, an option element can be a select element's placeholder label option. A placeholder label option does not represent an actual option, but instead represents a label for the select control.

The disabled attribute is a boolean attribute. An option element is disabled if its disabled attribute is present or if it is a child of an optgroup element whose disabled attribute is present.

An option element that is disabled must prevent any click events that are queued on the user interaction task source.
from being dispatched on the element.

The label attribute provides a label for element. The label of an option element is the value of the label content attribute, if there is one and its value is not the empty string, or, otherwise, the value of the element's text IDL attribute.

The label content attribute, if specified, must not be empty.

The value attribute provides a value for element. The value of an option element is the value of the value content attribute, if there is one, or, if there is not, the value of the element's text IDL attribute.

The selected attribute is a boolean attribute. It represents the default selectedness of the element.

The dirtiness of an option element is a boolean state, initially false. It controls whether adding or removing the selected content attribute has any effect.

The selectedness of an option element is a boolean state, initially false. Except where otherwise specified, when the element is created, its selectedness must be set to true if the element has a selected attribute. Whenever an option element's selected attribute is added, if its dirtiness is false, its selectedness must be set to true. Whenever an option element's selected attribute is removed, if its dirtiness is false, its selectedness must be set to false.

A select element whose multiple attribute is not specified must not have more than one descendant option element with its selected attribute set.

An option element's index is the number of option elements that are in the same list of options but that come before it in tree order. If the option element is not in a list of options, then the option element's index is zero.

For web developers (non-normative)

```javascript
option . selected

Returns true if the element is selected, and false otherwise.

Can be set, to override the current state of the element.

option . index

Returns the index of the element in its select element's options list.

option . form

Returns the element's form element, if any, or null otherwise.

option . text

Same as textContent, except that spaces are collapsed and script elements are skipped.

option = new Option([ text [, value [, defaultSelected [, selected ] ]]])

Returns a new option element.

The text argument sets the contents of the element.

The value argument sets the value attribute.

The defaultSelected argument sets the selected attribute.

The selected argument sets whether or not the element is selected. If it is omitted, even if the defaultSelected argument is true, the element is not selected.
```

The disabled IDL attribute must reflect the content attribute of the same name. The defaultSelected IDL attribute must reflect the selected content attribute.

The label IDL attribute, on getting, if there is a label content attribute, must return that attribute's value; otherwise, it must return the element's label. On setting, the element's label content attribute must be set to the new value.
The value IDL attribute, on getting, must return the element's value content attribute must be set to the new value.

The selected IDL attribute, on getting, must return true if the element's selectedness is true, and false otherwise. On setting, it must set the element's selectedness to the new value, set its dirtiness to true, and then cause the element to ask for a reset.

The index IDL attribute must return the element's index.

The text IDL attribute, on getting, must return the result of stripping and collapsing ASCII whitespace from the concatenation of data of all the Text node descendants of the option element, in tree order, excluding any that are descendants of descendants of the option that are themselves script or SVG script elements.

On setting, the text attribute must act as if the textContent IDL attribute on the element had been set to the new value.

The form IDL attribute's behavior depends on whether the option element is in a select element or not. If the option has a select element as its parent, or has an optgroup element as its parent and that optgroup element has a select element as its parent, then the form IDL attribute must return the same value as the form IDL attribute on that select element. Otherwise, it must return null.

A constructor is provided for creating HTMLOptionElement objects (in addition to the factory methods from DOM such as createElement()). Option(text, value, defaultSelected, selected). When invoked, the constructor must perform the following steps:

1. Let document be the current global object's associated Document.
2. Let option be the result of creating an element given document, option, and the HTML namespace.
3. If text is not the empty string, then append to option a new Text node whose data is text.
4. If value is given, then set an attribute value for option using "value" and value.
5. If defaultSelected is true, then set an attribute value for option using "selected" and the empty string.
6. If selected is true, then set option's selectedness to true; otherwise set its selectedness to false (even if defaultSelected is true).
7. Return option.

4.10.11 The textarea element

Categories:
Flow content.
Phrasing content.
Interactive content.
Listed, labelable, submittable, resettable, and autocapitalize-inheriting form-associated element.
Palpable content.

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
Text.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
Global attributes:
autocomplete — Hint for form autofill feature
autofocus — Automatically focus the form control when the page is loaded
cols — Maximum number of characters per line
dirname — Name of form control to use for sending the element's directionality in form submission
disabled — Whether the form control is disabled
form — Associates the control with a form element
The `textarea` element represents a multiline plain text edit control for the element's raw value. The contents of the control represent the control's default value.

The raw value of a `textarea` control must be initially the empty string.

**Note**

This element has rendering requirements involving the bidirectional algorithm.
The `readonly` attribute is a boolean attribute used to control whether the text can be edited by the user or not.

Example

In this example, a text control is marked read-only because it represents a read-only file:

```html
<code>/etc/bash.bashrc</code>

```html
<textarea name="buffer" readonly>
# System-wide .bashrc file for interactive bash(1) shells.

# To enable the settings / commands in this file for login shells as well,
# this file has to be sourced in /etc/profile.

# If not running interactively, don't do anything
[ -z "$PS1" ] && return

</textarea>
```

Constraint validation: If the `readonly` attribute is specified on a `textarea` element, the element is barred from constraint validation.

A `textarea` element is mutable if it is neither disabled nor has a `readonly` attribute specified.

When a `textarea` is mutable, its `raw value` should be editable by the user: the user agent should allow the user to edit, insert, and remove text, and to insert and remove line breaks in the form of U+000A LINE FEED (LF) characters. Any time the user causes the element's `raw value` to change, the user agent must queue a task to fire an event named `input` at the `textarea` element, with the `bubbles` attribute initialized to true. User agents may wait for a suitable break in the user's interaction before queuing the task; for example, a user agent could wait for the user to have not hit a key for 100ms, so as to only fire the event when the user pauses, instead of continuously for each keystroke.

A `textarea` element's `dirty value flag` must be set to true whenever the user interacts with the control in a way that changes the `raw value`.

The cloning steps for `textarea` elements must propagate the `raw value` and `dirty value flag` from the node being cloned to the copy.

The child text content change steps for `textarea` elements must, if the element's `dirty value flag` is false, set the element's `raw value` to its child text content.

The reset algorithm for `textarea` elements is to set the `dirty value flag` back to false, and set the `raw value` of element to its child text content.

When a `textarea` element is popped off the stack of open elements of an HTML parser or XML parser, then the user agent must invoke the element's reset algorithm.

If the element is mutable, the user agent should allow the user to change the writing direction of the element, setting it either to a left-to-right writing direction or a right-to-left writing direction. If the user does so, the user agent must then run the following steps:

1. Set the element's `dir` attribute to "ltr" if the user selected a left-to-right writing direction, and "rtl" if the user selected a right-to-left writing direction.

2. Queue a task to fire an event named `input` at the `textarea` element, with the `bubbles` attribute initialized to true.

The `cols` attribute specifies the expected maximum number of characters per line. If the `cols` attribute is specified, its value must be a valid non-negative integer greater than zero. If applying the rules for parsing non-negative integers to the attribute's value results in a number greater than zero, then the element's `character width` is that value; otherwise, it is 20.

The user agent may use the `textarea` element's `character width` as a hint to the user as to how many characters the server prefers per line (e.g. for visual user agents by making the width of the control be that many characters). In visual renderings, the user agent should wrap the user's input in the rendering so that each line is no wider than this number of characters.

The `rows` attribute specifies the number of lines to show. If the `rows` attribute is specified, its value must be a valid non-negative integer greater than zero. If applying the rules for parsing non-negative integers to the attribute's value results in a number greater than zero, then the element's `character width` is that value; otherwise, it is 20.

The user agent should use the `textarea` element's `character width` as a hint to the user as to how many characters the server prefers per line (e.g. for visual user agents by making the width of the control be that many characters). In visual renderings, the user agent should wrap the user's input in the rendering so that each line is no wider than this number of characters.
greater than zero, then the element's **character height** is that value; otherwise, it is 2.

Visual user agents should set the height of the control to the number of lines given by **character height**. The **wrap** attribute is an **enumerated attribute** with two keywords and states: the **soft** keyword which maps to the **Soft** state, and the **hard** keyword which maps to the **Hard** state. The **missing value default** and **invalid value default** are the **Soft** state.

The **Soft** state indicates that the text in the **textarea** is not to be wrapped when it is submitted (though it can still be wrapped in the rendering).

The **Hard** state indicates that the text in the **textarea** is to have newlines added by the user agent so that the text is wrapped when it is submitted.

If the element's **wrap** attribute is in the **Hard** state, the **cols** attribute must be specified.

For historical reasons, the element's value is normalized in three different ways for three different purposes. The **raw value** is the value as it was originally set. It is not normalized. The **API value** is the value used in the **value** IDL attribute, **textContent** IDL attribute, and by the **maxlength** and **minlength** content attributes. It is normalized so that line breaks use U+000A LINE FEED (LF) characters. Finally, there is the **value**, as used in form submission and other processing models in this specification. It is normalized so that line breaks use U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs, and in addition, if necessary given the element's **wrap** attribute, additional line breaks are inserted to wrap the text at the given width.

The algorithm for obtaining the element's **API value** is to return the element's **raw value** with the **textarea line break normalization transformation** applied. The **textarea line break normalization transformation** is the following algorithm, as applied to a string:

1. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair with a single U+000A LINE FEED (LF) character.
2. Replace every remaining U+000D CARRIAGE RETURN character with a single U+000A LINE FEED (LF) character.

The element's **value** is defined to be the element's **raw value** with the **textarea wrapping transformation** applied. The **textarea wrapping transformation** is the following algorithm, as applied to a string:

1. Replace every occurrence of a U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character, and every occurrence of a U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, by a two-character string consisting of a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair.
2. If the element's **wrap** attribute is in the **Hard** state, insert U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs into the string using a UA-defined algorithm so that each line has no more than **character width** characters. For the purposes of this requirement, lines are delimited by the start of the string, the end of the string, and U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs.

The **maxlength** attribute is a **form control**. If the **textarea** element has a **maximum allowed value length**, then the element's children must be such that the **JavaScript string length** of the value of the element's **textContent** IDL attribute with the **textarea line break normalization transformation** applied is equal to or less than the element's **maximum allowed value length**.

The **minlength** attribute is a **form control**. The **required** attribute is a **boolean attribute**. When specified, the user will be required to enter a value before submitting the form.

**Constraint validation**: If the element has its **required** attribute specified, and the element is **mutable**, and the element's **value** is the empty string, then the element is **suffering from being missing**.

The **placeholder** attribute represents a short hint (a word or short phrase) intended to aid the user with data entry when the control has no value. A hint could be a sample value or a brief description of the expected format.

The **placeholder** attribute should not be used as an alternative to a **label**. For a longer hint or other advisory text, the **title** attribute is more appropriate.

*Note: These mechanisms are very similar but subtly different: the hint given by the control's **label** is shown at all times; the short hint given in the **placeholder** attribute is shown before the user enters a value; and the hint in the **title** attribute is shown
User agents should present this hint to the user when the element's `value` is the empty string and the control is not `focused` (e.g. by displaying it inside a blank unfocused control). All U+000D CARRIAGE RETURN U+000A LINE FEED character pairs (CRLF) in the hint, as well as all other U+000D CARRIAGE RETURN (CR) and U+000A LINE FEED (LF) characters in the hint, must be treated as line breaks when rendering the hint.

The `name` attribute represents the element's name. The `dirname` attribute controls how the element's directionality is submitted. The `disabled` attribute is used to make the control non-interactive and to prevent its value from being submitted. The `form` attribute is used to explicitly associate the textarea element with its form owner. The `autoFocus` attribute controls focus. The `autocomplete` attribute controls how the user agent provides autofill behavior.

The `cols`, `placeholder`, `required`, `rows`, and `wrap` IDL attributes must reflect the respective content attributes of the same name. The `cols` and `rows` attributes are limited to only non-negative numbers greater than zero with fallback. The `cols` IDL attribute's default value is 20. The `rows` IDL attribute's default value is 2. The `dirName` IDL attribute must reflect the `dirname` content attribute. The `maxLength` IDL attribute must reflect the `maxlength` content attribute, limited to only non-negative numbers. The `minLength` IDL attribute must reflect the `minlength` content attribute, limited to only non-negative numbers.

The `readOnly` IDL attribute must reflect the `readonly` content attribute. The `type` IDL attribute must return the value "textarea". The `defaultValue` IDL attribute must, on getting, return the element's `child text content`. On setting, it must act as the setter for the element's `textContent` IDL attribute.

The `value` IDL attribute must, on getting, return the element's API value. On setting, it must perform the following steps:

1. Let `oldAPIValue` be this element's API value.
2. Set this element's `raw value` to the new value.
3. Set this element's `dirty value flag` to true.
4. If the new API value is different from `oldAPIValue`, then move the `text entry cursor position` to the end of the text control, unselecting any selected text and resetting the selection direction to "none".

The `textLength` IDL attribute must return the JavaScript string length of the element's api value.

The `willValidate`, `validity`, and `validationMessage` IDL attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the constraint validation API. The `labels` IDL attribute provides a list of the element's `label`'s. The `select()` method returns the `selectionStart`, `selectionEnd`, `selectionDirection`, `setRangeText()`, and `setSelectionRange()` methods and IDL attributes expose the element's text selection. The `autoFocus`, `disabled`, `form`, and `name` IDL attributes are part of the element's forms API.

Here is an example of a textarea being used for unrestricted free-form text input in a form:

```
<p>If you have any comments, please let us know: <textarea cols=80 name=comments></textarea></p>
```

To specify a maximum length for the comments, one can use the `maxlength` attribute:
If you have any short comments, please let us know:

```html
<textarea cols=80 name=comments maxlength=200></textarea>
```

To give a default value, text can be included inside the element:

```html
If you have any comments, please let us know: <textarea cols=80 name=comments>You rock!</textarea></p>
```

You can also give a minimum length. Here, a letter needs to be filled out by the user; a template (which is shorter than the minimum length) is provided, but is insufficient to submit the form:

```html
<textarea required minlength="500">Dear Madam Speaker,

Regarding your letter dated ... ... 

Yours Sincerely,

...</textarea>
```

A placeholder can be given as well, to suggest the basic form to the user, without providing an explicit template:

```html
<textarea placeholder="Dear Francine,

They closed the parks this week, so we won't be able to meet your there. Should we just have dinner?

Love, 

Daddy"></textarea>
```

To have the browser submit the directionality of the element along with the value, the `dirname` attribute can be specified:

```html
If you have any comments, please let us know (you may use either English or Hebrew for your comments):

<textarea cols=80 name=comments dirname=comments.dir></textarea></p>
```

### 4.10.12 The output element

**Categories:**

- Flow content
- Phrasing content
- Listed
- Labelable
- Resettable
- Autocapitalize-inheriting
- Form-associated element
- Palpable content

**Contexts in which this element can be used:**

Where phrasing content is expected.

**Content model:**

Phrasing content

**Tag omission in text/html:**

Neither tag is omissible.

**Content attributes:**

- Global attributes
- `for` — Specifies controls from which the output was calculated
form associates the control with a form element
name — Name of form control to use in the form.elements API

**DOM interface**:

```javascript
[Exposed=Window, HTMLConstructor]
interface HTMLOutputElement : HTMLElement {
    [SameObject, PutForwards=value] readonly attribute DOMTokenList htmlFor;
    readonly attribute HTMLFormElement? form;
    [CEReactions] attribute DOMString name;

    readonly attribute DOMString type;
    [CEReactions] attribute DOMString defaultValue;
    [CEReactions] attribute DOMString value;

    readonly attribute boolean willValidate;
    readonly attributeValidityState validity;
    readonly attribute DOMString validationMessage;
    boolean checkValidity();
    boolean reportValidity();
    void setCustomValidity(DOMString error);

    readonly attribute NodeList labels;
};
```

The **output** element represents the result of a calculation performed by the application, or the result of a user action.

**Note**

This element can be contrasted with the **samp** element, which is the appropriate element for quoting the output of other programs run previously.

The **for** content attribute allows an explicit relationship to be made between the result of a calculation and the elements that represent the values that went into the calculation or that otherwise influenced the calculation. The **for** attribute, if specified, must contain a string consisting of an unordered set of unique space-separated tokens that are case-sensitive, each of which must have the value of an ID of an element in the same tree.

The **form** attribute is used to explicitly associate the **output** element with its form. The **name** attribute represents the element's name. The **output** element is associated with a form so that it can be easily referenced from the event handlers of form controls; the element's value itself is not submitted when the form is submitted.

The element has a **value mode flag** which is either **value** or **default**. Initially, the **value mode flag** must be set to **default**.

The element also has a **default value**. Initially, the **default value** must be the empty string.

When the **value mode flag** is in mode **default**, the contents of the element represent both the value of the element and its **default value**. When the **value mode flag** is in mode **value**, the contents of the element represent the value of the element only, and the **default value** is only accessible using the **defaultValue** IDL attribute.

Whenever the element's descendants are changed in any way, if the **value mode flag** is in mode **default**, the element's **default value** must be set to the value of the element's **textContent** IDL attribute.

The **reset algorithm** for **output** elements is to set the element's **value mode flag** to **default**, and then to set the element's **textContent** IDL attribute to the value of the element's **default value** (thus replacing the element's child nodes).

**For web developers (non-normative)**

```
output.value [ = value ]
```

Returns the element's current value.

Can be set, to change the value.
The `defaultValue` IDL attribute must act like the element's `textContent` IDL attribute, except that on setting, in addition, before the child nodes are changed, the element's `value mode flag` must be set to `value`. On getting, must return the element's `default value`. On setting, the attribute must set the element's `default value`, and, if the element's `value mode flag` is in the mode `default`, set the element's `textContent` IDL attribute as well.

The `type` attribute must return the string "`output`".

The `htmlFor` IDL attribute must reflect the `for` content attribute.

The `willValidate`, `validity`, and `validationMessage` IDL attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the `constraint validation API`. The `labels` IDL attribute provides a list of the element's `label`'s. The `form` and `name` IDL attributes are part of the element's `forms API`.

**Example**

A simple calculator could use `output` for its display of calculated results:

```html
<form onsubmit="return false" oninput="o.value = a.valueAsNumber + b.valueAsNumber">
  <input id=a type=number step=any> +
  <input id=b type=number step=any> =
  <output id=o for="a b"></output>
</form>
```

**Example**

In this example, an `output` element is used to report the results of a calculation performed by a remote server, as they come in:

```html
<output id=result></output>
<script>
  var primeSource = new WebSocket('ws://primes.example.net/');
  primeSource.onmessage = function (event) {
    document.getElementById('result').value = event.data;
  }
</script>
```

### 4.10.13 The `progress` element

**Categories**: Flow content, Phrasing content, Labelable element, Palpable content.

**Contexts in which this element can be used**: Where phrasing content is expected.
The `progress` element represents the completion progress of a task. The progress is either indeterminate, indicating that progress is being made but that it is not clear how much more work remains to be done before the task is complete (e.g. because the task is waiting for a remote host to respond), or the progress is a number in the range zero to a maximum, giving the fraction of work that has so far been completed.

There are two attributes that determine the current task completion represented by the element. The `value` attribute specifies how much of the task has been completed, and the `max` attribute specifies how much work the task requires in total. The units are arbitrary and not specified.

To make a determinate progress bar, add a `value` attribute with the current progress (either a number from 0.0 to 1.0, or, if the `max` attribute is specified, a number from 0 to the value of the `max` attribute). To make an indeterminate progress bar, remove the `value` attribute.

Authors are encouraged to also include the current value and the maximum value inline as text inside the element, so that the progress is made available to users of legacy user agents.

Here is a snippet of a Web application that shows the progress of some automated task:

```html
<section>
  <h2>Task Progress</h2>
  <p>Progress: <progress id="p" max=100><span>0</span>%</progress></p>
  <script>
    var progressBar = document.getElementById('p');
    function updateProgress(newValue) {
      progressBar.value = newValue;
      progressBar.getElementsByTagName('span')[0].textContent = newValue;
    }
  </script>
</section>
```

(The `updateProgress()` method in this example would be called by some other code on the page to update the actual progress bar as the task progressed.)

The `value` and `max` attributes, when present, must have values that are valid floating-point numbers. The `value` attribute, if present, must have a value equal to or greater than zero, and less than or equal to the value of the `max` attribute, if present, or
1.0, otherwise. The \texttt{max} attribute, if present, must have a value greater than zero.

\textbf{Note} \quad The \texttt{progress} element is the wrong element to use for something that is just a gauge, as opposed to task progress. For instance, indicating disk space usage using \texttt{progress} would be inappropriate. Instead, the \texttt{meter} element is available for such use cases.

\textbf{User agent requirements}: If the \texttt{value} attribute is omitted, then the progress bar is an indeterminate progress bar. Otherwise, it is a determinate progress bar.

If the progress bar is a determinate progress bar and the element has a \texttt{max} attribute, the user agent must parse the \texttt{max} attribute's value according to the rules for parsing floating-point number values. If this does not result in an error, and if the parsed value is greater than zero, then the maximum value of the progress bar is that value. Otherwise, if the element has no \texttt{max} attribute, or if it has one but parsing it resulted in an error, or if the parsed value was less than or equal to zero, then the maximum value of the progress bar is 1.0.

If the progress bar is a determinate progress bar, user agents must parse the \texttt{value} attribute's value according to the rules for parsing floating-point number values. If this does not result in an error and the parsed value is greater than zero, then the value of the progress bar is that parsed value. Otherwise, if parsing the \texttt{value} attribute's value resulted in an error or a number less than or equal to zero, then the value of the progress bar is zero.

If the progress bar is a determinate progress bar, then the \texttt{current value} is the maximum value, if \texttt{value} is greater than the maximum value, and \texttt{value} otherwise.

\textbf{UA requirements for showing the progress bar}: When representing a \texttt{progress} element to the user, the UA should indicate whether it is a determinate or indeterminate progress bar, and in the former case, should indicate the relative position of the \texttt{current value} relative to the maximum value.

\textbf{For web developers (non-normative)}

\texttt{progress . position}

For a determinate progress bar (one with known current and maximum values), returns the result of dividing the current value by the maximum value.

For an indeterminate progress bar, returns $-1$.

If the progress bar is an indeterminate progress bar, then the \texttt{position} IDL attribute must return $-1$. Otherwise, it must return the result of dividing the \texttt{current value} by the \texttt{maximum value}.

If the progress bar is an indeterminate progress bar, then the \texttt{value} IDL attribute, on getting, must return 0. Otherwise, it must return the \texttt{current value}. On setting, the given value must be converted to the best representation of the number as a floating-point number, and then the \texttt{value} content attribute must be set to that string.

\textbf{Note} \quad Setting the \texttt{value} IDL attribute to itself when the corresponding content attribute is absent would change the progress bar from an indeterminate progress bar to a determinate progress bar with no progress.

The \texttt{max} IDL attribute must reflect the content attribute of the same name, limited to numbers greater than zero. The default value for \texttt{max} is 1.0.

The \texttt{labels} IDL attribute provides a list of the element's label\texttt{s}.
The `meter` element represents a scalar measurement within a known range, or a fractional value; for example disk usage, the relevance of a query result, or the fraction of a voting population to have selected a particular candidate.

This is also known as a gauge.

The `meter` element should not be used to indicate progress (as in a progress bar). For that role, HTML provides a separate `progress` element.

**Note**

The `meter` element also does not represent a scalar value of arbitrary range — for example, it would be wrong to use this to report a weight, or height, unless there is a known maximum value.

There are six attributes that determine the semantics of the gauge represented by the element.

The `min` attribute specifies the lower bound of the range, and the `max` attribute specifies the upper bound. The `value` attribute specifies the value to have the gauge indicate as the "measured" value.

The other three attributes can be used to segment the gauge’s range into "low", "medium", and "high" parts, and to indicate which part of the gauge is the "optimum" part. The `low` attribute specifies the range that is considered to be the "low" part, and the `high` attribute specifies the range that is considered to be the "high" part. The `optimum` attribute gives the position that is "optimum"; if that is higher than the "high" value then this indicates that the higher the value, the better; if it’s lower than the "low" mark then it indicates that lower values are better, and naturally if it is in between then it indicates that neither high nor low values are good.

**Authoring requirements:** The `value` attribute must be specified. The `value`, `min`, `low`, `high`, `max`, and `optimum` attributes, when present, must have values that are valid floating-point numbers.

In addition, the attributes' values are further constrained:

Let `value` be the `value` attribute's number.
If the \texttt{min} attribute is specified, then let \textit{minimum} be that attribute's value; otherwise, let it be zero.

If the \texttt{max} attribute is specified, then let \textit{maximum} be that attribute's value; otherwise, let it be 1.0.

The following inequalities must hold, as applicable:

- \texttt{minimum} \leq \texttt{value} \leq \texttt{maximum}
- \texttt{minimum} \leq \texttt{low} \leq \texttt{maximum} (if \texttt{low} is specified)
- \texttt{minimum} \leq \texttt{high} \leq \texttt{maximum} (if \texttt{high} is specified)
- \texttt{low} \leq \texttt{high} (if both \texttt{low} and \texttt{high} are specified)

\textbf{Note:} If no minimum or maximum is specified, then the range is assumed to be 0..1, and the value thus has to be within that range.

Authors are encouraged to include a textual representation of the gauge's state in the element's contents, for users of user agents that do not support the \texttt{meter} element.

When used with \texttt{microdata}, the \texttt{meter} element's \texttt{value} attribute provides the element's machine-readable value.

\textbf{Example}

The following examples show three gauges that would all be three-quarters full:

```
Storage space usage: <meter value=6 max=8>6 blocks used (out of 8 total)</meter>
Voter turnout: <meter value=0.75><img alt="75%" src="graph75.png"></meter>
Tickets sold: <meter min=0 max=100 value=75></meter>
```

The following example is incorrect use of the element, because it doesn't give a range (and since the default maximum is 1, both of the gauges would end up looking maxed out):

```
<p>The grapefruit pie had a radius of <meter value=12>12cm</meter>
and a height of <meter value=2>2cm</meter>.</p> <!-- BAD! -->
```

Instead, one would either not include the meter element, or use the meter element with a defined range to give the dimensions in context compared to other pies:

```
<p>The grapefruit pie had a radius of 12cm and a height of 2cm.</p>
<dl>
  <dt>Radius: <dd><meter min=0 max=20 value=12>12cm</meter>
  <dt>Height: <dd><meter min=0 max=10 value=2>2cm</meter>
</dl>
```

There is no explicit way to specify units in the \texttt{meter} element, but the units may be specified in the \texttt{title} attribute in free-form text.

\textbf{Example}

The example above could be extended to mention the units:

```
<dl>
  <dt>Radius: <dd><meter min=0 max=20 value=12 title="centimeters">12cm</meter>
  <dt>Height: <dd><meter min=0 max=10 value=2 title="centimeters">2cm</meter>
</dl>
```

\textbf{User agent requirements:} User agents must parse the \texttt{min}, \texttt{max}, \texttt{value}, \texttt{low}, \texttt{high}, and \texttt{optimum} attributes using the \texttt{rules for parsing floating-point number values}. User agents must then use all these numbers to obtain values for six points on the gauge, as follows. (The order in which these are evaluated is important, as some of the values refer to earlier ones.)
The minimum value
If the min attribute is specified and a value could be parsed out of it, then the minimum value is that value. Otherwise, the minimum value is zero.

The maximum value
If the max attribute is specified and a value could be parsed out of it, then the candidate maximum value is that value. Otherwise, the candidate maximum value is 1.0.

If the candidate maximum value is greater than or equal to the minimum value, then the maximum value is the candidate maximum value. Otherwise, the maximum value is the same as the minimum value.

The actual value
If the value attribute is specified and a value could be parsed out of it, then that value is the candidate actual value. Otherwise, the candidate actual value is zero.

If the candidate actual value is less than the minimum value, then the actual value is the minimum value.

Otherwise, if the candidate actual value is greater than the maximum value, then the actual value is the maximum value.

Otherwise, the actual value is the candidate actual value.

The low boundary
If the low attribute is specified and a value could be parsed out of it, then the candidate low boundary is that value. Otherwise, the candidate low boundary is the same as the minimum value.

If the candidate low boundary is less than the minimum value, then the low boundary is the minimum value.

Otherwise, if the candidate low boundary is greater than the maximum value, then the low boundary is the maximum value.

Otherwise, the low boundary is the candidate low boundary.

The high boundary
If the high attribute is specified and a value could be parsed out of it, then the candidate high boundary is that value. Otherwise, the candidate high boundary is the same as the maximum value.

If the candidate high boundary is less than the low boundary, then the high boundary is the low boundary.

Otherwise, if the candidate high boundary is greater than the maximum value, then the high boundary is the maximum value.

Otherwise, the high boundary is the candidate high boundary.

The optimum point
If the optimum attribute is specified and a value could be parsed out of it, then the candidate optimum point is that value. Otherwise, the candidate optimum point is the midpoint between the minimum value and the maximum value.

If the candidate optimum point is less than the minimum value, then the optimum point is the minimum value.

Otherwise, if the candidate optimum point is greater than the maximum value, then the optimum point is the maximum value.

Otherwise, the optimum point is the candidate optimum point.

All of which will result in the following inequalities all being true:

- minimum value ≤ actual value ≤ maximum value
- minimum value ≤ low boundary ≤ high boundary ≤ maximum value
- minimum value ≤ optimum point ≤ maximum value

UA requirements for regions of the gauge: If the optimum point is equal to the low boundary or the high boundary, or anywhere in between them, then the region between the low and high boundaries of the gauge must be treated as the optimum region, and the low and high parts, if any, must be treated as suboptimal. Otherwise, if the optimum point is less than the low boundary, then the region between the minimum value and the low boundary must be treated as the optimum region, the region from the low boundary up to the high boundary must be treated as a suboptimal region, and the remaining region must be treated as an even less good region. Finally, if the optimum point is higher than the high boundary, then the situation is reversed; the region between the high boundary and the maximum value must be treated as the optimum region, the region from the high boundary down to the low boundary must be treated as a suboptimal region, and the remaining region must be treated as an even less good region.
UA requirements for showing the gauge: When representing a meter p539 element to the user, the UA should indicate the relative
position of the actual value to the minimum and maximum values, and the relationship between the actual value and the three regions
of the gauge.

</ul>
Might be rendered as follows:

User agents may combine the value of the title p135 attribute and the other attributes to provide context-sensitive help or inline text
detailing the actual values.

Example
For example, the following snippet:
<meter min=0 max=60 value=23.2 title=seconds></meter>
...might cause the user agent to display a gauge with a tooltip saying "Value: 23.2 out of 60." on one line and "seconds" on a
second line.

543


The `value` IDL attribute, on getting, must return the actual value\(^{542}\). On setting, the given value must be converted to the best representation of the number as a floating-point number\(^{67}\) and then the `value`\(^{540}\) content attribute must be set to that string.

The `min` IDL attribute, on getting, must return the minimum value\(^{542}\). On setting, the given value must be converted to the best representation of the number as a floating-point number\(^{67}\) and then the `min`\(^{540}\) content attribute must be set to that string.

The `max` IDL attribute, on getting, must return the maximum value\(^{542}\). On setting, the given value must be converted to the best representation of the number as a floating-point number\(^{67}\) and then the `max`\(^{540}\) content attribute must be set to that string.

The `low` IDL attribute, on getting, must return the low boundary\(^{542}\). On setting, the given value must be converted to the best representation of the number as a floating-point number\(^{67}\) and then the `low`\(^{540}\) content attribute must be set to that string.

The `high` IDL attribute, on getting, must return the high boundary\(^{542}\). On setting, the given value must be converted to the best representation of the number as a floating-point number\(^{67}\) and then the `high`\(^{540}\) content attribute must be set to that string.

The `optimum` IDL attribute, on getting, must return the optimum value\(^{542}\). On setting, the given value must be converted to the best representation of the number as a floating-point number\(^{67}\) and then the `optimum`\(^{540}\) content attribute must be set to that string.

The `labels`\(^{470}\) IDL attribute provides a list of the element's `label`\(^{474}\)s.

### Example

The following example shows how a gauge could fall back to localized or pretty-printed text.

```html
<p>Disk usage: <meter min=0 value=170261928 max=233257824>170261928 bytes used out of 233257824 bytes available</meter></p>
```

---

### 4.10.15 The `fieldset` element

**Categories**\(^{124}\):
- Flow content\(^{128}\)
- Sectioning root\(^{192}\)
- Listed\(^{470}\) and autocapitalize-inheriting\(^{470}\) form-associated element\(^{470}\)
- Palpable content\(^{470}\)

**Contexts in which this element can be used**\(^{125}\):

Where flow content\(^{128}\) is expected.

**Content model**\(^{128}\):

Optionally a `legend`\(^{546}\) element, followed by flow content\(^{128}\).

**Tag omission in text/html**\(^{125}\):

Neither tag is omissible.

**Content attributes**\(^{125}\):

- `disabled`\(^{545}\) — Whether the form control is disabled
- `form`\(^{548}\) — Associates the control with a `form`\(^{5470}\) element
- `name`\(^{549}\) — Name of form control to use in the `form.elements`\(^{5472}\) API

**DOM interface**\(^{125}\):

```javascript
interface HTMLFieldSetElement : HTMLElement {
    [[CEReactions]] attribute boolean disabled;
    readonly attribute HTMLFormElement? form;
    [[CEReactions]] attribute DOMString name;

    readonly attribute DOMString type;
}
```

---

544
The `fieldset` element represents a set of form controls optionally grouped under a common name.

The name of the group is given by the first `legend` element that is a child of the `fieldset` element, if any. The remainder of the descendants form the group.

The `disabled` attribute, when specified, causes all the form control descendants of the `fieldset` element, excluding those that are descendants of the `fieldset` element's first `legend` element child, if any, to be disabled.

A `fieldset` element is a disabled `fieldset` if it matches any of the following conditions:

- Its `disabled` attribute is specified
- It is a descendant of another `fieldset` element whose `disabled` attribute is specified, and is not a descendant of that `fieldset` element's first `legend` element child, if any.

The `form` attribute is used to explicitly associate the `fieldset` element with its form owner. The `name` attribute represents the element's name.

For web developers (non-normative)

### fieldset . type

Returns the string "fieldset".

### fieldset . elements

Returns an `HTMLCollection` of the form controls in the element.

The `disabled` IDL attribute must reflect the content attribute of the same name.

The `type` IDL attribute must return the string "fieldset".

The `elements` IDL attribute must return an `HTMLCollection` rooted at the `fieldset` element, whose filter matches listed elements.

The `willValidate`, `validity`, and `validationMessage` attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the constraint validation API. The `form` and `name` IDL attributes are part of the element's forms API.

**Example**

This example shows a `fieldset` element being used to group a set of related controls:

```html
<fieldset>
  <legend>Display</legend>
  <p><label><input type=radio name=c value=0 checked> Black on White</label></p>
  <p><label><input type=radio name=c value=1> White on Black</label></p>
  <p><label><input type=checkbox name=g> Use grayscale</label></p>
  <p><label>Enhance contrast <input type=range name=e list=contrast min=0 max=100 value=0 step=1></label></p>
  <datalist id=contrast>
```

---

[SameObject] readonly attribute `HTMLCollection` elements;

readonly attribute boolean `willValidate`;
[SameObject] readonly attribute `ValidityState` validity;
readonly attribute DOMString `validationMessage`;
boolean `checkValidity`();
boolean `reportValidity`();
void `setCustomValidity`(DOMString error);
};
The following snippet shows a fieldset with a checkbox in the legend that controls whether or not the fieldset is enabled. The contents of the fieldset consist of two required text controls and an optional year/month control.

```html
<fieldset name="clubfields" disabled>
  <legend>
    <input type=checkbox name=club onchange="form.clubfields.disabled = !checked"> Use Club Card
  </legend>
  <p>Name on card: <input name=clubname required></p>
  <p>Card number: <input name=clubnum required pattern="[-0-9]+"></p>
  <p>Expiry date: <input name=clubexp type=month></p>
</fieldset>
```

Example

You can also nest `fieldset` elements. Here is an example expanding on the previous one that does so:

```html
<fieldset name="clubfields" disabled>
  <legend>
    <input type=checkbox name=club onchange="form.clubfields.disabled = !checked"> Use Club Card
  </legend>
  <p>Name on card: <input name=clubname required></p>
</fieldset>

<fieldset name="numfields">
  <legend>
    <input type=radio checked name=clubtype onchange="form.numfields.disabled = !checked"> My card has numbers on it
  </legend>
  <p>Card number: <input name=clubnum required pattern="[-0-9]+"></p>
</fieldset>

<fieldset name="letfields">
  <legend>
    <input type=radio name=clubtype onchange="form.letfields.disabled = !checked"> My card has letters on it
  </legend>
  <p>Card code: <input name=clublet required pattern="[A-Za-z]+"></p>
</fieldset>
```

In this example, if the outer "Use Club Card" checkbox is not checked, everything inside the outer `fieldset`, including the two radio buttons in the legends of the two nested `fieldset`s, will be disabled. However, if the checkbox is checked, then the radio buttons will both be enabled and will let you select which of the two inner `fieldset`s is to be enabled.

4.10.16 The `legend` element

Categories:
- None.
The **legend** element **represents** a caption for the rest of the contents of the **legend** element's parent **fieldset** element, if any.

**For web developers (non-normative)**

```
legend . form
```

Returns the element's `form` element, if any, or null otherwise.

The `form` IDL attribute's behavior depends on whether the **legend** element is in a **fieldset** element or not. If the **legend** has a **fieldset** element as its parent, then the `form` IDL attribute must return the same value as the `form` IDL attribute on that **fieldset** element. Otherwise, it must return null.

### 4.10.17 Form control infrastructure

#### 4.10.17.1 A form control's value

Most form controls have a **value** and a **checkedness**. (The latter is only used by **input** elements.) These are used to describe how the user interacts with the control.

A control's **value** is its internal state. As such, it might not match the user's current input.

**Example**

For instance, if a user enters the word “three” into a **numeric field** that expects digits, the user's input would be the string “three” but the control's **value** would remain unchanged. Or, if a user enters the email address "awesome@example.com" (with leading whitespace) into an **email field**, the user's input would be the string "awesome@example.com" but the browser's UI for email fields might translate that into a **value** of "awesome@example.com" (without the leading whitespace).

**input** and **textarea** elements have a **dirty value flag**. This is used to track the interaction between the **value** and default value. If it is false, **value** mirrors the default value. If it is true, the default value is ignored.

To define the behavior of constraint validation in the face of the **input** element's **multiple** attribute, **input** elements can also have separately defined **values**.

To define the behavior of the **maxlength** and **minlength** attributes, as well as other APIs specific to the **textarea** element, all form control with a **value** also have an algorithm for obtaining an **API value**. By default this algorithm is to simply return the control's **value**.

The **select** element does not have a **value**; the **selectedness** of its **option** elements is what is used instead.
4.10.17.2 Mutability

A form control can be designated as **mutable**.

Note

This determines (by means of definitions and requirements in this specification that rely on whether an element is so designated) whether or not the user can modify the `value` or `checkedness` of a form control, or whether or not a control can be automatically prefilled.

4.10.17.3 Association of controls and forms

A **form-associated element** can have a relationship with a **form** element, which is called the element’s **form owner**. If a **form-associated element** is not associated with a **form** element, its **form owner** is said to be null.

A **form-associated element** has an associated **parser inserted flag**.

A **form-associated element** is, by default, associated with its nearest ancestor **form** element (as described below), but, if it is **listed**, may have a **form** attribute specified to override this.

Note

This feature allows authors to work around the lack of support for nested **form** elements.

If a **listed** **form-associated element** has a **form** attribute specified, then that attribute’s value must be the ID of a **form** element in the element’s **tree**.

Note

The rules in this section are complicated by the fact that although conforming documents or **trees** will never contain nested **form** elements, it is quite possible (e.g., using a script that performs DOM manipulation) to generate **trees** that have such nested elements. They are also complicated by rules in the HTML parser that, for historical reasons, can result in a **form-associated element** being associated with a **form** element that is not its ancestor.

When a **form-associated element** is created, its **form owner** must be initialized to null (no owner).

When a **form-associated element** is to be associated with a form, its **form owner** must be set to that form.

When a **form-associated element** or one of its ancestors is inserted, then:

1. If the **form-associated element**’s **parser inserted flag** is set, then return.
2. Reset the **form owner** of the **form-associated element**.

When a **form-associated element** or one of its ancestors is removed, then:

1. If the **form-associated element** has a **form** and the **form-associated element** and its **form owner** are no longer in the same **tree**, then reset the **form owner** of the **form-associated element**.

When a **listed** **form-associated element**’s **form** attribute is set, changed, or removed, then the user agent must reset the **form owner** of that element.

When a **listed** **form-associated element** has a **form** attribute and the ID of any of the elements in the **tree** changes, then the user agent must reset the **form owner** of that **form-associated element**.

When a **listed** **form-associated element** has a **form** attribute and an element with an ID is inserted into or removed from the **Document**, then the user agent must reset the **form owner** of that **form-associated element**.

When the user agent is to reset the **form owner** of a **form-associated element** element, it must run the following steps:

1. Unset element’s **parser inserted flag**.
2. If all of the following conditions are true
   - element’s **form owner** is not null
   - element is not **listed** or its **form** content attribute is not present
element's \textit{form owner} is its nearest \textit{form} element ancestor after the change to the ancestor chain then do nothing, and return.

3. Set element's \textit{form owner} to null.

4. If element is listed, has a \textit{form} content attribute, and is connected, then:
   1. If the first element in element's \textit{tree}, in \textit{tree order}, to have an \textit{ID} that is case-sensitively equal to element's \textit{form} content attribute's value, is a \textit{form} element, then associate the element with that \textit{form} element.
   5. Otherwise, if element has an ancestor \textit{form} element, then associate element with the nearest such ancestor \textit{form} element.

\begin{example}
In the following non-conforming snippet:

\begin{verbatim}
...
<form id="a">
  <div id="b"></div>
</form>
<script>
  document.getElementById('b').innerHTML = '
    <table><tr><td></form>
  <form id="c"><input id="d"></table>' +
    '<input id="e">';
</script>
...
\end{verbatim}

The \textit{form owner} of "d" would be the inner nested form "c", while the \textit{form owner} of "e" would be the outer form "a".

This happens as follows: First, the "e" node gets associated with "c" in the HTML parser. Then, the \textit{innerHTML} algorithm moves the nodes from the temporary document to the "b" element. At this point, the nodes see their ancestor chain change, and thus all the "magic" associations done by the parser are reset to normal ancestor associations.

This example is a non-conforming document, though, as it is a violation of the content models to nest \textit{form} elements, and there is a \textit{parse error} for the </form> tag.
\end{example}

\textbf{For web developers (non-normative)}

\textbf{element . form}

Returns the element's \textit{form owner}.

Returns null if there isn't one.

\textbf{Listed form-associated elements} have a \textit{form} IDL attribute, which, on getting, must return the element's \textit{form owner}, or null if there isn't one.

\section{4.10.18 Attributes common to form controls}

\subsection{4.10.18.1 Naming form controls: the name attribute}

The \textit{name} content attribute gives the name of the form control, as used in \textit{form submission} and in the \textit{form} element's \textit{elements} object. If the attribute is specified, its value must not be the empty string or \textit{isindex}.

\textbf{Note}

A number of user agents historically implemented special support for first-in-form text controls with the name \textit{isindex}, and this specification previously defined related user agent requirements for it. However, some user agents subsequently dropped that special support, and the related requirements were removed from this specification. So, to avoid problematic reinterpretations in legacy user agents, the name \textit{isindex} is no longer allowed.
Other than \textit{isindex}, any non-empty value for \texttt{name} is allowed. The name \texttt{_charset} is special: if used as the name of a \texttt{Hidden} control with no \texttt{value} attribute, then during submission the \texttt{value} attribute is automatically given a value consisting of the submission character encoding.

The \texttt{name} IDL attribute must \texttt{reflect} the \texttt{name} content attribute.

\textbf{Note}

\textit{DOM clobbering is a common cause of security issues. Avoid using the names of built-in form properties with the \texttt{name} content attribute.}

\textit{In this example, the \texttt{input} element overrides the built-in \texttt{method} property:}

\begin{verbatim}
let form = document.createElement("form");
let input = document.createElement("input");
form.appendChild(input);

form.method; // => "get"
input.name = "method"; // DOM clobbering occurs here
form.method === input; // => true
\end{verbatim}

\textit{Since the input name takes precedence over built-in form properties, the JavaScript reference \texttt{form.method} will point to the \texttt{input} element named "method" instead of the built-in \texttt{method} property.}

4.10.18.2 Submitting element directionality: the \texttt{dirname} attribute

The \texttt{dirname} attribute on a form control element enables the submission of the \texttt{directionality} of the element, and gives the name of the control that contains this value during \texttt{form submission}. If such an attribute is specified, its value must not be the empty string.

\textbf{Example}

In this example, a form contains a text control and a submission button:

\begin{verbatim}
<form action="addcomment.cgi" method=post>
  <p><label>Comment: <input type=text name="comment" dirname="comment.dir" required></label></p>
  <p><button name="mode" type=submit value="add">Post Comment</button></p>
</form>
\end{verbatim}

When the user submits the form, the user agent includes three fields, one called "comment", one called "comment.dir", and one called "mode"; so if the user types "Hello", the submission body might be something like:

\begin{verbatim}
comment=Hello&comment.dir=ltr&mode=add
\end{verbatim}

If the user manually switches to a right-to-left writing direction and enters "مرحبا", the submission body might be something like:

\begin{verbatim}
comment=%D9%85%D8%B1%D8%AD%D8%A8%D8%A7&comment.dir=rtl&mode=add
\end{verbatim}

4.10.18.3 Limiting user input length: the \texttt{maxlength} attribute

A form control \texttt{maxlength} attribute, controlled by the \texttt{dirty value flag}, declares a limit on the number of characters a user can input. The "number of characters" is measured using JavaScript string length and, in the case of \texttt{textarea} elements, with all newlines normalized to a single character (as opposed to CRLF pairs).

If an element has its \texttt{form control maxlength} attribute specified, the attribute's value must be a valid non-negative integer. If the attribute is specified and applying the \texttt{rules for parsing non-negative integers} to its value results in a number, then that number is the element's maximum allowed value length. If the attribute is omitted or parsing its value results in an error, then there is no maximum allowed value length.
**Constraint validation:** If an element has a **maximum allowed value length**[^550], its **dirty value**[^547] is true, its **value**[^547] was last changed by a user edit (as opposed to a change made by a script), and the **JavaScript string length** of the element's **API value**[^547] is greater than the element's **maximum allowed value length**[^550], then the element is **suffering from being too long**[^573].

User agents may prevent the user from causing the element's **API value**[^547] to be set to a value whose **JavaScript string length** is greater than the element's **maximum allowed value length**[^550].

**Note**

In the case of **textarea**[^538] elements, the **API**[^547] and **value**[^547] differ. In particular, the **textarea line break normalization transformation**[^533] is applied before the **maximum allowed value length**[^550] is checked (whereas the **textarea wrapping transformation**[^533] is not applied).

---

### 4.10.18.4 Setting minimum input length requirements: the **minlength**[^551] attribute

A form control **minlength** attribute[^551], controlled by the **dirty value**[^547], declares a lower bound on the number of characters a user can input. The "number of characters" is measured using **JavaScript string length** and, in the case of **textarea**[^538] elements, with all newlines normalized to a single character (as opposed to CRLF pairs).

**Note**

The **minlength**[^551] attribute does not imply the **required** attribute. If the form control has no **required** attribute, then the value can still be omitted; the **minlength**[^551] attribute only kicks in once the user has entered a value at all. If the empty string is not allowed, then the **required attribute also needs to be set**.

If an element has its **form control minlength** attribute[^551], specified, the attribute's value must be a **valid non-negative integer**[^566]. If the attribute is specified and applying the **rules for parsing non-negative integers**[^566] to its value results in a number, then that number is the element's **minimum allowed value length**[^551]. If the attribute is omitted or parsing its value results in an error, then there is no **minimum allowed value length**[^551].

If an element has both a **maximum allowed value length**[^550] and a **minimum allowed value length**[^551], the **minimum allowed value length**[^551] must be smaller than or equal to the **maximum allowed value length**[^550].

**Constraint validation:** If an element has a **minimum allowed value length**[^551], its **dirty value**[^547] is true, its **value**[^547] was last changed by a user edit (as opposed to a change made by a script), its **value**[^547] is not the empty string, and the **JavaScript string length** of the element's **API value**[^547] is less than the element's **minimum allowed value length**[^551], then the element is **suffering from being too short**[^573].

**Example**

In this example, there are four text controls. The first is required, and has to be at least 5 characters long. The other three are optional, but if the user fills one in, the user has to enter at least 10 characters.

```html
<form action="/events/menu.cgi" method="post">
  <p><label>Name of Event: <input required minlength=5 maxlength=50 name=event></label></p>
  <p><label>Describe what you would like for breakfast, if anything:<textarea name="breakfast" minlength=10"></textarea></label></p>
  <p><label>Describe what you would like for lunch, if anything:<textarea name="lunch" minlength=10"></textarea></label></p>
  <p><label>Describe what you would like for dinner, if anything:<textarea name="dinner" minlength=10"></textarea></label></p>
  <p><input type="submit" value="Submit Request"></p>
</form>
```

---

### 4.10.18.5 Enabling and disabling form controls: the **disabled**[^551] attribute

The **disabled** content attribute is a **boolean attribute**[^66].
The `disabled` attribute for `option` elements and the `disabled` attribute for `optgroup` elements are defined separately.

A form control is disabled if any of the following conditions are met:

1. The element is a `button`, `input`, `select`, or `textarea` element, and the `disabled` attribute is specified on this element (regardless of its value).
2. The element is a descendant of a `fieldset` element whose `disabled` attribute is specified, and is not a descendant of that `fieldset` element’s first `legend` element child, if any.

A form control that is disabled must prevent any click events that are queued on the `user interaction task source` from being dispatched on the element.

**Constraint validation**: If an element is disabled, it is barred from constraint validation.

The `disabled` IDL attribute must `reflect` the `disabled` content attribute.

### 4.10.18.6 Form submission

**Attributes for form submission** can be specified both on `form` elements and on submit buttons (elements that represent buttons that submit forms, e.g. an `input` element whose `type` attribute is in the Submit Button state).

The attributes for form submission that may be specified on `form` elements are `action`, `enctype`, `method`, `novalidate`, and `target`.

The corresponding attributes for form submission that may be specified on submit buttons are `formaction`, `formenctype`, `formmethod`, `formnovalidate`, and `formtarget`. When omitted, they default to the values given on the corresponding attributes on the `form` element.

The `action` and `formaction` content attributes, if specified, must have a value that is a valid non-empty URL, potentially surrounded by spaces.

The `action` of an element is the value of the element’s `formaction` attribute, if the element is a submit button and has such an attribute, or the value of its `form owner`’s `action` attribute, if it has one, or else the empty string.

The `method` and `formmethod` content attributes are enumerated attributes with the following keywords and states:

- The keyword `get`, mapping to the state `GET`, indicating the HTTP GET method.
- The keyword `post`, mapping to the state `POST`, indicating the HTTP POST method.
- The keyword `dialog`, mapping to the state `dialog`, indicating that submitting the `form` is intended to close the `dialog` box in which the form finds itself, if any, and otherwise not submit.

The `invalid value default` for these attributes is the `GET` state. The `missing value default` for the `method` attribute is also the `GET` state. (There is no `missing value default` or `invalid value default` for the `formmethod` attribute.)

The `method` of an element is one of those states. If the element is a submit button and has a `formmethod` attribute, then the element’s `method` is that attribute’s state; otherwise, it is the `form owner`’s `method` attribute’s state.

**Example**

Here the `method` attribute is used to explicitly specify the default value, “get”, so that the search query is submitted in the URL:

```html
<form method="get" action="/search.cgi">
  <p><label>Search terms: <input type=search name=q></label></p>
</form>
```
The `enctype` and `formenctype` content attributes are enumerated attributes, with the following keywords and states:

- The "application/x-www-form-urlencoded" keyword and corresponding state.
- The "multipart/form-data" keyword and corresponding state.
- The "text/plain" keyword and corresponding state.

The `invalid value default` for these attributes is the `application/x-www-form-urlencoded` state. The `missing value default` for the `enctype` attribute is also the `application/x-www-form-urlencoded` state. (There is no `missing value default` for the `formenctype` attribute.)

The `enctype` of an element is one of those three states. If the element is a `submit button` and has a `formenctype` attribute, then the element's `enctype` is that attribute's state; otherwise, it is the `form owner`'s `enctype` attribute's state.

The `target` and `formtarget` content attributes, if specified, must have values that are valid browsing context names or keywords.

The `novalidate` and `formnovalidate` content attributes are boolean attributes. If present, they indicate that the form is not to be validated during submission.
The **no-validate state** of an element is true if the element is a **submit button** and the element's **formnovalidate** attribute is present, or if the element's **form owner**'s **novalidate** attribute is present, and false otherwise.

### Example

This attribute is useful to include "save" buttons on forms that have validation constraints, to allow users to save their progress even though they haven't fully entered the data in the form. The following example shows a simple form that has two required fields. There are three buttons: one to submit the form, which requires both fields to be filled in; one to save the form so that the user can come back and fill it in later; and one to cancel the form altogether.

```html
<form action="editor.cgi" method="post">
  <p><label>Name: <input required name=fn/></label></p>
  <p><label>Essay: <textarea required name=essay></textarea></label></p>
  <p><input type=submit name=submit value="Submit essay"></p>
  <p><input type=submit formnovalidate name=save value="Save essay"></p>
  <p><input type=submit formnovalidate name=cancel value="Cancel"></p>
</form>
```

The **action** IDL attribute must **reflect** the content attribute of the same name, except that on getting, when the content attribute is missing or its value is the empty string, the element's **node document**'s URL must be returned instead. The **target** IDL attribute must **reflect** the content attribute of the same name. The **method** and **enctype** IDL attributes must **reflect** the respective content attributes of the same name, **limited to only known values**. The **encoding** IDL attribute must **reflect** the **enctype** content attribute, **limited to only known values**. The **noValidate** IDL attribute must **reflect** the **novalidate** content attribute. The **formAction** IDL attribute must **reflect** the **formaction** content attribute, except that on getting, when the content attribute is missing or its value is the empty string, the element's **node document**'s **URL** must be returned instead. The **formEnctype** IDL attribute must **reflect** the **enctype** content attribute, **limited to only known values**. The **formMethod** IDL attribute must **reflect** the **method** content attribute, **limited to only known values**. The **formNoValidate** IDL attribute must **reflect** the **novalidate** content attribute. The **formTarget** IDL attribute must **reflect** the **target** content attribute.

#### 4.10.18.6.1 Autofocusing a form control: the [autofocus](https://html.spec.whatwg.org/multipage/forms.html#autofocus) attribute

The **autofocus** attribute allows the author to indicate that a control is to be focused as soon as the page is loaded or as soon as the **dialog** within which it finds itself is shown, allowing the user to just start typing without having to manually focus the main control.

The **autofocus** attribute is a **boolean attribute**.

An element's **nearest ancestor autofocus scoping root element** is the element itself if the element is a **dialog** element, or else is the element's nearest ancestor **dialog** element, if any, or else is the element's last **inclusive ancestor** element.

There must not be two elements with the same **nearest ancestor autofocus scoping root element** that both have the **autofocus** attribute specified.

When an element with the **autofocus** attribute specified is included in a document, queued a task on the user interaction task source to run the following steps:

1. If the user has indicated (for example, by starting to type in a form control) that they do not wish focus to be changed, then optionally return.
2. Let target be the element's **node document**.
3. If target has no **browsing context**, then return.
4. If target's **browsing context** has no top-level **browsing context** (e.g., it is a nested **browsing context** with no parent **browsing context**), then return.
5. If target's **active sandboxing flag set** has the sandboxed automatic features **browsing context flag**, then return.
6. If target's **origin** is not the same as the **origin** of the **node document** of the currently focused element in target's top-level **browsing context**, then return.
7. If target's `origin` is not the same as the `origin` of the `active document` of target's `top-level browsing context`, then return.

8. If the user agent has already reached the last step of this list of steps in response to an element being inserted into a `Document` whose `top-level browsing context`'s `active document` is the same as target's `top-level browsing context`'s active document, then return.

9. Run the focusing steps for the element. User agents may also change the scrolling position of the document, or perform some other action that brings the element to the user's attention.

**Note**

This handles the automatic focusing during document load. The `show()` and `showModal()` methods of `dialog` elements also processes the `autofocus` attribute.

**Note**

Focusing the control does not imply that the user agent has to focus the browser window if it has lost focus.

The `autofocus` IDL attribute must reflect the content attribute of the same name.

**Example**

In the following snippet, the text control would be focused when the document was loaded.

```html
<input maxlength="256" name="q" value="" autofocus>
<input type="submit" value="Search"
```

### 4.10.18.7 Autofill

**4.10.18.7.1 Autofilling form controls: the `autocomplete` attribute**

User agents sometimes have features for helping users fill forms in, for example prefilling the user's address based on earlier user input. The `autocomplete` content attribute can be used to hint to the user agent how to, or indeed whether to, provide such a feature.

There are two ways this attribute is used. When wearing the **autocomplete expectation mantle**, the `autocomplete` attribute describes what input is expected from users. When wearing the **autocomplete anchor mantle**, the `autocomplete` attribute describes the meaning of the given value.

On an `input` element whose `type` attribute is in the `Hidden` state, the `autocomplete` attribute wears the **autocomplete anchor mantle**. In all other cases, it wears the **autocomplete expectation mantle**.

When wearing the **autocomplete expectation mantle**, the `autocomplete` attribute, if specified, must have a value that is an ordered set of space-separated tokens consisting of either a single token that is an ASCII case-insensitive match for the string "on" (i.e. the "on" and "off" keywords are not allowed).

When wearing the **autocomplete anchor mantle**, the `autocomplete` attribute, if specified, must have a value that is an ordered set of space-separated tokens consisting of just `autofill detail tokens` (i.e. the "on" and "off" keywords are not allowed).

**Autofill detail tokens** are the following, in the order given below:

1. Optionally, a token whose first eight characters are an ASCII case-insensitive match for the string "section-", meaning that the field belongs to the named group.

**Example**

For example, if there are two shipping addresses in the form, then they could be marked up as:

```html
<fieldset>
  <legend>Ship the blue gift to...</legend>
  <p> <label> Address: <textarea name=ba autocomplete="section-blue shipping street-address"></textarea> </label>
```
2. Optionally, a token that is an ASCII case-insensitive match for one of the following strings:
   
   ◦ "shipping", meaning the field is part of the shipping address or contact information
   ◦ "billing", meaning the field is part of the billing address or contact information

3. Either of the following two options:
   
   ◦ A token that is an ASCII case-insensitive match for one of the following autofill field names, excluding those that are inappropriate for the control:

   ```
   "name",
   "honorific-prefix",
   "given-name",
   "additional-name",
   "family-name",
   "honorific-suffix",
   "nickname",
   "username",
   "new-password",
   "current-password",
   "organization-title",
   "organization",
   "street-address",
   "address-line1",
   "address-line2",
   "address-line3",
   "address-level4",
   "address-level3",
   "address-level2",
   "address-level1",
   "country",
   "country-name",
   "postal-code",
   "cc-name",
   "cc-given-name",
   "cc-additional-name",
   "cc-family-name",
   "cc-number",
   "cc-exp",
   "cc-exp-month",
   "cc-exp-year",
   "cc-csc",
   "cc-type",
   "transaction-currency",
   "transaction-amount",
   "language",
   "bday",
   "bday-day",
   "bday-month",
   "bday-year",
   "sex",
   "url",
   "photo"
   ```

   (See the table below for descriptions of these values.)
The following, in the given order:

1. Optionally, a token that is an **ASCII case-insensitive** match for one of the following strings:
   - "home", meaning the field is for contacting someone at their residence
   - "work", meaning the field is for contacting someone at their workplace
   - "mobile", meaning the field is for contacting someone regardless of location
   - "fax", meaning the field describes a fax machine’s contact details
   - "pager", meaning the field describes a pager’s or beeper’s contact details

2. A token that is an **ASCII case-insensitive** match for one of the following **autofill field** names, excluding those that are inappropriate for the control:
   - tel
   - tel-country-code
   - tel-national
   - tel-area-code
   - tel-local
   - tel-local-prefix
   - tel-local-suffix
   - tel-extension
   - email
   - impp

(See the table below for descriptions of these values.)

As noted earlier, the meaning of the attribute and its keywords depends on the mantle that the attribute is wearing.

**When wearing the autofill expectation mantle...**

The "off" keyword indicates either that the control’s input data is particularly sensitive (for example the activation code for a nuclear weapon); or that it is a value that will never be reused (for example a one-time-key for a bank login) and the user will therefore have to explicitly enter the data each time, instead of being able to rely on the UA to prefill the value for them; or that the document provides its own autocomplete mechanism and does not want the user agent to provide autocompletion values.

The "on" keyword indicates that the user agent is allowed to provide the user with autocompletion values, but does not provide any further information about what kind of data the user might be expected to enter. User agents would have to use heuristics to decide what autocompletion values to suggest.

The **autofill field** listed above indicate that the user agent is allowed to provide the user with autocompletion values, and specifies what kind of value is expected. The meaning of each such keyword is described in the table below.

If the **autocomplete** attribute is omitted, the default value corresponding to the state of the element’s **form owner**’s **autocomplete** attribute is used instead (either ”on” or ”off”). If there is no **form owner**, then the value ”on” is used.

**When wearing the autofill anchor mantle...**

The **autofill field** listed above indicate that the value of the particular kind of value specified is that value provided for this element. The meaning of each such keyword is described in the table below.

### Example

In this example the page has explicitly specified the currency and amount of the transaction. The form requests a credit card and other billing details. The user agent could use this information to suggest a credit card that it knows has sufficient balance and that supports the relevant currency.

```xml
<form method=post action="step2.cgi">
  <input type=hidden autocomplete=transaction-currency value="CHF">
  <input type=hidden autocomplete=transaction-amount value="15.00">
  <p><label>Credit card number: <input type=text inputmode=numeric autocomplete=cc-number></label></p>
  <p><label>Expiry Date: <input type=month autocomplete=cc-exp></label></p>
  <p><input type=submit value="Continue..."> </p>
</form>
```

The **autofill field** keywords relate to each other as described in the table below. Each field name listed on a row of this table corresponds to the meaning given in the cell for that row in the column labeled "Meaning". Some fields correspond to subparts of other fields; for example, a credit card expiry date can be expressed as one field giving both the month and year of expiry ("cc-exp"), or as two fields, one giving the month ("cc-exp-month") and one the year ("cc-exp-year"). In such cases, the names of the
broader fields cover multiple rows, in which the narrower fields are defined.

Note

Generally, authors are encouraged to use the broader fields rather than the narrower fields, as the narrower fields tend to expose Western biases. For example, while it is common in some Western cultures to have a given name and a family name, in that order (and thus often referred to as a first name and a surname), many cultures put the family name first and the given name second, and many others simply have one name (a mononym). Having a single field is therefore more flexible.

Some fields are only appropriate for certain form controls. An autofill field\(^{557}\) name is **inappropriate for a control** if the control does not belong to the group listed for that autofill field\(^{557}\) in the fifth column of the first row describing that autofill field\(^{557}\) in the table below. What controls fall into each group is described below the table.

</table>

The groups correspond to controls as follows:

**Text**

- `input` elements with a `type` attribute in the **Hidden** state
- `input` elements with a `type` attribute in the **Text** state
- `textarea` elements
- `select` elements

**Multiline**

- `input` elements with a `type` attribute in the **Hidden** state
- `textarea` elements
- `select` elements

**Password**

- `input` elements with a `type` attribute in the **Hidden** state
- `input` elements with a `type` attribute in the **Text** state
- `input` elements with a `type` attribute in the **Search** state
- `textarea` elements
- `select` elements

**URL**

- `input` elements with a `type` attribute in the **Hidden** state
- `input` elements with a `type` attribute in the **Text** state
- `input` elements with a `type` attribute in the **Search** state
- `textarea` elements
- `select` elements

**E-mail**

- `input` elements with a `type` attribute in the **Hidden** state
- `input` elements with a `type` attribute in the **Text** state
- `input` elements with a `type` attribute in the **Search** state
- `textarea` elements
- `select` elements

**Tel**

- `input` elements with a `type` attribute in the **Hidden** state
- `input` elements with a `type` attribute in the **Text** state
- `input` elements with a `type` attribute in the **Search** state
- `textarea` elements
- `select` elements

**Numeric**

- `input` elements with a `type` attribute in the **Hidden** state
- `input` elements with a `type` attribute in the **Text** state
- `input` elements with a `type` attribute in the **Search** state
- `textarea` elements
- `select` elements

**Month**

- `input` elements with a `type` attribute in the **Hidden** state
- `input` elements with a `type` attribute in the **Text** state
Address levels: The "address-level1" - "address-level4" fields are used to describe the locality of the street address. Different locales have different numbers of levels. For example, the US uses two levels (state and town), the UK uses one or two depending on the address (the post town, and in some cases the locality), and China can use three (province, city, district). The "address-level1" field represents the widest administrative division. Different locales order the fields in different ways; for example, in the US the town (level 2) precedes the state (level 1); while in Japan the prefecture (level 1) precedes the city (level 2) which precedes the district (level 3). Authors are encouraged to provide forms that are presented in a way that matches the country's conventions (hiding, showing, and rearranging fields accordingly as the user changes the country).

4.10.18.7.2 Processing model

Each input element to which the autocomplete attribute applies, each select element, and each textarea element, has an autofill hint set, an autofill scope, an autofill field name, and an IDL-exposed autofill value.

The autofill field name specifies the specific kind of data expected in the field, e.g. "street-address" or "cc-exp".

The autofill hint set identifies what address or contact information type the user agent is to look at, e.g. "shipping", "fax" or "billing".

The autofill scope identifies the group of fields whose information concerns the same subject, and consists of the autofill hint set with, if applicable, the "section-*" prefix, e.g. "billing", "section-parent shipping", or "section-child shipping home".

These values are defined as the result of running the following algorithm:

1. If the element has no autocomplete attribute, then jump to the step labeled default.
2. Let tokens be the result of splitting the attribute's value on ASCII whitespace.
3. If tokens is empty, then jump to the step labeled default.
4. Let index be the index of the last token in tokens.
5. If the index-th token in tokens is not an ASCII case-insensitive match for one of the tokens given in the first column of the following table, or if the number of tokens in tokens is greater than the maximum number given in the cell in the second column of that token's row, then jump to the step labeled default. Otherwise, let field be the string given in the cell of the first column of the matching row, and let category be the value of the cell in the third column of that same row.

</table>

6. If category is Off or Automatic but the element's `autocomplete` attribute is wearing the `autofill anchor mantle`, then jump to the step labeled `default`.

7. If category is Off, let the element's `autofill field name` be the string "off", let its `autofill hint set` be empty, and let its `IDL-exposed autofill value` be the string "off". Then, return.

8. If category is Automatic, let the element's `autofill field name` be the string "on", let its `autofill hint set` be empty, and let its `IDL-exposed autofill value` be the string "on". Then, return.

9. Let `scope tokens` be an empty list.

10. Let `hint tokens` be an empty set.
11. Let IDL value have the same value as field.
12. If the indexth token in tokens is the first entry, then skip to the step labeled done.
13. Decrement index by one.
14. If category is Contact and the indexth token in tokens is an ASCII case-insensitive match for one of the strings in the following list, then run the substeps that follow:
   - "home"
   - "work"
   - "mobile"
   - "fax"
   - "pager"

   The substeps are:
   1. Let contact be the matching string from the list above.
   2. Insert contact at the start of scope tokens.
   3. Add contact to hint tokens.
   4. Let IDL value be the concatenation of contact, a U+0020 SPACE character, and the previous value of IDL value (which at this point will always be field).
   5. If the indexth entry in tokens is the first entry, then skip to the step labeled done.
   6. Decrement index by one.
15. If the indexth token in tokens is an ASCII case-insensitive match for one of the strings in the following list, then run the substeps that follow:
   - "shipping"
   - "billing"

   The substeps are:
   1. Let mode be the matching string from the list above.
   2. Insert mode at the start of scope tokens.
   3. Add mode to hint tokens.
   4. Let IDL value be the concatenation of mode, a U+0020 SPACE character, and the previous value of IDL value (which at this point will either be field or the concatenation of contact, a space, and field).
   5. If the indexth entry in tokens is the first entry, then skip to the step labeled done.
   6. Decrement index by one.
16. If the indexth entry in tokens is not the first entry, then jump to the step labeled default.
17. If the first eight characters of the indexth token in tokens are not an ASCII case-insensitive match for the string "section-", then jump to the step labeled default.
18. Let section be the indexth token in tokens, converted to ASCII lowercase.
19. Insert section at the start of scope tokens.
20. Let IDL value be the concatenation of section, a U+0020 SPACE character, and the previous value of IDL value.
21. Done: Let the element's autofill hint set be hint tokens.
22. Let the element's autofill scope be scope tokens.
23. Let the element's autofill field name be field.
24. Let the element's IDL-exposed autofill value be IDL value.
25. Return.
26. Default: Let the element's IDL-exposed autofill value be the empty string, and its autofill hint set and autofill scope be empty.
27. If the element’s `autocomplete` attribute is wearing the `autofill anchor mantle`, then let the element’s `autofill field name` be the empty string and return.

28. Let `form` be the element’s `form owner`, if any, or null otherwise.

29. If `form` is not null and `form`’s `autocomplete` attribute is in the `off` state, then let the element’s `autofill field name` be “off”.

Otherwise, let the element’s `autofill field name` be “on”.

For the purposes of autofill, a **control’s data** depends on the kind of control:

- **An `input` element with its `type` attribute in the E-mail state and with the `multiple` attribute specified**
  - The element’s `value`.

- **Any other `input` element**

- **A `textarea` element**
  - The element’s `value`.

- **A `select` element with its `multiple` attribute specified**
  - The `option` elements in the `select` element’s list of options that have their `selectedness` set to true.

- **Any other `select` element**
  - The `option` element in the `select` element’s list of options that has its `selectedness` set to true.

How to process the `autofill hint set`, `autofill scope`, and `autofill field name` depends on the mantle that the `autocomplete` attribute is wearing.

↪ When wearing the `autofill expectation mantle`...

When an element’s `autofill field name` is “off”, the user agent should not remember the control’s data, and should not offer past values to the user.

**Note**

In addition, when an element’s `autofill field name` is “off”, values are reset when traversing the history.

**Example**

Banks frequently do not want UAs to prefill login information:

```html
<p><label>Account: <input type="text" name="ac" autocomplete="off" /></label></p>
<p><label>PIN: <input type="password" name="pin" autocomplete="off" /></label></p>
```

When an element’s `autofill field name` is not “off”, the user agent may store the control’s data, and may offer previously stored values to the user.

**Example**

For example, suppose a user visits a page with this control:

```html
<select name="country">
  <option>Afghanistan</option>
  <option>Albania</option>
  <option>Algeria</option>
  <option>Andorra</option>
  <option>Angola</option>
  <option>Antigua and Barbuda</option>
  <option>Argentina</option>
  <option>Armenia</option>
  <!-- ... -->
  <option>Yemen</option>
  <option>Zambia</option>
  <option>Zimbabwe
```
When the autofill field name is "on", the user agent should attempt to use heuristics to determine the most appropriate values to offer the user, e.g. based on the element's name value, the position of the element in its tree, what other fields exist in the form, and so forth.

When the autofill field name is one of the names of the autofill fields described above, the user agent should provide suggestions that match the meaning of the field name as given in the table earlier in this section. The autofill hint set should be used to select amongst multiple possible suggestions.

Suppose that on the first visit to this page, the user selects "Zambia". On the second visit, the user agent could duplicate the entry for Zambia at the top of the list, so that the interface instead looks like this:

When the autofill field name is not the empty string, then the user agent must act as if the user had specified the control's data for the given autofill hint set, autofill scope, and autofill field name combination.

When a user agent autofills "country" and "country-name" fields with the same form owner and autofill scope, and the user agent has a value for the country field(s), then the "country-name" field(s) must be filled using a human-readable name for the same country. When a user agent fills in multiple fields at once, all fields with the same autofill field name, form owner, and autofill scope must be filled with the same value.

Example
For example, if a user once entered one address into fields that used the "shipping" keyword, and another address into fields that used the "billing" keyword, then in subsequent forms only the first address would be suggested for form controls whose autofill hint set contains the keyword "shipping". Both addresses might be suggested, however, for address-related form controls whose autofill hint set does not contain either keyword.

Example
When wearing the autofill anchor mantle...
When the autofill field name is not the empty string, then the user agent must act as if the user had specified the control's data for the given autofill hint set, autofill scope, and autofill field name combination.

When the user agent autofills form controls, elements with the same form owner and the same autofill scope must use data relating to the same person, address, payment instrument, and contact details. When a user agent autofills "country" and "country-name" fields with the same form owner and autofill scope, and the user agent has a value for the country field(s), then the "country-name" field(s) must be filled using a human-readable name for the same country. When a user agent fills in multiple fields at once, all fields with the same autofill field name, form owner, and autofill scope must be filled with the same value.

Example
Suppose a user agent knows of two phone numbers, +1 555 123 1234 and +1 555 666 7777. It would not be conforming for the user agent to fill a field with autocomplete="shipping tel-local-prefix" with the value "123" and another field in the same form with autocomplete="shipping tel-local-suffix" with the value "7777". The only valid prefilled values given the...
The "section-*" tokens in the `autofill scope` are opaque; user agents must not attempt to derive meaning from the precise values of these tokens.

Similarly, if a form for some reason contained both a "cc-exp" field and a "cc-exp-month" field, and the user agent prefilled the form, then the month component of the former would have to match the latter.

This requirement interacts with the `autofill anchor mantle` also. Consider the following markup snippet:

```html
<form>
  <input type=hidden autocomplete="nickname" value="TreePlate"/>
  <input type=text autocomplete="nickname">
</form>
```

The only value that a conforming user agent could suggest in the text control is "TreePlate", the value given by the hidden `input` element.

The "section-*" tokens in the `autofill scope` are opaque; user agents must not attempt to derive meaning from the precise values of these tokens.

A user agent prefilling a form control must not discriminate between form controls that are in a document tree and those that are connected; that is, it is not conforming to make the decision on whether or not to autofill based on whether the element's `root` is a `shadow root` versus a `Document`.

A user agent prefilling a form control's `value` must not cause that control to suffer from a type mismatch, suffer from being too long, suffer from being too short, suffer from an underflow, suffer from an overflow, or suffer from a step mismatch. A user agent prefilling a form control's `value` must not cause that control to suffer from a pattern mismatch either. Where possible given the control's constraints, user agents must use the format given as canonical in the aforementioned table. Where it's not possible for the canonical format to be used, user agents should use heuristics to attempt to convert values so that they can be used.

A more elaborate example would be with month values. If the user agent knows that the user's birthday is the 27th of July 2012,
A user agent may allow the user to override an element's autofill field name, e.g. to change it from "off" to "on" to allow values to be remembered and prefilled despite the page author's objections, or to always "off", never remembering values.

More specifically, user agents may in particular consider replacing the autofill field name of form controls that match the description given in the first column of the following table, when their autofill field name is either "on" or "off", with the value given in the second cell of that row. If this table is used, the replacements must be done in tree order, since all but the first row references the autofill field name of earlier elements. When the descriptions below refer to form controls being preceded or followed by others, they mean in the list of listed elements that share the same form owner.

<table>
<thead>
<tr>
<th>Form control</th>
<th>New autofill field name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>an input</code> whose type attribute is in the Text state that is followed by an input whose type attribute is in the Password state</td>
<td>&quot;username&quot;</td>
</tr>
<tr>
<td><code>an input</code> whose type attribute is in the Text state that is preceded by an input whose autofill field name is &quot;username&quot;</td>
<td>&quot;current-password&quot;</td>
</tr>
<tr>
<td><code>an input</code> whose type attribute is in the Password state that is preceded by an input whose autofill field name is &quot;username&quot;</td>
<td>&quot;new-password&quot;</td>
</tr>
<tr>
<td><code>an input</code> whose type attribute is in the Password state that is preceded by an input whose autofill field name is &quot;current-password&quot;</td>
<td>&quot;new-password&quot;</td>
</tr>
<tr>
<td><code>an input</code> whose type attribute is in the Password state that is preceded by an input whose autofill field name is &quot;new-password&quot;</td>
<td>&quot;new-password&quot;</td>
</tr>
</tbody>
</table>

The autocomplete IDL attribute, on getting, must return the element's IDL-exposed autofill value, and on setting, must reflect the content attribute of the same name.

### 4.10.19 APIs for the text control selections

The `input` and `textarea` elements define several attributes and methods for handling their selection. Their shared algorithms are defined here.

For web developers (non-normative)
All input elements to which these APIs apply, and all textarea elements, have either a selection or a text entry cursor position at all times (even for elements that are not being rendered). The initial state must consist of a text entry cursor at the beginning of the control.

For input elements, these APIs must operate on the element's value. For textarea elements, these APIs must operate on the element's API value. In the below algorithms, we call the value string being operated on the relevant value.

Example

The use of API value instead of raw value for textarea elements means that U+000D (CR) characters are normalized away. For example,

```html
textarea id="demo">
<script>
  demo.value = "A\r\nB";
  demo.setRangeText("replaced", 0, 2);
  assert(demo.value === "replacedB");
</script>
```
Whenever the relevant value\textsuperscript{568} changes for an element to which these APIs apply, run these steps:

1. If the element has a selection\textsuperscript{568}:
   
   1. If the start of the selection is now past the end of the relevant value\textsuperscript{568}, set it to the end of the relevant value\textsuperscript{568}.
   
   2. If the end of the selection is now past the end of the relevant value\textsuperscript{568}, set it to the end of the relevant value\textsuperscript{568}.
   
   3. If the user agent does not support empty selection, and both the start and end of the selection are now pointing to the end of the relevant value\textsuperscript{568}, then instead set the element's text entry cursor position\textsuperscript{568} to the end of the relevant value\textsuperscript{568}, removing any selection.

2. Otherwise, the element must have a text entry cursor position\textsuperscript{568} position. If it is now past the end of the relevant value\textsuperscript{568}, set it to the end of the relevant value\textsuperscript{568}.

**Note**

In some cases where the relevant value\textsuperscript{568} changes, other parts of the specification will also modify the text entry cursor position\textsuperscript{568}, beyond just the clamping steps above. For example, see the value\textsuperscript{534} setter for textarea\textsuperscript{530}.

Characters with no visible rendering, such as U+200D ZERO WIDTH JOINER, still count as characters. Thus, for instance, the selection can include just an invisible character, and the text insertion cursor can be placed to one side or another of such a character.

Where possible, user interface features for changing the text selection in input and textarea elements must be implemented using the set the selection range\textsuperscript{570} algorithm so that, e.g., all the same events fire.

The selections\textsuperscript{568} of input\textsuperscript{476} and textarea\textsuperscript{530} elements have a selection direction, which is either "forward", "backward", or "none". This direction is set when the user manipulates the selection. The exact meaning of the selection direction depends on the platform. To set the selection direction of an element to a given direction, update the element's selection direction\textsuperscript{569} to the given direction, unless the direction is "none" and the platform does not support that direction; in that case, update the element's selection direction\textsuperscript{569} to "forward".

**Note**

On Windows, the direction indicates the position of the caret relative to the selection: a "forward" selection has the caret at the end of the selection and a "backward" selection has the caret at the start of the selection. Windows has no "none" direction.

On Mac, the direction indicates which end of the selection is affected when the user adjusts the size of the selection using the arrow keys with the Shift modifier: the "forward" direction means the end of the selection is modified, and the "backward" direction means the start of the selection is modified. The "none" direction is the default on Mac, it indicates that no particular direction has yet been selected. The user sets the direction implicitly when first adjusting the selection, based on which directional arrow key was used.

The select() method, when invoked, must run the following steps:

1. If this element is an input\textsuperscript{476} element, and either select() does not apply\textsuperscript{479} to this element or the corresponding control has no selectable text, return.

**Example**

For instance, in a user agent where <input type=\"color\">\textsuperscript{495} is rendered as a color well with a picker, as opposed to a text control accepting a hexadecimal color code, there would be no selectable text, and thus calls to the method are ignored.

2. Set the selection range\textsuperscript{570} with 0 and infinity.

The selectionStart attribute's getter must run the following steps:

1. If this element is an input\textsuperscript{476} element, and selectionStart does not apply\textsuperscript{479} to this element, return null.
2. If there is no selection\(^{568}\), return the offset (in logical order) within the relevant value\(^{568}\) to the character that immediately follows the text entry cursor\(^{568}\).

3. Return the offset (in logical order) within the relevant value\(^{568}\) to the character that immediately follows the start of the selection\(^{568}\).

The selectionStart\(^{569}\) attribute's setter must run the following steps:

1. If this element is an input\(^{476}\) element, and selectionStart\(^{569}\) does not apply\(^{479}\) to this element, throw an "InvalidStateError" DOMException.
2. Let end be the value of this element's selectionEnd\(^{579}\) attribute.
3. If end is less than the given value, set end to the given value.
4. Set the selection range\(^{570}\) with the given value, end, and the value of this element's selectionDirection\(^{579}\) attribute.

The selectionEnd\(^{579}\) attribute's getter must run the following steps:

1. If this element is an input\(^{476}\) element, and selectionEnd\(^{579}\) does not apply\(^{479}\) to this element, return null.
2. If there is no selection\(^{568}\), return the offset (in logical order) within the relevant value\(^{568}\) to the character that immediately follows the text entry cursor\(^{568}\).
3. Return the offset (in logical order) within the relevant value\(^{568}\) to the character that immediately follows the end of the selection\(^{568}\).

The selectionEnd\(^{579}\) attribute's setter must run the following steps:

1. If this element is an input\(^{476}\) element, and selectionEnd\(^{579}\) does not apply\(^{479}\) to this element, throw an "InvalidStateError" DOMException.
2. Set the selection range\(^{570}\) with the value of this element's selectionStart\(^{569}\) attribute, the given value, and the value of this element's selectionDirection\(^{579}\) attribute.

The selectionDirection\(^{579}\) attribute's getter must run the following steps:

1. If this element is an input\(^{476}\) element, and selectionDirection\(^{579}\) does not apply\(^{479}\) to this element, return null.
2. Return this element's selection direction\(^{569}\).

The selectionDirection\(^{579}\) attribute's setter must run the following steps:

1. If this element is an input\(^{476}\) element, and selectionDirection\(^{579}\) does not apply\(^{479}\) to this element, throw an "InvalidStateError" DOMException.
2. Set the selection range\(^{570}\) with the value of this element's selectionStart\(^{569}\) attribute, the value of this element's selectionEnd\(^{579}\) attribute, and the given value.

The setSelectionRange\((\text{start}, \text{end}, \text{direction})\) method, when invoked, must run the following steps:

1. If this element is an input\(^{476}\) element, and setSelectionRange\()\(^{578}\) does not apply\(^{479}\) to this element, throw an "InvalidStateError" DOMException.
2. Set the selection range\(^{570}\) with start, end, and direction.

To set the selection range with an integer or null start, an integer or null or the special value infinity end, and optionally a string direction, run the following steps:

1. If start is null, let start be zero.
2. If end is null, let end be zero.
3. Set the selection\(^{568}\) of the text control to the sequence of characters within the relevant value\(^{568}\) starting with the character at the start position (in logical order) and ending with the character at the (end-1)th position. Arguments greater than the length of the relevant value\(^{568}\) of the text control (including the special value infinity) must be treated as pointing at the end of the text control. If end is less than or equal to start then the start of the selection and the end of the selection must both be placed immediately before the character with offset end. In UAs where there is no concept of an empty selection, this
must set the cursor to be just before the character with offset end.

4. If direction is not a case-sensitive match for either the string “backward” or “forward”, or if the direction argument was omitted, set direction to “none”.

5. Set the selection direction of the text control to direction.

6. If the previous steps caused the selection of the text control to be modified (in either extent or direction), then queue a task, using the user interaction task source, to fire an event named select at the element, with the bubbles attribute initialized to true.

The setRangeText(replacement, start, end, selectMode) method, when invoked, must run the following steps:

1. If this element is an input element, and setRangeText() does not apply to this element, throw an "InvalidStateError" DOMException.

2. Set this element’s dirty value flag to true.

3. If the method has only one argument, then let start and end have the values of the selectionStart attribute and the selectionEnd attribute respectively.

   Otherwise, let start, end have the values of the second and third arguments respectively.

4. If start is greater than end, then throw an "RangeSizeError" DOMException.

5. If start is greater than the length of the relevant value of the text control, then set it to the length of the relevant value of the text control.

6. If end is greater than the length of the relevant value of the text control, then set it to the length of the relevant value of the text control.

7. Let selection start be the current value of the selectionStart attribute.

8. Let selection end be the current value of the selectionEnd attribute.

9. If start is less than end, delete the sequence of characters within the element’s relevant value starting with the character at the startth position (in logical order) and ending with the character at the (end-1)th position.

10. Insert the value of the first argument into the text of the relevant value of the text control, immediately before the startth character.

11. Let new length be the length of the first argument.

12. Let new end be the sum of start and new length.

13. Run the appropriate set of substeps from the following list:

    If the fourth argument’s value is "select"
      Let selection start be start.
      Let selection end be new end.

    If the fourth argument’s value is "start"
      Let selection start and selection end be start.

    If the fourth argument’s value is "end"
      Let selection start and selection end be new end.

    If the fourth argument’s value is "preserve"

    If the method has only one argument
      1. Let old length be end minus start.
      2. Let delta be new length minus old length.
      3. If selection start is greater than end, then increment it by delta. (If delta is negative, i.e. the new text is shorter than the old text, then this will decrease the value of selection start.)

      Otherwise: if selection start is greater than start, then set it to start. (This snaps the start of the selection to
the start of the new text if it was in the middle of the text that it replaced.)

4. If selection end is greater than end, then increment it by \( \text{delta} \) in the same way.

Otherwise: if selection end is greater than start, then set it to new end. (This snaps the end of the selection to the end of the new text if it was in the middle of the text that it replaced.)

14. Set the selection range with selection start and selection end.

The `setRangeText()` method uses the following enumeration:

```idl
enum SelectionMode {
  "select",
  "start",
  "end",
  "preserve" // default
};
```

---

Example

To obtain the currently selected text, the following JavaScript suffices:

```javascript
var selectionText = control.value.substring(control.selectionStart, control.selectionEnd);
```

...where control is the `input` or `textarea` element.

Example

To add some text at the start of a text control, while maintaining the text selection, the three attributes must be preserved:

```javascript
var oldStart = control.selectionStart;
var oldEnd = control.selectionEnd;
var oldDirection = control.selectionDirection;
var prefix = "http://";
control.value = prefix + control.value;
control.setSelectionRange(oldStart + prefix.length, oldEnd + prefix.length, oldDirection);
```

...where control is the `input` or `textarea` element.

---

4.10.20 Constraints

4.10.20.1 Definitions

A submittable element is a candidate for constraint validation except when a condition has barred the element from constraint validation. (For example, an element is barred from constraint validation if it is an object element.)

An element can have a custom validity error message defined. Initially, an element must have its custom validity error message set to the empty string. When its value is not the empty string, the element is suffering from a custom error. It can be set using the `setCustomValidity()` method. The user agent should use the custom validity error message when alerting the user to the problem with the control.

An element can be constrained in various ways. The following is the list of validity states that a form control can be in, making the control invalid for the purposes of constraint validation. (The definitions below are non-normative; other parts of this specification define more precisely when each state applies or does not.)

**Suffering from being missing**

When a control has no value but has a required attribute (`input`, `textarea` required); or, more
complicated rules for select elements and controls in radio button groups, as specified in their sections.

**Suffering from a type mismatch**
When a control that allows arbitrary user input has a value that is not in the correct syntax (E-mail, URL).

**Suffering from a pattern mismatch**
When a control has a value that doesn't satisfy the pattern attribute.

**Suffering from being too long**
When a control has a value that is too long for the form control maxlength attribute (input, textarea maxlength).

**Suffering from being too short**
When a control has a value that is too short for the form control minlength attribute (input, textarea minlength).

**Suffering from an underflow**
When a control has a value that is not the empty string and is too low for the min attribute.

**Suffering from an overflow**
When a control has a value that is not the empty string and is too high for the max attribute.

**Suffering from a step mismatch**
When a control has a value that doesn't fit the rules given by the step attribute.

**Suffering from bad input**
When a control has incomplete input and the user agent does not think the user ought to be able to submit the form in its current state.

**Suffering from a custom error**
When a control's custom validity error message (as set by the element's setCustomValidity() method) is not the empty string.

An element can still suffer from these states even when the element is disabled, thus these states can be represented in the DOM even if validating the form during submission wouldn't indicate a problem to the user.

An element satisfies its constraints if it is not suffering from any of the above validity states.

### 4.10.20.2 Constraint validation
When the user agent is required to statically validate the constraints of form element form, it must run the following steps, which return either a positive result (all the controls in the form are valid) or a negative result (there are invalid controls) along with a (possibly empty) list of elements that are invalid and for which no script has claimed responsibility:

1. Let controls be a list of all the submittable elements, whose form owner is form, in tree order.
2. Let invalid controls be an initially empty list of elements.
3. For each element field in controls, in tree order:
   1. If field is not a candidate for constraint validation, then move on to the next element.
   2. Otherwise, if field satisfies its constraints, then move on to the next element.
   3. Otherwise, add field to invalid controls.
4. If invalid controls is empty, then return a positive result.
5. Let unhandled invalid controls be an initially empty list of elements.
6. For each element field in invalid controls, if any, in tree order:
1. Let `notCanceled` be the result of firing an event named `invalid` at field, with the `cancelable` attribute initialized to true.

2. If `notCanceled` is true, then add field to unhandled invalid controls.

7. Return a negative result with the list of elements in the unhandled invalid controls list.

If a user agent is to interactively validate the constraints of form element form, then the user agent must run the following steps:

1. Statically validate the constraints of form, and let unhandled invalid controls be the list of elements returned if the result was negative.

2. If the result was positive, then return that result.

3. Report the problems with the constraints of at least one of the elements given in unhandled invalid controls to the user. User agents may focus one of those elements in the process, by running the focusing steps for that element, and may change the scrolling position of the document, or perform some other action that brings the element to the user's attention. User agents may report more than one constraint violation. User agents may coalesce related constraint violation reports if appropriate (e.g. if multiple radio buttons in a group are marked as required, only one error need be reported). If one of the controls is not being rendered (e.g. it has the `hidden` attribute set) then user agents may report a script error.

4. Return a negative result.

### 4.10.20.3 The constraint validation API

**element**. `willValidate`

Returns true if the element will be validated when the form is submitted; false otherwise.

**element**. `setCustomValidity`(message)

Sets a custom error, so that the element would fail to validate. The given message is the message to be shown to the user when reporting the problem to the user.

If the argument is the empty string, clears the custom error.

**element**. `validity`. `valueMissing`

Returns true if the element has no value but is a required field; false otherwise.

**element**. `validity`. `typeMismatch`

Returns true if the element's value is not in the correct syntax; false otherwise.

**element**. `validity`. `patternMismatch`

Returns true if the element's value doesn't match the provided pattern; false otherwise.

**element**. `validity`. `tooLong`

Returns true if the element's value is longer than the provided maximum length; false otherwise.

**element**. `validity`. `tooShort`

Returns true if the element's value, if it is not the empty string, is shorter than the provided minimum length; false otherwise.

**element**. `validity`. `rangeUnderflow`

Returns true if the element's value is lower than the provided minimum; false otherwise.

**element**. `validity`. `rangeOverflow`

Returns true if the element's value is higher than the provided maximum; false otherwise.

**element**. `validity`. `stepMismatch`

Returns true if the element's value doesn't fit the rules given by the `step` attribute; false otherwise.
The **willValidate** attribute's getter must return true, if this element is a candidate for constraint validation, and false otherwise (i.e., false if any conditions are barring it from constraint validation).

The **setCustomValidity**(message) method, when invoked, must set the custom validity error message to message.

The **validity** attribute's getter must return a **ValidityState** object that represents the validity states of this element. This object is **live**.

```
[Exposed=Window]
interface ValidityState {
  readonly attribute boolean valueMissing;
  readonly attribute boolean typeMismatch;
  readonly attribute boolean patternMismatch;
  readonly attribute boolean tooLong;
  readonly attribute boolean tooShort;
  readonly attribute boolean rangeUnderflow;
  readonly attribute boolean rangeOverflow;
  readonly attribute boolean stepMismatch;
```

In the following example, a script checks the value of a form control each time it is edited, and whenever it is not a valid value, uses the **setCustomValidity**(message) method to set an appropriate message.

```html
<label>Feeling: <input name=f type="text" oninput="check(this)"></label>
<script>
  function check(input) {
    if (input.value == "good" ||
        input.value == "fine" ||
        input.value == "tired") {
      input.setCustomValidity('' + input.value + '' is not a feeling.);
    } else {
      // input is fine -- reset the error message
      input.setCustomValidity('');
    }
  }
</script>
```

The **validity** attribute's getter must return a **ValidityState** object that represents the validity states of this element. This object is **live**.
A `ValidityState` object has the following attributes. On getting, they must return true if the corresponding condition given in the following list is true, and false otherwise.

**valueMissing**
- The control is suffering from being missing.

**typeMismatch**
- The control is suffering from a type mismatch.

**patternMismatch**
- The control is suffering from a pattern mismatch.

**tooLong**
- The control is suffering from being too long.

**tooShort**
- The control is suffering from being too short.

**rangeUnderflow**
- The control is suffering from an underflow.

**rangeOverflow**
- The control is suffering from an overflow.

**stepMismatch**
- The control is suffering from a step mismatch.

**badInput**
- The control is suffering from bad input.

**customError**
- The control is suffering from a custom error.

**valid**
- None of the other conditions are true.

The `checkValidity()` method, when invoked, must run these steps:

1. If this element is a candidate for constraint validation and does not satisfy its constraints, then:
   1. Fire an event named `invalid` at this element, with the `cancelable` attribute initialized to true (though canceling has no effect).
   2. Return false.
2. Return true.

The `reportValidity()` method, when invoked, must run these steps:

1. If this element is a candidate for constraint validation and does not satisfy its constraints, then:
   1. Let report be the result of firing an event named `invalid` at this element, with the `cancelable` attribute initialized to true.
   2. If report is true, then report the problems with the constraints of this element to the user. When reporting the problem with the constraints to the user, the user agent may run the focusing steps for this element, and may change the scrolling position of the document, or perform some other action that brings this element to the user's attention. User agents may report more than one constraint violation, if this element suffers from multiple
problems at once. If this element is not being rendered, then the user agent may, instead of notifying the user, report the error for the running script.

3. Return false.

2. Return true.

The `validationMessage` attribute's getter must run these steps:

1. If this element is not a candidate for constraint validation or if this element satisfies its constraints, then return the empty string.

2. Return a suitably localized message that the user agent would show the user if this were the only form control with a validity constraint problem. If the user agent would not actually show a textual message in such a situation (e.g., it would show a graphical cue instead), then return a suitably localized message that expresses (one or more of) the validity constraint(s) that the control does not satisfy. If the element is a candidate for constraint validation and is suffering from a custom error, then the custom validity error message should be present in the return value.

### 4.10.20.4 Security

Servers should not rely on client-side validation. Client-side validation can be intentionally bypassed by hostile users, and unintentionally bypassed by users of older user agents or automated tools that do not implement these features. The constraint validation features are only intended to improve the user experience, not to provide any kind of security mechanism.

### 4.10.21 Form submission

#### 4.10.21.1 Introduction

This section is non-normative.

When a form is submitted, the data in the form is converted into the structure specified by the `enctype`, and then sent to the destination specified by the `action` using the given `method`.

For example, take the following form:

```html
<form action="/find.cgi" method=get>
    <input type=text name=t>
    <input type=search name=q>
    <input type=submit>
</form>
```

If the user types in "cats" in the first field and "fur" in the second, and then hits the submit button, then the user agent will load `/find.cgi?t=cats&q=fur`.

On the other hand, consider this form:

```html
<form action="/find.cgi" method=post enctype="multipart/form-data">
    <input type=text name=t>
    <input type=search name=q>
    <input type=submit>
</form>
```

Given the same user input, the result on submission is quite different: the user agent instead does an HTTP POST to the given URL, with as the entity body something like the following text:

```
------kYFrd4jNJegCervE
Content-Disposition: form-data; name="t"
cats
------kYFrd4jNJegCervE
```
4.10.21.2 Implicit submission

A form element’s default button is the first submit button in tree order whose form owner is that form element.

If the user agent supports letting the user submit a form implicitly (for example, on some platforms hitting the “enter” key while a text control is focused implicitly submits the form), then doing so for a form, whose default button has activation behavior and is not disabled, must cause the user agent to fire a click event at that default button.

There are pages on the Web that are only usable if there is a way to implicitly submit forms, so user agents are strongly encouraged to support this.

If the form has no submit button, then the implicit submission mechanism must do nothing if the form has more than one field that blocks implicit submission, and must submit the form element from the form element itself otherwise.

For the purpose of the previous paragraph, an element is a field that blocks implicit submission of a form element if it is an input element whose form owner is that form element and whose type attribute is in one of the following states: Text, Search, URL, Telephone, E-mail, Password, Date, Month, Week, Time, Local Date and Time, Number.

4.10.21.3 Form submission algorithm

When a form element is submitted from an element submitter (typically a button), optionally with a submitted from submit() method flag set, the user agent must run the following steps:

1. If form cannot navigate, then return.
2. Let form document be form’s node document.
3. If form document’s active sandboxing flag set has its sandboxed forms browsing context flag set, then return.
4. Let form browsing context be the browsing context of form document.
5. If the submitted from submit() method flag is not set, and the submitter element’s no-validate state is false, then interactively validate the constraints of form and examine the result: if the result is negative (the constraint validation concluded that there were invalid fields and probably informed the user of this) then fire an event named invalid at the form element and then return.
6. If the submitted from submit() method flag is not set, then:
   1. Let continue be the result of firing an event named submit at form, with the bubbles attribute initialized to true and the cancelable attribute initialized to true.
   2. If continue is false, then return.
   3. If form cannot navigate, then return.

   Cannot navigate is run again as dispatching the submit event could have changed the outcome.

7. Let encoding be the result of picking an encoding for the form.
8. Let entry list be the result of constructing the entry list with form, submitter, and encoding.
9. Let action be the submitter element’s action.
10. If action is the empty string, let action be the URL of the form document.
11. Parse the URL action, relative to the submitter element's node document. If this fails, return.

12. Let parsed action be the resulting URL record.

13. Let scheme be the scheme of parsed action.

14. Let enctype be the submitter element's enctype.

15. Let method be the submitter element's method.

16. Let target be the submitter element's formtarget attribute value, if the element is a submit button and has such an attribute. Otherwise, let it be the result of getting an element's target given submitter's form owner.

17. Let target browsing context and replace be the result of applying the rules for choosing a browsing context using target and form browsing context.

18. If target browsing context is null, then return.

19. If form document has not yet completely loaded and the submitted from submit() method flag is set, then set replace to true.

20. If the value of method is dialog then jump to the submit dialog steps.

Otherwise, select the appropriate row in the table below based on the value of scheme as given by the first cell of each row. Then, select the appropriate cell on that row based on the value of method as given in the first cell of each column. Then, jump to the steps named in that cell and defined below the table.

<table>
<thead>
<tr>
<th>scheme</th>
<th>GET</th>
<th>POST</th>
</tr>
</thead>
<tbody>
<tr>
<td>http</td>
<td>Mutate action URL Submit as entity body</td>
<td>Submit as entity body</td>
</tr>
<tr>
<td>https</td>
<td>Mutate action URL Submit as entity body</td>
<td>Submit as entity body</td>
</tr>
<tr>
<td>ftp</td>
<td>Get action URL</td>
<td>Get action URL</td>
</tr>
<tr>
<td>javascript</td>
<td>Get action URL</td>
<td>Get action URL</td>
</tr>
<tr>
<td>data</td>
<td>Mutate action URL</td>
<td>Get action URL</td>
</tr>
<tr>
<td>mailto</td>
<td>Mail with headers</td>
<td>Mail as body</td>
</tr>
</tbody>
</table>

If scheme is not one of those listed in this table, then the behavior is not defined by this specification. User agents should, in the absence of another specification defining this, act in a manner analogous to that defined in this specification for similar schemes.

Each form element has a planned navigation, which is either null or a task: when the form is first created, its planned navigation must be set to null. In the behaviors described below, when the user agent is required to plan to navigate to a particular resource destination, it must run the following steps:

1. If the form has a non-null planned navigation, remove it from its task queue.

2. Let the form's planned navigation be a new task that consists of running the following steps:
   1. Let the form's planned navigation be null.
   2. Navigate target browsing context to destination. If replace is true, then target browsing context must be navigated with replacement enabled.

For the purposes of this task, target browsing context and replace are the variables that were set up when the overall form submission algorithm was run, with their values as they stood when this planned navigation was queued.

3. Queue the task that is the form's new planned navigation.

The task source for this task is the DOM manipulation task source.

The behaviors are as follows:

Mutate action URL

Let query be the result of running the application/x-www-form-urlencoded serializer with entry list and encoding.

Set parsed action's query component to query.

Plan to navigate to parsed action.
Submit as entity body

Switch on enctype:

↪ application/x-www-form-urlencoded\(^{553}\)

Let body be the result of running the application/x-www-form-urlencoded serializer with entry list and encoding.

Set body to the result of encoding body.

Let MIME type be "application/x-www-form-urlencoded".

↪ multipart/form-data\(^{553}\)

Let body be the result of running the multipart/form-data encoding algorithm\(^{583}\) with entry list and encoding.

Let MIME type be the concatenation of the string "multipart/form-data;", a U+0020 SPACE character, the string "boundary=", and the multipart/form-data boundary string\(^{584}\) generated by the multipart/form-data encoding algorithm\(^{583}\).

↪ text/plain\(^{553}\)

Let body be the result of running the text/plain encoding algorithm\(^{584}\) with entry list.

Set body to the result of encoding body using encoding.

Let MIME type be "text/plain".

Plan to navigate\(^{579}\) to a new request whose url is parsed action, method is method, header list consists of 'Content-Type' MIME type, and body is body.

Get action URL

Plan to navigate\(^{579}\) to parsed action.

Mail with headers

Let headers be the result of running the application/x-www-form-urlencoded serializer with entry list and encoding.

Replace occurrences of U+002B PLUS SIGN characters (+) in headers with the string "%20".

Set parsed action's query to headers.

Plan to navigate\(^{579}\) to parsed action.

Mail as body

Switch on enctype:

↪ text/plain\(^{553}\)

Let body be the result of running the text/plain encoding algorithm\(^{584}\) with entry list.

Set body to the result of concatenating the result of UTF-8 percent encoding each code point in body, using the default encode set. [URL]\(^{527}\).

↪ Otherwise

Let body be the result of running the application/x-www-form-urlencoded serializer with entry list and encoding.

If parsed action's query is null, then set it to the empty string.

If parsed action's query is not the empty string, then append a single U+0026 AMPERSAND character (&) to it.

Append "body=" to parsed action's query.

Append body to parsed action's query.

Plan to navigate\(^{579}\) to parsed action.
Submit dialog

Let subject be the nearest ancestor dialog element of form, if any.

If there isn’t one, or if it does not have an open attribute, do nothing. Otherwise, proceed as follows:

If submitter is an input element whose type attribute is in the Image Button state, then let result be the string formed by concatenating the selected coordinate’s x-component, expressed as a base-ten number using ASCII digits, a U+002C COMMA character (,), and the selected coordinate’s y-component, expressed in the same way as the x-component.

Otherwise, if submitter has a value, then let result be that value.

Otherwise, there is no result.

Then, close the dialog subject. If there is a result, let that be the return value.

4.10.21.4 Constructing the entry list

The algorithm to construct the entry list given a form, an optional submitter, and an optional encoding, is as follows. If not specified otherwise, submitter is null.

1. Let controls be a list of all the submittable elements whose form owner is form, in tree order.
2. Let entry list be a new empty list of entries.
3. For each element field in controls, in tree order:
   1. If any of the following is true:
      ■ The field element has a datalist element ancestor.
      ■ The field element is disabled.
      ■ The field element is a button but it is not submitter.
      ■ The field element is an input element whose type attribute is in the Checkbox state and whose checkedness is false.
      ■ The field element is an input element whose type attribute is in the Radio Button state and whose checkedness is false.
      ■ The field element is not an input element whose type attribute is in the Image Button state, and either the field element does not have a name attribute specified, or its name attribute’s value is the empty string.
      ■ The field element is an object element that is not using a plugin.

Then continue.

2. If the field element is an input element whose type attribute is in the Image Button state, then:
   1. If the field element has a name attribute and its value is not the empty string, let name be that value followed by a single U+002E FULL STOP character (.). Otherwise, let name be the empty string.
   2. Let name\textsubscript{x} be the string consisting of the concatenation of name and a single U+0078 LATIN SMALL LETTER X character (x).
   3. Let name\textsubscript{y} be the string consisting of the concatenation of name and a single U+0079 LATIN SMALL LETTER Y character (y).
   4. The field element is submitter, and before this algorithm was invoked the user indicated a coordinate. Let x be the x-component of the coordinate selected by the user, and let y be the y-component of the coordinate selected by the user.
   5. Append an entry to entry list with name\textsubscript{x} and x.
6. Append an entry\textsuperscript{p582} to entry list with name\textsuperscript{y} and y.

7. Continue.

3. Let name be the value of the field element's name\textsuperscript{p549} attribute.

4. If the field element is a select\textsuperscript{p526} element, then for each option\textsuperscript{p528} element in the select\textsuperscript{p526} element's list of options\textsuperscript{p522}, whose selectedness\textsuperscript{p529} is true and that is not disabled\textsuperscript{p528}, append an entry\textsuperscript{p582} to entry list with name and the value\textsuperscript{p529} of the option\textsuperscript{p528} element.

5. Otherwise, if the field element is an input\textsuperscript{p476} element whose type\textsuperscript{p478} attribute is in the Checkbox\textsuperscript{p496} state or the Radio Button\textsuperscript{p497} state, then:
   1. If the field element has a value\textsuperscript{p488} attribute specified, then let value be the value of that attribute; otherwise, let value be the string "on".
   2. Append an entry\textsuperscript{p582} to entry list with name and value.

6. Otherwise, if the field element is an input\textsuperscript{p476} element whose type\textsuperscript{p478} attribute is in the File Upload\textsuperscript{p498} state, then:
   1. If there are no selected files\textsuperscript{p548}, then append an entry\textsuperscript{p582} to entry list with name and a new File object with an empty name, application/octet-stream as type, and an empty body.
   2. Otherwise, for each file in selected files\textsuperscript{p548}, append an entry\textsuperscript{p582} to entry list with name and a File object representing the file.

7. Otherwise, if the field element is an object\textsuperscript{p558} element: try to obtain a form submission value from the plugin\textsuperscript{p545}, and if that is successful, append an entry\textsuperscript{p582} to entry list with name and the returned form submission value.

8. Otherwise, if the field element is an input\textsuperscript{p476} element whose type\textsuperscript{p478} attribute is in the Hidden\textsuperscript{p582} state and name is ".charset\textsuperscript{p556}:
   1. Let charset be the name of encoding if encoding is given, and "UTF-8" otherwise.
   2. Append an entry\textsuperscript{p582} to entry list with name and charset.

9. Otherwise, if the field element is a textarea\textsuperscript{p530} element, append an entry\textsuperscript{p582} to entry list with name and the value\textsuperscript{p547} of the field element, and the prevent line break normalization flag set.

Note

In the case of the value\textsuperscript{p547} of textarea\textsuperscript{p530} elements, the line break normalization is already performed during the conversion of the control's raw value\textsuperscript{p531} into the control's value\textsuperscript{p547} (which also performs any necessary line wrapping).

10. Otherwise, append an entry\textsuperscript{p582} to entry list with name and the value\textsuperscript{p547} of the field element.

11. If the element has a dirname\textsuperscript{p551} attribute, and that attribute's value is not the empty string, then:
   1. Let dirname be the value of the element's dirname\textsuperscript{p555} attribute.
   2. Let dir be the string "ltr" if the directionality\textsuperscript{p538} of the element is 'ltr\textsuperscript{p518}', and "rtl" otherwise (i.e., when the directionality\textsuperscript{p538} of the element is 'rtl\textsuperscript{p518}').
   3. Append an entry\textsuperscript{p582} to entry list with dirname and dir.

Note

An element can only have a dirname\textsuperscript{p556} attribute if it is a textarea\textsuperscript{p530} element or an input\textsuperscript{p476} element whose type\textsuperscript{p478} attribute is in either the Text\textsuperscript{p482} state or the Search\textsuperscript{p482} state.

4. Return entry list.

To append an entry to entry list, given name, value, and optional prevent line break normalization flag, run these steps:

1. For name, replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), by a string consisting of a U+000D (CR) and U+000A (LF).

2. Replace name with the result of converting to a sequence of Unicode scalar values.

3. If value is not a File object, then:
1. If the `prevent line break normalization flag` is unset, then replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR) in `value`, by a string consisting of a U+000D (CR) and U+000A (LF).

2. Replace `value` with the result of converting to a sequence of Unicode scalar values.

4. Create an entry with name and value, and append it to `entry list`.

### 4.10.21.5 Selecting a form submission encoding

If the user agent is to pick an encoding for a form, it must run the following steps:

1. Let `encoding` be the document's character encoding.

2. If the `form` element has an `accept-charset` attribute, set `encoding` to the return value of running these substeps:
   1. Let `input` be the value of the `form` element's `accept-charset` attribute.
   2. Let `candidate encoding labels` be the result of splitting `input` on ASCII whitespace.
   3. Let `candidate encodings` be an empty list of character encodings.
   4. For each token in `candidate encoding labels` in turn (in the order in which they were found in `input`), get an `encoding` for the token and, if this does not result in failure, append the `encoding` to `candidate encodings`.
   5. If `candidate encodings` is empty, return UTF-8.
   6. Return the first encoding in `candidate encodings`.

3. Return the result of getting an output encoding from `encoding`.

### 4.10.21.6 URL-encoded form data

See the WHATWG URL standard for details on application/x-www-form-urlencoded. [URL]

### 4.10.21.7 Multipart form data

The multipart/form-data encoding algorithm, given an `entry list` and `encoding`, is as follows:

1. Let `result` be the empty string.

2. For each `entry` in `entry list`:
   1. For each character in the entry's name and value that cannot be expressed using the selected character encoding, replace the character by a string consisting of a U+0026 AMPERSAND character (&), a U+0023 NUMBER SIGN character (#), one or more ASCII digits representing the code point of the character in base ten, and finally a U+003B (;).
   3. Encode the (now mutated) `entry list` using the rules described by RFC 7578, Returning Values from Forms: multipart/form-data, and return the resulting byte stream. [RFC7578]

Each entry in `entry list` is a field, the name of the entry is the field name and the value of the entry is the field value.

The order of parts must be the same as the order of fields in `entry list`. Multiple entries with the same name must be treated as distinct fields.

The parts of the generated multipart/form-data resource that correspond to non-file fields must not have a `Content-Type` header specified. Their names and values must be encoded using the character encoding selected above.

File names included in the generated multipart/form-data resource (as part of file fields) must use the character encoding selected above, though the precise name may be approximated if necessary (e.g. newlines could be removed from file names, quotes could be changed to "%22", and characters not expressible in the selected character encoding could be replaced by other characters).
The boundary used by the user agent in generating the return value of this algorithm is the `multipart/form-data` boundary string. (This value is used to generate the MIME type of the form submission payload generated by this algorithm.)

For details on how to interpret `multipart/form-data` payloads, see RFC 7578. [RFC7578][1226]

### 4.10.21.8 Plain text form data

The `text/plain` encoding algorithm, given an entry list, is as follows:

1. Let `result` be the empty string.
2. For each `entry` in `entry list`:
   1. If the entry's value is a `File` object, then set its value to the `File` object's `name`.
   2. Append the entry's name to `result`.
   3. Append a single U+003D EQUALS SIGN character (=) to `result`.
   4. Append the entry's value to `result`.
   5. Append a U+000D CARRIAGE RETURN (CR) U+000A LINE FEED (LF) character pair to `result`.
3. Return `result`.

Payloads using the `text/plain` format are intended to be human readable. They are not reliably interpretable by computer, as the format is ambiguous (for example, there is no way to distinguish a literal newline in a value from the newline at the end of the value).

### 4.10.22 Resetting a form

When a `form` element `form` is `reset`, run these steps:

1. Let `reset` be the result of firing an event named `reset` at `form`, with the `bubbles` and `cancelable` attributes initialized to true.
2. If `reset` is true, then invoke the `reset algorithm` of each `resettable element` whose `form owner` is `form`.

Each `resettable element` defines its own `reset algorithm`. Changes made to form controls as part of these algorithms do not count as changes caused by the user (and thus, e.g., do not cause `input` events to fire).

### 4.11 Interactive elements

#### 4.11.1 The `details` element

**Categories**:
- Flow content
- Sectioning root
- Interactive content
- Palpable content

**Contexts in which this element can be used**:
Where `flow content` is expected.

**Content model**:
- One `summary` element followed by `flow content`.

**Tag omission in `text/html`**:
Neither tag is omissible.
The `details` element represents a disclosure widget from which the user can obtain additional information or controls.

The first `summary` element child of the element, if any, represents the summary or legend of the details. If there is no child `summary` element, the user agent should provide its own legend (e.g. "Details").

The rest of the element's contents represents the additional information or controls.

The `open` content attribute is a boolean attribute. If present, it indicates that both the summary and the additional information is to be shown to the user. If the attribute is absent, only the summary is to be shown.

When the element is created, if the attribute is absent, the additional information should be hidden; if the attribute is present, that information should be shown. Subsequently, if the attribute is removed, then the information should be hidden; if the attribute is added, the information should be shown.

The user agent should allow the user to request that the additional information be shown or hidden. To honor a request for the details to be shown, the user agent must set the `open` attribute on the element to the empty string. To honor a request for the information to be hidden, the user agent must remove the `open` attribute from the element.

Whenever the `open` attribute is added to or removed from a `details` element, the user agent must queue a task that runs the following steps, which are known as the details notification task steps, for this `details` element:

1. If another task has been queued to run the details notification task steps for this `details` element, then return.

   This ability to request that additional information be shown or hidden may simply be the activation behavior of the appropriate `summary` element, in the case such an element exists. However, if no such element exists, user agents can still provide this ability through some other user interface affordance.

2. Fire an event named `toggle` at the `details` element.

   The `task source` for this task must be the DOM manipulation task source.

The `open` IDL attribute must reflect the `open` content attribute.

The following example shows the `details` element being used to hide technical details in a progress report.

```html
<section class="progress window">
  <h1>Copied "Really Achieving Your Childhood Dreams"</h1>
</section>
```
The following shows how a `details` element can be used to hide some controls by default:

```html
<details>
  <summary><label for=fn>Name & Extension:</label></summary>
  <p><input type=text id=fn name=fn value="Pillar Magazine.pdf"/></p>
  <p><label><input type=checkbox name=ext checked> Hide extension</label></p>
</details>
```

One could use this in conjunction with other `details` in a list to allow the user to collapse a set of fields down to a small set of headings, with the ability to open each one.
In these examples, the summary really just summarizes what the controls can change, and not the actual values, which is less than ideal.

Because the `open` attribute is added and removed automatically as the user interacts with the control, it can be used in CSS to style the element differently based on its state. Here, a style sheet is used to animate the color of the summary when the element is opened or closed:

```html
<details>
  <summary>Automated Status: Operational</summary>
</details>
```

```css
<style>
  details > summary { transition: color 1s; color: black; }
  details[open] > summary { color: red; }
</style>
```
The `summary` element

Categories:
None.

Contexts in which this element can be used:
As the first child of a `details` element.

Content model:
Either: phrasing content.
Or: one element of heading content.

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
Global attributes

DOM interface:
Uses `HTMLElement`.

The `summary` element represents a summary, caption, or legend for the rest of the contents of the `summary` element's parent `details` element, if any.

The activation behavior of `summary` elements is to run the following steps:

1. If this `summary` element has no parent node, then return.
2. Let `parent` be this `summary` element's parent node.
3. If `parent` is not a `details` element, then return.
4. If `parent`'s first `summary` element child is not this `summary` element, then return.
5. If the `open` attribute is present on `parent`, then remove it. Otherwise, set `parent`'s `open` attribute to the empty string.

This will then run the details notification task steps.

4.11.3 Commands

4.11.3.1 Facets

A command is the abstraction behind menu items, buttons, and links. Once a command is defined, other parts of the interface can refer to the same command, allowing many access points to a single feature to share facets such as the Disabled State.

Commands are defined to have the following facets:

Label
The name of the command as seen by the user.

Access Key
A key combination selected by the user agent that triggers the command. A command might not have an Access Key.
**Hidden State**
Whether the command is hidden or not (basically, whether it should be shown in menus).

**Disabled State**
Whether the command is relevant and can be triggered or not.

**Action**
The actual effect that triggering the command will have. This could be a scripted event handler, a URL to which to navigate, or a form submission.

User agents may expose the commands that match the following criteria:

- The Hidden State facet is false (visible)
- The element is in a document that has an associated browsing context.
- Neither the element nor any of its ancestors has a hidden attribute specified.

User agents are encouraged to do this especially for commands that have Access Keys, as a way to advertise those keys to the user.

### Example
For example, such commands could be listed in the user agent’s menu bar.

#### 4.11.3.2 Using the a element to define a command
An `a` element with an `href` attribute defines a command.

The Label of the command is the string given by the element's `textContent` IDL attribute.

The AccessKey of the command is the element's assigned access key, if any.

The Hidden State of the command is true (hidden) if the element has a hidden attribute, and false otherwise.

The Disabled State facet of the command is true if the element or one of its ancestors is inert, and false otherwise.

The Action of the command is to fire a click event at the element.

#### 4.11.3.3 Using the button element to define a command
A `button` element always defines a command.

The Label, Access Key, Hidden State, and Action facets of the command are determined as for a elements (see the previous section).

The Disabled State of the command is true if the element or one of its ancestors is inert, or if the element's disabled state is set, and false otherwise.

#### 4.11.3.4 Using the input element to define a command
An `input` element whose `type` attribute is in one of the Submit Button, Reset Button, Image Button, Button, Radio Button, or Checkbox states defines a command.

The Label of the command is determined as follows:

- If the `type` attribute is in one of the Submit Button, Reset Button, Image Button, or Button states, then the Label is the string given by the `value` attribute, if any, and a UA-dependent, locale-dependent value that the UA uses to label the button itself if the attribute is absent.
- Otherwise, if the element is a labeled control, then the Label is the string given by the `textContent` of the first labeled control element in tree order whose labeled control is the element in question. (In DOM terms, this is the string given by `element.labels[0].textContent`.)
• Otherwise, if the `value` attribute is present, then the `Label` is the value of that attribute.

• Otherwise, the `Label` is the empty string.

The `AccessKey` of the command is the element's `assigned access key`, if any.

The `Hidden State` of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The `Disabled State` of the command is true if the element or one of its ancestors is `inert`, or if the element's `disabled` state is set, and false otherwise.

The `Action` of the command is to fire a click event at the element.

4.11.3.5 Using the option element to define a command

An `option` element with an ancestor `select` element and either no `value` attribute or a `value` attribute that is not the empty string defines a command.

The `Label` of the command is the value of the `option` element's `label` attribute, if there is one, or else the value of `option` element's `textContent` IDL attribute, with ASCII whitespace stripped and collapsed.

The `AccessKey` of the command is the element's `assigned access key`, if any.

The `Hidden State` of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The `Disabled State` of the command is true if the element is `disabled`, or if its nearest ancestor `select` element is `disabled`, or if it or one of its ancestors is `inert`, and false otherwise.

If the `option`'s nearest ancestor `select` element has a `multiple` attribute, the `Action` of the command is to toggle the `option` element. Otherwise, the `Action` is to pick the `option` element.

4.11.3.6 Using the accesskey attribute on a legend element to define a command

A `legend` element that has an `assigned access key`, and is a child of a `fieldset` element that has a descendant that is not a descendant of the `legend` element and is neither a `label` element nor a `legend` element but that defines a command, itself defines a command.

The `Label` of the command is the string given by the element's `textContent` IDL attribute.

The `AccessKey` of the command is the element's `assigned access key`.

The `Hidden State`, `Disabled State`, and `Action` facets of the command are the same as the respective facets of the first element in tree order that is a descendant of the `legend` element that defines a command but is not a descendant of the `legend` element and is neither a `label` nor a `legend` element.

4.11.3.7 Using the accesskey attribute to define a command on other elements

An element that has an `assigned access key` defines a command.

If one of the earlier sections that define elements that define commands, define that element defines a command, then that section applies to this element, and this section does not. Otherwise, this section applies to that element.

The `Label` of the command depends on the element. If the element is a `labeled control`, the `textContent` of the first `label` element in tree order whose `labeled control` is the element in question is the `Label` (in DOM terms, this is the string given by `element.labels[0].textContent`). Otherwise, the `Label` is the `textContent` of the element itself.

The `AccessKey` of the command is the element's `assigned access key`.

The `Hidden State` of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.
The **disabled state** of the command is true if the element or one of its ancestors is **inert**, and false otherwise.

The **action** of the command is to run the following steps:

1. Run the focusing steps for the element.
2. Fire a **click event** at the element.

### 4.11.4 The `dialog` element

**Categories**

- Flow content
- Sectioning root

**Contexts in which this element can be used:**

Where **flow content** is expected.

**Content model:**

Flow content

**Tag omission in text/html:**

Neither tag is omissible.

**Content attributes:**

- **Global attributes**
  - `open` — Whether the dialog box is showing

**DOM interface:**

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLDialogElement : HTMLElement {
  [CEReactions] attribute boolean open;
  attribute DOMString returnValue;
  [CEReactions] void show();
  [CEReactions] void showModal();
  [CEReactions] void close(optional DOMString returnValue);
};
```

The `dialog` element represents a part of an application that a user interacts with to perform a task, for example a dialog box, inspector, or window.

The `open` attribute is a **boolean attribute**. When specified, it indicates that the `dialog` element is active and that the user can interact with it.

A `dialog` element without an `open` attribute specified should not be shown to the user. This requirement may be implemented indirectly through the style layer. For example, user agents that support the suggested default rendering implement this requirement using the CSS rules described in the rendering section.

**Note**

Removing the `open` attribute will usually hide the dialog. However, doing so has a number of strange additional consequences:

- The `close` event will not be fired.
- The `close()` method, and any user-agent provided cancelation interface, will no longer be able to close the dialog.
- If the dialog was shown using its `showModal()` method, the `Document` will still be **blocked**.

For these reasons, it is generally better to never remove the `open` attribute manually. Instead, use the `close` method to close the dialog, or the `hidden` attribute to hide it.
The `tabindex` attribute must not be specified on `dialog` elements.

For web developers (non-normative)

`dialog.show()`

Displays the `dialog` element.

`dialog.showModal()`

Displays the `dialog` element and makes it the top-most modal dialog.
This method honors the `autofocus` attribute.

`dialog.close([result])`

Closes the `dialog` element.
The argument, if provided, provides a return value.

`dialog.returnValue[=result]`

Returns the `dialog`’s return value.
Can be set, to update the return value.

When the `show()` method is invoked, the user agent must run the following steps:

1. If the element already has an `open` attribute, then return.
2. Add an `open` attribute to the `dialog` element, whose value is the empty string.
3. Set the `dialog` to the `normal alignment` mode.
4. Run the `dialog focusing steps` for the `dialog` element.

When the `showModal()` method is invoked, the user agent must run the following steps:

1. Let `subject` be the `dialog` element on which the method was invoked.
2. If `subject` already has an `open` attribute, then throw an "InvalidStateError" DOMException.
3. If `subject` is not `connected`, then throw an "InvalidStateError" DOMException.
4. Add an `open` attribute to `subject`, whose value is the empty string.
5. Set the `dialog` to the `centered alignment` mode.
6. Let `subject`’s node document be blocked by the modal dialog subject.
7. If `subject`’s node document’s top layer does not already contain `subject`, then add `subject` to subject’s node document’s top layer.
8. Run the `dialog focusing steps` for `subject`.

The `dialog focusing steps` for a `dialog` element `subject` are as follows:

1. If `subject` is `inert`, return.
2. Let `control` be the first descendant element of `subject`, in tree order, that is not `inert` and has the `autofocus` attribute specified.
   If there isn’t one, then let `control` be the first non-`inert` descendant element of `subject`, in tree order.
   If there isn’t one of those either, then let `control` be `subject`.
3. Run the `focusing steps` for `control`.

If at any time a `dialog` element is removed from a Document, then if that `dialog` is in that Document’s top layer, it must be removed from it.

When the `close()` method is invoked, the user agent must `close the dialog` that the method was invoked on. If the method was
invoked with an argument, that argument must be used as the return value; otherwise, there is no return value.

When a `dialog` element `subject` is to be `closed`, optionally with a return value `result`, the user agent must run the following steps:

1. If `subject` does not have an `open` attribute, then return.
2. Remove `subject`'s `open` attribute.
3. If the argument `result` was provided, then set the `returnValue` attribute to the value of `result`.
4. If `subject` is in its Document's top layer, then remove it.
5. Queue a task to fire an event named `close` at `subject`.

The `returnValue` IDL attribute, on getting, must return the last value to which it was set. On setting, it must be set to the new value. When the element is created, it must be set to the empty string.

**Canceling dialogs:** When Document is blocked by a modal dialog dialog, user agents may provide a user interface that, upon activation, queues a task to run these steps:

1. Let `close` be the result of firing an event named `cancel` at dialog, with the `cancelable` attribute initialized to true.
2. If `close` is true and dialog has an `open` attribute, then close the dialog with no return value.

An example of such a UI mechanism would be the user pressing the "Escape" key.

A `dialog` element is in one of two modes: normal alignment or centered alignment. When a `dialog` element is created, it must be placed in the normal alignment mode. In this mode, normal CSS requirements apply to the element. The centered alignment mode is only used for `dialog` elements that are in the top layer, [FULLSCREEN] [CSS].

When an element `subject` is placed in centered alignment mode, and when it is in that mode and has new rendering boxes created, the user agent must set up the element such that its static position of the edge that corresponds to `subject`'s parent's block-start edge, for the purposes of calculating the used value of the appropriate box offset property (top, right, bottom, or left), is the value that would place the element's margin edge on the side that corresponds to `subject`'s parent's block-start side as far from the same-side edge of the viewport as the element's opposing side margin edge from that same-side edge of the viewport, if the element's dimension (width or height) in `subject`'s parent's block flow direction is less than the same-axis dimension of the viewport, and otherwise is the value that would place the element's margin edge on the side that corresponds to `subject`'s parent's block-start side at the same-side edge of the viewport.

If there is a `dialog` element with centered alignment and that is being rendered when its browsing context changes viewport dimensions (as measured in CSS pixels), or when this `dialog` element's parent changes block flow direction, then the user agent must recreate the element's boxes, recalculating its edge that corresponds to this `dialog` element's parent's block-start edge as in the previous paragraph.

This static position of a `dialog` element's edge with centered alignment must remain the element's static position of that edge until its boxes are recreated. (The element's static position is only used in calculating the used value of the appropriate box offset property (top, right, bottom, or left) in certain situations; it's not used, for instance, to position the element if its position property is set to 'static'.)

User agents in visual interactive media should allow the user to pan the viewport to access all parts of a `dialog` element's border box, even if the element is larger than the viewport and the viewport would otherwise not have a scroll mechanism (e.g. because the viewport's overflow property is set to 'hidden').

The open IDL attribute must reflect the open content attribute.

This dialog box has some small print. The `strong` element is used to draw the user's attention to the more important part.
4.12 Scripting

Scripts allow authors to add interactivity to their documents.

Authors are encouraged to use declarative alternatives to scripting where possible, as declarative mechanisms are often more maintainable, and many users disable scripting.

Example

For example, instead of using script to show or hide a section to show more details, the details element could be used.

Authors are also encouraged to make their applications degrade gracefully in the absence of scripting support.

Example

For example, if an author provides a link in a table header to dynamically resort the table, the link could also be made to function without scripts by requesting the sorted table from the server.

4.12.1 The script element

Categories:

Metadata content
Flow content
Phrasing content
Script-supporting element

Contexts in which this element can be used:

Where metadata content is expected.
Where phrasing content is expected.
Where script-supporting elements are expected.

Content model:

If there is no src attribute, depends on the value of the type attribute, but must match script content restrictions. If there is a src attribute, the element must be either empty or contain only script documentation that also matches script content restrictions.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes:

src — Address of the resource
type — Type of script
module — Prevents execution in user agents that support module scripts
async — Execute script when available, without blocking
deferrable — Defer script execution

crossorigin — How the element handles crossorigin requests

integrity — Integrity metadata used in Subresource Integrity checks [SRI]

treferrerpolicy — Referrer policy for fetches initiated by the element

DOM interface:

```idl
[Exposed=Window,
 HTMLConstructor]
interface HTMLScriptElement : HTMLElement {
 [CEReactions] attribute USVString src;
 [CEReactions] attribute DOMString type;
 [CEReactions] attribute boolean noModule;
 [CEReactions] attribute boolean async;
 [CEReactions] attribute boolean defer;
 [CEReactions] attribute DOMString? crossOrigin;
 [CEReactions] attribute DOMString text;
 [CEReactions] attribute DOMString integrity;
 [CEReactions] attribute DOMString referrerPolicy;

};
```

The `script` element allows authors to include dynamic script and data blocks in their documents. The element does not represent content for the user.

The `type` attribute allows customization of the type of script represented:

- Omitting the attribute, setting it to the empty string, or setting it to a JavaScript MIME type essence match, means that the script is a classic script, to be interpreted according to the JavaScript Script top-level production. Classic scripts are affected by the `async` and `defer` attributes, but only when the `src` attribute is set. Authors should omit the `type` attribute instead of redundantly setting it.

- Setting the attribute to an ASCII case-insensitive match for the string "module" means that the script is a module script, to be interpreted according to the JavaScript Module top-level production. Module scripts are not affected by the `defer` attribute, but are affected by the `async` attribute (regardless of the state of the `src` attribute).

- Setting the attribute to any other value means that the script is a data block, which is not processed. None of the `script` attributes (except `type` itself) have any effect on data blocks. Authors must use a valid MIME type string that is not a JavaScript MIME type essence match to denote data blocks.

**Note**

The requirement that data blocks must be denoted using a valid MIME type string is in place to avoid potential future collisions. If this specification ever adds additional types of script, they will be triggered by setting the `type` attribute to something which is not a MIME type, like how the "module" value denotes module scripts. By using a valid MIME type string now, you ensure that your data block will not ever be reinterpreted as a different script type, even in future user agents.

Classic scripts and module scripts may either be embedded inline or may be imported from an external file using the `src` attribute, which if specified gives the URL of the external script resource to use. If `src` is specified, it must be a valid non-empty URL potentially surrounded by spaces. The contents of inline script elements, or the external script resource, must conform with the requirements of the JavaScript specification's Script or Module productions, for classic scripts and module scripts respectively. [JAVASCRIPT]

When used to include data blocks, the data must be embedded inline, the format of the data must be given using the `script` attribute, and the contents of the `script` element must conform to the requirements defined for the format used. The `src`, `async`, `nomodule`, `defer`, `crossorigin`, `integrity`, and `referrerpolicy` attributes must not be specified.

The `nomodule` attribute is a boolean attribute that prevents a script from being executed in user agents that support module scripts. This allows selective execution of module scripts in modern user agents and classic scripts in older user agents, as shown below. The `nomodule` attribute must not be specified on module scripts (and will be ignored if it is).

The `async` and `defer` attributes are boolean attributes that indicate how the script should be evaluated. Classic scripts may specify `defer` or `async`, but must not specify either unless the `src` attribute is present. Module scripts may specify the
async\textsuperscript{595} attribute, but must not specify the defer\textsuperscript{595} attribute.

There are several possible modes that can be selected using these attributes, and depending on the script's type.

For classic scripts\textsuperscript{588}, if the async\textsuperscript{595} attribute is present, then the classic script will be fetched in parallel\textsuperscript{442} to parsing and evaluated as soon as it is available (potentially before parsing completes). If the async\textsuperscript{595} attribute is not present but the defer\textsuperscript{595} attribute is present, then the classic script will be fetched in parallel\textsuperscript{442} and evaluated when the page has finished parsing. If neither attribute is present, then the script is fetched and evaluated immediately, blocking parsing until these are both complete.

For module scripts\textsuperscript{588}, if the async\textsuperscript{595} attribute is present, then the module script and all its dependencies will be fetched in parallel\textsuperscript{442} to parsing, and the module script will be evaluated as soon as it is available (potentially before parsing completes). Otherwise, the module script and its dependencies will be fetched in parallel\textsuperscript{442} to parsing and evaluated when the page has finished parsing. (The defer\textsuperscript{595} attribute has no effect on module scripts.)

This is all summarized in the following schematic diagram:

\begin{verbatim}
<script>       Scripting: HTML Parser: runtime
<script defer> Scripting: HTML Parser: runtime
<script async> Scripting: HTML Parser: runtime
<script type="module"> Scripting: HTML Parser: runtime
<script type="module" async> Scripting: HTML Parser: runtime
\end{verbatim}

Note

The exact processing details for these attributes are, for mostly historical reasons, somewhat non-trivial, involving a number of aspects of HTML. The implementation requirements are therefore by necessity scattered throughout the specification. The algorithms below (in this section) describe the core of this processing, but these algorithms reference and are referenced by the parsing rules for script\textsuperscript{594} start\textsuperscript{1008} and end\textsuperscript{1008} tags in HTML, in foreign content\textsuperscript{1016}, and in XML\textsuperscript{1130}, the rules for the document.write()\textsuperscript{918} method, the handling of scripting\textsuperscript{867}, etc.

The defer\textsuperscript{595} attribute may be specified even if the async\textsuperscript{595} attribute is specified, to cause legacy Web browsers that only support defer\textsuperscript{595} (and not async\textsuperscript{595}) to fall back to the defer\textsuperscript{595} behavior instead of the blocking behavior that is the default.

The crossorigin attribute is a CORS settings attribute\textsuperscript{588}. For classic scripts\textsuperscript{588}, it controls whether error information will be exposed, when the script is obtained from other origins\textsuperscript{583}. For module scripts\textsuperscript{588}, it controls the credentials mode used for cross-origin requests.

Note

Unlike classic scripts\textsuperscript{588}, module scripts\textsuperscript{588} require the use of the CORS protocol for cross-origin fetching.

The integrity attribute represents the integrity metadata for requests which this element is responsible for. The value is text. The integrity\textsuperscript{590} attribute must not be specified when embedding a module script\textsuperscript{595} or when the src\textsuperscript{595} attribute is not specified.\textsuperscript{1125}

The refererpolicy attribute is a referer policy attribute\textsuperscript{599}. Its purpose is to set the referer policy used when fetching the script, as well as any scripts imported from it.\textsuperscript{1122}

Example

An example of a <script>'s referer policy being used when fetching imported scripts but not other subresources.

```
<script src="main.js" refererpolicy="origin">
  fetch('/api/data'); // not fetched with <script>'s referer policy
  import('./utils.mjs'); // is fetched with <script>'s referer policy ("origin" in this case)
</script>
```
Changing the `src`, `type`, `defer`, `crossorigin`, `integrity`, and `referrerPolicy` attributes dynamically has no direct effect; these attributes are only used at specific times described below.

The IDL attributes `src`, `type`, `defer`, and `integrity`, must each `reflect` the respective content attributes of the same name.

The `referrerPolicy` IDL attribute must `reflect` the `referrerPolicy` content attribute, `limited to only known values`.

The `crossOrigin` IDL attribute must `reflect` the `crossorigin` content attribute, `limited to only known values`.

The `noModule` IDL attribute must `reflect` the `nomodule` content attribute.

The `async` IDL attribute controls whether the element will execute asynchronously or not. If the element's "non-blocking" flag is set, then, on getting, the `async` IDL attribute must return true, and on setting, the "non-blocking" flag must first be unset, and then the content attribute must be removed if the IDL attribute's new value is false, and must be set to the empty string if the IDL attribute's new value is true. If the element's "non-blocking" flag is not set, the IDL attribute must `reflect` the `async` content attribute.

The IDL attribute `text` must return the child text content of the `script` element. On setting, it must act the same way as the `textContent` IDL attribute.

The following sample shows how a `script` element can be used to define a function that is then used by other parts of the document, as part of a `classic script`. It also shows how a `script` element can be used to invoke script while the document is being parsed, in this case to initialize the form's output.

```html
<script>
    function calculate(form) {
        var price = 52000;
        if (form.elements.brakes.checked) price += 1000;
        if (form.elements.radio.checked)
</script>
```

The data in this case might be used by the script to generate the map of a video game. The data doesn't have to be used that way, though; maybe the map data is actually embedded in other parts of the page's markup, and the data block here is just used by the site's search engine to help users who are looking for particular features in their game maps.
```javascript
price += 2500;
if (form.elements.turbo.checked)
  price += 5000;
if (form.elements.sticker.checked)
  price += 250;
form.elements.result.value = price;
}
</script>
<form name="pricecalc" onsubmit="return false" onchange="calculate(this)"
<fieldset>
  <legend>Work out the price of your car</legend>
  <p>Base cost: £52000.</p>
  <p>Select additional options:</p>
  <ul>
    <li><label><input type=checkbox name=brakes> Ceramic brakes (£1000)</label></li>
    <li><label><input type=checkbox name=radio> Satellite radio (£2500)</label></li>
    <li><label><input type=checkbox name=turbo> Turbo charger (£5000)</label></li>
    <li><label><input type=checkbox name=sticker> "XZ" sticker (£250)</label></li>
  </ul>
  <p>Total: £<output name=result></output></p>
</fieldset>
<script>
  calculate(document.forms.pricecalc);
</script>
</form>
```

The following sample shows how a `script` element can be used to include an external `module script`.

```html
<script type="module" src="app.mjs"></script>
```

This module, and all its dependencies (expressed through JavaScript `import` statements in the source file), will be fetched. Once the entire resulting module graph has been imported, and the document has finished parsing, the contents of `app.mjs` will be evaluated.

Additionally, if code from another `script` element in the same `Window` imports the module from `app.mjs` (e.g. via `import './app.mjs';`), then the same `module script` created by the former `script` element will be imported.

This example shows how to include a `module script` for modern user agents, and a `classic script` for older user agents:

```html
<script type="module" src="app.mjs"></script>
<script nomodule src="classic-app-bundle.mjs"></script>
```

In modern user agents that support `module scripts`, the `script` element with the `nomodule` attribute will be ignored, and the `script` element with a `type` of "module" will be fetched and evaluated (as a `module script`). Conversely, older user agents will ignore the `script` element with a `type` of "module", as that is an unknown script type for them — but they will have no problem fetching and evaluating the other `script` element (as a `classic script`), since they do not implement the `nomodule` attribute.

The following sample shows how a `script` element can be used to write an inline `module script` that performs a number of substitutions on the document's text, in order to make for a more interesting reading experience (e.g. on a news site):
A script element has several associated pieces of state. The first is a flag indicating whether or not the script block has been "already started". Initially, script elements must have this flag unset (script blocks, when created, are not "already started"). The cloning steps for script elements must set the "already started" flag on the copy if it is set on the element being cloned.

The second is a flag indicating whether the element was "parser-inserted". Initially, script elements must have this flag unset. It is set by the HTML parser and the XML parser on script elements they insert and affects the processing of those elements.

The third is a flag indicating whether the element will be "non-blocking". Initially, script elements must have this flag set. It is unset by the HTML parser and the XML parser on script elements they insert. In addition, whenever a script element whose "non-blocking" flag is set has an async content attribute added, the element's "non-blocking" flag must be unset.

The fourth is a flag indicating whether or not the script block is "ready to be parser-executed". Initially, script elements must have this flag unset (script blocks, when created, are not "ready to be parser-executed"). This flag is used only for elements that are also "parser-inserted", to let the parser know when to execute the script.

The fifth is the script's type, which is either "classic" or "module". It is determined when the script is prepared, based on the type attribute of the element at that time.
The sixth is a flag indicating whether or not the script is from an external file. It is determined when the script is prepared, based on the src attribute of the element at that time.

Finally, a script element has the script's script, which is a script resulting from preparing the element. This is set asynchronously after the classic script or module graph is fetched. Once it is set, either to a script in the case of success or to null in the case of failure, the fetching algorithms will note that the script is ready, which can trigger other actions. The user agent must delay the load event of the element's node document until the script is ready.

When a script element that is not marked as being "parser-inserted" experiences one of the events listed in the following list, the user agent must immediately prepare the script element:

- The script element becomes connected.
- The script element is connected and a node or document fragment is inserted into the script element, after any script elements inserted at that time.
- The script element is connected and has a src attribute set where previously the element had no such attribute.

To prepare a script, the user agent must act as follows:

1. If the script element is marked as having "already started", then return. The script is not executed.
2. If the element has its "parser-inserted" flag set, then set was-parser-inserted to true and unset the element's "parser-inserted" flag. Otherwise, set was-parser-inserted to false.
   
   **Note**
   
   This is done so that if parser-inserted script elements fail to run when the parser tries to run them, e.g. because they are empty or specify an unsupported scripting language, another script can later mutate them and cause them to run again.

3. If was-parser-inserted is true and the element does not have an async attribute, then set the element's "non-blocking" flag to true.
   
   **Note**
   
   This is done so that if a parser-inserted script element fails to run when the parser tries to run it, but it is later executed after a script dynamically updates it, it will execute in a non-blocking fashion even if the async attribute isn't set.

4. Let source text be the element's child text content.
5. If the element has no src attribute, and source text is the empty string, then return. The script is not executed.
6. If the element is not connected, then return. The script is not executed.
7. If either:
   - the script element has a type attribute and its value is the empty string, or
   - the script element has no type attribute but it has a language attribute and that attribute's value is the empty string, or
   - the script element has neither a type attribute nor a language attribute, then let the script block's type string for this script element be "text/javascript".
   
   Otherwise, if the script element has a type attribute, let the script block's type string for this script element be the value of that attribute with leading and trailing ASCII whitespace stripped.

Otherwise, the element has a non-empty language attribute; let the script block's type string for this script element be the concatenation of the string "text/" followed by the value of the language attribute.

**Note**

The language attribute is never conforming, and is always ignored if there is a type attribute present.

Determine the script's type as follows:

- If the script block's type string is a JavaScript MIME type essence match, the script's type is "classic".
If the script block's type string is an ASCII case-insensitive match for the string "module", the script's type is "module".

If neither of the above conditions are true, then return. No script is executed.

If was-parser-inserted is true, then flag the element as "parser-inserted" again, and set the element's "non-blocking" flag to false.

Set the element's "already started" flag.

If the script element has an event attribute and a for attribute, and the script's type is "classic", then:

1. Let for be the value of the for attribute.
2. Let event be the value of the event attribute.
3. Strip leading and trailing ASCII whitespace from event and for.
4. If for is not an ASCII case-insensitive match for the string "window", then return. The script is not executed.
5. If event is not an ASCII case-insensitive match for either the string "onload" or the string "onload()", then return. The script is not executed.

If the script element has a charset attribute, then let encoding be the result of getting an encoding from the value of the charset attribute.

If the script element does not have a charset attribute, or if getting an encoding failed, let encoding be the same as the encoding of the script element's node document.

Note: If the script's type is "module", this encoding will be ignored.

Let classic script CORS setting be the current state of the element's crossorigin content attribute.

Let module script credentials mode be the module script credentials mode for the element's crossorigin content attribute.

Let cryptographic nonce be the element's [[CryptographicNonce]] internal slot's value.

If the script element has an integrity attribute, then let integrity metadata be that attribute's value.

Otherwise, let integrity metadata be the empty string.

Let referrer policy be the current state of the element's referrerpolicy content attribute.

Let parser metadata be "parser-inserted" if the script element has been flagged as "parser-inserted" and "not-parser-inserted" otherwise.
22. Let options be a `script fetch options` whose `cryptographic nonce` is `cryptographic nonce`, `integrity metadata` is `integrity metadata`, `parser metadata` is `parser metadata`, `credentials mode` is `module script credentials mode`, and `referrer policy` is `referrer policy`.

23. Let settings object be the element's `node document`'s `Window` object's `environment settings object`.

24. If the element has a `src` content attribute, then:
   1. Let `src` be the value of the element's `src` attribute.
   2. If `src` is the empty string, queue a task to fire an event named `error` at the element, and return.
   3. Set the element's `from an external file` flag.
   4. Parse `src` relative to the element's `node document`.
   5. If the previous step failed, queue a task to fire an event named `error` at the element, and return. Otherwise, let `url` be the `resulting URL record`.
   6. Switch on the script's type:
      - "classic"
        Fetch a classic script given `url`, `settings object`, `options`, `classic script CORS setting`, and `encoding`.
      - "module"
        Fetch a module script graph given `url`, `settings object`, "script", and `options`.

When the chosen algorithm asynchronously completes, set the script's `script` to the result. At that time, the script is ready.

For performance reasons, user agents may start fetching the classic script or module graph (as defined above) as soon as the `src` attribute is set, instead, in the hope that the element will be inserted into the document (and that the `crossorigin` attribute won't change value in the meantime). Either way, once the element is inserted into the document, the load must have started as described in this step. If the UA performs such prefetching, but the element is never inserted in the document, or the `src` attribute is dynamically changed, or the `crossorigin` attribute is dynamically changed, then the user agent will not execute the script so obtained, and the fetching process will have been effectively wasted.

25. If the element does not have a `src` content attribute, run these substeps:
   1. Let `base URL` be the `script` element's `node document`'s `document base URL`.
   2. Switch on the script's type:
      - "classic"
        Let `script` be the result of creating a classic script using `source text`, `settings object`, `base URL`, and `options`.
        Set the script's `script` to `script`.
        The script is ready.
      - "module"
        Let `script` be the result of creating a module script using `source text`, `settings object`, `base URL`, and `options`.
        If this returns null, set the script's `script` to null and return; the script is ready.
        Fetch the descendants of and instantiate script, given `settings object` and the destination "script". When this asynchronously completes, set the script's `script` to the result. At that time, the script is ready.

26. Then, follow the first of the following options that describes the situation:
→ If the script's type is "classic", and the element has a src attribute, and the element has a defer attribute, and the element has been flagged as "parser-inserted", and the element does not have an async attribute

→ If the script's type is "module", and the element has been flagged as "parser-inserted", and the element does not have an async attribute

  Add the element to the end of the list of scripts that will execute when the document has finished parsing associated with the Document of the parser that created the element.

  When the script is ready, set the element's "ready to be parser-executed" flag. The parser will handle executing the script.

→ If the script's type is "classic", and the element has a src attribute, and the element has been flagged as "parser-inserted", and the element does not have an async attribute

  The element is the pending parsing-blocking script of the Document of the parser that created the element. (There can only be one such script per Document at a time.)

  When the script is ready, set the element's "ready to be parser-executed" flag. The parser will handle executing the script.

→ If the script's type is "classic", and the element has a src attribute, and the element does not have an async attribute, and the element does not have the "non-blocking" flag set

→ If the script's type is "module", and the element does not have an async attribute, and the element does not have the "non-blocking" flag set

  Add the element to the end of the list of scripts that will execute in order as soon as possible associated with the node document of the script element at the time the prepare a script algorithm started.

  When the script is ready, run the following steps:

  1. If the element is not now the first element in the list of scripts that will execute in order as soon as possible to which it was added above, then mark the element as ready but return without executing the script yet.

  2. Execution: Execute the script block corresponding to the first script element in this list of scripts that will execute in order as soon as possible.

  3. Remove the first element from this list of scripts that will execute in order as soon as possible.

  4. If this list of scripts that will execute in order as soon as possible is still not empty and the first entry has already been marked as ready, then jump back to the step labeled execution.

→ If the script's type is "classic", and the element has a src attribute

→ If the script's type is "module"

  The element must be added to the set of scripts that will execute as soon as possible of the node document of the script element at the time the prepare a script algorithm started.

  When the script is ready, execute the script block and then remove the element from the set of scripts that will execute as soon as possible.

→ If the element does not have a src attribute, and the element has been flagged as "parser-inserted", and either the parser that created the script is an XML parser or it's an HTML parser whose script nesting level is not greater than one, and the Document of the HTML parser or XML parser that created the script has a style sheet that is blocking scripts.

  The element is the pending parsing-blocking script of the Document of the parser that created the element. (There can only be one such script per Document at a time.)

  Set the element's "ready to be parser-executed" flag. The parser will handle executing the script.

→ Otherwise

  Immediately execute the script block, even if other scripts are already executing.

The pending parsing-blocking script of a Document is used by the Document's parser(s).
When the user agent is required to **execute a script block**, it must run the following steps.

1. If the element is flagged as "parser-inserted", but the element's node document is not the Document of the parser that created the element, then return.

2. If the script's script is null, fire an event named `error` at the element, and return.

3. If the script is from an external file, or the script's type is "module", then increment the ignore-destructive-writes counter of the script element's node document. Let neutralized doc be that Document.

4. Let old script element be the value to which the script element's node document's `currentScript` object was most recently set.

5. Switch on the script's type:

   1. If the script element's root is not a shadow root, then set the script element's node document's `currentScript` attribute to the script element. Otherwise, set it to null.

   2. Run the classic script given by the script's script.

   3. Run the module script given by the script's script.

6. Set the script element's node document's `currentScript` attribute to old script element.

7. Decrement the ignore-destructive-writes counter of neutralized doc, if it was incremented in the earlier step.

8. If the script is from an external file, then fire an event named `load` at the script element.

### 4.12.1.2 Scripting languages

User agents are not required to support JavaScript. This standard needs to be updated if a language other than JavaScript comes along and gets similar wide adoption by web browsers. Until such a time, implementing other languages is in conflict with this standard, given the processing model defined for the script element.

Servers should use `text/javascript` for JavaScript resources. Servers should not use other JavaScript MIME types for JavaScript resources, and must not use non-JavaScript MIME types.

For external JavaScript resources, MIME type parameters in `Content-Type` headers are generally ignored. (In some cases the `charset` parameter has an effect.) However, for the script element's `type` attribute they are significant; it uses the JavaScript MIME type essence match concept.

For example, scripts with their `type` attribute set to "text/javascript; charset=utf-8" will not be evaluated, even though that is a valid JavaScript MIME type when parsed.

Furthermore, again for external JavaScript resources, special considerations apply around `Content-Type` header processing as detailed in the prepare a script algorithm and the WHATWG Fetch standard. [FETCH]
4.12.1.3 Restrictions for contents of \texttt{script} elements

The easiest and safest way to avoid the rather strange restrictions described in this section is to always escape "<!- -" as "<!--", "<script>" as "<script", and "</script>" as "</script" when these sequences appear in literals in scripts (e.g. in strings, regular expressions, or comments), and to avoid writing code that uses such constructs in expressions. Doing so avoids the pitfalls that the restrictions in this section are prone to triggering: namely, that, for historical reasons, parsing of \texttt{script} blocks in HTML is a strange and exotic practice that acts unintuitively in the face of these sequences.

The \texttt{textContent} of a \texttt{script} element must match the \texttt{script} production in the following ABNF, the character set for which is Unicode. [ABNF]

\begin{verbatim}
script        = outer *{ comment-open inner comment-close outer }
outer         = < any string that doesn't contain a substring that matches not-in-outer >
not-in-outer  = comment-open
inner         = < any string that doesn't contain a substring that matches not-in-inner >
not-in-inner  = comment-close / script-open

comment-open = "<!-
comment-close = "-->"
script-open   = "<" s c r i p t tag-end

s             = %x0053 ; U+0053 LATIN CAPITAL LETTER S
s             =/ %x0073 ; U+0073 LATIN SMALL LETTER S
c             = %x0043 ; U+0043 LATIN CAPITAL LETTER C
c             =/ %x0063 ; U+0063 LATIN SMALL LETTER C
r             = %x0052 ; U+0052 LATIN CAPITAL LETTER R
r             =/ %x0072 ; U+0072 LATIN SMALL LETTER R
i             = %x0049 ; U+0049 LATIN CAPITAL LETTER I
i             =/ %x0069 ; U+0069 LATIN SMALL LETTER I
p             = %x0050 ; U+0050 LATIN CAPITAL LETTER P
p             =/ %x0070 ; U+0070 LATIN SMALL LETTER P
t             = %x0054 ; U+0054 LATIN CAPITAL LETTER T
t             =/ %x0074 ; U+0074 LATIN SMALL LETTER T
tag-end       = %x0009 ; U+0009 CHARACTER TABULATION (tab)
tag-end       =/ %x000A ; U+000A LINE FEED (LF)
tag-end       =/ %x000C ; U+000C FORM FEED (FF)
tag-end       =/ %x0020 ; U+0020 SPACE
tag-end       =/ %x002F ; U+002F SOLIDUS (/)
tag-end       =/ %x003E ; U+003E GREATER-THAN SIGN (>)
\end{verbatim}

When a \texttt{script} element contains \texttt{script documentation}, there are further restrictions on the contents of the element, as described in the section below.

Example

The following script illustrates this issue. Suppose you have a script that contains a string, as in:

\begin{verbatim}
var example = 'Consider this string: <!-- <script>,'
console.log(example);
\end{verbatim}

If one were to put this string directly in a \texttt{script} block, it would violate the restrictions above:

\begin{verbatim}
<script>
var example = 'Consider this string: <!-- <script>,'
console.log(example);
</script>
\end{verbatim}

The bigger problem, though, and the reason why it would violate those restrictions, is that actually the script would get parsed
If a script element's src attribute is specified, then the contents of the script element, if any, must be such that the value of the text IDL attribute, which is derived from the element's contents, matches the documentation production in the following ABNF, the character set for which is Unicode.

```
documentation = *( *( space / tab / comment ) [ line-comment ] newline )
```

weirdly: the script block above is not terminated. That is, what looks like a "</script>" end tag in this snippet is actually still part of the script block. The script doesn't execute (since it's not terminated); if it somehow were to execute, as it might if the markup looked as follows, it would fail because the script (highlighted here) is not valid JavaScript:

```html
<script>
  var example = 'Consider this string: <!-- <!-- <script> '
  console.log(example);
</script>
<!-- despite appearances, this is actually part of the script still! -->
<script>
  ... // this is the same script block still...
</script>
```

What is going on here is that for legacy reasons, "<!--" and "<script>" strings in script elements in HTML need to be balanced in order for the parser to consider closing the block.

By escaping the problematic strings as mentioned at the top of this section, the problem is avoided entirely:

```html
<script>
  // Note: \s is an escape sequence for \s.
  var example = 'Consider this string: <!-- <!-- <script> ';
  console.log(example);
</script>
<!-- this is just a comment between script blocks -->
<script>
  ... // this is a new script block
</script>
```

It is possible for these sequences to naturally occur in script expressions, as in the following examples:

```javascript
if (x<!--y) { ... }
if ( player<script ) { ... }
```

In such cases the characters cannot be escaped, but the expressions can be rewritten so that the sequences don't occur, as in:

```javascript
if ( x < !--y) { ... }
if ( !--y > x) { ... }
if ( !(!--y) > x) { ... }
if ( player < script ) { ... }
if ( script > player ) { ... }
```

Doing this also avoids a different pitfall as well: for related historical reasons, the string "<!--" in classic scripts is actually treated as a line comment start, just like "//".

### 4.12.1.4 Inline documentation for external scripts

If a script element's src attribute is specified, then the contents of the script element, if any, must be such that the value of the text IDL attribute, which is derived from the element's contents, matches the documentation production in the following ABNF, the character set for which is Unicode. [ABNF]#1221

```plaintext
; characters
tab = %x0009 ; U+0009 CHARACTER TABULATION (tab)
```
This section is non-normative.

This specification does not define how XSLT interacts with the `script` element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, based on existing implementations:

- When an XSLT transformation program is triggered by an `<?xml-stylesheet?>` processing instruction and the browser implements a direct-to-DOM transformation, `script` elements created by the XSLT processor need to be marked "parser-inserted" and run in document order (modulo scripts marked `defer` or `async`), immediately, as the transformation is occurring.

- The `XSLTProcessor.transformToDocument()` method adds elements to a `Document` that does not have a browsing context, and, accordingly, any `script` elements they create need to have their "already started" flag set in the `prepare a script` algorithm and never get executed (scripting is disabled). Such `script` elements still need to be marked "parser-inserted", though, such that their `async` IDL attribute will return false in the absence of an `async` content attribute.

- The `XSLTProcessor.transformToFragment()` method needs to create a fragment that is equivalent to one built manually by creating the elements using `document.createElementNS()`. For instance, it needs to create `script` elements that aren't "parser-inserted" and that don't have their "already started" flag set, so that they will execute when the fragment is inserted into a document.

The main distinction between the first two cases and the last case is that the first two operate on `Document`s and the last operates on a fragment.

Note

This corresponds to putting the contents of the element in JavaScript comments.

Note

This requirement is in addition to the earlier restrictions on the syntax of contents of `script` elements.

Example

This allows authors to include documentation, such as license information or API information, inside their documents while still referring to external script files. The syntax is constrained so that authors don’t accidentally include what looks like valid script while also providing a `src` attribute.

```xml
<script src="cool-effects.js">
// create new instances using:
// var e = new Effect();
// start the effect using .play, stop using .stop:
// e.play();
// e.stop();
</script>
```

4.12.1.5 Interaction of `script` elements and XSLT

This section is non-normative.

This specification does not define how XSLT interacts with the `script` element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, based on existing implementations:

- When an XSLT transformation program is triggered by an `<?xml-stylesheet?>` processing instruction and the browser implements a direct-to-DOM transformation, `script` elements created by the XSLT processor need to be marked "parser-inserted" and run in document order (modulo scripts marked `defer` or `async`), immediately, as the transformation is occurring.

- The `XSLTProcessor.transformToDocument()` method adds elements to a `Document` that does not have a browsing context, and, accordingly, any `script` elements they create need to have their "already started" flag set in the `prepare a script` algorithm and never get executed (scripting is disabled). Such `script` elements still need to be marked "parser-inserted", though, such that their `async` IDL attribute will return false in the absence of an `async` content attribute.

- The `XSLTProcessor.transformToFragment()` method needs to create a fragment that is equivalent to one built manually by creating the elements using `document.createElementNS()`. For instance, it needs to create `script` elements that aren't "parser-inserted" and that don't have their "already started" flag set, so that they will execute when the fragment is inserted into a document.

The main distinction between the first two cases and the last case is that the first two operate on `Document`s and the last operates on a fragment.
4.12.2 The **noscript** element

**Categories**
- Metadata content
- Flow content
- Phrasing content

**Contexts in which this element can be used**:
In a **head** element of an **HTML document**, if there are no ancestor **noscript** elements. Where phrasing content is expected in **HTML documents**, if there are no ancestor **noscript** elements.

**Content model**:
- When scripting is disabled, in a **head** element: in any order, zero or more **link** elements, zero or more **style** elements, and zero or more **meta** elements.
- When scripting is disabled, not in a **head** element: transparent, but there must be no **noscript** element descendants.
- Otherwise: text that conforms to the requirements given in the prose.

**Tag omission in text/html**: Neither tag is omissible.

**Content attributes**:
- Global attributes

**DOM interface**:
- Uses **HTMLElement**

The **noscript** element represents nothing if scripting is enabled, and represents its children if scripting is disabled. It is used to present different markup to user agents that support scripting and those that don’t support scripting, by affecting how the document is parsed.

When used in **HTML documents**, the allowed content model is as follows:

**In a **head** element, if scripting is disabled** for the **noscript** element
- The **noscript** element must contain only **link**, **style**, and **meta** elements.

**In a **head** element, if scripting is enabled** for the **noscript** element
- The **noscript** element must contain only text, except that invoking the **HTML fragment parsing algorithm** with the **noscript** element as the **context** and the text contents as the input must result in a list of nodes that consists only of **link**, **style**, and **meta** elements that would be conforming if they were children of the **noscript** element, and no parse errors.

**Outside of **head** elements, if scripting is disabled** for the **noscript** element
- The **noscript** element’s content model is transparent, with the additional restriction that a **noscript** element must not have a **noscript** element as an ancestor (that is, **noscript** can’t be nested).

**Outside of **head** elements, if scripting is enabled** for the **noscript** element
- The **noscript** element must contain only text, except that the text must be such that running the following algorithm results in a conforming document with no **noscript** elements and no **script** elements, and such that no step in the algorithm throws an exception or causes an **HTML parser** to flag a parse error:

1. Remove every **script** element from the document.
2. Make a list of every **noscript** element in the document. For every **noscript** element in that list, perform the following steps:
   1. Let s be the child text content of the **noscript** element.
   2. Set the outerHTML attribute of the **noscript** element to the value of s. (This, as a side-effect, causes the **noscript** element to be removed from the document.)

**Note**: All these contortions are required because, for historical reasons, the **noscript** element is handled differently by the **HTML parser** based on whether **scripting was enabled or not** when the parser was invoked.
The `noscript` element must not be used in XML documents.

The `noscript` element is only effective in the HTML syntax; it has no effect in the XML syntax. This is because the way it works is by essentially “turning off” the parser when scripts are enabled, so that the contents of the element are treated as pure text and not as real elements. XML does not define a mechanism by which to do this.

The `noscript` element has no other requirements. In particular, children of the `noscript` element are not exempt from form submission, scripting, and so forth, even when scripting is enabled for the element.

In the following example, a `noscript` element is used to provide fallback for a script.

```html
<form action="calcSquare.php">
  <p>
    <label for="x">Number</label>
    <input id="x" name="x" type="number">
  </p>

  <script>
    var x = document.getElementById('x');
    var output = document.createElement('p');
    output.textContent = 'Type a number; it will be squared right then!';
    x.form.appendChild(output);
    x.form.onSubmit = function () { return false; }
    x.oninput = function () {
      var v = x.valueAsNumber;
      output.textContent = v + ' squared is ' + v * v;
    }
  </script>

  <noscript>
    <input type="submit" value="Calculate Square">
  </noscript>

</form>
```

When script is disabled, a button appears to do the calculation on the server side. When script is enabled, the value is computed on-the-fly instead.

The `noscript` element is a blunt instrument. Sometimes, scripts might be enabled, but for some reason the page's script might fail. For this reason, it's generally better to avoid using `noscript`, and to instead design the script to change the page from being a scriptless page to a scripted page on the fly, as in the next example:

```html
<form action="calcSquare.php">
  <p>
    <label for="x">Number</label>
    <input id="x" name="x" type="number">
  </p>

  <input id="submit" type="submit" value="Calculate Square">

  <script>
    var x = document.getElementById('x');
    var output = document.createElement('p');
    output.textContent = 'Type a number; it will be squared right then!';
    x.form.appendChild(output);
    x.form.onSubmit = function () { return false; }
    x.oninput = function () {
      var v = x.valueAsNumber;
      output.textContent = v + ' squared is ' + v * v;
    };
    var submit = document.getElementById('submit');
    submit.parentNode.removeChild(submit);
  </script>
```
The above technique is also useful in XML documents, since noscript is not allowed there.

4.12.3 The template element

Categories:
- Metadata content
- Flow content
- Phrasing content
- Script-supporting element

Contexts in which this element can be used:
- Where metadata content is expected.
- Where phrasing content is expected.
- Where script-supporting elements are expected.

As a child of a colgroup element that doesn't have a span attribute.

Content model:
Nothing (for clarification, see example).

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
Global attributes

DOM interface:

IDL
[Exposed=Window,
HTMLConstructor]
interface HTMLTemplateElement : HTMLElement {
readonly attribute DocumentFragment content;
};

The template element is used to declare fragments of HTML that can be cloned and inserted in the document by script.

In a rendering, the template element represents nothing.

The template contents of a template element are not children of the element itself.

Note
It is also possible, as a result of DOM manipulation, for a template element to contain Text nodes and element nodes; however, having any is a violation of the template element's content model, since its content model is defined as nothing.

Example
For example, consider the following document:

```html
<!doctype html>
<html lang="en">
<head>
<title>Homework</title>
<body>
<template id="template"><p>Smile!</p></template>
<script>
let num = 3;
```
Each template element has an associated DocumentFragment object that is its template contents. The template contents have no conformance requirements. When a template element is created, the user agent must run the following steps to establish the template contents:

1. Let doc be the template element's node document's appropriate template contents owner document.
2. Create a DocumentFragment object whose node document is doc and host is the template element.
3. Set the template element's template contents to the newly created DocumentFragment object.

A Document node's appropriate template contents owner document is the Document returned by the following algorithm:

1. If doc is not a Document created by this algorithm, then:
   1. Let new doc be a new Document (that does not have a browsing context). This is "a Document created by this algorithm" for the purposes of the step above.
   2. If doc is an HTML document, mark new doc as an HTML document also.
   3. Let doc's associated inert template document be new doc.
2. Set doc to doc's associated inert template document.

Each template element has an associated DocumentFragment object that is its template contents. The template contents have no conformance requirements. When a template element is created, the user agent must run the following steps to establish the template contents:

1. Let doc be the template element's node document's appropriate template contents owner document.
2. Create a DocumentFragment object whose node document is doc and host is the template element.
3. Set the template element's template contents to the newly created DocumentFragment object.

For web developers (non-normative)

**template.content**

Returns the template contents (a DocumentFragment).

The p element in the template is not a child of the template in the DOM; it is a child of the DocumentFragment returned by the template element's content IDL attribute.

If the script were to call appendChild() on the template element, that would add a child to the template element (as for any other element); however, doing so is a violation of the template element's content model.

```javascript
const fragment = document.getElementById('template').content.cloneNode(true);
while (num-- > 1) {
    fragment.firstChild.before(fragment.firstChild.cloneNode(true));
    fragment.firstChild.textContent += fragment.lastChild.textContent;
}
document.body.appendChild(fragment);
</script>
</html>
```

The p element in the template is not a child of the template in the DOM; it is a child of the DocumentFragment returned by the template element's content IDL attribute.

The adopting steps (with node and oldDocument as parameters) for template elements are the following:

1. Let doc be node's node document's appropriate template contents owner document.

Note

Each Document not created by this algorithm thus gets a single Document to act as its proxy for owning the template contents of all its template elements, so that they aren't in a browsing context and thus remain inert (e.g. scripts do not run). Meanwhile, template elements inside Document objects that are created by this algorithm just reuse the same Document owner for their contents.

2. Return doc.

The adopting steps (with node and oldDocument as parameters) for template elements are the following:

1. Let doc be node's node document's appropriate template contents owner document.

Note

node's node document is the Document object that node was just adopted into.

2. Adopt node's template contents (a DocumentFragment object) into doc.
The content IDL attribute must return the template element's template contents.

The cloning steps for a template element node being cloned to a copy must run the following steps:

1. If the clone children flag is not set in the calling clone algorithm, return.

2. Let copied contents be the result of cloning all the children of node's template contents, with document set to copy's template contents's node document, and with the clone children flag set.

3. Append copied contents to copy's template contents.

This section is non-normative.

This specification does not define how XSLT and XPath interact with the template element. However, in the absence of another...
specification actually defining this, here are some guidelines for implementers, which are intended to be consistent with other processing described in this specification:

- An XSLT processor based on an XML parser that acts as described in this specification needs to act as if template elements contain as descendants their template contents, for the purposes of the transform.
- An XSLT processor that outputs a DOM needs to ensure that nodes that would go into a template element are instead placed into the element's template contents.
- XPath evaluation using the XPath DOM API when applied to a Document parsed using the HTML parser or the XML parser described in this specification needs to ignore template contents.

4.12.4 The slot element

Categories:
- Flow content
- Phrasing content

Contexts in which this element can be used:
Where phrasing content is expected.

Content model:
- Transparent

Tag omission in text/html:
Neither tag is omissible.

Content attributes:
- Global attributes
  - name — Name of shadow tree slot

DOM interface:

```idl
[Exposed=Window, HTMLConstructor]
interface HTMLSlotElement : HTMLElement {
  [CFReactions] attribute DOMString name;
  sequence<Node> assignedNodes(optional AssignedNodesOptions options);
  sequence<Element> assignedElements(optional AssignedNodesOptions options);
};
```

dictionary AssignedNodesOptions {
  boolean flatten = false;
};

The slot element defines a slot. It is typically used in a shadow tree. A slot element represents its assigned nodes, if any, and its contents otherwise.

The name content attribute may contain any string value. It represents a slot's name.

Note

The name attribute is used to assign slots to other elements: a slot element with a name attribute creates a named slot to which any element is assigned if that element has a slot attribute whose value matches that name attribute's value, and the slot element is a child of the shadow tree whose root's host has that corresponding slot attribute value.

For web developers (non-normative)

```html
slot . name
```

Can be used to get and set slot's name.
The `name` IDL attribute must reflect the content attribute of the same name.

The `assignedNodes(options)` method, when invoked, must run these steps:

1. If the value of `options`'s `flatten` member is false, then return this element's `assigned nodes`.
2. Return the result of finding flattened slotables with this element.

The `assignedElements(options)` method, when invoked, must run these steps:

1. If the value of `options`'s `flatten` member is false, then return this element's `assigned nodes`, filtered to contain only Element nodes.
2. Return the result of finding flattened slotables with this element, filtered to contain only Element nodes.

4.12.5 The `canvas` element

**Categories**
- Flow content
- Phrasing content
- Embedded content
- Palpable content

**Contexts in which this element can be used**

Where embedded content is expected.

**Content model**

Transparent, but with no interactive content descendants except for `a` elements, `img` elements with `usemap` attributes, `button` elements, `input` elements whose `type` attribute are in the `Checkbox` or `Radio Button` states, `input` elements that are buttons, `select` elements with a `multiple` attribute or a `display size` greater than 1, and elements that would not be interactive content except for having the `tabindex` attribute specified.

**Tag omission in text/html**

Neither tag is omissible.

**Content attributes**

- `Global attributes`
  - `width` — Horizontal dimension
  - `height` — Vertical dimension

**DOM interface**

```idl
typedef (CanvasRenderingContext2D or ImageBitmapRenderingContext or WebGLRenderingContext)RenderingContext;

[Exposed=Window,
IDL]
The `canvas` element provides scripts with a resolution-dependent bitmap canvas, which can be used for rendering graphs, game graphics, art, or other visual images on the fly.

Authors should not use the `canvas` element in a document when a more suitable element is available. For example, it is inappropriate to use a `canvas` element to render a page heading: if the desired presentation of the heading is graphically intense, it should be marked up using appropriate elements (typically `<h1>`) and then styled using CSS and supporting technologies such as shadow trees.

When authors use the `canvas` element, they must also provide content that, when presented to the user, conveys essentially the same function or purpose as the `canvas`’s bitmap. This content may be placed as content of the `canvas` element. The contents of the `canvas` element, if any, are the element’s fallback content.

In interactive visual media, if scripting is enabled for the `canvas` element, and if support for `canvas` elements has been enabled, then the `canvas` element represents, embedded content consisting of a dynamically created image, the element’s bitmap.

In non-interactive, static, visual media, if the `canvas` element has been previously associated with a rendering context (e.g. if the page was viewed in an interactive visual medium and is now being printed, or if some script that ran during the page layout process painted on the element), then the `canvas` element represents, embedded content with the element’s current bitmap and size. Otherwise, the element represents its fallback content instead.

In non-visual media, and in visual media if scripting is disabled for the `canvas` element or if support for `canvas` elements has been disabled, the `canvas` element represents its fallback content instead.

When a `canvas` element represents, embedded content, the user can still focus descendants of the `canvas` element (in the fallback content). When an element is focused, it is the target of keyboard interaction events (even though the element itself is not visible). This allows authors to make an interactive canvas keyboard-accessible: authors should have a one-to-one mapping of interactive regions to focusable areas in the fallback content. (Focus has no effect on mouse interaction events.)

An element whose nearest `canvas` element ancestor is being rendered and represents, embedded content, is an element that is being used as relevant canvas fallback content.

The `canvas` element has two attributes to control the size of the element’s bitmap: `width` and `height`. These attributes, when specified, must have values that are valid non-negative integers. The rules for parsing non-negative integers must be used to obtain their numeric values. If an attribute is missing, or if parsing its value returns an error, then the default value must be used instead. The `width` attribute defaults to 300, and the `height` attribute defaults to 150.

When setting the value of the `width` or `height` attribute, if the context mode of the `canvas` element is set to `placeholder`, the user agent must throw an `InvalidStateError` and leave the attribute’s value unchanged.

The intrinsic dimensions of the `canvas` element when it represents, embedded content are equal to the dimensions of the element’s bitmap.

The user agent must use a square pixel density consisting of one pixel of image data per coordinate space unit for the bitmaps of a `canvas` and its rendering contexts.
A canvas element can be sized arbitrarily by a style sheet, its bitmap is then subject to the 'object-fit' CSS property.

The bitmaps of canvas elements, the bitmaps of ImageBitmap objects, as well as some of the bitmaps of rendering contexts, such as those described in the sections on the CanvasRenderingContext2D and ImageBitmapRenderingContext objects below, have an origin-clean flag, which can be set to true or false. Initially, when the canvas element or ImageBitmap object is created, its bitmap’s origin-clean flag must be set to true.

A canvas element can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, a canvas also has a canvas context mode, which is initially none but can be changed to either placeholder, 2d, bitmaprenderer, or webgl by algorithms defined in this specification.

When its canvas context mode is none, a canvas element has no rendering context, and its bitmap must be transparent black with an intrinsic width equal to the numeric value of the element's width attribute and an intrinsic height equal to the numeric value of the element's height attribute, those values being interpreted in CSS pixels, and being updated as the attributes are set, changed, or removed.

When its canvas context mode is placeholder, a canvas element has no rendering context. It serves as a placeholder for an OffscreenCanvas object, and the content of the canvas element is updated by calling the commit() method of the OffscreenCanvas object's rendering context.

When a canvas element represents embedded content, it provides a paint source whose width is the element's intrinsic width, whose height is the element's intrinsic height, and whose appearance is the element's bitmap.

Whenever the width and height content attributes are set, removed, changed, or redundantly set to the value they already have, then the user agent must perform the action from the row of the following table that corresponds to the canvas element's context mode.

<table>
<thead>
<tr>
<th>Context Mode</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>2d</td>
<td>Follow the steps to set bitmap dimensions to the numeric values of the width and height content attributes.</td>
</tr>
<tr>
<td>webgl</td>
<td>Follow the behavior defined in the WebGL specification. [WEBGL]</td>
</tr>
<tr>
<td>bitmaprenderer</td>
<td>If the context's bitmap mode is set to blank, run the steps to set an ImageBitmapRenderingContext's output bitmap, passing the canvas element's rendering context.</td>
</tr>
<tr>
<td>placeholder</td>
<td>Do nothing.</td>
</tr>
<tr>
<td>none</td>
<td>Do nothing.</td>
</tr>
</tbody>
</table>

The width and height IDL attributes must reflect the respective content attributes of the same name, with the same defaults.

For web developers (non-normative)

canvas.getContext(contextId [, options ] )

Returns an object that exposes an API for drawing on the canvas. contextId specifies the desired API: "2d", "bitmaprenderer", or "webgl". options is handled by that API.

This specification defines the "2d" and "bitmaprenderer" contexts below. There is also a specification that defines a "webgl" context. [WEBGL]

Returns null if contextId is not supported, or if the canvas has already been initialized with another context type (e.g., trying to get a "2d" context after getting a "webgl" context).
1. If `options` is not an `object`, then set `options` to null.

2. Set `options` to the result of converting `options` to a JavaScript value.

3. Run the steps in the cell of the following table whose column header matches this `canvas` element's `canvas context mode` and whose row header matches `contextId`:

<table>
<thead>
<tr>
<th><code>contextId</code></th>
<th><code>none</code></th>
<th><code>2d</code></th>
<th><code>bitmaprenderer</code></th>
<th><code>webgl</code></th>
<th><code>placeholder</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;2d&quot;</td>
<td>Follow the 2D context creation algorithm defined in the section below, passing this canvas element and options, to obtain a CanvasRenderingContext2D object; if this does not throw an exception, then set this canvas element's <code>context mode</code> to <code>2d</code>, and return the CanvasRenderingContext2D object.</td>
<td>Return the same object as was returned the last time the method was invoked with this same first argument.</td>
<td>Return null.</td>
<td>Return null.</td>
<td>Throw an &quot;InvalidStateError&quot; DOMException.</td>
</tr>
<tr>
<td>&quot;bitmaprenderer&quot;</td>
<td>Follow the ImageBitmapRenderingContext creation algorithm defined in the section below, passing this canvas element and options, to obtain an ImageBitmapRenderingContext object; then set this canvas element's <code>context mode</code> to bitmaprenderer, and return the ImageBitmapRenderingContext object.</td>
<td>Return null.</td>
<td>Return the same object as was returned the last time the method was invoked with this same first argument.</td>
<td>Return null.</td>
<td>Return null.</td>
</tr>
</tbody>
</table>
| "webgl", if the user agent supports the WebGL feature in its current configuration | Follow the instructions given in the WebGL specification's Context Creation section to obtain either a WebGLRenderingContext or null; if the returned value is null, then return null; otherwise, set this canvas element's `context mode` to webgl, and return the WebGLRenderingContext object. [WEBGL]

* For example, the "webgl" value in the case of a user agent having exhausted the graphics hardware's abilities and having no software fallback implementation.

---

**For web developers (non-normative)**

```javascript
url = canvas.toDataURL([type [, quality ]])
```

Returns a `data: URL` for the image in the canvas.

The first argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "image/png"; that type is also used if the given type isn't supported. The second argument applies if the type is an image format that supports variable quality (such as "image/jpeg"), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

When trying to use types other than "image/png", authors can check if the image was really returned in the requested format by checking to see if the returned string starts with one of the exact strings "data:image/png," or "data:image/png;". If it does, the image is PNG, and thus the requested type was not supported. (The one exception to this is if the canvas has either no height or no width, in which case the result might simply be "data:,").

```javascript
canvas.toBlob([callback [, type [, quality ]]])
```

Creates a `Blob` object representing a file containing the image in the canvas, and invokes a callback with a handle to that object.

The second argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "image/png"; that type is also used if the given type isn't supported. The third argument applies if the type is an image format that supports variable quality (such as "image/jpeg"), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

```javascript
canvas.transferControlToOffscreen()
```

Returns a newly created `OffscreenCanvas` object that uses the canvas element as a placeholder. Once the canvas element has become a placeholder for an `OffscreenCanvas` object, its intrinsic size can no longer be changed, and it cannot have a rendering context. The content of the placeholder canvas is updated by calling the `commit()` method of the...
The `toDataURL(type, quality)` method, when invoked, must run these steps:

1. If this `canvas` element's bitmap's `origin-clean` flag is set to false, then throw a "SecurityError" DOMException.
2. If this `canvas` element's bitmap has no pixels (i.e. either its horizontal dimension or its vertical dimension is zero) then return the string "data:;". (This is the shortest data: URL; it represents the empty string in a text/plain resource.)
3. Let `file` be a serialization of this `canvas` element's bitmap as a file, passing `type` and `quality` if they were given.
4. If `file` is null then return "data:;".
5. Return a data: URL representing `file`. [RFC2397]

The `toBlob(callback, type, quality)` method, when invoked, must run these steps:

1. If this `canvas` element's bitmap's `origin-clean` flag is set to false, then throw a "SecurityError" DOMException.
2. Let `result` be null.
3. If this `canvas` element's bitmap has pixels (i.e., neither its horizontal dimension nor its vertical dimension is zero), then set `result` to a copy of this `canvas` element's bitmap.
4. Run these steps in parallel:
   1. If `result` is non-null, then set `result` to a serialization of `result` as a file, with `type` and `quality` if they were given.
   2. Queue a task to run these steps:
      1. If `result` is non-null, then set `result` to a new Blob object, created in the relevant Realm of this `canvas` element, representing `result`. [FILEAPI]
      2. Invoke `callback` with « `result` ».

The task source for this task is the canvas blob serialization task source.

The `transferControlToOffscreen()` method, when invoked, must run these steps:

1. If this `canvas` element's `context mode` is not set to `none`, throw an "InvalidStateError" DOMException.
2. Let `offscreenCanvas` be a new OffscreenCanvas object with its width and height equal to the values of the `width` and `height` content attributes of this `canvas` element.
3. Set the `placeholder` canvas element of `offscreenCanvas` to be a weak reference to this `canvas` element.
4. Set this `canvas` element's `context mode` to `placeholder`.
5. Return `offscreenCanvas`.

**4.12.5.1 The 2D rendering context**

```idl
typedef (HTMLImageElement or SVGImageElement) HTMLOrSVGImageElement;
typedef (HTMLOrSVGImageElement or HTMLVideoElement or HTMLCanvasElement or ImageBitmap or OffscreenCanvas) CanvasImageSource;
enum CanvasFillRule { "nonzero", "evenodd" };
```
dictionary CanvasRenderingContext2DSettings {
  boolean alpha = true;
};

enum ImageSmoothingQuality { "low", "medium", "high" };

[Exposed=Window]
interface CanvasRenderingContext2D {
  // back-reference to the canvas
  readonly attribute HTMLCanvasElement canvas;
};
CanvasRenderingContext2D includes CanvasState;
CanvasRenderingContext2D includes CanvasTransform;
CanvasRenderingContext2D includes CanvasCompositing;
CanvasRenderingContext2D includes CanvasImageSmoothing;
CanvasRenderingContext2D includes CanvasFillStrokeStyles;
CanvasRenderingContext2D includes CanvasShadowStyles;
CanvasRenderingContext2D includes CanvasFilters;
CanvasRenderingContext2D includes CanvasRect;
CanvasRenderingContext2D includes CanvasDrawPath;
CanvasRenderingContext2D includes CanvasUserInterface;
CanvasRenderingContext2D includes CanvasText;
CanvasRenderingContext2D includes CanvasDrawImage;
CanvasRenderingContext2D includes CanvasImageData;
CanvasRenderingContext2D includes CanvasPathDrawingStyles;
CanvasRenderingContext2D includes CanvasTextDrawingStyles;
CanvasRenderingContext2D includes CanvasPath;

interface mixin CanvasState {
  // state
  void save(); // push state on state stack
  void restore(); // pop state stack and restore state
};

interface mixin CanvasTransform {
  // transformations (default transform is the identity matrix)
  void scale(unrestricted double x, unrestricted double y);
  void rotate(unrestricted double angle);
  void translate(unrestricted double x, unrestricted double y);
  void transform(unrestricted double a, unrestricted double b, unrestricted double c, unrestricted double d, unrestricted double e, unrestricted double f);

  [NewObject] DOMMatrix getTransform();
  void setTransform(unrestricted double a, unrestricted double b, unrestricted double c, unrestricted double d, unrestricted double e, unrestricted double f);
  void setTransform(optional DOMMatrix2DInit transform);
  void resetTransform();
};

To maintain compatibility with existing Web content, user agents need to enumerate methods defined in `CanvasUserInterface` immediately after the `stroke()` method on `CanvasRenderingContext2D` objects.

**For web developers (non-normative)**

```javascript
context = canvas .getContext('2d', { [alpha: false] })
```

Returns a `CanvasRenderingContext2D` object that is permanently bound to a particular `canvas` element. If the `alpha` setting is provided and set to false, then the canvas is forced to always be opaque.

```javascript
context .canvas
```

Returns the `canvas` element.

A `CanvasRenderingContext2D` object has an output bitmap that is initialized when the object is created.

The output bitmap has an origin-clean flag, which can be set to true or false. Initially, when one of these bitmaps is created, its origin-clean flag must be set to true.

The `CanvasRenderingContext2D` object also has an alpha flag, which can be set to true or false. Initially, when the context is created, its alpha flag must be set to true. When a `CanvasRenderingContext2D` object has its alpha flag set to false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

**Note**

Thus, the bitmap of such a context starts off as opaque black instead of transparent black; `clearRect()` always results in opaque black pixels, every fourth byte from `getImageData()` is always 255, the `putImageData()` method effectively ignores every fourth byte in its input, and so on. However, the alpha component of styles and images drawn onto the canvas are still honoured up to the point where they would impact the output bitmap's alpha channel; for instance, drawing a 50% transparent white square on a freshly created output bitmap with its alpha flag set to false will result in a fully-opaque gray square.

The `CanvasRenderingContext2D` 2D rendering context represents a flat linear Cartesian surface whose origin (0,0) is at the top left corner, with the coordinate space having x values increasing when going right, and y values increasing when going down. The x-coordinate of the right-most edge is equal to the width of the rendering context's output bitmap in CSS pixels; similarly, the y-coordinate of the bottom-most edge is equal to the height of the rendering context's output bitmap in CSS pixels.

The size of the coordinate space does not necessarily represent the size of the actual bitmaps that the user agent will use internally or during rendering. On high-definition displays, for instance, the user agent may internally use bitmaps with four device pixels per unit in the coordinate space, so that the rendering remains at high quality throughout. Anti-aliasing can similarly be implemented using oversampling with bitmaps of a higher resolution than the final image on the display.

**Example**

Using `CSS pixels` to describe the size of a rendering context's output bitmap does not mean that when rendered the canvas will cover an equivalent area in `CSS pixels`; `CSS pixels` are reused for ease of integration with CSS features, such as text layout.

In other words, the `canvas` element below's rendering context has a 200x200 output bitmap (which internally uses `CSS pixels` as a unit for ease of integration with CSS) and is rendered as 100x100 `CSS pixels`:

```html
<canvas width=200 height=200 style=width:100px;height:100px>
```

The 2D context creation algorithm, which is passed a target (a `canvas` element) and options, consists of running these steps:

1. Let `settings` be the result of converting options to the dictionary type `CanvasRenderingContext2DSettings`. (This can throw an exception.).
2. Let `context` be a new `CanvasRenderingContext2D` object.
3. Initialize context's `canvas` attribute to point to target.
4. Set context's output bitmap to the same bitmap as target's bitmap (so that they are shared).

5. Set bitmap dimensions to the numeric values of target's width and height content attributes.

6. Process each of the members of settings as follows:
   
   \[ \text{alpha} \]
   
   If false, then set context's alpha flag to false.

7. Return context.

When the user agent is to set bitmap dimensions to width and height, it must run these steps:

1. Reset the rendering context to its default state.

2. Resize the output bitmap to the new width and height and clear it to transparent black.

3. Let canvas be the canvas element to which the rendering context's canvas attribute was initialized.

4. If the numeric value of canvas's width content attribute differs from width, then set canvas's width content attribute to the shortest possible string representing width as a valid non-negative integer.

5. If the numeric value of canvas's height content attribute differs from height, then set canvas's height content attribute to the shortest possible string representing height as a valid non-negative integer.

Example

Only one square appears to be drawn in the following example:

```javascript
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');
context.fillRect(0, 0, 50, 50);
canvas.setAttribute('width', '300'); // clears the canvas
context.fillRect(0, 100, 50, 50);
canvas.width = canvas.width; // clears the canvas
context.fillRect(100, 0, 50, 50); // only this square remains
```

The canvas attribute must return the value it was initialized to when the object was created.

The CanvasFillRule enumeration is used to select the fill rule algorithm by which to determine if a point is inside or outside a path.

The value "nonzero" value indicates the nonzero winding rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path going in one direction is equal to the number of times it crosses the path going in the other direction.

The "evenodd" value indicates the even-odd rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path is even.

If a point is not outside a shape, it is inside the shape.

The ImageSmoothingQuality enumeration is used to express a preference for the interpolation quality to use when smoothing images.

The "low" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "medium" value indicates a preference for a medium level of image interpolation quality.

The "high" value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.
4.12.5.1.1 Implementation notes

This section is non-normative.

The output bitmap, when it is not directly displayed by the user agent, implementations can, instead of updating this bitmap, merely remember the sequence of drawing operations that have been applied to it until such time as the bitmap's actual data is needed (for example because of a call to drawImage() or the createImageBitmap() factory method). In many cases, this will be more memory efficient.

The bitmap of a canvas element is the one bitmap that's pretty much always going to be needed in practice. The output bitmap of a rendering context, when it has one, is always just an alias to a canvas element's bitmap.

Additional bitmaps are sometimes needed, e.g. to enable fast drawing when the canvas is being painted at a different size than its intrinsic size, or to enable double buffering so that graphics updates, like page scrolling for example, can be processed concurrently while canvas draw commands are being executed.

4.12.5.1.2 The canvas state

Objects that implement the CanvasState interface maintain a stack of drawing states. Drawing states consist of:

- The current transformation matrix.
- The current clipping region.
- The current values of the following attributes: strokeStyle, fillStyle, globalAlpha, lineWidth, lineCap, lineJoin, miterLimit, lineDashOffset, shadowOffsetX, shadowOffsetY, ShadowBlur, shadowColor, filter, globalCompositeOperation, font, textAlign, textBaseline, direction, imageSmoothingEnabled, imageSmoothingQuality.
- The current dash list.

The save() method, when invoked, must push a copy of the current state onto the stack.

The restore() method, when invoked, must pop the top entry in the drawing state stack, and reset the drawing state it describes. If there is no saved state, then the method must do nothing.

When the user agent is to reset the rendering context to its default state, it must clear the drawing state stack and everything that drawing state consists of to initial values.

4.12.5.1.3 Line styles

For web developers (non-normative)
Objects that implement the CanvasPathDrawingStyles interface have attributes and methods (defined in this section) that control how lines are treated by the object.

The lineWidth attribute gives the width of lines, in coordinate space units. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the CanvasPathDrawingStyles interface is created, the lineWidth attribute must initially have the value 1.0.

The lineCap attribute defines the type of endings that UAs will place on the end of lines. The three valid values are "butt", "round", and "square". Other values are ignored.

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the CanvasPathDrawingStyles interface is created, the lineCap attribute must initially have the value "butt".

The lineJoin attribute returns the current line join style. Can be set, to change the line join style. The possible line join styles are "bevel", "round", and "miter". Other values are ignored.

The miterLimit attribute returns the current miter limit ratio. Can be set, to change the miter limit ratio. Values that are not finite values greater than zero are ignored.

The setLineDash method sets the current line dash pattern (as used when stroking). The argument is a list of distances for which to alternately have the line on and the line off.

The getLineDash method returns a copy of the current line dash pattern. The array returned will always have an even number of entries (i.e. the pattern is normalized).

The lineDashOffset method returns the phase offset (in the same units as the line dash pattern). Can be set, to change the phase offset. Values that are not finite values are ignored.

context.lineWidth [ = value ]
styles.lineWidth [ = value ]

Returns the current line width. Can be set, to change the line width. Values that are not finite values greater than zero are ignored.

context.lineCap [ = value ]
styles.lineCap [ = value ]

Returns the current line cap style. Can be set, to change the line cap style. The possible line cap styles are "butt", "round", and "square". Other values are ignored.

context.lineJoin [ = value ]
styles.lineJoin [ = value ]

Returns the current line join style. Can be set, to change the line join style. The possible line join styles are "bevel", "round", and "miter". Other values are ignored.

context.miterLimit [ = value ]
styles.miterLimit [ = value ]

Returns the current miter limit ratio. Can be set, to change the miter limit ratio. Values that are not finite values greater than zero are ignored.

context.setLineDash(segments)
styles.setLineDash(segments)

Sets the current line dash pattern (as used when stroking). The argument is a list of distances for which to alternately have the line on and the line off.

segments = context.getLineDash()
segments = styles.getLineDash()

Returns a copy of the current line dash pattern. The array returned will always have an even number of entries (i.e. the pattern is normalized).

context.lineDashOffset
styles.lineDashOffset

Returns the phase offset (in the same units as the line dash pattern). Can be set, to change the phase offset. Values that are not finite values are ignored.
The `lineJoin` attribute defines the type of corners that UAs will place where two lines meet. The three valid values are "bevel", "round", and "miter".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `lineJoin` attribute must initially have the value "miter".

When the `lineJoin` attribute has the value "miter", strokes use the miter limit ratio to decide how to render joins. The miter limit ratio can be explicitly set using the `miterLimit` attribute. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `miterLimit` attribute must initially have the value 10.0.

Each `CanvasPathDrawingStyles` object has a dash list, which is either empty or consists of an even number of non-negative numbers. Initially, the dash list must be empty.

The `setLineDash()` method, when invoked, must run these steps:

1. Let a be the argument.
2. If any value in a is not finite (e.g. an Infinity or a NaN value), or if any value is negative (less than zero), then return (without throwing an exception; user agents could show a message on a developer console, though, as that would be helpful for debugging).
3. If the number of elements in a is odd, then let a be the concatenation of two copies of a.
4. Let the object’s dash list be a.

When the `getLineDash()` method is invoked, it must return a sequence whose values are the values of the object’s dash list, in the same order.

It is sometimes useful to change the “phase” of the dash pattern, e.g. to achieve a “marching ants” effect. The phase can be set using the `lineDashOffset` attribute. On getting, it must return the current value. On setting, infinite and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `lineDashOffset` attribute must initially have the value 0.0.

When a user agent is to trace a path, given an object style that implements the `CanvasPathDrawingStyles` interface, it must run the following algorithm. This algorithm returns a new `path`.

1. Let `path` be a copy of the path being traced.
2. Prune all zero-length line segments from `path`.
3. Remove from `path` any subpaths containing no lines (i.e. subpaths with just one point).
4. Replace each point in each subpath of `path` other than the first point and the last point of each subpath by a join that joins the line leading to that point to the line leading out of that point, such that the subpaths all consist of two points (a starting point with a line leading out of it, and an ending point with a line leading into it), one or more lines (connecting the points and the joins), and zero or more joins (each connecting one line to another), connected together such that each subpath is a series of one or more lines with a join between each one and a point on each end.
5. Add a straight closing line to each closed subpath in `path` connecting the last point and the first point of that subpath; change the last point to a join (from the previously last line to the newly added closing line), and change the first point to a join (from the newly added closing line to the first line).
6. If `style`’s dash list is empty, then jump to the step labeled convert.
7. Let `pattern width` be the concatenation of all the entries of `style`’s dash list, in coordinate space units.
8. For each subpath `subpath` in `path`, run the following substeps. These substeps mutate the subpaths in `path in vivo`.  

627
1. Let subpath width be the length of all the lines of subpath, in coordinate space units.

2. Let offset be the value of style's lineDashOffset\textsuperscript{627}, in coordinate space units.

3. While offset is greater than pattern width, decrement it by pattern width.
   While offset is less than zero, increment it by pattern width.

4. Define L to be a linear coordinate line defined along all lines in subpath, such that the start of the first line in the subpath is defined as coordinate 0, and the end of the last line in the subpath is defined as coordinate subpath width.

5. Let position be zero minus offset.

6. Let index be 0.

7. Let current state be off (the other states being on and zero-on).

8. Dash on: Let segment length be the value of style's dash list\textsuperscript{627}'s indexth entry.

9. Increment position by segment length.

10. If position is greater than subpath width, then end these substeps for this subpath and start them again for the next subpath; if there are no more subpaths, then jump to the step labeled convert instead.

11. If segment length is nonzero, then let current state be on.

12. Increment index by one.

13. Dash off: Let segment length be the value of style's dash list\textsuperscript{627}'s indexth entry.

14. Let start be the offset position on L.

15. Increment position by segment length.

16. If position is less than zero, then jump to the step labeled post-cut.

17. If start is less than zero, then let start be zero.

18. If position is greater than subpath width, then let end be the offset subpath width on L. Otherwise, let end be the offset position on L.

19. Jump to the first appropriate step:

   → If segment length is zero and current state is off
     Do nothing, just continue to the next step.

   → If current state is off
     Cut the line on which end finds itself short at end and place a point there, cutting in two the subpath that it was in; remove all line segments, joins, points, and subpaths that are between start and end; and finally place a single point at start with no lines connecting to it.
     The point has a directionality for the purposes of drawing line caps (see below). The directionality is the direction that the original line had at that point (i.e. when L was defined above).

   → Otherwise
     Cut the line on which start finds itself into two at start and place a point there, cutting in two the subpath that it was in, and similarly cut the line on which end finds itself short at end and place a point there, cutting in two the subpath that it was in, and then remove all line segments, joins, points, and subpaths that are between start and end.
     If start and end are the same point, then this results in just the line being cut in two and two points being inserted there, with nothing being removed, unless a join also happens to be at that point, in which case the join must be removed.

20. Post-cut: If position is greater than subpath width, then jump to the step labeled convert.

21. If segment length is greater than zero, then let positioned-at-on-dash be false.

22. Increment index by one. If it is equal to the number of entries in style's dash list\textsuperscript{627}, then let index be 0.

\textsuperscript{627}
23. Return to the step labeled dash on.

9. **Convert**: This is the step that converts the path to a new path that represents its stroke.

Create a new path that describes the edge of the areas that would be covered if a straight line of length equal to style's `lineWidth` was swept along each subpath in path while being kept at an angle such that the line is orthogonal to the path being swept, replacing each point with the end cap necessary to satisfy style's `lineCap` attribute as described previously and elaborated below, and replacing each join with the join necessary to satisfy style's `lineJoin` type, as defined below.

**Caps**: Each point has a flat edge perpendicular to the direction of the line coming out of it. This is then augmented according to the value of style's `lineCap`. The "butt" value means that no additional line cap is added. The "round" value means that a semi-circle with the diameter equal to style's `lineWidth` width must additionally be placed on to the line coming out of each point. The "square" value means that a rectangle with the length of style's `lineWidth` width and the width of half style's `lineWidth` width, placed flat against the edge perpendicular to the direction of the line coming out of the point, must be added at each point.

Points with no lines coming out of them must have two caps placed back-to-back as if it was really two points connected to each other by an infinitesimally short straight line in the direction of the point's directionality (as defined above).

**Joins**: In addition to the point where a join occurs, two additional points are relevant to each join, one for each line: the two corners found half the line width away from the join point, one perpendicular to each line, each on the side furthest from the other line.

A triangle connecting these two opposite corners with a straight line, with the third point of the triangle being the join point, must be added at all joins. The `lineJoin` attribute controls whether anything else is rendered. The three aforementioned values have the following meanings:

The "bevel" value means that this is all that is rendered at joins.

The "round" value means that an arc connecting the two aforementioned corners of the join, abutting (and not overlapping) the aforementioned triangle, with the diameter equal to the line width and the origin at the point of the join, must be added at joins.

The "miter" value means that a second triangle must (if it can given the miter length) be added at the join, with one line being the line between the two aforementioned corners, abutting the first triangle, and the other two being continuations of the outside edges of the two joining lines, as long as required to intersect without going over the miter length.

The miter length is the distance from the point where the join occurs to the intersection of the line edges on the outside of the join. The miter limit ratio is the maximum allowed ratio of the miter length to half the line width. If the miter length would cause the miter limit ratio (as set by style's `miterLimit` attribute) to be exceeded, then this second triangle must not be added.

The subpaths in the newly created path must be oriented such that for any point, the number of times a half-infinite straight line drawn from that point crosses a subpath is even if and only if the number of times a half-infinite straight line drawn from that same point crosses a subpath going in one direction is equal to the number of times it crosses a subpath going in the other direction.

10. Return the newly created path.

### 4.12.5.1.4 Text styles

**For web developers (non-normative)**

- `context . font [ = value ]`
- `styles . font [ = value ]`

Returns the current font settings.

Can be set, to change the font. The syntax is the same as for the CSS `font` property; values that cannot be parsed as CSS font values are ignored.

Relative keywords and lengths are computed relative to the font of the `canvas` element.
Objects that implement the `CanvasTextDrawingStyles` interface have attributes (defined in this section) that control how text is laid out (rasterized or outlined) by the object. Such objects can also have a font style source object. For `CanvasRenderingContext2D` objects, this is the `canvas` element given by the value of the context's `canvas` attribute. For `OffscreenCanvasRenderingContext2D` objects, this is the associated `OffscreenCanvas` object.

Font resolution for the font style source object requires a font source. This is determined for a given object implementing `CanvasTextDrawingStyles` by the following steps:

1. If object's font style source object is a `canvas` element, return the element's node document.
2. Otherwise, object's font style source object is an `OffscreenCanvas` object:
   1. Let `global` be object's relevant global object.
   2. If `global` is a `Window` object, then return `global`'s associated Document.
   3. Assert: `global` implements `WorkerGlobalScope`.
   4. Return `global`.

Example

This is an example of font resolution with a regular `canvas` element with ID `c1`.

```javascript
const font = new FontFace("MyCanvasFont", "url(mycanvasfont.ttf)");
documents.fonts.add(font);

const context = document.getElementById("c1").getContext("2d");
document.fonts.ready.then(function() {
  context.font = "64px MyCanvasFont";
  context.fillText("hello", 0, 0);
});
```

In this example, the canvas will display text using mycanvasfont.ttf as its font.

Example

This is an example of how font resolution can happen using `OffscreenCanvas`. Assuming a `canvas` element with ID `c2` which is transferred to a worker like so:

```javascript
const font = new FontFace("MyCanvasFont", "url(mycanvasfont.ttf)");
documents.fonts.add(font);

const context = document.getElementById("c2").getContext("2d");
document.fonts.ready.then(function() {
  context.font = "64px MyCanvasFont";
  context.fillText("hello", 0, 0);
});
```
const offscreenCanvas = document.getElementById("c2").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);

Then, in the worker:

self.onmessage = function(ev) {
    const transferredCanvas = ev.data;
    const context = transferredCanvas.getContext("2d");
    const font = new FontFace("MyFont", "url(myfont.ttf)");
    self.fonts.add(font);
    self.fonts.ready.then(function() {
        context.font = "64px MyFont";
        context.fillText("hello", 0, 0);
    });
};

In this example, the canvas will display a text using myfont.ttf. Notice that the font is only loaded inside the worker, and not in the document context.

The **font** IDL attribute, on setting, must be parsed as a CSS `<font>` value (but without supporting property-independent style sheet syntax like "inherit"), and the resulting font must be assigned to the context, with the 'line-height' component forced to 'normal', with the 'font-size' component converted to CSS pixels, and with system fonts being computed to explicit values. If the new value is syntactically incorrect (including using property-independent style sheet syntax like 'inherit' or 'initial'), then it must be ignored, without assigning a new font value. [CSS][1221]

Font family names must be interpreted in the context of the [font style source object](#css-font-style-source-object) when the font is to be used; any fonts embedded using @font-face or loaded using FontFace objects that are visible to the [font style source object](#css-font-style-source-object) must therefore be available once they are loaded. (Each [font style source object](#css-font-style-source-object) has a [font source](#css-font-source), which determines what fonts are available.) If a font is used before it is fully loaded, or if the [font style source object](#css-font-style-source-object) does not have that font in scope at the time the font is to be used, then it must be treated as if it was an unknown font, falling back to another as described by the relevant CSS specifications. [CSSFONTS][1222] [CSSFONTLOAD][1222]

On getting, the **font** attribute must return the serialized form of the current font of the context (with no 'line-height' component). [CSSOM][1222]

Example

For example, after the following statement:

```javascript
context.font = 'italic 400 12px/2 Unknown Font, sans-serif';
```

...the expression `context.font` would evaluate to the string "italic 12px "Unknown Font", sans-serif". The "400" font-weight doesn't appear because that is the default value. The line-height doesn't appear because it is forced to "normal", the default value.

When the object implementing the [CanvasTextDrawingStyles](#canvas-text-drawing-styles) interface is created, the font of the context must be set to 10px sans-serif. When the 'font-size' component is set to lengths using percentages, 'em' or 'ex' units, or the 'larger' or 'smaller' keywords, these must be interpreted relative to the [computed value](#computed-value) of the 'font-size' property of the [font style source object](#css-font-style-source-object) at the time that the attribute is set, if it is an element. When the 'font-weight' component is set to the relative values 'bolder' and 'lighter', these must be interpreted relative to the [computed value](#computed-value) of the 'font-weight' property of the [font style source object](#css-font-style-source-object) at the time that the attribute is set, if it is an element. If the [computed values](#computed-values) are undefined for a particular case (e.g. because the [font style source object](#css-font-style-source-object) is not an element or is not being rendered), then the relative keywords must be interpreted relative to the normal-weight 10px sans-serif default.

The **textAlign** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#canvas-text-drawing-styles) interface is created, the **textAlign** attribute must initially have the value **start**.[623]

The **textBaseline** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value.
value. When the object implementing the CanvasTextDrawingStyles interface is created, the textBaseline attribute must initially have the value alphabetic.

The direction IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles interface is created, the direction attribute must initially have the value "inherit".

The textAlign attribute's allowed keywords are as follows:

- **start**
  - Align to the start edge of the text (left side in left-to-right text, right side in right-to-left text).

- **end**
  - Align to the end edge of the text (right side in left-to-right text, left side in right-to-left text).

- **left**
  - Align to the left.

- **right**
  - Align to the right.

- **center**
  - Align to the center.

The textBaseline attribute's allowed keywords correspond to alignment points in the font:

- **top**
  - The top of the em square

- **hanging**
  - The hanging baseline

- **middle**
  - The middle of the em square

- **alphabetic**
  - The alphabetic baseline

- **ideographic**
  - The ideographic baseline

The keywords map to these alignment points as follows:

- **top**
  - The top of the em square

- **hanging**
  - The hanging baseline

- **middle**
  - The middle of the em square

- **alphabetic**
  - The alphabetic baseline

- **ideographic**
  - The ideographic baseline
The bottom of the em square

The \texttt{direction} attribute's allowed keywords are as follows:

\texttt{ltr}

Treat input to the \texttt{text preparation algorithm} as left-to-right text.

\texttt{rtl}

Treat input to the \texttt{text preparation algorithm} as right-to-left text.

\texttt{inherit}

Default to the directionality of the \texttt{canvas} element or \texttt{Document} as appropriate.

The \texttt{text preparation algorithm} is as follows. It takes as input a string \texttt{text}, a \texttt{CanvasTextDrawingStyles} object \texttt{target}, and an optional length \texttt{maxWidth}. It returns an array of glyph shapes, each positioned on a common coordinate space, a physical alignment whose value is one of \texttt{left}, \texttt{right}, and \texttt{center}, and an inline box. (Most callers of this algorithm ignore the physical alignment and the inline box.)

1. If \texttt{maxWidth} was provided but is less than or equal to zero or equal to NaN, then return an empty array.
2. Replace all ASCII whitespace in \texttt{text} with U+0020 SPACE characters.
3. Let \texttt{font} be the current font of \texttt{target}, as given by that object's \texttt{font} attribute.
4. Apply the appropriate step from the following list to determine the value of \texttt{direction}:
   - If the \texttt{target object}'s \texttt{direction} attribute has the value "ltr":
     Let \texttt{direction} be 'ltr'.
   - If the \texttt{target object}'s \texttt{direction} attribute has the value "rtl":
     Let \texttt{direction} be 'rtl'.
   - If the \texttt{target object's font style source object} is an element:
     Let \texttt{direction} be the directionality of the \texttt{target object's font style source object}.
   - If the \texttt{target object's font style source object} is a \texttt{Document} with a non-null document element:
     Let \texttt{direction} be the directionality of the \texttt{target object's font style source object}'s document element.
   - Otherwise
     Let \texttt{direction} be 'ltr'.
5. Form a hypothetical infinitely-wide CSS line box containing a single inline box containing the text \texttt{text}, with all the properties at their initial values except the 'font' property of the inline box set to \texttt{font}, the 'direction' property of the inline box set to \texttt{direction}, and the 'white-space' property set to 'pre'. [CSS]
6. If \texttt{maxWidth} was provided and the hypothetical width of the inline box in the hypothetical line box is greater than \texttt{maxWidth} CSS pixels, then change \texttt{font} to have a more condensed font (if one is available or if a reasonably readable one can be synthesized by applying a horizontal scale factor to the font) or a smaller font, and return to the previous step.
7. The anchor point is a point on the inline box, and the physical alignment is one of the values \texttt{left}, \texttt{right}, and \texttt{center}. These variables are determined by the \texttt{textAlign} and \texttt{textBaseline} values as follows:

   Horizontal position:
   - If \texttt{textAlign} is \texttt{left}:
     Let the anchor point's horizontal position be the left edge of the inline box, and let physical alignment be left.
   - If \texttt{textAlign} is \texttt{right}:
     Let the anchor point's horizontal position be the right edge of the inline box, and let physical alignment be right.
If `textAlign` is `center`:
Let the anchor point's horizontal position be half way between the left and right edges of the inline box, and let physical alignment be center.

Vertical position:

If `textBaseline` is `top`:
Let the anchor point's vertical position be the top of the em box of the first available font of the inline box.

If `textBaseline` is `hanging`:
Let the anchor point's vertical position be the hanging baseline of the first available font of the inline box.

If `textBaseline` is `middle`:
Let the anchor point's vertical position be half way between the bottom and the top of the em box of the first available font of the inline box.

If `textBaseline` is `alphabetic`:
Let the anchor point's vertical position be the alphabetic baseline of the first available font of the inline box.

If `textBaseline` is `ideographic`:
Let the anchor point's vertical position be the ideographic baseline of the first available font of the inline box.

If `textBaseline` is `bottom`:
Let the anchor point's vertical position be the bottom of the em box of the first available font of the inline box.

8. Let `result` be an array constructed by iterating over each glyph in the inline box from left to right (if any), adding to the array, for each glyph, the shape of the glyph as it is in the inline box, positioned on a coordinate space using CSS pixels with its origin is at the anchor point.

9. Return `result`, physical alignment, and the inline box.

4.12.5.1.5 Building paths

Objects that implement the CanvasPath interface have a path. A path has a list of zero or more subpaths. Each subpath consists of a list of one or more points, connected by straight or curved line segments, and a flag indicating whether the subpath is closed or not. A closed subpath is one where the last point of the subpath is connected to the first point of the subpath by a straight line. Subpaths with only one point are ignored when painting the path.

Paths have a need new subpath flag. When this flag is set, certain APIs create a new subpath rather than extending the previous one. When a path is created, its need new subpath flag must be set.

When an object implementing the CanvasPath interface is created, its path must be initialized to zero subpaths.

For web developers (non-normative)

```
context.moveTo(x, y)
```

Creates a new subpath with the given point.

```
context.closePath()
```

Marks the current subpath as closed, and starts a new subpath with a point the same as the start and end of the newly closed subpath.

```
context.lineTo(x, y)
```

Adds the given point to the current subpath, connected to the previous one by a straight line.

```
context.quadraticCurveTo(cpx, cpy, x, y)
```

Adds the given point to the current subpath, connected to the previous one by a quadratic Bézier curve with the given control point.
context.bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)

path.bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)

Adds the given point to the current subpath, connected to the previous one by a cubic Bézier curve with the given control points.

context.arcTo(x1, y1, x2, y2, radius)

path.arcTo(x1, y1, x2, y2, radius)

Adds an arc with the given control points and radius to the current subpath, connected to the previous point by a straight line. Throws an "IndexSizeError" DOMException if the given radius is negative.
The following methods allow authors to manipulate the paths of objects implementing the CanvasPath interface.

```javascript
context.arc(x, y, radius, startAngle, endAngle [, anticlockwise ])
path.arc(x, y, radius, startAngle, endAngle [, anticlockwise ])
```

Adds points to the subpath such that the arc described by the circumference of the circle described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an "IndexSizeError" DOMException if the given radius is negative.

```javascript
context.ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle [, anticlockwise] )
path.ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle [, anticlockwise] )
```

Adds points to the subpath such that the arc described by the circumference of the ellipse described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an "IndexSizeError" DOMException if the given radius is negative.

```javascript
context.rect(x, y, w, h)
path.rect(x, y, w, h)
```

Adds a new closed subpath to the path, representing the given rectangle.
For objects implementing the `CanvasDrawPath` and `CanvasTransform` interfaces, the points passed to the methods, and the resulting lines added to the current default path by these methods, must be transformed according to the current transformation matrix before being added to the path.

The `moveTo(x, y)` method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Create a new subpath with the specified point as its first (and only) point.

When the user agent is to ensure there is a subpath for a coordinate (x, y) on a path, the user agent must check to see if the path has its need new subpath flag set. If it does, then the user agent must create a new subpath with the point (x, y) as its first (and only) point, as if the `moveTo()` method had been called, and must then unset the path's need new subpath flag.

The `closePath()` method, when invoked, must do nothing if the object's path has no subpaths. Otherwise, it must mark the last subpath as closed, create a new subpath whose first point is the same as the previous subpath's first point, and finally add this new subpath to the path.

New points and the lines connecting them are added to subpaths using the methods described below. In all cases, the methods only modify the last subpath in the object's path.

The `lineTo(x, y)` method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. If the object's path has no subpaths, then ensure there is a subpath for (x, y).
3. Otherwise, connect the last point in the subpath to the given point (x, y) using a straight line, and then add the given point (x, y) to the subpath.

The `quadraticCurveTo(cpx, cpy, x, y)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Ensure there is a subpath for (cpx, cpy).
3. Connect the last point in the subpath to the given point (x, y) using a quadratic Bézier curve with control point (cpx, cpy).
4. Add the given point (x, y) to the subpath.

The `bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Ensure there is a subpath for (cp1x, cp1y).
3. Connect the last point in the subpath to the given point (x, y) using a cubic Bézier curve with control points (cp1x, cp1y) and (cp2x, cp2y).
4. Add the point (x, y) to the subpath.

The `arcTo(x1, y1, x2, y2, radius)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Ensure there is a subpath for (x1, y1).
3. If radius is negative, then throw an "IndexSizeError" DOMException.
4. Let the point (x0, y0) be the last point in the subpath, transformed by the inverse of the current transformation matrix, which is equivalent to adding a straight line connecting the last point back to the first point of the last subpath, thus “closing” the subpath.
that it is in the same coordinate system as the points passed to the method).

5. If the point \((x_0, y_0)\) is equal to the point \((x_1, y_1)\), or if the point \((x_1, y_1)\) is equal to the point \((x_2, y_2)\), or if radius is zero, then add the point \((x_1, y_1)\) to the subpath, and connect that point to the previous point \((x_0, y_0)\) by a straight line.

6. Otherwise, if the points \((x_0, y_0), (x_1, y_1),\) and \((x_2, y_2)\) all lie on a single straight line, then add the point \((x_1, y_1)\) to the subpath, and connect that point to the previous point \((x_0, y_0)\) by a straight line.

7. Otherwise, let The Arc be the shortest arc given by circumference of the circle that has radius radius, and that has one point tangent to the half-infinite line that crosses the point \((x_0, y_0)\) and ends at the point \((x_1, y_1)\), and that has a different point tangent to the half-infinite line that ends at the point \((x_1, y_1)\) and crosses the point \((x_2, y_2)\). The points at which this circle touches these two lines are called the start and end tangent points respectively. Connect the point \((x_0, y_0)\) to the start tangent point by a straight line, adding the start tangent point to the subpath, and then connect the start tangent point to the end tangent point by The Arc, adding the end tangent point to the subpath.

The \(arc(x, y, radius, startAngle, endAngle, anticlockwise)\) method, when invoked, must run the ellipse method steps\(^{p638}\) with this, \(x, y, radius, radius, 0, startAngle, endAngle,\) and \(anticlockwise\).

\[\text{Note}\]
\[\text{This makes it equivalent to ellipse(})^{p638} \text{ except that both radii are equal and rotation is 0.}\]

The \(ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle, anticlockwise)\) method, when invoked, must run the ellipse method steps\(^{p638}\) with this, \(x, y, radiusX, radiusY, rotation, startAngle, endAngle,\) and \(anticlockwise\).

The ellipse method steps, given canvasPath, \(x, y, radiusX, radiusY, rotation, startAngle, endAngle,\) and \(anticlockwise\), are:

1. If any of the arguments are infinite or NaN, then return.
2. If either \(radiusX\) or \(radiusY\) are negative, then throw an "IndexSizeError" DOMException.
3. If canvasPath's path has any subpaths, then add a straight line from the last point in the subpath to the start point of the arc.
4. Add the start and end points of the arc to the subpath, and connect them with an arc. The arc and its start and end points are defined as follows:

   Consider an ellipse that has its origin at \((x, y)\), that has a major-axis radius \(radiusX\) and a minor-axis radius \(radiusY\), and that is rotated about its origin such that its semi-major axis is inclined rotation radians clockwise from the x-axis.

   If anticlockwise is false and endAngle-startAngle is equal to or greater than \(2\pi\), or, if anticlockwise is true and startAngle-endAngle is equal to or greater than \(2\pi\), then the arc is the whole circumference of this ellipse, and the point at startAngle along this circle's circumference, measured in radians clockwise from the ellipse's semi-major axis, acts as both the start point and the end point.

   Otherwise, the points at startAngle and endAngle along this circle's circumference, measured in radians clockwise from the ellipse's semi-major axis, are the start and end points respectively, and the arc is the path along the circumference of this ellipse from the start point to the end point, going anti-clockwise if anticlockwise is true, and clockwise otherwise. Since the points are on the ellipse, as opposed to being simply angles from zero, the arc can never cover an angle greater than \(2\pi\) radians.

\[\text{Note}\]
Even if the arc covers the entire circumference of the ellipse and there are no other points in the subpath, the path is not closed unless the closePath(})^{p637} method is appropriately invoked.

The \(rect(x, y, w, h)\) method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Create a new subpath containing just the four points \((x, y), (x+w, y), (x+w, y+h), (x, y+h)\), in that order, with those four points connected by straight lines.
3. Mark the subpath as closed.
4. Create a new subpath with the point \((x, y)\) as the only point in the subpath.
4.12.5.1.6 Path2D objects

Path2D objects can be used to declare paths that are then later used on objects implementing the CanvasDrawPath interface. In addition to many of the APIs described in earlier sections, Path2D objects have methods to combine paths, and to add text to paths.

For web developers (non-normative)

```javascript
path = new Path2D()
Creates a new empty Path2D object.

path = new Path2D(path)
When path is a Path2D object, returns a copy.
When path is a string, creates the path described by the argument, interpreted as SVG path data. [SVG]

path . addPath(path[, transform])
Adds to the path the path given by the argument.
```

The Path2D(path) constructor, when invoked, must run these steps:

1. Let output be a new Path2D object.
2. If path is not given, then return output.
3. If path is a Path2D object, then add all subpaths of path to output and return output. (In other words, it returns a copy of the argument.)
4. Let svgPath be the result of parsing and interpreting path according to the SVG specification's rules for path data. [SVG]

Note

The resulting path could be empty. SVG defines error handling rules for parsing and applying path data.

5. Let (x, y) be the last point in svgPath.
6. Add all the subpaths, if any, from svgPath to output.
7. Create a new subpath in output with (x, y) as the only point in the subpath.
8. Return output.

The addPath(b[, transform]) method, when invoked on a Path2D object a, must run these steps:

1. If the Path2D object b has no subpaths, then return.
2. Let matrix be the result of creating a DOMMatrix from the 2D dictionary transform.
3. If one or more of matrix's m11 element, m12 element, m21 element, m22 element, m41 element, or m42 element are infinite or NaN, then return.
4. Create a copy of all the subpaths in b. Let this copy be known as c.
5. Transform all the coordinates and lines in c by the transform matrix matrix.
6. Let (x, y) be the last point in the last subpath of c.
7. Add all the subpaths in c to a.
8. Create a new subpath in a with (x, y) as the only point in the subpath.

4.12.5.1.7 Transformations

Objects that implement the CanvasTransform interface have a current transformation matrix, as well as methods (described in this section) to manipulate it. When an object implementing the CanvasTransform interface is created, its transformation matrix must be initialized to the identity matrix.
The current transformation matrix is applied to coordinates when creating the current default path, and when painting text, shapes, and Path2D objects, on objects implementing the CanvasTransform interface.

The transformations must be performed in reverse order.

Note
For instance, if a scale transformation that doubles the width is applied to the canvas, followed by a rotation transformation that rotates drawing operations by a quarter turn, and a rectangle twice as wide as it is tall is then drawn on the canvas, the actual result will be a square.

For web developers (non-normative)

context.scale(x, y)
Changes the current transformation matrix to apply a scaling transformation with the given characteristics.

context.rotate(angle)
Changes the current transformation matrix to apply a rotation transformation with the given characteristics. The angle is in radians.

context.translate(x, y)
Changes the current transformation matrix to apply a translation transformation with the given characteristics.

context.transform(a, b, c, d, e, f)
Changes the current transformation matrix to apply the matrix given by the arguments as described below.

matrix = context.getTransform()
Returns a copy of the current transformation matrix, as a newly created DOMMatrix object.

context.setTransform(a, b, c, d, e, f)
Changes the current transformation matrix to the matrix given by the arguments as described below.

context.setTransform(transform)
Changes the current transformation matrix to the matrix represented by the passed DOMMatrix2DInit dictionary.

context.resetTransform()
Changes the current transformation matrix to the identity matrix.

The scale(x, y) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Add the scaling transformation described by the arguments to the current transformation matrix. The x argument represents the scale factor in the horizontal direction and the y argument represents the scale factor in the vertical direction. The factors are multiples.

The rotate(angle) method, when invoked, must run these steps:

1. If angle is infinite or NaN, then return.
2. Add the rotation transformation described by the argument to the current transformation matrix. The angle argument represents a clockwise rotation angle expressed in radians.

The translate(x, y) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Add the translation transformation described by the arguments to the current transformation matrix. The x argument represents the translation distance in the horizontal direction and the y argument represents the translation distance in the vertical direction. The arguments are in coordinate space units.

The transform(a, b, c, d, e, f) method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Replace the current transformation matrix with the result of multiplying the current transformation matrix with the matrix described by:

\[
\begin{bmatrix}
  a & c & e \\
  b & d & f \\
  0 & 0 & 1
\end{bmatrix}
\]

**Note**

The arguments a, b, c, d, e, and f are sometimes called m11, m12, m21, m22, dx, and dy or m11, m12, m21, m22, dx, and dy. Care ought to be taken in particular with the order of the second and third arguments (b and c) as their order varies from API to API and APIs sometimes use the notation m12/m21 and sometimes m21/m12 for those positions.

The `getTransform()` method, when invoked, must return a newly created `DOMMatrix` representing a copy of the current transformation matrix of the context.

**Note**

This returned object is not live, so updating it will not affect the current transformation matrix and updating the current transformation matrix will not affect an already returned `DOMMatrix`.

The `setTransform(a, b, c, d, e, f)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Reset the current transformation matrix to the identity matrix.
3. Invoke the `transform(a, b, c, d, e, f)` method with the same arguments.

The `setTransform(transform)` method, when invoked, must run these steps:

1. Let matrix be the result of creating a `DOMMatrix` from the 2D dictionary `transform`.
2. If one or more of matrix's `m11 element`, `m12 element`, `m21 element`, `m22 element`, `m41 element`, or `m42 element` are infinite or NaN, then return.
3. Reset the current transformation matrix to matrix.

The `resetTransform()` method, when invoked, must reset the current transformation matrix to the identity matrix.

### 4.12.5.1.8 Image sources for 2D rendering contexts

Some methods on the `CanvasDrawImage` and `CanvasFillStrokeStyles` interfaces take the union type `CanvasImageSource` as an argument.

This union type allows objects implementing any of the following interfaces to be used as image sources:

- `HTMLOrSVGImageElement` (img or SVG elements)
- `HTMLVideoElement` (video elements)
- `HTMLCanvasElement` (canvas elements)
- `ImageBitmap`

**Note**

Although not formally specified as such, SVG image elements are expected to be implemented nearly identical to img elements. That is, SVG image elements share the fundamental concepts and features of img elements.

**Note**

The `ImageBitmap` interface can be created from a number of other image-representing types, including `ImageData`.

To check the usability of the `image` argument, where `image` is a `CanvasImageSource` object, run these steps:

1. Switch on image:
If image's current request's state is broken, then throw an "InvalidStateError" DOMException.

If image is not fully decodable, then return bad.

If image has an intrinsic width or intrinsic height (or both) equal to zero, then return bad.

If image's readyState attribute is either HAVE_NOTHING or HAVE_METADATA, then return bad.

If image has either a horizontal dimension or a vertical dimension equal to zero, then throw an "InvalidStateError" DOMException.

If image's [[Detached]] internal slot value is set to true, then throw an "InvalidStateError" DOMException.

2. Return good.

When a CanvasImageSource object represents an HTMLOrSVGImageElement, the element's image must be used as the source image.

Specifically, when a CanvasImageSource object represents an animated image in an HTMLOrSVGImageElement, the user agent must use the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation, when rendering the image for CanvasRenderingContext2D APIs.

When a CanvasImageSource object represents an HTMLVideoElement, then the frame at the current playback position when the method with the argument is invoked must be used as the source image when rendering the image for CanvasRenderingContext2D APIs, and the source image's dimensions must be the intrinsic width and intrinsic height of the media resource (i.e. after any aspect-ratio correction has been applied).

When a CanvasImageSource object represents an HTMLCanvasElement, the element's bitmap must be used as the source image.

When a CanvasImageSource object represents an element that is being rendered and that element has been resized, the original image data of the source image must be used, not the image as it is rendered (e.g. width and height attributes on the source element have no effect on how the object is interpreted when rendering the image for CanvasRenderingContext2D APIs).

When a CanvasImageSource object represents an ImageBitmap, the object's bitmap image data must be used as the source image.

An object image is not origin-clean if, switching on image:

- HTMLOrSVGImageElement's origin is not same origin with entry settings object's origin.

When a CanvasImageSource object represents an HTMLVideoElement, then image's origin is not same origin with entry settings object's origin.

When a HTMLCanvasElement object represents an ImageBitmap, image's bitmap's origin-clean flag is false.

### 4.12.5.1.9 Fill and stroke styles

For web developers (non-normative)

```javascript
context.fillStyle[ = value ]
```

Returns the current style used for filling shapes.

Can be set, to change the fill style.
The style can be either a string containing a CSS color, or a CanvasGradient or CanvasPattern object. Invalid values are ignored.

```plaintext
context . strokeStyle [ = value ]

Returns the current style used for stroking shapes.
Can be set, to change the stroke style.
The style can be either a string containing a CSS color, or a CanvasGradient or CanvasPattern object. Invalid values are ignored.
```

Objects that implement the CanvasFillStrokeStyles interface have attributes and methods (defined in this section) that control how shapes are treated by the object.

The `fillStyle` attribute represents the color or style to use inside shapes, and the `strokeStyle` attribute represents the color or style to use for the lines around the shapes.

Both attributes can be either strings, CanvasGradient s, or CanvasPattern s. On setting, strings must be parsed with this canvas element and the color assigned, and CanvasGradient and CanvasPattern objects must be assigned themselves. If parsing the value results in failure, then it must be ignored, and the attribute must retain its previous value. If the new value is a CanvasPattern object that is marked as not origin-clean, then the CanvasRenderingContext2D's origin-clean flag must be set to false.

When set to a CanvasPattern or CanvasGradient object, the assignment is live, meaning that changes made to the object after the assignment do affect subsequent stroking or filling of shapes.

On getting, if the value is a color, then the serialization of the color must be returned. Otherwise, if it is not a color but a CanvasGradient or CanvasPattern, then the respective object must be returned. (Such objects are opaque and therefore only useful for assigning to other attributes or for comparison to other gradients or patterns.)

The serialization of a color for a color value is a string, computed as follows: if it has alpha equal to 1.0, then the string is a lowercase six-digit hex value, prefixed with a "#" character (U+0023 NUMBER SIGN), with the first two digits representing the red component, the next two digits representing the green component, and the last two digits representing the blue component, the digits being ASCII lower hex digits. Otherwise, the color value has alpha less than 1.0, and the string is the color value in the CSS `rgba()` functional-notation format: the literal string "rgba" (U+0072 U+0067 U+0062 U+0061) followed by a U+0028 LEFT PARENTHESIS, a base-ten integer in the range 0-255 representing the red component (using ASCII digits in the shortest form possible), a literal U+002C COMMA and U+0020 SPACE, an integer for the green component, a comma and a space, an integer for the blue component, another comma and space, a U+0030 DIGIT ZERO, if the alpha value is greater than zero then a U+002E FULL STOP (representing the decimal point), if the alpha value is greater than zero then one or more ASCII digits representing the fractional part of the alpha, and finally a U+0029 RIGHT PARENTHESIS. User agents must express the fractional part of the alpha value, if any, with the level of precision necessary for the alpha value, when reparsed, to be interpreted as the same alpha value.

When the context is created, the `fillStyle` and `strokeStyle` attributes must initially have the string value #000000.

When the value is a color, it must not be affected by the transformation matrix when used to draw on bitmaps.

There are two types of gradients, linear gradients and radial gradients, both represented by objects implementing the opaque CanvasGradient interface.

Once a gradient has been created (see below), stops are placed along it to define how the colors are distributed along the gradient. The color of the gradient at each stop is the color specified for that stop. Between each such stop, the colors and the alpha component must be linearly interpolated over the RGBA space without premultiplying the alpha value to find the color to use at that offset. Before the first stop, the color must be the color of the first stop. After the last stop, the color must be the color of the last stop. When there are no stops, the gradient is transparent black.

```
For web developers (non-normative)

   gradient . addColorStop(offset, color)

   Adds a color stop with the given color to the gradient at the given offset. 0.0 is the offset at one end of the gradient, 1.0 is the offset at the other end.
```
The `addColorStop(offset, color)` method on the `CanvasGradient` object, when invoked, must run these steps:

1. If the `offset` is less than 0 or greater than 1, then throw an "IndexSizeError" DOMException.
2. Let `parsed color` be the result of parsing color.

   **Note**
   
   No element is passed to the parser because `CanvasGradient` objects are canvas-neutral — a `CanvasGradient` object created by one canvas can be used by another, and there is therefore no way to know which is the "element in question" at the time that the color is specified.

3. If `parsed color` is failure, throw a "SyntaxError" DOMException.
4. Place a new stop on the gradient, at offset `offset` relative to the whole gradient, and with the color `parsed color`.

   If multiple stops are added at the same offset on a gradient, then they must be placed in the order added, with the first one closest to the start of the gradient, and each subsequent one infinitesimally further along towards the end point (in effect causing all but the first and last stop added at each point to be ignored).

The `createLinearGradient(x0, y0, x1, y1)` method takes four arguments that represent the start point `(x0, y0)` and end point `(x1, y1)` of the gradient. The method, when invoked, must return a linear `CanvasGradient` initialized with the specified line.

Linear gradients must be rendered such that all points on a line perpendicular to the line that crosses the start and end points have the color at the point where those two lines cross (with the colors coming from the interpolation and extrapolation described above). The points in the linear gradient must be transformed as described by the current transformation matrix when rendering.

If `x0 = x1` and `y0 = y1`, then the linear gradient must paint nothing.

The `createRadialGradient(x0, y0, x1, y1, r0, r1)` method takes six arguments, the first three representing the start circle with origin `(x0, y0)` and radius `r0`, and the last three representing the end circle with origin `(x1, y1)` and radius `r1`. The values are in coordinate space units. If either of `r0` or `r1` are negative, then an "IndexSizeError" DOMException must be thrown. Otherwise, the method, when invoked, must return a radial `CanvasGradient` initialized with the two specified circles.

Radial gradients must be rendered by following these steps:

1. If `x0 = x1` and `y0 = y1` and `r0 = r1`, then the radial gradient must paint nothing. Return.
2. Let `x(ω) = (x1-x0)ω + x0`
   
   Let `y(ω) = (y1-y0)ω + y0`
   
   Let `r(ω) = (r1-r0)ω + r0`
   
   Let the color at `ω` be the color at that position on the gradient (with the colors coming from the interpolation and extrapolation described above).

3. For all values of `ω` where `r(ω) > 0`, starting with the value of `ω` nearest to positive infinity and ending with the value of `ω` nearest to negative infinity, draw the circumference of the circle with radius `r(ω)` at position `(x(ω), y(ω))`, with the color at `ω`, but only painting on the parts of the bitmap that have not yet been painted on by earlier circles in this step for this rendering of the gradient.
The resulting radial gradient must then be transformed as described by the current transformation matrix when rendering. Gradients must be painted only where the relevant stroking or filling effects requires that they be drawn.

Patterns are represented by objects implementing the opaque CanvasPattern interface.

**For web developers (non-normative)**

\[ \text{pattern} = \text{context} . \text{createPattern}(\text{image}, \text{repetition}) \]

Returns a CanvasPattern object that uses the given image and repeats in the direction(s) given by the `repetition` argument.

The allowed values for `repetition` are `repeat` (both directions), `repeat-x` (horizontal only), `repeat-y` (vertical only), and `no-repeat` (neither). If the `repetition` argument is empty, the value `repeat` is used.

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an "InvalidStateError" DOMException.

\[ \text{pattern} . \text{setTransform}(\text{transform}) \]

Sets the transformation matrix that will be used when rendering the pattern during a fill or stroke painting operation.

The `createPattern(image, repetition)` method, when invoked, must run these steps:

1. Let `usability` be the result of checking the usability of image.
2. If `result` is `bad`, then return null.
3. Assert: `result` is `good`.
4. If `repetition` is the empty string, then set it to "repeat".
5. If `repetition` is not a case-sensitive match for one of "repeat", "repeat-x", "repeat-y", or "no-repeat", then throw a "SyntaxError" DOMException.
6. Let `pattern` be a new CanvasPattern object with the image `image` and the repetition behavior given by `repetition`.
7. If `image` is not origin-clean, then mark `pattern` as not origin-clean.
8. Return `pattern`.

Modifying the image used when creating a CanvasPattern object after calling the `createPattern` method must not affect the pattern(s) rendered by the CanvasPattern object.

Patterns have a transformation matrix, which controls how the pattern is used when it is painted. Initially, a pattern's transformation matrix must be the identity matrix.

The `setTransform(transform)` method, when invoked, must run these steps:

1. Let `matrix` be the result of creating a DOMMatrix from the 2D dictionary `transform`.
2. If one or more of `matrix`'s m11 element, m12 element, m21 element, m22 element, m41 element, or m42 element are infinite or NaN, then return.
3. Reset the pattern's transformation matrix to `matrix`.

When a pattern is to be rendered within an area, the user agent must run the following steps to determine what is rendered:

1. Create an infinite transparent black bitmap.
2. Place a copy of the image on the bitmap, anchored such that its top left corner is at the origin of the coordinate space, with one coordinate space unit per CSS pixel of the image, then place repeated copies of this image horizontally to the left and right, if the repetition behavior is "repeat-x", or vertically up and down, if the repetition behavior is "repeat-y", or in all four

**Note**

This effectively creates a cone, touched by the two circles defined in the creation of the gradient, with the part of the cone before the start circle (0.0) using the color of the first offset, the part of the cone after the end circle (1.0) using the color of the last offset, and areas outside the cone untouched by the gradient (transparent black).
directions all over the bitmap, if the repetition behavior is "repeat".

If the original image data is a bitmap image, then the value painted at a point in the area of the repetitions is computed by filtering the original image data. When scaling up, if the `imageSmoothingEnabled` attribute is set to false, then the image must be rendered using nearest-neighbor interpolation. Otherwise, the user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). User agents which support multiple filtering algorithms may use the value of the `imageSmoothingQuality` attribute to guide the choice of filtering algorithm. When such a filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from wrapping the pixel's coordinates to the original image's dimensions. (That is, the filter uses 'repeat' behavior, regardless of the value of the pattern's repetition behavior.)

3. Transform the resulting bitmap according to the pattern's transformation matrix.
4. Transform the resulting bitmap again, this time according to the current transformation matrix.
5. Replace any part of the image outside the area in which the pattern is to be rendered with transparent black.
6. The resulting bitmap is what is to be rendered, with the same origin and same scale.

If a radial gradient or repeated pattern is used when the transformation matrix is singular, then the resulting style must be transparent black (otherwise the gradient or pattern would be collapsed to a point or line, leaving the other pixels undefined). Linear gradients and solid colors always define all points even with singular transformation matrices.

### 4.12.5.1.10 Drawing rectangles to the bitmap

Objects that implement the `CanvasRect` interface provide the following methods for immediately drawing rectangles to the bitmap. The methods each take four arguments; the first two give the x and y coordinates of the top left of the rectangle, and the second two give the width w and height h of the rectangle, respectively.

The current transformation matrix must be applied to the following four coordinates, which form the path that must then be closed to get the specified rectangle: (x, y), (x+w, y), (x+w, y+h), (x, y+h).

Shapes are painted without affecting the current default path, and are subject to the clipping region, and, with the exception of `clearRect()`, also shadow effects, global alpha, and global composition operators.

**For web developers (non-normative)**

```
context.clearRect(x, y, w, h)
```

Clears all pixels on the bitmap in the given rectangle to transparent black.

```
context.fillRect(x, y, w, h)
```

Paints the given rectangle onto the bitmap, using the current fill style.

```
context.strokeRect(x, y, w, h)
```

Paints the box that outlines the given rectangle onto the bitmap, using the current stroke style.

The `clearRect(x, y, w, h)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Let pixels be the set of pixels in the specified rectangle that also intersect the current clipping region.
3. Clear the pixels in pixels to a transparent black, erasing any previous image.

**Note**

*If either height or width are zero, this method has no effect, since the set of pixels would be empty.*

The `fillRect(x, y, w, h)` method, when invoked, must must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. If either \( w \) or \( h \) are zero, then return.

3. Paint the specified rectangular area using the \texttt{fillStyle}.

The \texttt{strokeRect(\( x, y, w, h \))} method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Take the result of \texttt{tracing the path\textsuperscript{643}} described below, using the \texttt{CanvasPathDrawingStyles\textsuperscript{621}} interface's line styles, and fill it with the \texttt{strokeStyle\textsuperscript{643}}.

If both \( w \) and \( h \) are zero, the path has a single subpath with just one point \((x, y)\), and no lines, and this method thus has no effect (the \texttt{trace a path\textsuperscript{627}} algorithm returns an empty path in that case).

If just one of either \( w \) or \( h \) is zero, then the path has a single subpath consisting of two points, with coordinates \((x, y)\) and \((x+w, y+h)\), in that order, connected by a single straight line.

Otherwise, the path has a single subpath consisting of four points, with coordinates \((x, y)\), \((x+w, y)\), \((x+w, y+h)\), and \((x, y+h)\), connected to each other in that order by straight lines.

4.12.5.11 Drawing text to the bitmap \textsuperscript{644}

For web developers (non-normative)

\begin{verbatim}
context.fillText(text, x, y [ , maxWidth ])
context.strokeText(text, x, y [ , maxWidth ])
\end{verbatim}

Fills or strokes (respectively) the given text at the given position. If a maximum width is provided, the text will be scaled to fit that width if necessary.

\begin{verbatim}
metrics = context.measureText(text)
\end{verbatim}

Returns a \texttt{TextMetrics\textsuperscript{622}} object with the metrics of the given text in the current font.

\begin{verbatim}
metrics.width
metrics.actualBoundingBoxLeft
metrics.actualBoundingBoxRight
metrics.fontBoundingBoxAscent
metrics.fontBoundingBoxDescent
metrics.actualBoundingBoxAscent
metrics.actualBoundingBoxDescent
metrics.emHeightAscent
metrics.emHeightDescent
metrics.hangingBaseline
metrics.alphabeticBaseline
metricsideographicBaseline
\end{verbatim}

Returns the measurement described below.

Objects that implement the \texttt{CanvasText\textsuperscript{628}} interface provide the following methods for rendering text.

The \texttt{fillText()} and \texttt{strokeText()} methods take three or four arguments, \texttt{text}, \texttt{x}, \texttt{y}, and optionally \texttt{maxWidth}, and render the given text at the given \((x, y)\) coordinates ensuring that the text isn't wider than \texttt{maxWidth} if specified, using the current \texttt{font\textsuperscript{631}}, \texttt{textAlign\textsuperscript{631}}, and \texttt{textBaseline\textsuperscript{631}} values. Specifically, when the methods are invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Run the \texttt{text preparation algorithm\textsuperscript{633}}, passing it \texttt{text}, the object implementing the \texttt{CanvasText\textsuperscript{628}} interface, and, if the \texttt{maxWidth} argument was provided, that argument. Let \texttt{glyphs} be the result.

3. Move all the shapes in \texttt{glyphs} to the right by \texttt{x CSS pixels} and down by \texttt{y CSS pixels}.

4. Paint the shapes given in \texttt{glyphs}, as transformed by the \texttt{current transformation matrix\textsuperscript{639}}, with each \texttt{CSS pixel} in the
coordinate space of glyphs mapped to one coordinate space unit.

For `fillText()`⁶⁴⁷, `fillStyle`⁶⁴⁴ must be applied to the shapes and `strokeStyle`⁶⁴³ must be ignored. For `strokeText()`⁶⁴¹, the reverse holds; `strokeStyle`⁶⁴⁴ must be applied to the result of `tracking`⁶⁵⁷, the shapes using the object implementing the `CanvasText`⁶⁴⁸ interface for the line styles, and `fillStyle`⁶⁴⁵ must be ignored.

These shapes are painted without affecting the current path, and are subject to `shadow effects`⁶⁶⁰, `global alpha`⁶⁵⁹, the `clipping region`⁶⁵⁰, and `global composition operators`⁶⁵⁹.

The `measureText()` method takes one argument, text. When the method is invoked, the user agent must run the `text preparation algorithm`⁶³⁹, passing it text and the object implementing the `CanvasText`⁶⁴⁸ interface, and then using the returned `inline box` must create a new `TextMetrics`⁶³² object with its attributes set as described in the following list. If doing these measurements requires using a font that has an `origin`⁶⁸⁰ that is not the `same`⁶⁸⁰ as that of the `Document`⁶¹⁰ object that owns the `canvas`⁶¹⁴ element (even if "using a font" means just checking if that font has a particular glyph in it before falling back to another font), then the method, when invoked, must throw a "`SecurityError`" `DOMException`. Otherwise, it must return the new `TextMetrics`⁶³² object. [CSS]¹²²

`width` attribute

The width of that `inline box`, in `CSS pixels`. (The text's advance width.)

`actualBoundingBoxLeft` attribute

The distance parallel to the baseline from the alignment point given by the `textAlign`⁶³¹ attribute to the left side of the bounding rectangle of the given text, in `CSS pixels`; positive numbers indicating a distance going left from the given alignment point.

**Note**

The sum of this value and the next (`actualBoundingBoxRight`⁶⁴⁸) can be wider than the width of the `inline box` (`width`⁶⁴⁴), in particular with slanted fonts where characters overhang their advance width.

`actualBoundingBoxRight` attribute

The distance parallel to the baseline from the alignment point given by the `textAlign`⁶³¹ attribute to the right side of the bounding rectangle of the given text, in `CSS pixels`; positive numbers indicating a distance going right from the given alignment point.

`fontBaseline` attribute

The distance from the horizontal line indicated by the `textBaseline`⁶³¹ attribute to the top of the highest bounding rectangle of all the fonts used to render the text, in `CSS pixels`; positive numbers indicating a distance going up from the given baseline.

**Note**

This value and the next are useful when rendering a background that have to have a consistent height even if the exact text being rendered changes. The `actualBoundingBoxAscent`⁶⁴⁸ attribute (and its corresponding attribute for the descent) are useful when drawing a bounding box around specific text.

`fontBaselineDescent` attribute

The distance from the horizontal line indicated by the `textBaseline`⁶³¹ attribute to the bottom of the lowest bounding rectangle of all the fonts used to render the text, in `CSS pixels`; positive numbers indicating a distance going down from the given baseline.

`actualBoundingBoxAscent` attribute

The distance from the horizontal line indicated by the `textBaseline`⁶³¹ attribute to the top of the bounding rectangle of the given text, in `CSS pixels`; positive numbers indicating a distance going up from the given baseline.

**Note**

This number can vary greatly based on the input text, even if the first font specified covers all the characters in the input. For example, the `actualBoundingBoxAscent`⁶⁴⁸ of a lowercase "o" from an alphabetic baseline would be less than that of an uppercase "F". The value can easily be negative; for example, the distance from the top of the em box (`textBaseline`⁶³¹ value "top"⁶³²) to the top of the bounding rectangle when the given text is just a single comma ",," would likely (unless the font is quite unusual) be negative.

`actualBoundingBoxDescent` attribute

The distance from the horizontal line indicated by the `textBaseline`⁶³¹ attribute to the bottom of the bounding rectangle of the given text, in `CSS pixels`; positive numbers indicating a distance going down from the given baseline.

`emHeightAscent` attribute

The distance from the horizontal line indicated by the `textBaseline`⁶³¹ attribute to the highest top of the em squares in the `line box`, in `CSS pixels`; positive numbers indicating that the given baseline is below the top of that em square (so this value will usually...
be positive). Zero if the given baseline is the top of that em square; half the font size if the given baseline is the middle of that em square.

**emHeightDescent** attribute

The distance from the horizontal line indicated by the `textBaseline` attribute to the lowest bottom of the em squares in the line box, in CSS pixels; positive numbers indicating that the given baseline is below the bottom of that em square (so this value will usually be negative). (Zero if the given baseline is the bottom of that em square.)

**hangingBaseline** attribute

The distance from the horizontal line indicated by the `textBaseline` attribute to the hanging baseline of the line box, in CSS pixels; positive numbers indicating that the given baseline is below the hanging baseline. (Zero if the given baseline is the hanging baseline.)

**alphabeticBaseline** attribute

The distance from the horizontal line indicated by the `textBaseline` attribute to the alphabetic baseline of the line box, in CSS pixels; positive numbers indicating that the given baseline is below the alphabetic baseline. (Zero if the given baseline is the alphabetic baseline.)

**ideographicBaseline** attribute

The distance from the horizontal line indicated by the `textBaseline` attribute to the ideographic baseline of the line box, in CSS pixels; positive numbers indicating that the given baseline is below the ideographic baseline. (Zero if the given baseline is the ideographic baseline.)

---

**Note**

Glyphs rendered using `fillText()` and `strokeText()` can spill out of the box given by the font size (the em square size) and the width returned by `measureText()` (the text width). Authors are encouraged to use the bounding box values described above if this is an issue.

**Note**

A future version of the 2D context API might provide a way to render fragments of documents, rendered using CSS, straight to the canvas. This would be provided in preference to a dedicated way of doing multiline layout.

---

### 4.12.5.1.12 Drawing paths to the canvas

Objects that implement the `CanvasDrawPath` interface have a current default path. There is only one current default path, it is not part of the drawing state. The current default path is a path, as described above.

**For web developers (non-normative)**

```
context.beginPath()
    Resets the current default path.
context.fill([fillRule])
context.fill(path [, fillRule])
    Fills the subpaths of the current default path or the given path with the current fill style, obeying the given fill rule.
context.stroke()
context.stroke(path)
    Strokes the subpaths of the current default path or the given path with the current stroke style.
context.clip([fillRule])
context.clip(path [, fillRule])
    Further constrains the clipping region to the current default path or the given path, using the given fill rule to determine what points are in the path.
context.isPointInPath(x, y [, fillRule])
context.isPointInPath(path, x, y [, fillRule])
    Returns true if the given point is in the current default path or the given path, using the given fill rule to determine what points are in the path.
```
The `beginPath()` method, when invoked, must empty the list of subpaths in the context's `current default path` so that the it once again has zero subpaths.

Where the following method definitions use the term intended path, it means the `Path2D` argument, if one was provided, or the `current default path` otherwise.

When the intended path is a `Path2D` object, the coordinates and lines of its subpaths must be transformed according to the current transformation matrix on the object implementing the `CanvasTransform` interface when used by these methods (without affecting the `Path2D` object itself). When the intended path is the current default path, it is not affected by the transform. (This is because transformations already affect the current default path when it is constructed, so applying it when it is painted as well would result in a double transformation.)

The `fill()` method, when invoked, must fill all the subpaths of the intended path, using `fillStyle`, and using the fill rule indicated by the `fillRule` argument. Open subpaths must be implicitly closed when being filled (without affecting the actual subpaths).

The `stroke()` method, when invoked, must trace the intended path, using this `CanvasPathDrawingStyles` object for the line styles, and then fill the resulting path using the `strokeStyle` attribute, using the nonzero winding rule.

Paths, when filled or stroked, must be painted without affecting the current default path or any `Path2D` objects, and must be subject to shadow effects, global alpha, the clipping region, and global composition operators. (The effect of transformations is described above and varies based on which path is being used.)

The `clip()` method, when invoked, must create a new clipping region by calculating the intersection of the current clipping region and the area described by the intended path, using the fill rule indicated by the fillRule argument. Open subpaths must be implicitly closed when computing the clipping region, without affecting the actual subpaths. The new clipping region replaces the current clipping region.

When the context is initialized, the clipping region must be set to the largest infinite surface (i.e. by default, no clipping occurs).

The `isPointInPath()` method, when invoked, must return true if the point given by the x and y coordinates passed to the method, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the intended path as determined by the fill rule indicated by the fillRule argument; and must return false otherwise. Open subpaths must be implicitly closed when computing the area inside the path, without affecting the actual subpaths. Points on the path itself must be considered to be inside the path. If either of the arguments are infinite or NaN, then the method must return false.

The `isPointInStroke()` method, when invoked, must return true if the point given by the x and y coordinates passed to the method, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the path that results from tracing the intended path, using the nonzero winding rule, and using the `CanvasPathDrawingStyles` interface for the line styles; and must return false otherwise. Points on the resulting path must be considered to be inside the path. If either of the arguments are infinite or NaN, then the method must return false.
This `<canvas>` element has a couple of checkboxes. The path-related commands are highlighted:

```html
<canvas height=400 width=750>
  <label><input type=checkbox id=showA> Show As</label>
  <label><input type=checkbox id=showB> Show Bs</label>
</canvas>
```

```javascript
function drawCheckbox(context, element, x, y, paint) {
  context.save();
  context.font = '10px sans-serif';
  context.textAlign = 'left';
  context.textBaseline = 'middle';
  var metrics = context.measureText(element.labels[0].textContent);
  if (paint) {
    context.beginPath();
    context.strokeStyle = 'black';
    context.rect(x-5, y-5, 10, 10);
    context.stroke();
    if (element.checked) {
      context.fillStyle = 'black';
      context.fill();
    }
    context.fillText(element.labels[0].textContent, x+5, y);
  }
  context.beginPath();
  context.rect(x-7, y-7, 12 + metrics.width*2, 14);
  context.drawFocusIfNeeded(element);
  context.restore();
}

function drawBase() {
  // ... */ }
function drawAs() {
  // ... */ }
function drawBs() {
  // ... */ }
function redraw() {
  var canvas = document.getElementsByTagName('canvas')[0];
  var context = canvas.getContext('2d');
  context.clearRect(0, 0, canvas.width, canvas.height);
  drawCheckbox(context, document.getElementById('showA'), 20, 40, true);
  drawCheckbox(context, document.getElementById('showB'), 20, 60, true);
  drawBase();
  if (document.getElementById('showA').checked) {
    drawAs();
  }
  if (document.getElementById('showB').checked) {
    drawBs();
  }
}

function processClick(event) {
  var canvas = document.getElementsByTagName('canvas')[0];
  var context = canvas.getContext('2d');
  var x = event.clientX;
  var y = event.clientY;
  var node = event.target;
  while (node) {
    x -= node.offsetLeft - node.scrollLeft;
    y -= node.offsetTop - node.scrollTop;
    node = node.offsetParent;
  }
  drawCheckbox(context, document.getElementById('showA'), 20, 40, false);
  if (context.isPointInPath(x, y)) {
    document.getElementById('showA').checked = !document.getElementById('showA').checked;
  }
```

Example 651
Objects that implement the `CanvasUserInterface` interface provide the following methods to control drawing focus rings and scrolling paths into view.

The `drawFocusIfNeeded(element)` method, when invoked, must run these steps:

1. If `element` is not `focused` or is not a descendant of the element with whose context the method is associated, then return.
2. Draw a focus ring of the appropriate style along the intended path, following platform conventions.
3. Inform the user that the focus is at the location given by the intended path. User agents may wait until the next time the event loop reaches its update the rendering step to optionally inform the user.

User agents should not implicitly close open subpaths in the intended path when drawing the focus ring.

### For web developers (non-normative)

**context . drawFocusIfNeeded(element)**

**context . drawFocusIfNeeded(path, element)**

If the given element is `focused`, draws a focus ring around the `current default path` or the given path, following the platform conventions for focus rings.

**context . scrollTopIntoView()**

**context . scrollTopIntoView(path)**

Scrolls the `current default path` or the given path into view. This is especially useful on devices with small screens, where the whole canvas might not be visible at once.

4.12.5.1.13 Drawing focus rings and scrolling paths into view

For web developers (non-normative)

Some platforms only draw focus rings around elements that have been focused from the keyboard, and not those focused from the mouse. Other platforms simply don't draw focus rings around some elements at all unless relevant accessibility features are enabled. This API is intended to follow these conventions. User agents that implement distinctions based on the manner in which the element was focused are encouraged to classify focus driven by the `focus()` method based on the kind of user interaction event from which the call was triggered (if any).

The focus ring should not be subject to the `shadow effects`, the `global alpha`, the `global composition operators`, or any of the members in the `CanvasFillStrokeStyles`, `CanvasPathDrawingStyles`, `CanvasTextDrawingStyles` interfaces, but should be subject to the `clipping region`. (The effect of transformations is described above and varies based on which path is being used.)

3. Inform the user that the focus is at the location given by the intended path. User agents may wait until the next time the event loop reaches its update the rendering step to optionally inform the user.

User agents should not implicitly close open subpaths in the intended path when drawing the focus ring.

This might be a moot point, however. For example, if the focus ring is drawn as an axis-aligned bounding rectangle around the points in the intended path, then whether the subpaths are closed or not has no effect. This specification intentionally does not specify precisely how focus rings are to be drawn: user agents are expected to honor their platform's native conventions.
The `scrollPathIntoView()` method, when invoked, must run these steps:

1. Let `specifiedRectangle` be the rectangle of the bounding box of the intended path.
2. Let `notionalChild` be a hypothetical element that is a rendered child of the `canvas` element whose dimensions are those of `specifiedRectangle`.
3. Scroll `notionalChild` into view with behavior set to "auto", block set to "start", and inline set to "nearest".
4. Optionally, inform the user that the caret or selection (or both) cover `specifiedRectangle` of the canvas. The user agent may wait until the next time the `event loop` reaches its `update the rendering` step to optionally inform the user.

"Inform the user", as used in this section, does not imply any persistent state change. It could mean, for instance, calling a system accessibility API to notify assistive technologies such as magnification tools so that the user’s magnifier moves to the given area of the canvas. However, it does not associate the path with the element, or provide a region for tactile feedback, etc.

### 4.12.5.1.14 Drawing images

Objects that implement the `CanvasDrawImage` interface have the `drawImage` method to draw images.

This method can be invoked with three different sets of arguments:

- `drawImage(image, dx, dy)`
- `drawImage(image, dx, dy, dw, dh)`
- `drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`

For web developers (non-normative)

```javascript
context.drawImage(image, dx, dy)
context.drawImage(image, dx, dy, dw, dh)
context.drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)
```

Draws the given image onto the canvas. The arguments are interpreted as follows:

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an "InvalidStateError" `DOMException`.

When the `drawImage()` method is invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Let usability be the result of checking the usability of image\(^{641}\).

3. If usability is bad, then return (without drawing anything).

4. Establish the source and destination rectangles as follows:

   If not specified, the \(dw\) and \(dh\) arguments must default to the values of \(sw\) and \(sh\), interpreted such that one CSS pixel in the image is treated as one unit in the output bitmap\(^{623}\)'s coordinate space. If the \(sx\), \(sy\), \(sw\), and \(sh\) arguments are omitted, then they must default to 0, 0, the image's intrinsic width\(^{658}\) in image pixels, and the image's intrinsic height\(^{658}\) in image pixels, respectively. If the image has no intrinsic dimensions, then the concrete object size must be used instead, as determined using the CSS "Concrete Object Size Resolution" algorithm, with the specified size having neither a definite width nor height, nor any additional constraints, the object's intrinsic properties being those of the image argument, and the default object size being the size of the output bitmap\(^{623}\). [CSSIMAGES]\(^{51222}\)

   The source rectangle is the rectangle whose corners are the four points \((sx, sy), (sx+sw, sy), (sx+sw, sy+sh), (sx, sy+sh)\).

   The destination rectangle is the rectangle whose corners are the four points \((dx, dy), (dx+dw, dy), (dx+dw, dy+dh), (dx, dy+dh)\).

   When the source rectangle is outside the source image, the source rectangle must be clipped to the source image and the destination rectangle must be clipped in the same proportion.

   **Note**
   
   *When the destination rectangle is outside the destination image (the output bitmap\(^{623}\)), the pixels that land outside the output bitmap\(^{623}\) are discarded, as if the destination was an infinite canvas whose rendering was clipped to the dimensions of the output bitmap\(^{623}\).*

   5. If one of the \(sw\) or \(sh\) arguments is zero, then return. Nothing is painted.

   6. Paint the region of the image argument specified by the source rectangle on the region of the rendering context’s output bitmap\(^{623}\) specified by the destination rectangle, after applying the current transformation matrix\(^{639}\) to the destination rectangle.

   The image data must be processed in the original direction, even if the dimensions given are negative.

   When scaling up, if the imageSmoothingEnabled\(^{666}\) attribute is set to true, the user agent should attempt to apply a smoothing algorithm to the image data when it is scaled. User agents which support multiple filtering algorithms may use the value of the imageSmoothingQuality\(^{666}\) attribute to guide the choice of filtering algorithm when the imageSmoothingEnabled\(^{666}\) attribute is set to true. Otherwise, the image must be rendered using nearest-neighbor interpolation.

   **Note**
   
   *This specification does not define the precise algorithm to use when scaling an image down, or when scaling an image up when the imageSmoothingEnabled\(^{666}\) attribute is set to true.*

   **Note**
   
   *When a canvas\(^{614}\) element is drawn onto itself, the drawing model\(^{662}\) requires the source to be copied before the image is drawn, so it is possible to copy parts of a canvas\(^{614}\) element onto overlapping parts of itself.*

   If the original image data is a bitmap image, then the value painted at a point in the destination rectangle is computed by filtering the original image data. The user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). When the filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from the nearest edge pixel. (That is, the filter uses ‘clamp-to-edge’ behavior.) When the filtering algorithm requires a pixel value from outside the source rectangle but inside the original image data, then the value from the original image data must be used.

   **Note**
   
   *Thus, scaling an image in parts or in whole will have the same effect. This does mean that when sprites coming from a single sprite sheet are to be scaled, adjacent images in the sprite sheet can interfere. This can be avoided by ensuring each sprite in the sheet is surrounded by a border of transparent black, or by copying sprites to be scaled into temporary canvas\(^{614}\) elements and drawing the scaled sprites from there.*

   Images are painted without affecting the current path, and are subject to shadow effects\(^{660}\), global alpha\(^{659}\), the clipping region\(^{650}\), and global composition operators\(^{659}\).

   7. If image is not origin-clean\(^{642}\), then set the CanvasRenderingContext2D\(^{619}\)'s origin-clean\(^{616}\) flag to false.
Objects that implement the CanvasImageData interface provide the following methods for reading and writing pixel data to the bitmap.

The ImageData() constructors and the createImageData() methods are used to instantiate new ImageData objects.

When the ImageData() constructor is invoked with two numeric arguments sw and sh, it must run these steps:

1. If one or both of sw and sh are zero, then throw an "IndexSizeError" DOMException.
2. Create an ImageData object with parameter pixelsPerRow set to sw, and rows set to sh.
3. Initialize the image data of the newly created ImageData object to transparent black.
4. Return the newly created ImageData object.

When the ImageData() constructor is invoked with its first argument being an Uint8ClampedArray source and its second and optional third arguments being numeric arguments sw and sh, it must run these steps:

1. Let length be the number of bytes in source.
2. If \( \text{length} \) is not a nonzero integral multiple of four, then throw an "InvalidStateError" DOMException.

3. Let \( \text{length} \) be \( \text{length} \) divided by four.

4. If \( \text{length} \) is not an integral multiple of \( \text{sw} \), then throw an "IndexSizeError" DOMException.

Note
At this step, the length is guaranteed to be greater than zero (otherwise the second step above would have aborted the steps), so if \( \text{sw} \) is zero, this step will throw the exception and return.

5. Let \( \text{height} \) be \( \text{length} \) divided by \( \text{sw} \).

6. If the \( \text{sh} \) argument was not omitted, and its value is not equal to \( \text{height} \), then throw an "IndexSizeError" DOMException.

7. Create an ImageData object\(^{656} \), with parameter \( \text{pixelsPerRow} \) set to \( \text{sw} \), \( \text{rows} \) set to \( \text{sh} \), and using \( \text{source} \). Return the newly created ImageData\(^{622} \) object.

Note
The resulting object's data is not a copy of source, it's the actual Uint8ClampedArray object passed as the first argument to the constructor.

When the `createImageBitmap()`\(^{655} \) method is invoked with two numeric arguments \( \text{sw} \) and \( \text{sh} \), it must create an ImageData object\(^{656} \), with parameter \( \text{pixelsPerRow} \) set to the absolute magnitude of \( \text{sw} \), and parameter \( \text{rows} \) set to the absolute magnitude of \( \text{sh} \). Initialize the image data of the new ImageData\(^{622} \) object to transparent black. If both \( \text{sw} \) and \( \text{sh} \) are nonzero, then return the new ImageData\(^{622} \) object. If one or both of \( \text{sw} \) and \( \text{sh} \) are zero, then throw an "IndexSizeError" DOMException instead.

When the `createImageBitmap()`\(^{655} \) method is invoked with a single imagedata argument, it must create an ImageData object\(^{656} \), with parameter \( \text{pixelsPerRow} \) set to the value of the \( \text{width} \) attribute of the ImageData\(^{622} \) object passed as the argument, and the \( \text{rows} \) parameter set to the value of the \( \text{height} \) attribute. Initialize the image data of the new ImageData\(^{622} \) object to transparent black. Return the newly created ImageData\(^{622} \) object.

The `getImageData(sx, sy, sw, sh)` method, when invoked, must, if either the \( \text{sw} \) or \( \text{sh} \) arguments are zero, throw an "IndexSizeError" DOMException; otherwise, if the CanvasRenderingContext2D\(^{619} \)'s origin-clean\(^{616} \) flag is set to false, it must throw a "SecurityError" DOMException; otherwise, it must create an ImageData object\(^{656} \), with parameter \( \text{pixelsPerRow} \) set to \( \text{sw} \), and parameter \( \text{rows} \) set to \( \text{sh} \). Set the pixel values of the image data of the newly created ImageData\(^{622} \) object to represent the output bitmap\(^{623} \) for the area of that bitmap denoted by the rectangle whose corners are the four points \((sx, sy), (sx+sw, sy), (sx+sw, sy+sh), (sx, sy+sh))\(^{623} \), in the bitmap's coordinate space units. Pixels outside the output bitmap\(^{623} \) must be set to transparent black. Pixel values must not be premultiplied by alpha.

When the user agent is required to create an ImageData object, given a positive integer number of rows \( \text{rows} \), a positive integer number of pixels per row \( \text{pixelsPerRow} \), and an optional Uint8ClampedArray \( \text{source} \), it must run these steps:

1. Let \( \text{imageData} \) be a new uninitialized ImageData\(^{622} \) object.
2. If \( \text{source} \) is specified, then assign the data attribute of \( \text{imageData} \) to \( \text{source} \).
3. If \( \text{source} \) is not specified, then initialize the data attribute of \( \text{imageData} \) to a new Uint8ClampedArray object. The Uint8ClampedArray object must use a new CanvasPixelArrayBuffer\(^{657} \) for its storage, and must have a zero start offset and a length equal to the length of its storage, in bytes. The CanvasPixelArrayBuffer\(^{657} \) must have the correct size to store \( \text{rows} \times \text{pixelsPerRow} \) pixels.
   If the CanvasPixelArrayBuffer\(^{657} \) cannot be allocated, then rethrow the RangeError thrown by JavaScript, and return.
4. Initialize the width attribute of \( \text{imageData} \) to \( \text{pixelsPerRow} \).
5. Initialize the height attribute of \( \text{imageData} \) to \( \text{rows} \).
6. Return \( \text{imageData} \).

ImageData\(^{622} \) objects are serializable objects\(^{968} \). Their serialization steps\(^{998} \), given value and serialized, are:

1. Set serialized.[[Data]] to the sub-serialization\(^{9103} \) of the value of value's data\(^{656} \) attribute.
2. Set serialized.[[Width]] to the value of value's width\(^{656} \) attribute.
3. Set serialized.[[Height]] to the value of value's height\(^{656} \) attribute.
Their deserialization steps\(^{656}\), given serialized and value, are:

1. Initialize value's data\(^{656}\) attribute to the sub-deserialization\(^{610}\) of serialized.[[Data]].
2. Initialize value's width\(^{656}\) attribute to serialized.[[Width]].
3. Initialize value's height\(^{656}\) attribute to serialized.[[Height]].

A Canvas Pixel ArrayBuffer is an ArrayBuffer whose data is represented in left-to-right order, row by row top to bottom, starting with the top left, with each pixel’s red, green, blue, and alpha components being given in that order for each pixel. Each component of each pixel represented in this array must be in the range 0..255, representing the 8 bit value for that component. The components must be assigned consecutive indices starting with 0 for the top left pixel’s red component.

The putImageData() method writes data from ImageData\(^{652}\) structures back to the rendering context’s output bitmap\(^{663}\). Its arguments are: imagedata, dx, dy, dirtyX, dirtyY, dirtyWidth, and dirtyHeight.

When the last four arguments to this method are omitted, they must be assumed to have the values 0, 0, the width\(^{656}\) member of the imagedata structure, and the height\(^{656}\) member of the imagedata structure, respectively.

The method, when invoked, must act as follows:

1. Let buffer be imagedata’s data\(^{656}\) attribute value’s [[ViewedArrayBuffer]] internal slot.
2. If IsDetachedBuffer(buffer) is true, then throw an "InvalidStateError" DOMException.
3. If dirtyWidth is negative, then let dirtyX be dirtyX+dirtyWidth, and let dirtyWidth be equal to the absolute magnitude of dirtyWidth.
   
   If dirtyHeight is negative, then let dirtyY be dirtyY+dirtyHeight, and let dirtyHeight be equal to the absolute magnitude of dirtyHeight.
4. If dirtyX is negative, then let dirtyWidth be dirtyWidth+dirtyX, and let dirtyX be zero.
   
   If dirtyY is negative, then let dirtyHeight be dirtyHeight+dirtyY, and let dirtyY be zero.
5. If dirtyX+dirtyWidth is greater than the width\(^{656}\) attribute of the imagedata argument, then let dirtyWidth be the value of that width\(^{656}\), minus the value of dirtyX.
   
   If dirtyY+dirtyHeight is greater than the height\(^{656}\) attribute of the imagedata argument, then let dirtyHeight be the value of that height\(^{656}\), minus the value of dirtyY.
6. If, after those changes, either dirtyWidth or dirtyHeight are negative or zero, then return without affecting any bitmaps.
7. For all integer values of \(x\) and \(y\) where dirtyX \(\leq x <\) dirtyX+dirtyWidth and dirtyY \(\leq y <\) dirtyY+dirtyHeight, copy the four channels of the pixel with coordinate \((x, y)\) in the imagedata data structure’s Canvas Pixel ArrayBuffer\(^{657}\) to the pixel with coordinate \((dx+x, dy+y)\) in the rendering context’s output bitmap\(^{663}\).

**Note**

Due to the lossy nature of converting to and from premultiplied alpha color values, pixels that have just been set using putImageData()\(^{657}\) might be returned to an equivalent getImageData()\(^{656}\) as different values.

The current path, transformation matrix\(^{639}\), shadow attributes\(^{640}\), global alpha\(^{659}\), the clipping region\(^{650}\), and global composition operator\(^{659}\) must not affect the methods described in this section.

**Example**

In the following example, the script generates an ImageData\(^{622}\) object so that it can draw onto it.

```javascript
// canvas is a reference to a <canvas> element
var context = canvas.getContext(‘2d’);

// create a blank slate
var data = context.createImageData(canvas.width, canvas.height);

// create some plasma
FillPlasma(data, ‘green’); // green plasma
```
// add a cloud to the plasma
AddCloud(data, data.width/2, data.height/2); // put a cloud in the middle

// paint the plasma+cloud on the canvas
context.putImageData(data, 0, 0);

// support methods
function FillPlasma(data, color) {...}
function AddCloud(data, x, y) {...}

Example

Here is an example of using `getImageData()` and `putImageData()` to implement an edge detection filter.

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
<title>Edge detection demo</title>
<script>
var image = new Image();
function init() {
    image.onload = demo;
    image.src = "image.jpeg";
}
function demo() {
    var canvas = document.getElementsByTagName('canvas')[0];
    var context = canvas.getContext('2d');

    // draw the image onto the canvas
    context.drawImage(image, 0, 0);

    // get the image data to manipulate
    var input = context.getImageData(0, 0, canvas.width, canvas.height);

    // get an empty slate to put the data into
    var output = context.createImageData(canvas.width, canvas.height);

    // alias some variables for convenience
    // In this case input.width and input.height
    // match canvas.width and canvas.height
    // but we'll use the former to keep the code generic.
    var w = input.width, h = input.height;
    var inputData = input.data;
    var outputData = output.data;

    // edge detection
    for (var y = 1; y < h - 1; y += 1) {
        for (var x = 1; x < w - 1; x += 1) {
            for (var c = 0; c < 3; c += 1) {
                var i = (y*w + x)*4 + c;
                outputData[i] = 127 + -inputData[i - w*4 - 4] - inputData[i - w*4] - inputData[i - w*4 + 4] + 
                                -inputData[i - 4] + 8*inputData[i] - inputData[i + 4] + 
                                -inputData[i + w*4 - 4] - inputData[i + w*4] - inputData[i + w*4 + 4];
            }
        }
    }
    outputData[(y*w + x)*4 + 3] = 255; // alpha
```
4.12.5.16 Compositing

For web developers (non-normative)

```javascript
context.globalAlpha = value
```

Returns the current alpha value applied to rendering operations.
Can be set, to change the alpha value. Values outside of the range 0.0 .. 1.0 are ignored.

```javascript
context.globalCompositeOperation = value
```

Returns the current composition operation, from the values defined in the Compositing and Blending specification.
Can be set, to change the composition operation. Unknown values are ignored.

All drawing operations on an object which implements the CanvasCompositing interface are affected by the global compositing attributes, `globalAlpha` and `globalCompositeOperation`.

The `globalAlpha` attribute gives an alpha value that is applied to shapes and images before they are composited onto the output bitmap. The value must be in the range from 0.0 (fully transparent) to 1.0 (no additional transparency). If an attempt is made to set the attribute to a value outside this range, including Infinity and Not-a-Number (NaN) values, then the attribute must retain its previous value. When the context is created, the `globalAlpha` attribute must initially have the value 1.0.

The `globalCompositeOperation` attribute sets the current composition operator, which controls how shapes and images are drawn onto the output bitmap, once they have had `globalAlpha` and the current transformation matrix applied. The possible values are those defined in the Compositing and Blending specification, and include the values `source-over` and `copy`.

These values are all case-sensitive — they must be used exactly as defined. User agents must not recognize values that are not a case-sensitive match for one of the values given in the Compositing and Blending specification.

On setting, if the user agent does not recognize the specified value, it must be ignored, leaving the value of `globalCompositeOperation` unaffected. Otherwise, the attribute must be set to the given new value.

When the context is created, the `globalCompositeOperation` attribute must initially have the value `source-over`.

4.12.5.17 Image smoothing

For web developers (non-normative)

```javascript
context.imageSmoothingEnabled = value
```

Returns whether pattern fills and the `drawImage()` method will attempt to smooth images if their pixels don't line up exactly with the display, when scaling images up.
Objects that implement the CanvasImageSmoothing\(^{619}\) interface have attributes that control how image smoothing is performed.

The imageSmoothingEnabled attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the CanvasImageSmoothing\(^{619}\) interface is created, the attribute must be set to true.

The imageSmoothingQuality attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the CanvasImageSmoothing\(^{619}\) interface is created, the attribute must be set to "low\(^{624}\)."

4.12.5.1.18 Shadows \(^{18}\)

All drawing operations on an object which implements the CanvasShadowStyles\(^{620}\) interface are affected by the four global shadow attributes.

For web developers (non-normative)

- **context.shadowColor\(^{660}\) \(= value\)**
  
  Returns the current shadow color.
  
  Can be set, to change the shadow color. Values that cannot be parsed as CSS colors are ignored.

- **context.shadowOffsetX\(^{660}\) \(= value\)**

- **context.shadowOffsetY\(^{660}\) \(= value\)**

  Returns the current shadow offset.
  
  Can be set, to change the shadow offset. Values that are not finite numbers are ignored.

- **context.shadowBlur\(^{660}\) \(= value\)**

  Returns the current level of blur applied to shadows.
  
  Can be set, to change the blur level. Values that are not finite numbers greater than or equal to zero are ignored.

The shadowColor attribute sets the color of the shadow.

When the context is created, the shadowColor\(^{660}\) attribute initially must be transparent black.

On getting, the serialization of the color\(^{663}\) must be returned.

On setting, the new value must be parsed\(^{657}\) with this canvas\(^{614}\) element and the color assigned. If parsing the value results in failure then it must be ignored, and the attribute must retain its previous value. [CSSCOLOR]\(^{9222}\)

The shadowOffsetX and shadowOffsetY attributes specify the distance that the shadow will be offset in the positive horizontal and positive vertical distance respectively. Their values are in coordinate space units. They are not affected by the current transformation matrix.

When the context is created, the shadow offset attributes must initially have the value 0.

On getting, they must return their current value. On setting, the attribute being set must be set to the new value, except if the value is infinite or NaN, in which case the new value must be ignored.

The shadowBlur attribute specifies the level of the blurring effect. (The units do not map to coordinate space units, and are not affected by the current transformation matrix.)
When the context is created, the `shadowBlur` attribute must initially have the value 0.

On getting, the attribute must return its current value. On setting the attribute must be set to the new value, except if the value is negative, infinite or NaN, in which case the new value must be ignored.

**Shadows are only drawn if** the opacity component of the alpha component of the color of `shadowColor` is nonzero and either the `shadowBlur` is nonzero, or the `shadowOffsetX` is nonzero, or the `shadowOffsetY` is nonzero.

When shadows are drawn, they must be rendered as follows:

1. Let A be an infinite transparent black bitmap on which the source image for which a shadow is being created has been rendered.
2. Let B be an infinite transparent black bitmap, with a coordinate space and an origin identical to A.
3. Copy the alpha channel of A to B, offset by `shadowOffsetX` in the positive x direction, and `shadowOffsetY` in the positive y direction.
4. If `shadowBlur` is greater than 0:
   1. Let σ be half the value of `shadowBlur`.
   2. Perform a 2D Gaussian Blur on B, using σ as the standard deviation.

User agents may limit values of σ to an implementation-specific maximum value to avoid exceeding hardware limitations during the Gaussian blur operation.

5. Set the red, green, and blue components of every pixel in B to the red, green, and blue components (respectively) of the color of `shadowColor`.
6. Multiply the alpha component of every pixel in B by the alpha component of the color of `shadowColor`.
7. The shadow is in the bitmap B, and is rendered as part of the drawing model described below.

If the current composition operation is `copy`, then shadows effectively won't render (since the shape will overwrite the shadow).

### 4.12.5.1.19 Filters

All drawing operations on an object which implements the `CanvasFilters` interface are affected by the global `filter` attribute.

**For web developers (non-normative)**

```javascript
context.filter = value
```

Returns the current filter.

Can be set, to change the filter. Values that cannot be parsed as a `<filter-function-list>` value are ignored.

The `filter` attribute, on getting, must return the last value it was successfully set to. The value must not be re-serialized. On setting, if the new value is 'none' (not the empty string, null, or undefined), filters must be disabled for the context. Otherwise, the value must be parsed as a `<filter-function-list>` value. If the value cannot be parsed as a `<filter-function-list>` value, where using property-independent style sheet syntax like 'inherit' or 'initial' is considered an invalid value, then it must be ignored, and the attribute must retain its previous value. When creating the object implementing the `CanvasFilters` interface, the attribute must be set to 'none'.

A `<filter-function-list>` value consists of a sequence of one or more filter functions or references to SVG filters. The input to the filter is used as the input to the first item in the list. Subsequent items take the output of the previous item as their input. [FILTERS]

Coordinates used in the value of the `filter` attribute are interpreted such that one pixel is equivalent to one SVG user space unit and to one canvas coordinate space unit. Filter coordinates are not affected by the current transformation matrix. The current transformation matrix affects only the input to the filter. Filters are applied in the output bitmap's coordinate space.

When the value of the `filter` attribute defines lengths using percentages or using 'em' or 'ex' units, these must be interpreted relative to the computed value of the 'font-size' property of the font style source object at the time that the attribute is set, if it is an element. If the computed values are undefined for a particular case (e.g. because the font style source object is not an element
or is not being rendered, then the relative keywords must be interpreted relative to the default value of the font attribute. The 'larger' and 'smaller' keywords are not supported.

If the value of the filter attribute refers to an SVG filter in the same document, and this SVG filter changes, then the changed filter is used for the next draw operation.

If the value of the filter attribute refers to an SVG filter in an external resource document and that document is not loaded when a drawing operation is invoked, then the drawing operation must proceed with no filtering.

4.12.5.1.20 Working with externally-defined SVG filters

This section is non-normative.

Since drawing is performed using filter value 'none' until an externally-defined filter has finished loading, authors might wish to determine whether such a filter has finished loading before proceeding with a drawing operation. One way to accomplish this is to load the externally-defined filter elsewhere within the same page in some element that sends a load event (for example, an SVG use element), and wait for the load event to be dispatched.

4.12.5.1.21 Drawing model

When a shape or image is painted, user agents must follow these steps, in the order given (or act as if they do):

1. Render the shape or image onto an infinite transparent black bitmap, creating image A, as described in the previous sections. For shapes, the current fill, stroke, and line styles must be honored, and the stroke must itself also be subjected to the current transformation matrix.

2. When the filter attribute is set to a value other than 'none' and all the externally-defined filters it references, if any, are in documents that are currently loaded, then use image A as the input to the filter, creating image B. Otherwise, let B be an alias for A.

3. When shadows are drawn, render the shadow from image B, using the current shadow styles, creating image C.

4. When shadows are drawn, multiply the alpha component of every pixel in C by globalAlpha.

5. When shadows are drawn, composite C within the clipping region over the current output bitmap using the current composition operator.

6. Multiply the alpha component of every pixel in B by globalAlpha.

7. Composite B within the clipping region over the current output bitmap using the current composition operator.

When compositing onto the output bitmap, pixels that would fall outside of the output bitmap must be discarded.

4.12.5.1.22 Best practices

When a canvas is interactive, authors should include focusable elements in the element's fallback content corresponding to each focusable part of the canvas, as in the example above.

When rendering focus rings, to ensure that focus rings have the appearance of native focus rings, authors should use the drawFocusIfNeeded method, passing it the element for which a ring is being drawn. This method only draws the focus ring if the element is focused, so that it can simply be called whenever drawing the element, without checking whether the element is focused or not first.

In addition to drawing focus rings, authors should use the scrollPathIntoView method when an element in the canvas is focused, to make sure it is visible on the screen (if applicable).

Authors should avoid implementing text editing controls using the canvas element. Doing so has a large number of disadvantages:

- Mouse placement of the caret has to be reimplemented.
- Keyboard movement of the caret has to be reimplemented (possibly across lines, for multiline text input).
• Scrolling of the text control has to be implemented (horizontally for long lines, vertically for multiline input).
• Native features such as copy-and-paste have to be reimplemented.
• Native features such as spell-checking have to be reimplemented.
• Native features such as drag-and-drop have to be reimplemented.
• Native features such as page-wide text search have to be reimplemented.
• Native features specific to the user, for example custom text services, have to be reimplemented. This is close to impossible since each user might have different services installed, and there is an unbounded set of possible such services.
• Bidirectional text editing has to be reimplemented.
• For multiline text editing, line wrapping has to be implemented for all relevant languages.
• Text selection has to be reimplemented.
• Dragging of bidirectional text selections has to be reimplemented.
• Platform-native keyboard shortcuts have to be reimplemented.
• Platform-native input method editors (IMEs) have to be reimplemented.
• Undo and redo functionality has to be reimplemented.
• Accessibility features such as magnification following the caret or selection have to be reimplemented.

This is a huge amount of work, and authors are most strongly encouraged to avoid doing any of it by instead using the input element, the textarea element, or the contenteditable attribute.

4.12.5.1.23 Examples

This section is non-normative.

Example

Here is an example of a script that uses canvas to draw pretty glowing lines.

```html
<canvas width="800" height="450"></canvas>
<script>

var context = document.getElementsByTagName('canvas')[0].getContext('2d');

var lastX = context.canvas.width * Math.random();
var lastY = context.canvas.height * Math.random();
var hue = 0;

function line() {
context.save();
context.translate(context.canvas.width/2, context.canvas.height/2);
context.scale(0.9, 0.9);
context.translate(-context.canvas.width/2, -context.canvas.height/2);
context.beginPath();
context.lineWidth = 5 + Math.random() * 10;
context.moveTo(lastX, lastY);
lastX = context.canvas.width * Math.random();
lastY = context.canvas.height * Math.random();
context.bezierCurveTo(context.canvas.width * Math.random(),
context.canvas.height * Math.random(),
context.canvas.width * Math.random(),
context.canvas.height * Math.random(),
lastX, lastY);

</script>
```
The 2D rendering context for canvas is often used for sprite-based games. The following example demonstrates this:

```
var Landscape = function (context, width, height) {
    this.offset = 0;
    this.width = width;
    this.advance = function (dx) {
        this.offset += dx;
    };
    this.horizon = height * 0.7;
    // This creates the sky gradient (from a darker blue to white at the bottom)
    this.sky = context.createLinearGradient(0, 0, 0, this.horizon);
    this.sky.addColorStop(0, 'rgb(55,121,179)');
    this.sky.addColorStop(0.7, 'rgb(121,194,245)');
    this.sky.addColorStop(1, 'white');
}
```

```
setInterval(Landscape, 50);
```

```
function blank() {
    context.fillStyle = 'rgba(0,0,0,0.1)';
    context.fillRect(0, 0, context.canvas.width, context.canvas.height);
}
```

```
setInterval(blank, 40);
```
this.sky.addColorStop(1.0, 'rgb(164,200,214)');
// this creates the grass gradient (from a darker green to a lighter green)
this.earth = context.createLinearGradient(0, this.horizon, 0, height);
this.earth.addColorStop(0.0, 'rgb(81,140,20)');
this.earth.addColorStop(1.0, 'rgb(123,177,57)');
this.paintBackground = function (context, width, height) {
  // first, paint the sky and grass rectangles
  context.fillStyle = this.sky;
  context.fillRect(0, 0, width, this.horizon);
  context.fillStyle = this.earth;
  context.fillRect(0, this.horizon, width, height-this.horizon);
  // then, draw the cloudy banner
  // we make it cloudy by having the draw text off the top of the
  // canvas, and just having the blurred shadow shown on the canvas
  context.save();
  context.translate(width-((this.offset+this.width*0.2) % (this.width*4.0))+0, 0);
  context.shadowColor = 'white';
  context.shadowOffsetY = 30+this.horizon/3; // offset down on canvas
  context.shadowBlur = '5';
  context.fillStyle = 'white';
  context.textAlign = 'left';
  context.textBaseline = 'top';
  context.font = '20px sans-serif';
  context.fillText('WHATWG ROCKS', 10, -30); // text up above canvas
  context.restore();
  // then, draw the background tree
  context.save();
  context.translate(width-((this.offset+this.width*0.2) % (this.width*1.5))+30, 0);
  context.beginPath();
  context.fillStyle = 'rgb(143,89,2)';
  context.strokeStyle = 'rgb(10,10,10)';
  context.lineWidth = 2;
  context.fillRect(0, this.horizon+5, 10, -50); // trunk
  context.fill();
  context.stroke();
  context.beginPath();
  context.fillStyle = 'rgb(78,154,6)';
  context.strokeStyle = 'rgb(10,10,10)';
  context.lineWidth = 2;
  context.stroke();
  context.restore();
};
this.paintForeground = function (context, width, height) {
  // draw the box that goes in front
  context.save();
  context.translate(width-((this.offset+this.width*0.7) % (this.width*1.1))+0, 0);
  context.beginPath();
  context.rect(0, this.horizon-5, 25, 25);
  context.fillStyle = 'rgb(220,154,94)';
  context.strokeStyle = 'rgb(10,10,10)';
  context.lineWidth = 2;
  context.stroke();
  context.restore();
};
}

var BlueRobot = function () {
  this.sprites = new Image();
this.sprites.src = 'blue-robot.png'; // this sprite sheet has 8 cells
this.targetMode = 'idle';
this.walk = function () {
    this.targetMode = 'walk';
};
this.stop = function () {
    this.targetMode = 'idle';
};
this.frameIndex = {
    'idle': [0], // first cell is the idle frame
    'walk': [1,2,3,4,5,6], // the walking animation is cells 1-6
    'stop': [7], // last cell is the stopping animation
};
this.mode = 'idle';
this.frame = 0; // index into frameIndex
this.tick = function () {
    // this advances the frame and the robot
    // the return value is how many pixels the robot has moved
    this.frame += 1;
    if (this.frame >= this.frameIndex[this.mode].length) {
        // we've reached the end of this animation cycle
        this.frame = 0;
        if (this.mode != this.targetMode) {
            // switch to next cycle
            if (this.mode == 'walk') {
                // we need to stop walking before we decide what to do next
                this.mode = 'stop';
            } else if (this.mode == 'stop') {
                if (this.targetMode == 'walk')
                    this.mode = 'walk';
                else
                    this.mode = 'idle';
            } else if (this.mode == 'idle') {
                if (this.targetMode == 'walk')
                    this.mode = 'walk';
            }
        }
    }
    if (this.mode == 'walk')
        return 8;
    return 0;
},
this.paint = function (context, x, y) {
    if (!this.sprites.complete) return;
    // draw the right frame out of the sprite sheet onto the canvas
    // we assume each frame is as high as the sprite sheet
    // the x,y coordinates give the position of the bottom center of the sprite
    context.drawImage(this.sprites, this.frameIndex[this.mode][this.frame] * this.sprites.height, 0, this.sprites.height, this.sprites.height, x-this.sprites.height/2, y-this.sprites.height, this.sprites.height, this.sprites.height);
};
<script>
var canvas = document.getElementsByTagName('canvas')[0];
var context = canvas.getContext('2d');
var landscape = new Landscape(context, canvas.width, canvas.height);
var blueRobot = new BlueRobot();
</script>
4.12.5.2 The `ImageBitmap` rendering context

4.12.5.2.1 Introduction

`ImageBitmapRenderingContext` is a performance-oriented interface that provides a low overhead method for displaying the contents of `ImageBitmap` objects. It uses transfer semantics to reduce overall memory consumption. It also streamlines performance by avoiding intermediate compositing, unlike the `drawImage()` method of `CanvasRenderingContext2D`.

Using an `img` element as an intermediate for getting an image resource into a canvas, for example, would result in two copies of the decoded image existing in memory at the same time: the `img` element's copy, and the one in the canvas's backing store. This memory cost can be prohibitive when dealing with extremely large images. This can be avoided by using `ImageBitmapRenderingContext`.

### Example

Using `ImageBitmapRenderingContext`, here is how to transcode an image to the JPEG format in a memory- and CPU-efficient way:

```javascript
// paint when the browser wants us to, using requestAnimationFrame()
function paint()
{
  context.clearRect(0, 0, canvas.width, canvas.height);
  landscape.paintBackground(context, canvas.width, canvas.height);
  blueRobot.paint(context, canvas.width/2, landscape.horizon*1.1);
  landscape.paintForeground(context, canvas.width, canvas.height);
  requestAnimationFrame(paint);
}
paint();
// but tick every 100ms, so that we don't slow down when we don't paint
setInterval(function () {
  var dx = blueRobot.tick();
  landscape.advance(dx);
}, 100);
</script>
<p class="buttons">
<input type="button" value="Walk" onclick="blueRobot.walk()">
<input type="button" value="Stop" onclick="blueRobot.stop()">
</p>

</Footer>
createImageBitmap(inputImageBlob).then(image => {
const canvas = document.createElement('canvas');
const context = canvas.getContext('bitmaprenderer');
context.transferFromImageBitmap(image);

canvas.toBlob(outputJPEGBlob => {
  // Do something with outputJPEGBlob.
}, 'image/jpeg');
});
```
4.12.5.2.2 The ImageBitmapRenderingContext interface

IDL

```javascript
[Exposed=Window]
interface ImageBitmapRenderingContext {
  readonly attribute HTMLCanvasElement canvas;
  void transferFromImageBitmap(ImageBitmap? bitmap);
};

dictionary ImageBitmapRenderingContextSettings {
  boolean alpha = true;
};
```

For web developers (non-normative)

```javascript
context = canvas . getContext('bitmaprenderer', { [ alpha: false ] })
```

Returns an ImageBitmapRenderingContext object that is permanently bound to a particular canvas element. If the alpha setting is provided and set to false, then the canvas is forced to always be opaque.

```javascript
context . canvas
```

Returns the canvas element that the context is bound to.

```javascript
context . transferFromImageBitmap(imageBitmap)
```

Transfers the underlying bitmap data from imageBitmap to context, and the bitmap becomes the contents of the canvas element to which context is bound.

```javascript
context . transferFromImageBitmap(null)
```

Replaces contents of the canvas element to which context is bound with a transparent black bitmap whose size corresponds to the width and height content attributes of the canvas element.

The canvas attribute must return the value it was initialized to when the object was created.

An ImageBitmapRenderingContext object has an output bitmap, which is a reference to bitmap data.

An ImageBitmapRenderingContext object has a bitmap mode, which can be set to valid or blank. A value of valid indicates that the context's output bitmap refers to bitmap data that was acquired via transferFromImageBitmap(). A value blank indicates that the context's output bitmap is a default transparent bitmap.

An ImageBitmapRenderingContext object also has an alpha flag, which can be set to true or false. When an ImageBitmapRenderingContext object has its alpha flag set to false, the contents of the canvas element to which the context is bound are obtained by compositing the context's output bitmap onto an opaque black bitmap of the same size using the source-over composite operation. If the alpha flag is set to true, then the output bitmap is used as the contents of the canvas element to which the context is bound. [COMPOSITE]

Note

The step of compositing over an opaque black bitmap ought to be elided whenever equivalent results can be obtained more efficiently by other means.

When a user agent is required to set an ImageBitmapRenderingContext's output bitmap, with a context argument that is an ImageBitmapRenderingContext object and an optional argument bitmap that refers to bitmap data, it must run these steps:

1. If a bitmap argument was not provided, then:
   1. Set context's bitmap mode to blank.
   2. Let canvas be the canvas element to which context is bound.
   3. Set context's output bitmap to be transparent black with an intrinsic width equal to the numeric value of canvas's width attribute and an intrinsic height equal to the numeric value of canvas's height attribute, those values being interpreted in CSS pixels.
   4. Set the output bitmap's origin-clean flag to true.
2. If a `bitmap` argument was provided, then:
   1. Set context's `bitmap mode` to `valid`.
   2. Set context's `output bitmap` to refer to the same underlying bitmap data as `bitmap`, without making a copy.

```plaintext
Note

The origin-clean flag of bitmap is included in the bitmap data to be referenced by context's output bitmap.
```

The **ImageBitmapRenderingContext creation algorithm**, which is passed a `target` (a `canvas` element) and `options`, consists of running these steps:

1. Let `settings` be the result of converting `options` to the dictionary type `ImageBitmapRenderingContextSettings`. (This can throw an exception.)
2. Let `context` be a new `ImageBitmapRenderingContext` object.
3. Initialize `context`'s `canvas` attribute to point to `target`.
4. Set `context`'s `output bitmap` to the same bitmap as `target`'s bitmap (so that they are shared).
5. Run the steps to set an `ImageBitmapRenderingContext`'s `output bitmap`, with `context`.
6. Initialize `context`'s `alpha` flag to true.
7. Process each of the members of `settings` as follows:
   - `alpha`
     - If false, then set `context`'s `alpha` flag to false.
8. Return `context`.

The `transferFromImageBitmap(imageBitmap)` method, when invoked, must run these steps:

1. Let `bitmapContext` be the `ImageBitmapRenderingContext` object on which the `transferFromImageBitmap()` method was called.
2. If `imageBitmap` is null, then run the steps to set an `ImageBitmapRenderingContext`'s `output bitmap`, with `bitmapContext` as the context argument and no `bitmap` argument, then return.
3. If the value of `imageBitmap`'s `[[Detached]]` internal slot is set to true, then throw an "InvalidStateError" DOMException.
4. Run the steps to set an `ImageBitmapRenderingContext`'s `output bitmap`, with the `context` argument equal to `bitmapContext`, and the `bitmap` argument referring to `imageBitmap`'s underlying `bitmap data`.
5. Set the value of `imageBitmap`'s `[[Detached]]` internal slot to true.
6. Unset `imageBitmap`'s `bitmap data`.

### 4.12.5.3 The **OffscreenCanvas** interface

```IDL
typedef (OffscreenCanvasRenderingContext2D or WebGLRenderingContext) OffscreenRenderingContext;
dictionary ImageEncodeOptions {
    DOMString type = "image/png";
    unrestricted double quality = 1.0;
};
enum OffscreenRenderingContextId { "2d", "webgl" };
```
[Constructor([EnforceRange] unsigned long long width, [EnforceRange] unsigned long long height),
Exposed=(Window,Worker), Transferable]

interface OffscreenCanvas : EventTarget {
    attribute unsigned long long width;
    attribute unsigned long long height;

    OffscreenRenderingContext? getContext(OffscreenRenderingContextId contextId, optional any options = null);
    ImageBitmap transferToImageBitmap();
    Promise<Blob> convertToBlob(optional ImageEncodeOptions options);
};

---

Note

**OffscreenCanvas** is an `EventTarget` so that WebGL can fire `webglcontextlost` and `webglcontextrestored` events at it.  

**OffscreenCanvas** objects are used to create rendering contexts, much like an `HTMLCanvasElement`, but with no connection to the DOM. This makes it possible to use canvas rendering contexts in *workers*.

An **OffscreenCanvas** object may hold a weak reference to a **placeholder canvas element**, which is typically in the DOM, whose embedded content is provided by the **`OffscreenCanvas`** object. The bitmap of the **`OffscreenCanvas`** object is pushed to the **placeholder canvas element** by calling the `commit()` method of the **`OffscreenCanvas`** object's rendering context. All rendering context types that can be created by an **`OffscreenCanvas`** object must implement a `commit()` method. The exact behavior of the commit method (e.g. whether it copies or transfers bitmaps) may vary, as defined by the rendering contexts' respective specifications. Only the **2D context for offscreen canvases** is defined in this specification.

For web developers (non-normative)

`offscreenCanvas = new OffscreenCanvas(width, height)`

Returns a new **`OffscreenCanvas`** object that is not linked to a **placeholder canvas element**, and whose bitmap's size is determined by the `width` and `height` arguments.

`context = offscreenCanvas . getContext(contextId [, options ] )`

Returns an object that exposes an API for drawing on the **`OffscreenCanvas`** object. `contextId` specifies the desired API: "2d" or "webgl". `options` is handled by that API.

This specification defines the "2d" context below, which is similar but distinct from the "webgl" context that is created from a `canvas` element. There is also a specification that defines a "webgl" context. [WEBGL]  

Returns null if the canvas has already been initialized with another context type (e.g., trying to get a "2d" context after getting a "webgl" context).

An **`OffscreenCanvas`** object has an internal **bitmap** that is initialized when the object is created. The width and height of the **bitmap** are equal to the values of the `width` and `height` attributes of the **`OffscreenCanvas`** object. Initially, all the bitmap's pixels are **transparent black**.

An **`OffscreenCanvas`** object can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, an **`OffscreenCanvas`** object also has a **context mode**, which is initially **none** but can be changed to either **2d**, **webgl** or **detached** by algorithms defined in this specification.

The constructor **`OffscreenCanvas(width, height)`**, when invoked, must create a new **`OffscreenCanvas`** object with its **bitmap** initialized to a rectangular array of **transparent black** pixels of the dimensions specified by `width` and `height`; and its `width` and `height` attributes initialized to `width` and `height` respectively.

**`OffscreenCanvas`** objects are **transferable**. Their **transfer steps**, given value and `dataHolder`, are as follows:

1. If value's **context mode** is not equal to **none**, then throw an "**InvalidStateError**" DOMException.
2. Set value's **context mode** to **detached**.
3. Let width and height be the dimensions of value's bitmap.
4. Unset value's bitmap.
5. Set dataHolder.[[Width]] to width and dataHolder.[[Height]] to height.
6. Set dataHolder.[[PlaceholderCanvas]] to be a weak reference to value's placeholder canvas element, if value has one, or null if it does not.

Their transfer-receiving steps, given dataHolder and value, are:
1. Initialize value's bitmap to a rectangular array of transparent black pixels with width given by dataHolder.[[Width]] and height given by dataHolder.[[Height]].
2. If dataHolder.[[PlaceholderCanvas]] is not null, set value's placeholder canvas element to dataHolder.[[PlaceholderCanvas]] (while maintaining the weak reference semantics).

The `getContext(contextId, options)` method of an `OffscreenCanvas` object, when invoked, must run these steps:
1. If options is not an object, then set options to null.
2. Set options to the result of converting options to a JavaScript value.
3. Run the steps in the cell of the following table whose column header matches this `OffscreenCanvas` object's context mode and whose row header matches contextId:

<table>
<thead>
<tr>
<th>contextId</th>
<th>none</th>
<th>2d</th>
<th>webgl</th>
<th>detached</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;2d&quot;</td>
<td>Follow the steps to create an offscreen 2D context defined in the section below, passing it this <code>OffscreenCanvas</code> object and options, to obtain an <code>OffscreenCanvasRenderingContext2D</code> object; if this does not throw an exception, then set this <code>OffscreenCanvas</code> object's context mode to 2d, and return the new <code>OffscreenCanvasRenderingContext2D</code> object.</td>
<td>Return the same object as was returned the last time the method was invoked with this same first argument.</td>
<td>Return null.</td>
<td>Throw an &quot;InvalidStateError&quot; DOMException.</td>
</tr>
<tr>
<td>&quot;webgl&quot;</td>
<td>Follow the instructions given in the WebGL specification's Context Creation section to obtain either a WebGLRenderingContext or null; if the returned value is null, then return null; otherwise, set this <code>OffscreenCanvas</code> object's context mode to webgl, and return the WebGLRenderingContext object.</td>
<td>Return the same value as was returned the last time the method was invoked with this same first argument.</td>
<td>Return null.</td>
<td>Throw an &quot;InvalidStateError&quot; DOMException.</td>
</tr>
</tbody>
</table>

For web developers (non-normative)

```
offscreenCanvas.width = value
offscreenCanvas.height = value
```

These attributes return the dimensions of the `OffscreenCanvas` object's bitmap.

They can be set, to replace the bitmap with a new, transparent black bitmap of the specified dimensions (effectively resizing it).

If either the width or height attributes of an `OffscreenCanvas` object are set (to a new value or to the same value as before) and the `OffscreenCanvas` object's context mode is 2d, then replace the `OffscreenCanvas` object's bitmap with a new transparent black bitmap and reset the rendering context to its default state. The new bitmap's dimensions are equal to the new values of the width and height attributes.

The resizing behavior for "webgl" contexts is defined in the WebGL specification.

Note

If an `OffscreenCanvas` object whose dimensions were changed has a placeholder canvas element, then the placeholder canvas element's intrinsic size will only be updated via the `commit()` method of the `OffscreenCanvas` object's rendering context.
The `convertToBlob(options)` method, when invoked, must run the following steps:

1. If the value of this `OffscreenCanvas` object's `[[Detached]]` internal slot is set to true, then return a promise rejected with an "InvalidStateError" DOMException.
2. If this `OffscreenCanvas` object's `context mode` is `2d` and the rendering context's `bitmap`'s `origin-clean` flag is set to false, then return a promise rejected with a "SecurityError" DOMException.
3. If this `OffscreenCanvas` object's `bitmap` has no pixels (i.e., either its horizontal dimension or its vertical dimension is zero) then return a promise rejected with an "IndexSizeError" DOMException.
4. Let `bitmap` be a copy of this `OffscreenCanvas` object's `bitmap`.
5. Let `result` be a new promise object.
6. Run these steps in parallel:
   1. Let `file` be a serialization of `bitmap` as a file, with `options`'s `type` and `quality`.
   2. Queue a task to run these steps:
      1. If `file` is null, then reject `result` with an "EncodingError" DOMException.
      2. Otherwise, resolve `result` with a new `Blob` object, created in the relevant Realm of this `OffscreenCanvas` object, representing `file`.
   The `task source` for this task is the `canvas blob serialization task source`.
7. Return `result`.

The `transferToImageBitmap()` method, when invoked, must run the following steps:

1. If the value of this `OffscreenCanvas` object's `[[Detached]]` internal slot is set to true, then throw an "InvalidStateError" DOMException.
2. If this `OffscreenCanvas` object's `context mode` is `none`, then throw an "InvalidStateError" DOMException.
3. Let `image` be a newly created `ImageBitmap` object with the image in the `OffscreenCanvas` object. The image in the `OffscreenCanvas` object is replaced with a new blank image.
The `OffscreenCanvasRenderingContext2D` object is a rendering context for drawing to the `bitmap` of an `OffscreenCanvas` object. It is similar to the `CanvasRenderingContext2D` object, with the following differences:

- There is no support for `user interface` features;
- Its `canvas` attribute refers to an `OffscreenCanvas` object rather than a `canvas` element;
- It has a `commit()` method for pushing the rendered image to the context's `OffscreenCanvas` object's `placeholder canvas element`.

An `OffscreenCanvasRenderingContext2D` object has a `bitmap` that is initialized when the object is created.

The `bitmap` has an `origin-clean` flag, which can be set to true or false. Initially, when one of these bitmaps is created, its `origin-clean` flag must be set to true.

An `OffscreenCanvasRenderingContext2D` object also has an `alpha` flag, which can be set to true or false. Initially, when the context is created, its alpha flag must be set to true. When an `OffscreenCanvasRenderingContext2D` object has its `alpha` flag set to false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

An `OffscreenCanvasRenderingContext2D` object has an associated `OffscreenCanvas` object, which is the `OffscreenCanvas` object from which the `OffscreenCanvasRenderingContext2D` object was created.

For web developers (non-normative)

```
offscreenCanvasRenderingContext2D . commit()()

Copies the rendering context's bitmap to the bitmap of the placeholder canvas element of the associated OffscreenCanvas object. The copy operation is asynchronous.

offscreenCanvas = offscreenCanvasRenderingContext2D . canvas

Returns the associated OffscreenCanvas object.
```

The offscreen 2D context creation algorithm, which is passed a target (an `OffscreenCanvas` object) and optionally some arguments, consists of running the following steps:

1. If the algorithm was passed some arguments, let `arg` be the first such argument. Otherwise, let `arg` be undefined.
2. Let `settings` be the result of converting options to the dictionary type `CanvasRenderingContext2DSettings` (This can throw an exception.).
3. Let `context` be a new `OffscreenCanvasRenderingContext2D` object.
4. Set context’s associated OffscreenCanvas object to target.

5. Process each of the members of settings as follows:

   **alpha**

   If false, set context’s alpha flag to false.

6. Set context’s bitmap to a newly created bitmap with the dimensions specified by the width and height attributes of target, and set target’s bitmap to the same bitmap (so that they are shared).

7. If context’s alpha flag is set to true, initialize all the pixels of context’s bitmap to transparent black. Otherwise, initialize the pixels to opaque black.

8. Return context.

The **commit()** method, when invoked, must run the following steps:

1. If this OffscreenCanvasRenderingContext2D’s associated OffscreenCanvas object does not have a placeholder canvas element, then return.

2. Let image be a copy of this OffscreenCanvasRenderingContext2D’s bitmap, including the value of its origin-clean flag.

3. Queue a task in the placeholder canvas element’s relevant settings object’s responsible event loop (which will be a browsing context’s event loop) to set the placeholder canvas element’s output bitmap to be a reference to image.

   **Note**

   If image has different dimensions than the bitmap previously referenced as the placeholder canvas element’s output bitmap, then this task will result in a change in the placeholder canvas element’s intrinsic size, which can affect document layout.

**Note**

Implementations are encouraged to short-circuit the graphics update steps of the browsing context’s event loop for the purposes of updating the contents of a placeholder canvas element to the display. This could mean, for example, that the commit method can copy the bitmap contents directly to a graphics buffer that is mapped to the physical display location of the placeholder canvas element. This or similar short-circuiting approaches can significantly reduce display latency, especially in cases where the commit method is invoked from a worker and the event loop of the placeholder canvas element’s browsing context is busy. However, such shortcuts can not have any script-observable side-effects. This means that the committed bitmap still needs to be sent to the placeholder canvas element, in case the element is used as a CanvasImageSource, as an ImageBitmapSource, or in case toDataURL() or toBlob() are called on it.

The **canvas** attribute, on getting, must return this OffscreenCanvasRenderingContext2D’s associated OffscreenCanvas object.

### 4.12.5.4 Color spaces and color correction

The canvas APIs must perform color correction at only two points: when rendering images with their own gamma correction and color space information onto a bitmap, to convert the image to the color space used by the bitmaps (e.g. using the 2D Context’s drawImage method with an HTML5SVImageElement object), and when rendering the actual canvas bitmap to the output device.

**Note**

Thus, in the 2D context, colors used to draw shapes onto the canvas will exactly match colors obtained through the getImageData method.

The **toDataURL()** method, when invoked, must not include color space information in the resources they return. Where the output format allows it, the color of pixels in resources created by **toDataURL()** must match those returned by the getImageData method.

In user agents that support CSS, the color space used by a canvas element must match the color space used for processing any colors for that element in CSS.

The gamma correction and color space information of images must be handled in such a way that an image rendered directly using an
An `img` element would use the same colors as one painted on a `canvas` element that is then itself rendered. Furthermore, the rendering of images that have no color correction information (such as those returned by the `toDataURL()` method) must be rendered with no color correction.

**Note**

Thus, in the 2D context, calling the `drawImage()` method to render the output of the `toDataURL()` method to the canvas, given the appropriate dimensions, has no visible effect.

### 4.12.5.5 Serializing bitmaps to a file

When a user agent is to create a serialization of the bitmap as a file, given an optional type and quality, it must create an image file in the format given by type, or if type was not supplied, in the PNG format. If an error occurs during the creation of the image file (e.g. an internal encoder error), then the result of the serialization is null. [PNG]

The image file’s pixel data must be the bitmap’s pixel data scaled to one image pixel per coordinate space unit, and if the file format used supports encoding resolution metadata, the resolution must be given as 96dpi (one image pixel per CSS pixel).

If type is supplied, then it must be interpreted as a MIME type giving the format to use. If the type has any parameters, then it must be treated as not supported.

**Example**

For example, the value "image/png" would mean to generate a PNG image, the value "image/jpeg" would mean to generate a JPEG image, and the value "image/svg+xml" would mean to generate an SVG image (which would require that the user agent track how the bitmap was generated, an unlikely, though potentially awesome, feature).

User agents must support PNG ("image/png"). User agents may support other types. If the user agent does not support the requested type, then it must create the file using the PNG format. [PNG]

User agents must convert the provided type to ASCII lowercase before establishing if they support that type.

For image types that do not support an alpha channel, the serialized image must be the bitmap image composited onto an opaque black background using the source-over operator.

If type is an image format that supports variable quality (such as "image/jpeg") and quality is given, then, if `Type(q)` is Number, and quality is in the range 0.0 to 1.0 inclusive, the user agent must treat quality as the desired quality level. If `Type(q)` is not Number, or if quality is outside that range, the user agent must use its default quality value, as if the quality argument had not been given.

**Note**

The use of type-testing here, instead of simply declaring quality as a Web IDL double, is a historical artifact.

### 4.12.5.6 Security with `canvas` elements

This section is non-normative.

Information leakage can occur if scripts from one `origin` can access information (e.g. read pixels) from images from another origin (one that isn’t the same).

To mitigate this, bitmaps used with `canvas` elements and `ImageBitmap` objects are defined to have a flag indicating whether they are `origin-clean`. All bitmaps start with their `origin-clean` set to true. The flag is set to false when cross-origin images are used.

The `toDataURL()`, `toBlob()` and `getImageData()` methods check the flag and will throw a "SecurityError" DOMException rather than leak cross-origin data.

The value of the `origin-clean` flag is propagated from a source `canvas` element’s bitmap to a new `ImageBitmap` object by `createImageBitmap()`. Conversely, a destination `canvas` element’s bitmap will have its `origin-clean` flags set to false by `drawImage` if the source image is an `ImageBitmap` object whose bitmap has its `origin-clean` flag set to false.

The flag can be reset in certain situations; for example, when changing the value of the `width` or the `height` content attribute of
the `canvas` element to which a `CanvasRenderingContext2D` is bound, the bitmap is cleared and its `origin-clean` flag is reset.

When using an `ImageBitmapRenderingContext`, the value of the `origin-clean` flag is propagated from `ImageBitmap` objects when they are transferred to the `canvas` via `transferFromImageBitmap()`.

### 4.13 Custom elements

#### 4.13.1 Introduction

This section is non-normative.

Custom elements provide a way for authors to build their own fully-featured DOM elements. Although authors could always use non-standard elements in their documents, with application-specific behavior added after the fact by scripting or similar, such elements have historically been non-conforming and not very functional. By defining a custom element, authors can inform the parser how to properly construct an element and how elements of that class should react to changes.

Custom elements are part of a larger effort to "rationalise the platform", by explaining existing platform features (like the elements of HTML) in terms of lower-level author-exposed extensibility points (like custom element definition). Although today there are many limitations on the capabilities of custom elements—both functionally and semantically—that prevent them from fully explaining the behaviors of HTML's existing elements, we hope to shrink this gap over time.

#### 4.13.1.1 Creating an autonomous custom element

This section is non-normative.

For the purposes of illustrating how to create an autonomous custom element, let's define a custom element that encapsulates rendering a small icon for a country flag. Our goal is to be able to use it like so:

```html
<flag-icon country="nl"></flag-icon>
```

To do this, we first declare a class for the custom element, extending `HTMLElement`:

```javascript
class FlagIcon extends HTMLElement {
  constructor() {
    super();
    this._countryCode = null;
  }

  static get observedAttributes() { return ["country"]; }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "country" due to observedAttributes
    this._countryCode = newValue;
    this._updateRendering();
  }

  connectedCallback() {
    this._updateRendering();
  }

  get country() {
    return this._countryCode;
  }

  set country(v) {
    this.setAttribute("country", v);
  }

  _updateRendering() {
    // Left as an exercise for the reader. But, you'll probably want to
  }
```

We then need to use this class to define the element:

```javascript
customElements.define("flag-icon", FlagIcon);
```

At this point, our above code will work! The parser, whenever it sees the `flag-icon` tag, will construct a new instance of our FlagIcon class, and tell our code about its new `country` attribute, which we then use to set the element's internal state and update its rendering (when appropriate).

You can also create `flag-icon` elements using the DOM API:

```javascript
const flagIcon = document.createElement("flag-icon")
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

Finally, we can also use the `custom element constructor` itself. That is, the above code is equivalent to:

```javascript
const flagIcon = new FlagIcon()
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

### 4.13.1.2 Creating a customized built-in element

This section is non-normative.

Customized built-in elements are a distinct kind of custom element, which are defined slightly differently and used very differently compared to autonomous custom elements. They exist to allow reuse of behaviors from the existing elements of HTML, by extending those elements with new custom functionality. This is important since many of the existing behaviors of HTML elements can unfortunately not be duplicated by using purely autonomous custom elements. Instead, customized built-in elements allow the installation of custom construction behavior, lifecycle hooks, and prototype chain onto existing elements, essentially "mixing in" these capabilities on top of the already-existing element.

Customized built-in elements require a distinct syntax from autonomous custom elements because user agents and other software key off an element's local name in order to identify the element's semantics and behavior. That is, the concept of customized built-in elements building on top of existing behavior depends crucially on the extended elements retaining their original local name.

In this example, we'll be creating a customized built-in named `plastic-button`, which behaves like a normal button but gets fancy animation effects added whenever you click on it. We start by defining a class, just like before, although this time we extend `HTMLButtonElement` instead of `HTMLElement`:

```javascript
class PlasticButton extends HTMLButtonElement {
    constructor() {
        super();

        this.addEventListener("click", () => {
            // Draw some fancy animation effects!
        });
    }
}
```

When defining our custom element, we have to also specify the `extends` option:

```javascript
customElements.define("plastic-button", PlasticButton, { extends: "button" });
```
In general, the name of the element being extended cannot be determined simply by looking at what element interface it extends, as many elements share the same interface (such as `p` and `blockquote` both sharing `HTMLQuoteElement`).

To construct our customized built-in element\(^{682}\) from parsed HTML source text, we use the `is`\(^{667}\) attribute on a `button`\(^{658}\) element:

```html
<button is="plastic-button">Click Me!</button>
```

Trying to use a customized built-in element\(^{682}\) as an autonomous custom element\(^{642}\) will not work; that is, `<plastic-button>Click me?</plastic-button>` will simply create an `HTMLElement`\(^{726}\) with no special behavior.

If you need to create a customized built-in element programmatically, you can use the following form of `createElement()`:

```javascript
const plasticButton = document.createElement("button", { is: "plastic-button" });
plasticButton.textContent = "Click me!";
```

And as before, the constructor will also work:

```javascript
const plasticButton2 = new PlasticButton();
console.log(plasticButton2.localName); // will output "button"
console.assert(plasticButton2 instanceof PlasticButton);
console.assert(plasticButton2 instanceof HTMLButtonElement);
```

Note that when creating a customized built-in element programmatically, the `is`\(^{667}\) attribute will not be present in the DOM, since it was not explicitly set. However, it will be added to the output when serializing\(^{721}\):

```html
<button is="plastic-button"></button>
```

Regardless of how it is created, all of the ways in which `button`\(^{658}\) is special apply to such "plastic buttons" as well: their focus behavior, ability to participate in form submission\(^{679}\), the `disabled`\(^{551}\) attribute, and so on.

Customized built-in elements\(^{682}\) are designed to allow extension of existing HTML elements that have useful user-agent supplied behavior or APIs. As such, they can only extend existing HTML elements defined in this specification, and cannot extend legacy elements such as `bgsound`, `blink`, `isindex`, `keygen`, `multicol`, `nextid`, or `spacer` that have been defined to use `HTMLUnknownElement`\(^{721}\) as their element interface.

One reason for this requirement is future-compatibility: if a customized built-in element\(^{682}\) was defined that extended a currently-unknown element, for example `taco-box`, this would prevent this specification from defining a `taco-box` element in the future, as consumers of the derived customized built-in element\(^{682}\) would have come to depend on their base element having no interesting user-agent-supplied behavior.

### 4.13.1.3 Drawbacks of autonomous custom elements

This section is non-normative.

As specified below, and alluded to above, simply defining and using an element called `taco-button` does not mean that such elements represent\(^{120}\) buttons. That is, tools such as Web browsers, search engines, or accessibility technology will not automatically treat the resulting element as a button just based on its defined name.

To convey the desired button semantics to a variety of users, while still using an autonomous custom element\(^{682}\), a number of techniques would need to be employed:

- The addition of the `tabindex`\(^{746}\) attribute would make the `taco-button` interactive content\(^{5129}\), thus making it focusable\(^{744}\). Note that if the `taco-button` were to become logically disabled, the `tabindex`\(^{746}\) attribute would need to be removed.

- The addition of various ARIA attributes helps convey semantics to accessibility technology. For example, setting the `role`\(^{666}\) attribute to "button" will convey the semantics that this is a button, enabling users to successfully interact with the control using usual button-like interactions in their accessibility technology. Setting the `aria-label` attribute is necessary to give the button an accessible name, instead of having accessibility technology traverse its child text nodes and announce them. And setting `aria-disabled` to "true" when the button is logically disabled conveys to accessibility technology the button's...
The addition of event handlers to handle commonly-expected button behaviors helps convey the semantics of the button to Web browser users. In this case, the most relevant event handler would be one that proxies appropriate \textit{keydown} events to become \textit{click} events, so that you can activate the button both with keyboard and by clicking.

In addition to any default visual styling provided for \texttt{taco-button} elements, the visual styling will also need to be updated to reflect changes in logical state, such as becoming disabled; that is, whatever style sheet has rules for \texttt{taco-button} will also need to have rules for \texttt{taco-button[disabled]}.

With these points in mind, a full-featured \texttt{taco-button} that took on the responsibility of conveying button semantics (including the ability to be disabled) might look something like this:

```javascript
class TacoButton extends HTMLElement {
    static get observedAttributes() { return ["disabled"];

    constructor() {
        super();
        this.addEventListener("keydown", e => {
            if (e.keyCode === 32 || e.keyCode === 13) {
                this.dispatchEvent(new MouseEvent("click", {
                    bubbles: true,
                    cancelable: true
                }));
            }
        });

        this.addEventListener("click", e => {
            if (this.disabled) {
                e.preventDefault();
                e.stopPropagation();
            }
        });

        this._observer = new MutationObserver(() => {
            this.setAttribute("aria-label", this.textContent);
        });
    }

    connectedCallback() {
        this.setAttribute("role", "button");
        this.setAttribute("tabindex", "0");

        this._observer.observe(this, {
            childList: true,
            characterData: true,
            subtree: true
        });
    }

    disconnectedCallback() {
        this._observer.disconnect();
    }

    get disabled() {
        return this.hasAttribute("disabled");
    }

    set disabled(v) {
        if (v) {
            this.setAttribute("disabled", "");
        } else {
        }
    }
}
```
Even with this rather-complicated element definition, the element is not a pleasure to use for consumers: it will be continually "sprouting" `tabindex` and `aria-*` attributes of its own volition. This is because as of now there is no way to specify default accessibility semantics or focus behavior for custom elements, forcing the use of these attributes to do so (even though they are usually reserved for allowing the consumer to override default behavior).

In contrast, a simple customized built-in element, as shown in the previous section, would automatically inherit the semantics and behavior of the `button` element, with no need to implement these behaviors manually. In general, for any elements with nontrivial behavior and semantics that build on top of existing elements of HTML, customized built-in elements will be easier to develop, maintain, and consume.

### 4.13.1.4 Upgrading elements after their creation

This section is non-normative.

Because element definition can occur at any time, a non-custom element could be created, and then later become a custom element after an appropriate definition is registered. We call this process "upgrading" the element, from a normal element into a custom element.

Upgrades enable scenarios where it may be preferable for custom element definitions to be registered after relevant elements have been initially created, such as by the parser. They allow progressive enhancement of the content in the custom element. For example, in the following HTML document the element definition for `img-viewer` is loaded asynchronously:

```html
<!DOCTYPE html>
<html lang="en">
<title>Image viewer example</title>

<img-viewer filter="Kelvin">
  <img src="images/tree.jpg" alt="A beautiful tree towering over an empty savannah">
</img-viewer>

<script src="js/elements/img-viewer.js" async></script>
```

The definition for the `img-viewer` element here is loaded using a `script` element marked with the `async` attribute, placed after the `img-viewer` tag in the markup. While the script is loading, the `img-viewer` element will be treated as an undefined element, similar to a `span`. Once the script loads, it will define the `img-viewer` element, and the existing `img-viewer` element on the page will be upgraded, applying the custom element's definition (which presumably includes applying an image filter identified by the string "Kelvin", enhancing the image's visual appearance).

Note that upgrades only apply to elements in the document tree. (Formally, elements that are connected.) An element that is not inserted into a document will stay un-upgraded. An example illustrates this point:

```html
<!DOCTYPE html>
<html lang="en">
```
4.13.2 Requirements for custom element constructors

When authoring custom element constructors, authors are bound by the following conformance requirements:

- A parameter-less call to `super()` must be the first statement in the constructor body, to establish the correct prototype chain and `this` value before any further code is run.

- A `return` statement must not appear anywhere inside the constructor body, unless it is a simple early-return (`return` or `return this`).

- The constructor must not use the `document.write()` or `document.open(type, replace)` methods.

- The element’s attributes and children must not be inspected, as in the non-upgrade case none will be present, and relying on upgrades makes the element less usable.

- The element must not gain any attributes or children, as this violates the expectations of consumers who use the `createElement` or `createElementNS` methods.

- In general, work should be deferred to `connectedCallback` as much as possible—especially work involving fetching resources or rendering. However, note that `connectedCallback` can be called more than once, so any initialization work that is truly one-time will need a guard to prevent it from running twice.

- In general, the constructor should be used to set up initial state and default values, and to set up event listeners and possibly a shadow root.

Several of these requirements are checked during element creation, either directly or indirectly, and failing to follow them will result in a custom element that cannot be instantiated by the parser or DOM APIs. This is true even if the work is done inside a constructor-initiated microtask, as a microtask checkpoint can occur immediately after construction.

4.13.3 Core concepts

A custom element is an element that is custom. Informally, this means that its constructor and prototype are defined by the author, instead of by the user agent. This author-supplied constructor function is called the custom element constructor.
Two distinct types of custom elements can be defined:

1. An autonomous custom element, which is defined with no `extends` option. These types of custom elements have a local name equal to their defined name.

2. A customized built-in element, which is defined with an `extends` option. These types of custom elements have a local name equal to the value passed in their `extends` option, and their defined name is used as the value of the `is` attribute, which therefore must be a valid custom element name.

After a custom element is created, changing the value of the `is` attribute does not change the element's behavior, as it is saved on the element as its `is` value.

Autonomous custom elements have the following element definition:

**Categories**

- Flow content
- Phrasing content
- Palpable content

**Contexts in which this element can be used**:

Where phrasing content is expected.

**Content model**:

- Transparent

**Content attributes**:

- Global attributes, except the `is` attribute
- Any other attribute that has no namespace (see prose).

**DOM interface**:

- Supplied by the element's author (inherits from HTMLElement)

An autonomous custom element does not have any special meaning: it represents its children. A customized built-in element inherits the semantics of the element that it extends.

Any namespace-less attribute that is relevant to the element's functioning, as determined by the element's author, may be specified on an autonomous custom element, so long as the attribute name is XML-compatible and contains no ASCII upper alphas. The exception is the `is` attribute, which must not be specified on an autonomous custom element (and which will have no effect if it is).

Customized built-in elements follow the normal requirements for attributes, based on the elements they extend. To add custom attribute-based behavior, use `data-*` attributes.

A valid custom element name is a sequence of characters `name` that meets all of the following requirements:

- `name` must match the `PotentialCustomElementName` production:

  ```
  PotentialCustomElementName ::= [a-z] (PCENChar)* \- (PCENChar)*
  PCENChar ::= ";" | "." | [0-9] | "," | [a-z] | #xB7 | [xC0-#xD6] | [xD8-#xF6] | [#x80-#x87] | [#x90-#x9F] | [#xA0-#xC0] | [#xE0-#xFF] | [#x900-#xF0FF] | [#xF000-#x1FFF] |
  ```

  This uses the EBNF notation from the XML specification. [XML]

- `name` must not be any of the following:

  - annotation-xml
  - color-profile
  - font-face
  - font-face-src
  - font-face-uri
  - font-face-format
  - font-face-name
  - missing-glyph
A custom element definition describes a custom element and consists of:

A **name**
- A valid custom element name

A **local name**
- A local name

A **constructor**
- A Web IDL Function callback function type value wrapping the custom element constructor.

A list of **observed attributes**
- A sequence<DOMString>

A collection of **lifecycle callbacks**
- A map, whose four keys are the strings "connectedCallback", "disconnectedCallback", "adoptedCallback", and "attributeChangedCallback". The corresponding values are either a Web IDL Function callback function type value, or null. By default the value of each entry is null.

A **construction stack**
- A list, initially empty, that is manipulated by the upgrade an element algorithm and the HTML element constructors. Each entry in the list will be either an element or an already constructed marker.

To look up a custom element definition, given a document, namespace, localName, and is, perform the following steps. They will return either a custom element definition or null:

1. If namespace is not the HTML namespace, return null.
2. If document does not have a browsing context, return null.
3. Let registry be document’s browsing context’s Window’s CustomElementRegistry object.
4. If there is a custom element definition in registry with name and local name both equal to localName, return that custom element definition.
5. If there is a custom element definition in registry with name equal to is and local name equal to localName, return that custom element definition.
6. Return null.

---

**Note**

The list of names above is the summary of all hyphen-containing element names from the applicable specifications, namely SVG and MathML. [SVG][1227] [MATHML][1224]

These requirements ensure a number of goals for valid custom element names:

- They start with an ASCII lower alpha, ensuring that the HTML parser will treat them as tags instead of as text.
- They do not contain any ASCII upper alphas, ensuring that the user agent can always treat HTML elements ASCII-case-insensitively.
- They contain a hyphen, used for namespaces and to ensure forward compatibility (since no elements will be added to HTML, SVG, or MathML with hyphen-containing local names in the future).
- They can always be created with `createElement()` and `createElementNS()`, which have restrictions that go beyond the parser’s.

Apart from these restrictions, a large variety of names is allowed, to give maximum flexibility for use cases like `<math-α>` or `<emotion-😍>`.
4.13.4 The `CustomElementRegistry` interface

Each `Window` object is associated with a unique instance of a `CustomElementRegistry` object, allocated when the `Window` object is created.

**Note**

Custom element registries are associated with `Window` objects, instead of `Document` objects, since each `custom element constructor` inherits from the `HTMLElement` interface, and there is exactly one `HTMLElement` interface per `Window` object.

The `customElements` attribute of the `Window` interface must return the `CustomElementRegistry` object for that `Window` object.

```idl
[Exposed=Window]
interface CustomElementRegistry {
    [CEReactions] void define(DOMString name, CustomElementConstructor constructor, optional ElementDefinitionOptions options);
    any get(DOMString name);
    Promise<void> whenDefined(DOMString name);
    [CEReactions] void upgrade(Node root);
};
callback CustomElementConstructor = any();
dictionary ElementDefinitionOptions {
    DOMString extends;
};
```

Every `CustomElementRegistry` has a set of `custom element definitions`, initially empty. In general, algorithms in this specification look up elements in the registry by any of `name`, `local name`, or `constructor`.

Every `CustomElementRegistry` also has an `element definition is running` flag which is used to prevent reentrant invocations of `element definition`. It is initially unset.

Every `CustomElementRegistry` also has a `when-defined promise map`, mapping `valid custom element names` to promises. It is used to implement the `whenDefined()` method.

For web developers (non-normative)

```javascript
window . customElements . define(name, constructor)
Defines a new custom element, mapping the given name to the given constructor as an autonomous custom element.

window . customElements . define(name, constructor, { extends: baseLocalName })
Defines a new custom element, mapping the given name to the given constructor as a customized built-in element for the element type identified by the supplied baseLocalName. A `NotSupportedError` DOMException will be thrown upon trying to extend a custom element or an unknown element.

window . customElements . get(name)
Retrieves the custom element constructor defined for the given name. Returns undefined if there is no custom element definition with the given name.

window . customElements . whenDefined(name)
Returns a promise that will be fulfilled when a custom element becomes defined with the given name. (If such a custom element is already defined, the returned promise will be immediately fulfilled.) Returns a promise rejected with a `SyntaxError` DOMException if not given a valid custom element name.

window . customElements . upgrade(root)
Tries to upgrade all shadow-including inclusive descendant elements of root, even if they are not connected.
```

**Element definition** is a process of adding a `custom element definition` to the `CustomElementRegistry`. This is accomplished by the `define()` method. When invoked, the `define(name, constructor, options)` method must run these steps:
1. If `IsConstructor`(`constructor`) is false, then throw a `TypeError`.

2. If `name` is not a valid custom element name\(^{682}\), then throw a "SyntaxError" `DOMException`.

3. If this `CustomElementRegistry`\(^{684}\) contains an entry with `name`\(^{683}\) name, then throw a "NotSupportedError" `DOMException`.

4. If this `CustomElementRegistry`\(^{684}\) contains an entry with `constructor`\(^{683}\) `constructor`, then throw a "NotSupportedError" `DOMException`.

5. Let `localName` be `name`.

6. Let `extends` be the value of the `extends` member of `options`, or null if no such member exists.

7. If `extends` is not null, then:
   1. If `extends` is a valid custom element name\(^{683}\), then throw a "NotSupportedError" `DOMException`.
   2. If the element interface for `extends` and the HTML namespace is `HTMLUnknownElement`\(^{121}\) (e.g., if `extends` does not indicate an element definition in this specification), then throw a "NotSupportedError" `DOMException`.
   3. Set `localName` to `extends`.

8. If this `CustomElementRegistry`\(^{684}\)’s element definition is running\(^{684}\) flag is set, then throw a "NotSupportedError" `DOMException`.

9. Set this `CustomElementRegistry`\(^{684}\)’s element definition is running\(^{684}\) flag.

10. Run the following substeps while catching any exceptions:
    1. Let `prototype` be `Get`(`constructor`, "prototype"). Rethrow any exceptions.
    2. If `Type`(`prototype`) is not Object, then throw a `TypeError` exception.
    3. Let `lifecycleCallbacks` be a map with the four keys "connectedCallback", "disconnectedCallback", "adoptedCallback", and "attributeChangedCallback", each of which belongs to an entry whose value is null.
    4. For each of the four keys `callbackName` in `lifecycleCallbacks`, in the order listed in the previous step:
        1. Let `callbackValue` be `Get`(`prototype`, `callbackName`). Rethrow any exceptions.
        2. If `callbackValue` is not undefined, then set the value of the entry in `lifecycleCallbacks` with key `callbackName` to the result of converting `callbackValue` to the Web IDL `Function` callback type. Rethrow any exceptions from the conversion.
    5. Let `observedAttributes` be an empty sequence<DOMString>.
    6. If the value of the entry in `lifecycleCallbacks` with key "attributeChangedCallback" is not null, then:
        1. Let `observedAttributesIterable` be `Get`(`constructor`, "observedAttributes"). Rethrow any exceptions.
        2. If `observedAttributesIterable` is not undefined, then set `observedAttributes` to the result of converting `observedAttributesIterable` to a sequence<DOMString>. Rethrow any exceptions from the conversion.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Unset this `CustomElementRegistry`\(^{684}\)’s element definition is running\(^{684}\) flag.

Finally, if the first set of substeps threw an exception, then rethrow that exception (thus terminating this algorithm). Otherwise, continue onward.

11. Let `definition` be a new custom element definition\(^{683}\) with `name`\(^{683}\) `name`, `localName`\(^{683}\) `localName`, `constructor`\(^{683}\) `constructor`, `observed attributes`\(^{683}\) `observedAttributes`, and `lifecycle callbacks`\(^{683}\) `lifecycleCallbacks`.

12. Add `definition` to this `CustomElementRegistry`\(^{684}\).

13. Let `document` be this `CustomElementRegistry`\(^{684}\)’s relevant global object\(^{884}\)’s associated Document\(^{793}\).

14. Let `upgrade candidates` be all elements that are shadow-including descendants of `document`, whose namespace is the HTML namespace and whose local name is `localName`, in shadow-including tree order. Additionally, if `extends` is non-null, only include elements whose `is value` is equal to `name`.
15. For each element `element` in `upgrade candidates`, enqueue a custom element upgrade reaction, given `element` and `definition`.

16. If this `CustomElementRegistry`'s `when-defined` promise map contains an entry with key `name`:
   1. Let `promise` be the value of that entry.
   2. Resolve `promise` with undefined.
   3. Delete the entry with key `name` from this `CustomElementRegistry`'s `when-defined` promise map.

When invoked, the `get(name)` method must run these steps:

1. If this `CustomElementRegistry` contains an entry with `name` `name`, then return that entry's `constructor`.
2. Otherwise, return undefined.

When invoked, the `whenDefined(name)` method must run these steps:

1. If `name` is not a valid custom element name, then return a new promise rejected with a "SyntaxError" `DOMException`.
2. If this `CustomElementRegistry` contains an entry with `name` `name`, then return a new promise resolved with undefined.
3. Let `map` be this `CustomElementRegistry`'s `when-defined` promise map.
4. If `map` does not contain an entry with key `name`, create an entry in `map` with key `name` and whose value is a new promise.
5. Let `promise` be the value of the entry in `map` with key `name`.
6. Return `promise`.

Example

The `whenDefined()` method can be used to avoid performing an action until all appropriate custom elements are defined. In this example, we combine it with the `:defined` pseudo-class to hide a dynamically-loaded article's contents until we're sure that all of the autonomous custom elements it uses are defined.

```javascript
articleContainer.hidden = true;
fetch(articleURL)
  .then(response => response.text())
  .then(text => {
    articleContainer.innerHTML = text;
    return Promise.all([...articleContainer.querySelectorAll(":not(:defined)")]
      .map(el => customElements.whenDefined(el.localName)));
  })
  .then(() => {
    articleContainer.hidden = false;
  });
```

When invoked, the `upgrade(root)` method must run these steps:

1. Let `candidates` be a list of all of `root`'s shadow-including inclusive descendant elements, in shadow-including tree order.
2. For each `candidate` of `candidates`, try to upgrade candidate.

Example

The `upgrade()` method allows upgrading of elements at will. Normally elements are automatically upgraded when they become connected, but this method can be used if you need to upgrade before you're ready to connect the element.
To upgrade an element, given as input a `custom element definition` and an element `element`, run the following steps:

1. If `element` is `custom`, then return.

2. If `element`'s `custom element state` is "failed", then return.

3. Set `element`'s `custom element definition` to `definition`.

4. For each `attribute` in `element`'s `attribute list`, in order, enqueue a `custom element callback reaction` with `element`, callback name "attributeChangedCallback", and an argument list containing `attribute`'s local name, null, `attribute`'s value, and `attribute`'s namespace.

5. If `element` is `connected`, then enqueue a `custom element callback reaction` with `element`, callback name "connectedCallback", and an empty argument list.

6. Add `element` to the end of `definition`'s `construction stack`.

7. Let `C` be `definition`'s `constructor`.

---

4.13.5 Upgrades

To upgrade an element, given as input a `custom element definition` and an element `element`, run the following steps:

1. If `element` is `custom`, then return.

Example

This can occur due to reentrant invocation of this algorithm, as in the following example:

```html
<!DOCTYPE html>
<x-foo id="a"></x-foo>
<x-foo id="b"></x-foo>

<script>
// Defining enqueues upgrade reactions for both "a" and "b"
customElements.define("x-foo", class extends HTMLElement {
  constructor() {
    super();

    const b = document.querySelector("#b");
    b.remove();

    // While this constructor is running for "a", "b" is still undefined, and so inserting it into the document will enqueue a second upgrade reaction for "b" in addition to the one enqueued by defining x-foo.
    document.body.appendChild(b);
  }
});
</script>
```

This step will thus bail out the algorithm early when `upgrade an element` is invoked with "b" a second time.
8. Run the following substeps while catching any exceptions:

   1. Let `constructResult` be the result of constructing `C`, with no arguments.

      **Note** If `C` non-conformantly uses an API decorated with the `[CEReactions]` extended attribute, then the reactions enqueued at the beginning of this algorithm will execute during this step, before `C` finishes and control returns to this algorithm. Otherwise, they will execute after `C` and the rest of the upgrade process finishes.

   2. If `SameValue(constructResult, element)` is false, then throw an "InvalidStateError" DOMException.

      **Note** This can occur if `C` constructs another instance of the same custom element before calling `super()`, or if `C` uses JavaScript's return-override feature to return an arbitrary object from the constructor.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

   1. Remove the last entry from the end of `definition`'s construction stack.

      **Note** Assuming `C` calls `super()` (as it will if it is conformant), and that the call succeeds, this will be the already constructed marker that replaced the element we pushed at the beginning of this algorithm. (The HTML element constructor carries out this replacement.)

      If `C` does not call `super()` (i.e. it is not conformant), or if any step in the HTML element constructor throws, then this entry will still be element.

Finally, if the above steps threw an exception, then:

   1. Set `element`'s custom element state to "failed".
   2. Set `element`'s custom element definition to null.
   3. Empty `element`'s custom element reaction queue.
   4. Rethrow the exception (thus terminating this algorithm).

9. Set `element`'s custom element state to "custom".

To try to upgrade an element, given as input an element `element`, run the following steps:

   1. Let `definition` be the result of looking up a custom element definition given `element`'s node document, `element`'s namespace, `element`'s local name, and `element`'s `is` value.
   2. If `definition` is not null, then enqueue a custom element upgrade reaction given `element` and `definition`.

### 4.13.6 Custom element reactions

A custom element possesses the ability to respond to certain occurrences by running author code:

- When upgraded, its constructor is run, with no arguments.
- When it becomes connected, its connectedCallback is called, with no arguments.
- When it becomes disconnected, its disconnectedCallback is called, with no arguments.
- When it is adopted into a new document, its adoptedCallback is called, given the old document and new document as arguments.
- When any of its attributes are changed, appended, removed, or replaced, its attributeChangedCallback is called, given the attribute's local name, old value, new value, and namespace as arguments. (An attribute's old or new value is considered to be null when the attribute is added or removed, respectively.)
We call these reactions collectively **custom element reactions**.

The way in which custom element reactions are invoked is done with special care, to avoid running author code during the middle of delicate operations. Effectively, they are delayed until “just before returning to user script”. This means that for most purposes they appear to execute synchronously, but in the case of complicated composite operations (like cloning, or range manipulation), they will instead be delayed until after all the relevant user agent processing steps have completed, and then run together as a batch.

Additionally, the precise ordering of these reactions is managed via a somewhat-complicated stack-of-queues system, described below. The intention behind this system is to guarantee that custom element reactions always are invoked in the same order as their triggering actions, at least within the local context of a single custom element. (Because custom element reaction code can perform its own mutations, it is not possible to give a global ordering guarantee across multiple elements.)

Each unit of related similar-origin browsing contexts has a custom element reactions stack, which is initially empty. The current element queue is the element queue at the top of the custom element reactions stack. Each item in the stack is an element queue, which is initially empty as well. Each item in an element queue is an element. (The elements are not necessarily custom yet, since this queue is used for upgrades as well.)

Each custom element reactions stack has an associated backup element queue, which is initially-empty element queue. Elements are pushed onto the backup element queue during operations that affect the DOM without going through an API decorated with \[\text{CEReactions}\], or through the parser’s create an element for the token algorithm. An example of this is a user-initiated editing operation which modifies the descendants or attributes of an editable element. To prevent reentrancy when processing the backup element queue, each custom element reactions stack also has a processing the backup element queue flag, initially unset.

All elements have an associated custom element reaction queue, initially empty. Each item in the custom element reaction queue is of one of two types:

- An **upgrade reaction**, which will upgrade the custom element and contains a custom element definition; or
- A **callback reaction**, which will call a lifecycle callback, and contains a callback function as well as a list of arguments.

This is all summarized in the following schematic diagram:

To enqueue an element on the appropriate element queue, given an element element, run the following steps:

1. If the custom element reactions stack is empty, then:
1. Add `element` to the backup element queue.
2. If the processing the backup element queue flag is set, then return.
3. Set the processing the backup element queue flag.
4. Queue a microtask to perform the following steps:
   1. Invoke custom element reactions in the backup element queue.
   2. Unset the processing the backup element queue flag.
5. Otherwise, add `element` to the current element queue.

To enqueue a custom element callback reaction, given a custom element, a callback name `callbackName`, and a list of arguments `args`, run the following steps:

1. Let `definition` be `element`'s custom element definition.
2. Let `callback` be the value of the entry in `definition`'s lifecycle callbacks with key `callbackName`.
3. If `callback` is null, then return.
4. If `callbackName` is "attributeChangedCallback", then:
   1. Let `attributeName` be the first element of `args`.
   2. If `definition`'s observed attributes does not contain `attributeName`, then return.
5. Add a new callback reaction to `element`'s custom element reaction queue, with callback function `callback` and arguments `args`.
6. Enqueue an element on the appropriate element queue given `element`.

To enqueue a custom element upgrade reaction, given an element and custom element definition, run the following steps:

1. Add a new upgrade reaction to `element`'s custom element reaction queue, with custom element definition.
2. Enqueue an element on the appropriate element queue given `element`.

To invoke custom element reactions in an element queue queue, run the following steps:

1. For each custom element element in queue:
   1. Let `reactions` be `element`'s custom element reaction queue.
   2. Repeat until `reactions` is empty:
      1. Remove the first element of `reactions`, and let `reaction` be that element. Switch on `reaction`'s type:
         - upgrade reaction: Upgrade `element` using `reaction`'s custom element definition.
         - callback reaction: Invoke `reaction`'s callback function with `reaction`'s arguments, and with `element` as the callback this value.

If this throws an exception, catch it, and report the exception.

To ensure custom element reactions are triggered appropriately, we introduce the [CEReactions] IDL extended attribute. It indicates that the relevant algorithm is to be supplemented with additional steps in order to appropriately track and invoke custom element reactions.

The [CEReactions] extended attribute must take no arguments, and must not appear on anything other than an operation, attribute, setter, or deleter. Additionally, it must not appear on readonly attributes.
Operations, attributes, setters, or deleters annotated with the \[CEReactions]\ extended attribute must run the following steps in place of the ones specified in their description:

1. **Push** a new *element queue* onto the *custom element reactions stack*.
2. Run the originally-specified steps for this construct, catching any exceptions. If the steps return a value, let \(value\) be the returned value. If they throw an exception, let \(exception\) be the thrown exception.
3. Let \(queue\) be the result of **popping** from the *custom element reactions stack*.
4. **Invoke custom element reactions** in \(queue\).
5. If an exception \(exception\) was thrown by the original steps, rethrow \(exception\).
6. If a value \(value\) was returned from the original steps, return \(value\).

**Note**

The intent behind this extended attribute is somewhat subtle. One way of accomplishing its goals would be to say that every operation, attribute, setter, and deleter on the platform must have these steps inserted, and to allow implementers to optimize away unnecessary cases (where no DOM mutation is possible that could cause custom element reactions to occur).

However, in practice this imprecision could lead to non-interoperable implementations of custom element reactions, as some implementations might forget to invoke these steps in some cases. Instead, we settled on the approach of explicitly annotating all relevant IDL constructs, as a way of ensuring interoperable behavior and helping implementations easily pinpoint all cases where these steps are necessary.

Any nonstandard APIs introduced by the user agent that could modify the DOM in such a way as to cause enqueuing a custom element callback reaction or enqueuing a custom element upgrade reaction, for example by modifying any attributes or child elements, must also be decorated with the \[CEReactions\] attribute.

**Note**

As of the time of this writing, the following nonstandard or not-yet-standardized APIs are known to fall into this category:

- `HTMLElement`'s `outerText` IDL attribute
- `HTMLInputElement`'s `webkitdirectory` and `incremental` IDL attributes
- `HTMLLinkElement`'s `disabled` and `scope` IDL attributes
- `ShadowRoot`'s `innerHTML` IDL attribute

### 4.14 Common idioms without dedicated elements

#### 4.14.1 The main part of the content

The main content of a page — not including headers and footers, navigation links, sidebars, advertisements, and so forth — can be marked up in a variety of ways, depending on the needs of the author.

The simplest solution is to not mark up the main content at all, and just leave it as implicit. Another way to think of this is that the `body` elements marks up the main content of the page, and the bits that aren't main content are excluded through the use of more appropriate elements like `aside` and `nav`.

**Example**

Here is a short Web page marked up along this minimalistic school of thought. The main content is highlighted. Notice how all the other content in the `body` is marked up with elements to indicate that it's not part of the main content, in this case `header`, `nav`, and `footer`.
If the main content is an independent unit of content that one could imagine syndicating independently, then the `<article>` element would be appropriate to mark up the main content of the document.

Example

The document in the previous example is here recast as a blog post:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>The Boy Blog: My Toys</title>
</head>
<body>
  <header>
    <h1>The Boy Blog</h1>
  </header>
  <nav>
    <p><a href="/">Home</a></p>
    <p><a href="/contact">Contact</a></p>
  </nav>
  <article>
    <header>
      <h1>My toys</h1>
      <p>Published August 4th</p>
    </header>
    <p>I really like my chained book and my telephone. I'm not such a fan of my big ball.</p>
    <p>Another toy I like is my mirror.</p>
  </article>
  <footer>
    <p>© copyright 2010 by the boy</p>
  </footer>
</body>
</html>
```

If the main content is not an independent unit of content so much as a section of a larger work, for instance a chapter, then the `<section>` element would be appropriate to mark up the main content of the document.
Here is the same document, but as a chapter in an online book:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>Chapter 2: My Toys — The Book of the Boy</title>
</head>
<body>
  <header>
    <hgroup>
      <h1>The Book of the Boy</h1>
      <h2>A book about boy stuff</h2>
    </hgroup>
  </header>
  <nav>
    <p><a href="/">Front Page</a></p>
    <p><a href="/toc">Table of Contents</a></p>
    <p><a href="/c1">Chapter 1</a> — <a href="/c3">Chapter 3</a></p>
  </nav>
  <section>
    <h1>Chapter 2: My Toys</h1>
    <p>I really like my chained book and my telephone. I'm not such a fan of my big ball.</p>
    <p>Another toy I like is my mirror.</p>
  </section>
  <footer>
    <p>© copyright 2010 by the boy</p>
  </footer>
</body>
</html>
```

If neither `article` nor `section` would be appropriate, but the main content still needs an explicit element, for example for styling purposes, then the `main` element can be used.

This is the same as the original example, but using `main` for the main content instead of leaving it implied:

```html
<!DOCTYPE HTML>
<html lang="en">
  <head>
    <title>My Toys</title>
    <style>
      body > main { background: navy; color: yellow; }
    </style>
  </head>
  <body>
    <header>
      <h1>My toys</h1>
    </header>
    <nav>
      <p><a href="/">Home</a></p>
      <p><a href="/contact">Contact</a></p>
    </nav>
    <main>
      <p>I really like my chained book and my telephone. I'm not such a fan of my big ball.</p>
      <p>Another toy I like is my mirror.</p>
    </main>
    <footer>
      <p>© copyright 2010 by the boy</p>
    </footer>
</body>
</html>
```
4.14.2 Bread crumb navigation §69

This specification does not provide a machine-readable way of describing bread-crumb navigation menus. Authors are encouraged to just use a series of links in a paragraph. The nav element can be used to mark the section containing these paragraphs as being navigation blocks.

Example

In the following example, the current page can be reached via two paths.

```html
<nav>
  <p><a href="/">Main</a>▸<a href="/products/">Products</a>▸<a href="/products/dishwashers/">Dishwashers</a>▸Second hand</p>
  <p><a href="/">Main</a>▸<a href="/second-hand/">Second hand</a>▸Dishwashers</p>
</nav>
```

4.14.3 Tag clouds §69

This specification does not define any markup specifically for marking up lists of keywords that apply to a group of pages (also known as tag clouds). In general, authors are encouraged to either mark up such lists using ul elements with explicit inline counts that are then hidden and turned into a presentational effect using a style sheet, or to use SVG.

Example

Here, three tags are included in a short tag cloud:

```html
<style>
.tag-cloud > li > span { display: none; }
.tag-cloud > li { display: inline; }
.tag-cloud-1 { font-size: 0.7em; }
.tag-cloud-2 { font-size: 0.9em; }
.tag-cloud-3 { font-size: 1.1em; }
.tag-cloud-4 { font-size: 1.3em; }
.tag-cloud-5 { font-size: 1.5em; }
@media speech {
.tag-cloud > li > span { display:inline }
}
</style>

...<ul class="tag-cloud">
<li class="tag-cloud-4" title="28 instances" href="/t/apple">apple</li> <span>(popular)</span>
<li class="tag-cloud-2" title="6 instances" href="/t/kiwi">kiwi</li> <span>(rare)</span>
```
This specification does not define a specific element for marking up conversations, meeting minutes, chat transcripts, dialogues in screenplays, instant message logs, and other situations where different players take turns in discourse.

Instead, authors are encouraged to mark up conversations using `p` elements and punctuation. Authors who need to mark the speaker for styling purposes are encouraged to use `span` or `b`. Paragraphs with their text wrapped in the `i` element can be used for marking up stage directions.

The actual frequency of each tag is given using the `title` attribute. A CSS style sheet is provided to convert the markup into a cloud of differently-sized words, but for user agents that do not support CSS or are not visual, the markup contains annotations like “(popular)” or “(rare)” to categorize the various tags by frequency, thus enabling all users to benefit from the information.

The `ul` element is used (rather than `ol`) because the order is not particularly important: while the list is in fact ordered alphabetically, it would convey the same information if ordered by, say, the length of the tag.

The `tag`-`rel`-keyword is not used on these `a` elements because they do not represent tags that apply to the page itself; they are just part of an index listing the tags themselves.

### 4.14.4 Conversations

This specification does not define a specific element for marking up conversations, meeting minutes, chat transcripts, dialogues in screenplays, instant message logs, and other situations where different players take turns in discourse.

Instead, authors are encouraged to mark up conversations using `p` elements and punctuation. Authors who need to mark the speaker for styling purposes are encouraged to use `span` or `b`. Paragraphs with their text wrapped in the `i` element can be used for marking up stage directions.

**Example**

This example demonstrates this using an extract from Abbot and Costello’s famous sketch, *Who’s on first*:

```
<p>Costello: Look, you gotta first baseman?</p>
<p>Abbott: Certainly.</p>
<p>Costello: Who’s playing first?</p>
<p>Abbott: That's right.</p>
<p>Costello becomes exasperated.</p>
<p>Costello: When you pay off the first baseman every month, who gets the money?</p>
<p>Abbott: Every dollar of it.</p>
```

**Example**

The following extract shows how an IM conversation log could be marked up, using the `data` element to provide Unix timestamps for each line. Note that the timestamps are provided in a format that the `time` element does not support, so the `data` element is used instead (namely, Unix `time_t` timestamps). Had the author wished to mark up the data using one of the date and time formats supported by the `time` element, that element could have been used instead of `data`. This could be advantageous as it would allow data analysis tools to detect the timestamps unambiguously, without coordination with the page author.

```
<p>&lt;data value="1319898155"&gt;14:22&lt;/data&gt; &lt;b&gt;egof&lt;/b&gt; I'm not that nerdy, I've only seen 30% of the star trek episodes</p>
<p>&lt;data value="1319898192"&gt;14:23&lt;/data&gt; &lt;b&gt;kaj&lt;/b&gt; if you know what percentage of the star trek episodes you have seen, you are inarguably nerdy</p>
<p>&lt;data value="1319898200"&gt;14:23&lt;/data&gt; &lt;b&gt;egof&lt;/b&gt; it's unarguably</p>
<p>&lt;data value="1319898228"&gt;14:23&lt;/data&gt; &lt;i&gt;* kaj blinks&lt;/i&gt;</p>
<p>&lt;data value="1319898260"&gt;14:24&lt;/data&gt; &lt;b&gt;kaj&lt;/b&gt; you are not helping your case</p>
```

**Example**

HTML does not have a good way to mark up graphs, so descriptions of interactive conversations from games are more difficult to
mark up. This example shows one possible convention using \texttt{dl} elements to list the possible responses at each point in the conversation. Another option to consider is describing the conversation in the form of a DOT file, and outputting the result as an SVG image to place in the document. \texttt{[DOT]}.

Next, you meet a fisher. You can say one of several greetings:

\begin{description}
  \item["Hello there!"] She responds with "Hello, how may I help you?"; you can respond with:
  \begin{description}
    \item["I would like to buy a fish."] She sells you a fish and the conversation finishes.
    \item["Can I borrow your boat?"
      \begin{description}
        \item["Five gold." (if you have enough)]
        \item["Ten gold." (if you have enough)]
        \item["Fifteen gold." (if you have enough)]
        \item["No thanks", she replies. Your conversation options at this point are the same as they were after asking to borrow her boat, minus any options you've suggested before.}
    \end{description}
    \item["Vote for me in the next election!"
      \begin{description}
        \item["Madam, are you aware that your fish are running away?"
          \begin{description}
            \item["You got me!"
              \begin{description}
                \item["Only kidding."
                  \begin{description}
                    \item["Good one!"] she retorts. Your conversation options at this point are the same as those following "Hello there!" above.
                    \item["Oh, then what are they doing?"
                      \begin{description}
                        \item["No thanks", she replies. Your conversation options at this point are the same as they were after asking to borrow her boat, minus any options you've suggested before.}
                      \end{description}
                    \end{description}
                  \end{description}
                \end{description}
              \end{description}
            \end{description}
          \end{description}
        \end{description}
      \end{description}
      \end{description}
    \end{description}
\end{description}

In some games, conversations are simpler: each character merely has a fixed set of lines that they say. In this example, a game FAQ/walkthrough lists some of the known possible responses for each character:

\begin{section}
  \begin{h1}Dialogue\end{h1}
  \begin{p}\begin{small}Some characters repeat their lines in order each time you interact with them, others randomly pick from amongst their lines. Those who respond in order have numbered entries in the lists below.\end{small}\end{p}
  \begin{h2}The Shopkeeper\end{h2}
<ul>
  <li>How may I help you?</li>
  <li>Fresh apples!</li>
  <li>A loaf of bread for madam?</li>
</ul>

The pilot

<p>Before the accident:</p>

<ul>
  <li>I'm about to fly out, sorry!</li>
  <li>Sorry, I'm just waiting for flight clearance and then I'll be off!</li>
</ul>

<p>After the accident:</p>

<ol>
  <li>I'm about to fly out, sorry!</li>
  <li>Ok, I'm not leaving right now, my plane is being cleaned.</li>
  <li>Ok, it's not being cleaned, it needs a minor repair first.</li>
  <li>Ok, ok, stop bothering me! Truth is, I had a crash.</li>
</ol>

Clan Leader

<p>During the first clan meeting:</p>

<ul>
  <li>Hey, have you seen my daughter? I bet she's up to something nefarious again…</li>
  <li>Nice weather we're having today, eh?</li>
  <li>The name is Bailey, Jeff Bailey. How can I help you today?</li>
  <li>A glass of water? Fresh from the well!</li>
</ul>

<p>After the earthquake:</p>

<ol>
  <li>Everyone is safe in the shelter, we just have to put out the fire!</li>
  <li>I'll go and tell the fire brigade, you keep hosing it down!</li>
</ol>

### 4.14.5 Footnotes

HTML does not have a dedicated mechanism for marking up footnotes. Here are the suggested alternatives.

For short inline annotations, the `title` attribute could be used.

**Example**

In this example, two parts of a dialogue are annotated with footnote-like content using the `title` attribute.

```html
<p>Customer: Hello! I wish to register a complaint. Hello. Miss?</p>
<p>Shopkeeper: <span title="Colloquial pronunciation of 'What do you'">Watcha</span> mean, miss?</p>
<p>Customer: Uh, I'm sorry, I have a cold. I wish to make a complaint.</p>
<p>Shopkeeper: Sorry, <span title="This is, of course, a lie.">we're closing for lunch</span>.
```

**Note**

Unfortunately, relying on the `title` attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).
For longer annotations, the element should be used, pointing to an element later in the document. The convention is that the contents of the link be a number in square brackets.

For side notes, longer annotations that apply to entire sections of the text rather than just specific words or sentences, the element should be used.

In this example, a sidebar is given after a dialogue, giving it some context.

In this example, a table has cells with footnotes that are given in prose. A element is used to give a single legend to the combination of the table and its footnotes.
An element is said to be **actually disabled** if it is one of the following:

- a button element that is disabled
- an input element that is disabled
- a select element that is disabled
- a textarea element that is disabled
- an optgroup element that has a disabled attribute
- an option element that is disabled
- a fieldset element that is a disabled fieldset

---

**4.15 Disabled elements**

An element is said to be **actually disabled** if it is one of the following:

- a button element that is disabled
- an input element that is disabled
- a select element that is disabled
- a textarea element that is disabled
- an optgroup element that has a disabled attribute
- an option element that is disabled
- a fieldset element that is a disabled fieldset

---

**4.16 Matching HTML elements using selectors and CSS**

**4.16.1 Case-sensitivity of the CSS 'attr()' function**

The CSS Values and Units specification leaves the case-sensitivity of attribute names for the purpose of the 'attr()' function to be defined by the host language. [CSSVALUES]

When comparing the attribute name part of a CSS 'attr()' function to the names of namespace-less attributes on HTML elements in
HTML documents, the name part of the CSS `attr()` function must first be converted to ASCII lowercase. The same function when compared to other attributes must be compared according to its original case. In both cases, the comparison is case-sensitive.

Note

This is the same as comparing the name part of a CSS attribute selector, specified in the next section.

4.16.2 Case-sensitivity of selectors

The Selectors specification leaves the case-sensitivity of element names, attribute names, and attribute values to be defined by the host language. [SELECTORS]

When comparing a CSS element type selector to the names of HTML elements in HTML documents, the CSS element type selector must first be converted to ASCII lowercase. The same selector when compared to other elements must be compared according to its original case. In both cases, the comparison is case-sensitive.

When comparing the name part of a CSS attribute selector to the names of attributes on HTML elements in HTML documents, the name part of the CSS attribute selector must first be converted to ASCII lowercase. The same selector when compared to other attributes must be compared according to its original case. In both cases, the comparison is case-sensitive.

Attribute selectors on an HTML element in an HTML document must treat the values of attributes with the following names as ASCII case-insensitive, with one exception as noted in the rendering section:

- accept
- accept-charset
- align
- alink
- axis
- bgcolor
- charset
- checked
- clear
- codetype
- color
- compact
- declare
- defer
- dir
- direction
- disabled
- enctype
- face
- hreflang
- http-equiv
- lang
- language
- link
- media
- method
- multiple
- nohref
- noshadow
- nowrap
- disabled
- frameborder
- nowrap
- readonly
- rel
- rev
- rules
- scope
- scrolling
- selected
- shape
- size
- target
- text
- type (except as specified in the rendering section)
- valign
- valuetype
- vlink

Example
All other attribute values and everything else must be treated as entirely case-sensitive for the purposes of selector matching. This includes:

- IDs and classes in no-quirks mode and limited-quirks mode
- the names of elements not in the HTML namespace
- the names of HTML elements in XML documents
- the names of attributes of elements not in the HTML namespace
- the names of attributes of HTML elements in XML documents
- the names of attributes that themselves have namespaces

Note: Selectors defines that ID and class selectors (such as #foo and .bar), when matched against elements in documents that are in quirks mode, will be matched in an ASCII case-insensitive manner. However, this does not apply for attribute selectors with "id" or "class" as the name part. The selector [class="foobar"] will treat its value as case-sensitive even in quirks mode.

4.16.3 Pseudo-classes

There are a number of dynamic selectors that can be used with HTML. This section defines when these selectors match HTML elements. [SELECTORS][5122][CSSUI][5122]

:defined

The :defined pseudo-class must match any element that is defined.

:link

:visited

All a elements that have an href attribute, all area elements that have an href attribute, and all link elements that have an href attribute, must match one of :link and :visited.

Other specifications might apply more specific rules regarding how these elements are to match these pseudo-classes, to mitigate some privacy concerns that apply with straightforward implementations of this requirement.

:active

The :active pseudo-class is defined to match an element “while an element is being activated by the user”.

To determine whether a particular element is being activated, for the purposes of defining the :active pseudo-class only, an HTML user agent must use the first relevant entry in the following list.

If the element has a descendant that is currently matching the :active pseudo-class
The element is being activated.

If the element is the labeled control of a label element that is currently matching :active
The element is being activated.

If the element is a button element
If the element is an input element whose type attribute is in the Submit Button, Image Button, Reset Button, or Button state
The element is being activated if it is in a formal activation state and it is not disabled.

Example
For example, if the user is using a keyboard to push a button element by pressing the space bar, the element would match this pseudo-class in between the time that the element received the keydown event and the time the element received the keyup event.
If the element is an `a` element that has an `href` attribute
If the element is an `area` element that has an `href` attribute
If the element is a `link` element that has an `href` attribute
If the element has its `tabindex focus flag` set
   The element is `being activated` if it is in a formal activation state.

If the element is `being actively pointed at`
   The element is `being activated`.

An element is said to be in a formal activation state between the time the user begins to indicate an intent to trigger the element's activation behavior and either the time the user stops indicating an intent to trigger the element's activation behavior, or the time the element's activation behavior has finished running, whichever comes first.

An element is said to be being actively pointed at while the user indicates the element using a pointing device while that pointing device is in the "down" state (e.g. for a mouse, between the time the mouse button is pressed and the time it is depressed; for a finger in a multitouch environment, while the finger is touching the display surface).

`:hover`
   The `:hover` pseudo-class is defined to match an element "while the user designates an element with a pointing device". For the purposes of defining the `:hover`, only an HTML user agent must consider an element as being one that the user designates if it is:
      - An element that the user indicates using a pointing device.
      - An element that has a descendant that the user indicates using a pointing device.
      - An element that is the `labeled control` of a `label` element that is currently matching `:hover`.

Example
   Consider in particular a fragment such as:

   ```html
   <p> <label for=c> <input id=a> </label> <span id=b> <input id=c> </span> </p>
   ```

   If the user designates the element with ID "a" with their pointing device, then the `p` element (and all its ancestors not shown in the snippet above), the `label` element, the element with ID "a", and the element with ID "c" will match the `:hover` pseudo-class. The element with ID "a" matches it from condition 1, the `label` and `p` elements match it because of condition 2 (one of their descendants is designated), and the element with ID "c" matches it through condition 3 (its `label` element matches `:hover`). However, the element with ID "b" does not match `:hover`, its descendant is not designated, even though it matches `:hover`.

`:focus`
   For the purposes of the CSS `:focus`, an element has the focus when its top-level browsing context has the system focus, it is not itself a browsing context container, and it is one of the elements listed in the focus chain of the currently focused area of the top-level browsing context.

`:target`
   For the purposes of the CSS `:target`, the Document's target elements are a list containing the Document's target element, if it is not null, or containing no elements, if it is. [SELECTORS]

`:enabled`
   The `:enabled` pseudo-class must match any `button`, `input`, `select`, `textarea`, `optgroup`, `option`, or `fieldset` element that is not actually disabled.

`:disabled`
   The `:disabled` pseudo-class must match any element that is actually disabled.

`:checked`
   The `:checked` pseudo-class must match any element falling into one of the following categories:
   - `input` elements whose `type` attribute is in the Checkbox state and whose checkedness state is true
   - `input` elements whose `type` attribute is in the Radio Button state and whose checkedness state is true
• option elements whose selectedness is true

:indeterminate
The :indeterminate pseudo-class must match any element falling into one of the following categories:

• input elements whose type attribute is in the Checkbox state and whose indeterminate IDL attribute is set to true
• input elements whose type attribute is in the Radio Button state and whose radio button group contains no elements whose checked state is true.
• progress elements with no value content attribute

:default
The :default pseudo-class must match any element falling into one of the following categories:

• button elements that are their form's default button
• input elements whose type attribute is in the Submit Button or Image Button state, and that are their form's default button
• input elements to which the checked attribute applies and that have a checked attribute
• option elements that have a selected attribute

:placeholderShown
The :placeholderShown pseudo-class must match any element falling into one of the following categories:

• input elements that have a placeholder attribute whose value is currently being presented to the user.
• textarea elements that have a placeholder attribute whose value is currently being presented to the user.

:valid
The :valid pseudo-class must match any element falling into one of the following categories:

• elements that are candidates for constraint validation and that satisfy their constraints
• form elements that are not the form owner of any elements that themselves are candidates for constraint validation but do not satisfy their constraints
• fieldset elements that have no descendant elements that themselves are candidates for constraint validation but do not satisfy their constraints

:invalid
The :invalid pseudo-class must match any element falling into one of the following categories:

• elements that are candidates for constraint validation but that do not satisfy their constraints
• form elements that are the form owner of one or more elements that themselves are candidates for constraint validation but do not satisfy their constraints
• fieldset elements that have of one or more descendant elements that themselves are candidates for constraint validation but do not satisfy their constraints

:in-range
The :in-range pseudo-class must match all elements that are candidates for constraint validation, have range limitations, and that are neither suffering from an underflow nor suffering from an overflow.

:out-of-range
The :out-of-range pseudo-class must match all elements that are candidates for constraint validation, have range limitations, and that are either suffering from an underflow or suffering from an overflow.

:required
The :required pseudo-class must match any element falling into one of the following categories:

• input elements that are required
• select\(^{520}\) elements that have a \textit{required}\(^{521}\) attribute
• textarea\(^{530}\) elements that have a \textit{required}\(^{533}\) attribute

\textbf{optional}

The \textit{optional}\(^{574}\) \textbf{pseudo-class} must match any element falling into one of the following categories:

• input\(^{476}\) elements to which the \textit{required}\(^{506}\) attribute applies that are not \textit{required}\(^{506}\)
• select\(^{520}\) elements that do not have a \textit{required}\(^{521}\) attribute
• textarea\(^{530}\) elements that do not have a \textit{required}\(^{533}\) attribute

\textbf{read-only}

\textbf{read-write}

The \textit{read-write}\(^{270}\) \textbf{pseudo-class} must match any element falling into one of the following categories, which for the purposes of Selectors are thus considered \textit{user-alterable}: \cite{SELECTORS}\(^{1226}\)

• input\(^{476}\) elements to which the \textit{readonly}\(^{505}\) attribute applies, and that are \textit{mutable}\(^{544}\) (i.e. that do not have the \textit{readonly}\(^{505}\) attribute specified and that are not \textit{disabled}\(^{552}\))
• textarea\(^{530}\) elements that do not have a \textit{readonly}\(^{532}\) attribute, and that are not \textit{disabled}\(^{552}\)
• elements that are \textit{editing hosts} or \textit{editable} and are neither input\(^{476}\) elements nor textarea\(^{530}\) elements

The \textit{read-only}\(^{536}\) \textbf{pseudo-class} must match all other HTML elements\(^{644}\).

\textbf{dir(ltr)}

The \textit{dir}\(^{574}\) \textbf{pseudo-class} must match all elements whose \textit{directionality}\(^{618}\) is \textit{ltr}\(^{138}\).

\textbf{dir(rtl)}

The \textit{dir}\(^{574}\) \textbf{pseudo-class} must match all elements whose \textit{directionality}\(^{618}\) is \textit{rtl}\(^{138}\).

\textbf{Note}

\textit{This specification does not define when an element matches the :lang() \textit{dynamic pseudo-class}, as it is defined in sufficient detail in a language-agnostic fashion in the Selectors specification.} \cite{SELECTORS}\(^{1226}\).
5 Microdata

5.1 Introduction

5.1.1 Overview

This section is non-normative.

Sometimes, it is desirable to annotate content with specific machine-readable labels, e.g. to allow generic scripts to provide services that are customized to the page, or to enable content from a variety of cooperating authors to be processed by a single script in a consistent manner.

For this purpose, authors can use the microdata features described in this section. Microdata allows nested groups of name-value pairs to be added to documents, in parallel with the existing content.

5.1.2 The basic syntax

This section is non-normative.

At a high level, microdata consists of a group of name-value pairs. The groups are called items, and each name-value pair is a property. Items and properties are represented by regular elements.

To create an item, the itemscope attribute is used.

To add a property to an item, the itemprop attribute is used on one of the item's descendants.

Here there are two items, each of which has the property "name":

```
<div itemscope>
  <p>My name is <span itemprop="name">Elizabeth</span>.</p>
</div>

<div itemscope>
  <p>My name is <span itemprop="name">Daniel</span>.</p>
</div>
```

Example

Markup without the microdata-related attributes does not have any effect on the microdata model.

Example

These two examples are exactly equivalent, at a microdata level, as the previous two examples respectively:

```
<div itemscope>
  <p>My <em name>name</em> is <span itemprop="name">E<strong>liz</strong>abeth</span>.</p>
</div>

<section>
  <div itemscope>
    <aside>
      <p>My name is <span itemprop="name"><a href="/?user=daniel">Daniel</a></span>.</p>
    </aside>
  </div>
</section>
```
Properties generally have values that are strings.

Here the item has three properties:

```html
<div itemscope>
  <p>My name is <span itemprop="name">Neil</span>.</p>
  <p>My band is called <span itemprop="band">Four Parts Water</span>.</p>
  <p>I am <span itemprop="nationality">British</span>.</p>
</div>
```

When a string value is a URL, it is expressed using the `a` element and its `href` attribute, the `img` element and its `src` attribute, or other elements that link to or embed external resources.

```html
In this example, the item has one property, "image", whose value is a URL:

```html
<div itemscope>
  <img itemprop="image" src="google-logo.png" alt="Google">
</div>
```

When a string value is in some machine-readable format unsuitable for human consumption, it is expressed using the `value` attribute of the `data` element, with the human-readable version given in the element's contents.

```html
Here, there is an item with a property whose value is a product ID. The ID is not human-friendly, so the product's name is used the human-visible text instead of the ID.

```html
<h1 itemscope>
  <span itemprop="name">Panasonic White 60L Refrigerator</span>
  <img src="panasonic-fridge-60l-white.jpg" alt="">
  <div itemprop="aggregateRating" itemscope itemtype="http://schema.org/AggregateRating">
    <meter itemprop="ratingValue" min=0 max=5>Rated 3.5/5</meter>
    (based on <span itemprop="reviewCount">11</span> customer reviews)
  </div>
</h1>
```

For numeric data, the `meter` element and its `value` attribute can be used instead.

```html
Here a rating is given using a `meter` element.

```html
<div itemscope itemtype="http://schema.org/Product">
  <span itemprop="name">Panasonic White 60L Refrigerator</span>
  <img src="panasonic-fridge-60l-white.jpg" alt="">
  <div itemprop="aggregateRating" itemscope itemtype="http://schema.org/AggregateRating">
    <meter itemprop="ratingValue" min=0 max=5>Rated 3.5/5</meter>
    (based on <span itemprop="reviewCount">11</span> customer reviews)
  </div>
</div>
```

Similarly, for date- and time-related data, the `time` element and its `datetime` attribute can be used instead.

```html
In this example, the item has one property, “birthday”, whose value is a date:

```html
<div itemscope>
  <h1 itemprop="name">Neil's Birthday</h1>
  <time itemprop="birthDate" datetime="1977-06-09">June 9, 1977</time>
</div>
```
Properties can also themselves be groups of name-value pairs, by putting the `itemscope` attribute on the element that declares the property.

Items that are not part of others are called top-level microdata items.

Example

In this example, the outer item represents a person, and the inner one represents a band:

```html
<div itemscope>
  <p>Name: <span itemprop="name">Amanda</span></p>
  <p>Band: <span itemprop="name">Jazz Band</span> (<span itemprop="size">12</span> players)</p>
</div>
```

The outer item here has two properties, "name" and "band". The "name" is "Amanda", and the "band" is an item in its own right, with two properties, "name" and "size". The "name" of the band is "Jazz Band", and the "size" is "12".

The outer item in this example is a top-level microdata item.

Properties that are not descendants of the element with the `itemscope` attribute can be associated with the `item` using the `itemref` attribute. This attribute takes a list of IDs of elements to crawl in addition to crawling the children of the element with the `itemscope` attribute.

Example

This example is the same as the previous one, but all the properties are separated from their `items`.

```html
<div itemscope id="amanda" itemref="a b"></div>
<p id="a">Name: <span itemprop="name">Amanda</span></p>
<div id="b" itemprop="band" itemscope itemref="c"></div>
<p id="c">Band: <span itemprop="name">Jazz Band</span> (<span itemprop="size">12</span> players)</p>
```

This gives the same result as the previous example. The first item has two properties, "name", set to "Amanda", and "band", set to another item. That second item has two further properties, "name", set to "Jazz Band", and "size", set to "12".

An `item` can have multiple properties with the same name and different values.

Example

This example describes an ice cream, with two flavors:

```html
<div itemscope>
  <p>Flavors in my favorite ice cream:</p>
  <ul>
    <li itemprop="flavor">Lemon sorbet</li>
    <li itemprop="flavor">Apricot sorbet</li>
  </ul>
</div>
```

This thus results in an item with two properties, both "flavor", having the values "Lemon sorbet" and "Apricot sorbet".
An element introducing a property can also introduce multiple properties at once, to avoid duplication when some of the properties have the same value.

Example

Here we see an item with two properties, "favorite-color" and "favorite-fruit", both set to the value "orange":

```html
<div itemscope>
  <span itemprop="favorite-color favorite-fruit">orange</span>
</div>
```

It's important to note that there is no relationship between the microdata and the content of the document where the microdata is marked up.

Example

There is no semantic difference, for instance, between the following two examples:

```html
<figure>
  <img src="castle.jpeg">
  <figcaption><span itemscope><span itemprop="name">The Castle</span> (1986)</span></figcaption>
</figure>

<figure>
  <span itemscope><meta itemprop="name" content="The Castle"></span>
  <figcaption>The Castle (1986)</figcaption>
</figure>
```

Both have a figure with a caption, and both, completely unrelated to the figure, have an item with a name-value pair with the name "name" and the value "The Castle". The only difference is that if the user drags the caption out of the document, in the former case, the item will be included in the drag-and-drop data. In neither case is the image in any way associated with the item.

5.1.3 Typed items

This section is non-normative.

The examples in the previous section show how information could be marked up on a page that doesn't expect its microdata to be re-used. Microdata is most useful, though, when it is used in contexts where other authors and readers are able to cooperate to make new uses of the markup.

For this purpose, it is necessary to give each item a type, such as "https://example.com/person", or "https://example.org/cat", or "https://band.example.net". Types are identified as URLs.

The type for an item is given as the value of an `itemtype` attribute on the same element as the `itemscope` attribute.

Example

Here, the item's type is "https://example.org/animals#cat":

```html
<section itemscope itemtype="https://example.org/animals#cat">
  <h1 itemprop="name">Hedral</h1>
  <p itemprop="desc">Hedral is a male american domestic shorthair, with a fluffy black fur with white paws and belly.</p>
  <img itemprop="img" src="hedral.jpeg" alt="" title="Hedral, age 18 months">
</section>
```
In this example the "https://example.org/animals#cat" item has three properties, a "name" ("Hedral"), a "desc" ("Hedral is..."), and an "img" ("hedral.jpeg").

The type gives the context for the properties, thus selecting a vocabulary: a property named "class" given for an item with the type "https://census.example/person" might refer to the economic class of an individual, while a property named "class" given for an item with the type "https://example.com/school/teacher" might refer to the classroom a teacher has been assigned. Several types can share a vocabulary. For example, the types "https://example.org/people/teacher" and "https://example.org/people/engineer" could be defined to use the same vocabulary (though maybe some properties would not be especially useful in both cases, e.g. maybe the "https://example.org/people/engineer" type might not typically be used with the "classroom" property). Multiple types defined to use the same vocabulary can be given for a single item by listing the URLs as a space-separated list in the attribute' value. An item cannot be given two types if they do not use the same vocabulary, however.

5.1.4 Global identifiers for items

This section is non-normative.

Sometimes, an item gives information about a topic that has a global identifier. For example, books can be identified by their ISBN number.

Vocabularies (as identified by the itemtype attribute) can be designed such that items get associated with their global identifier in an unambiguous way by expressing the global identifiers as URLs given in an itemid attribute.

The exact meaning of the URLs given in itemid attributes depends on the vocabulary used.

Example

Here, an item is talking about a particular book:

```html
dl itemscope itemtype="https://vocab.example.net/book"
  itemid="urn:isbn:0-330-34032-8">
  <dt>Title
  <dd itemprop="title">The Reality Dysfunction
  <dt>Author
  <dd itemprop="author">Peter F. Hamilton
  <dt>Publication date
  <dd>time itemprop="pubdate" datetime="1996-01-26">26 January 1996</time>
</dl>
```

The "https://vocab.example.net/book" vocabulary in this example would define that the itemid attribute takes a urn: URL pointing to the ISBN of the book.

5.1.5 Selecting names when defining vocabularies

This section is non-normative.

Using microdata means using a vocabulary. For some purposes, an ad-hoc vocabulary is adequate. For others, a vocabulary will need to be designed. Where possible, authors are encouraged to re-use existing vocabularies, as this makes content re-use easier.

When designing new vocabularies, identifiers can be created either using URLs, or, for properties, as plain words (with no dots or colons). For URLs, conflicts with other vocabularies can be avoided by only using identifiers that correspond to pages that the author has control over.

Example
Properties whose names are just plain words can only be used within the context of the types for which they are intended; properties named using URLs can be reused in items of any type. If an item has no type, and is not part of another item, then if its properties have names that are just plain words, they are not intended to be globally unique, and are instead only intended for limited use. Generally speaking, authors are encouraged to use either properties with globally unique names (URLs) or ensure that their items are typed.

---

Example

Here, an item is an "https://example.org/animals#cat", and most of the properties have names that are words defined in the context of that type. There are also a few additional properties whose names come from other vocabularies.

```html
<section itemscope itemtype="https://example.org/animals#cat">
  <h1 itemprop="name https://example.com/fn">Hedral</h1>
  <p itemprop="desc">Hedral is a male american domestic shorthair, with a fluffy <span itemprop="https://example.com/color">black</span> fur with <span itemprop="https://example.com/color">white</span> paws and belly.</p>
  <img itemprop="img src=../hedral.jpeg alt="" title="Hedral, age 18 months">
</section>
```

This example has one item with the type "https://example.org/animals#cat" and the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Hedral</td>
</tr>
<tr>
<td><a href="https://example.com/fn">https://example.com/fn</a></td>
<td>Hedral</td>
</tr>
<tr>
<td>desc</td>
<td>Hedral is a male american domestic shorthair, with a fluffy black fur with white paws and belly.</td>
</tr>
<tr>
<td><a href="https://example.com/color">https://example.com/color</a></td>
<td>black</td>
</tr>
<tr>
<td><a href="https://example.com/color">https://example.com/color</a></td>
<td>white</td>
</tr>
<tr>
<td>img</td>
<td>../hedral.jpeg</td>
</tr>
</tbody>
</table>

---

5.2 Encoding microdata

5.2.1 The microdata model

The microdata model consists of groups of name-value pairs known as items.

Each group is known as an item. Each item can have item types, a global identifier (if the vocabulary specified by the item types support global identifiers), and a list of name-value pairs. Each name in the name-value pair is known as a property, and each property has one or more values. Each value is either a string or itself a group of name-value pairs (an item). The names are unordered relative to each other, but if a particular name has multiple values, they do have a relative order.

5.2.2 Items

Every HTML element may have an itemscope attribute specified. The itemscope attribute is a boolean attribute.

An element with the itemscope attribute specified creates a new item, a group of name-value pairs.

Elements with an itemscope attribute may have an itemtype attribute specified, to give the item types of the item.
The `itemtype` attribute, if specified, must have a value that is an unordered set of unique space-separated tokens that are case-sensitive, each of which is a valid URL string that is an absolute URL, and all of which are defined to use the same vocabulary. The attribute's value must have at least one token.

The item types of an `item` are the tokens obtained by splitting the element's `itemtype` attribute's value on ASCII whitespace. If the `itemtype` attribute is missing or parsing it in this way finds no tokens, the `item` is said to have no item types.

The item types must all be types defined in applicable specifications and must all be defined to use the same vocabulary.

Except if otherwise specified by that specification, the URLs given as the item types should not be automatically dereferenced.

Notes

A specification could define that its item type can be dereferenced to provide the user with help information, for example. In fact, vocabulary authors are encouraged to provide useful information at the given URL.

Item types are opaque identifiers, and user agents must not dereference unknown item types, or otherwise deconstruct them, in order to determine how to process items that use them.

The `itemtype` attribute must not be specified on elements that do not have an `itemscope` attribute specified.

An `item` is said to be a typed item when either it has an `itemtype`, or it is the value of a `property` of a typed item. The relevant types for a typed item is the `item`'s item types, if it has any, or else is the relevant types of the `item` for which it is a property's value.

Elements with an `itemscope` attribute and an `itemtype` attribute that references a vocabulary that is defined to support global identifiers for items may also have an `itemid` attribute specified, to give a global identifier for the `item`, so that it can be related to other `items` on pages elsewhere on the Web.

The `itemid` attribute, if specified, must have a value that is a valid URL potentially surrounded by spaces.

The global identifier of an `item` is the value of its element's `itemid` attribute, if it has one, parsed relative to the node document of the element on which the attribute is specified. If the `itemid` attribute is missing or if resolving it fails, it is said to have no global identifier.

The `itemid` attribute must not be specified on elements that do not have both an `itemscope` attribute and an `itemtype` attribute specified, and must not be specified on elements with an `itemscope` attribute whose `itemtype` attribute specifies a vocabulary that does not support global identifiers for items, as defined by that vocabulary's specification.

The exact meaning of a global identifier is determined by the vocabulary's specification. It is up to such specifications to define whether multiple items with the same global identifier (whether on the same page or on different pages) are allowed to exist, and what the processing rules for that vocabulary are with respect to handling the case of multiple items with the same ID.

Elements with an `itemscope` attribute may have an `itemref` attribute specified, to give a list of additional elements to crawl to find the name-value pairs of the `item`.

The `itemref` attribute, if specified, must have a value that is an unordered set of unique space-separated tokens that are case-sensitive, consisting of IDs of elements in the same tree.

The `itemref` attribute must not be specified on elements that do not have an `itemscope` attribute specified.

Note

The `itemref` attribute is not part of the microdata data model. It is merely a syntactic construct to aid authors in adding annotations to pages where the data to be annotated does not follow a convenient tree structure. For example, it allows authors to mark up data in a table so that each column defines a separate `item`, while keeping the properties in the cells.

Example

This example shows a simple vocabulary used to describe the products of a model railway manufacturer. The vocabulary has just five property names:
product-code
An integer that names the product in the manufacturer's catalog.

name
A brief description of the product.

scale
One of "HO", "1", or "Z" (potentially with leading or trailing whitespace), indicating the scale of the product.

digital
If present, one of "Digital", "Delta", or "Systems" (potentially with leading or trailing whitespace) indicating that the product has a digital decoder of the given type.

track-type
For track-specific products, one of "K", "M", "C" (potentially with leading or trailing whitespace) indicating the type of track for which the product is intended.

This vocabulary has four defined item types:

https://md.example.com/loco
Rolling stock with an engine

https://md.example.com/passengers
Passenger rolling stock

https://md.example.com/track
Track pieces

https://md.example.com/lighting
Equipment with lighting

Each item that uses this vocabulary can be given one or more of these types, depending on what the product is.

Thus, a locomotive might be marked up as:

<dl itemscope itemtype="https://md.example.com/loco
    https://md.example.com/lighting">
  <dt>Name:
  <dd itemprop="name">Tank Locomotive (DB 80)
  <dt>Product code:
  <dd itemprop="product-code">33041
  <dt>Scale:
  <dd itemprop="scale">HO
  <dt>Digital:
  <dd itemprop="digital">Delta
</dl>

A turnout lantern retrofit kit might be marked up as:

<dl itemscope itemtype="https://md.example.com/track
    https://md.example.com/lighting">
  <dt>Name:
  <dd itemprop="name">Turnout Lantern Kit
  <dt>Product code:
  <dd itemprop="product-code">74470
  <dt>Purpose:
  <dd>For retrofitting 2 <span itemprop="track-type">C</span> Track turnouts. <meta itemprop="scale" content="HO">
</dl>

A passenger car with no lighting might be marked up as:
Great care is necessary when creating new vocabularies. Often, a hierarchical approach to types can be taken that results in a vocabulary where each item only ever has a single type, which is generally much simpler to manage.

### 5.2.3 Names: the itemprop attribute

Every HTML element may have an `itemprop` attribute specified, if doing so adds one or more properties to one or more items (as defined below).

The `itemprop` attribute, if specified, must have a value that is an unordered set of unique space-separated tokens that are case-sensitive, representing the names of the name-value pairs that it adds. The attribute’s value must have at least one token.

Each token must be either:

- If the item is a typed item: a defined property name allowed in this situation according to the specification that defines the relevant types for the item, or
- A valid URL string that is an absolute URL defined as an item property name allowed in this situation by a vocabulary specification, or
- A valid URL string that is an absolute URL, used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification), or
- If the item is not a typed item: a string that contains no U+002E FULL STOP characters (.) and no U+003A COLON characters (:), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification).

Specifications that introduce defined property names must ensure all such property names contain no U+002E FULL STOP characters (.), no U+003A COLON characters (:), and no ASCII whitespace.

#### Note

The rules above disallow U+003A COLON characters (:). in non-URL values because otherwise they could not be distinguished from URLs. Values with U+002E FULL STOP characters (.) are reserved for future extensions. ASCII whitespace are disallowed because otherwise the values would be parsed as multiple tokens.

When an element with an `itemprop` attribute adds a property to multiple items, the requirement above regarding the tokens applies for each item individually.

The property names of an element are the tokens that the element’s `itemprop` attribute is found to contain when its value is split on ASCII whitespace, with the order preserved but with duplicates removed (leaving only the first occurrence of each name).

Within an item, the properties are unordered with respect to each other, except for properties with the same name, which are ordered in the order they are given by the algorithm that defines the properties of an item.

#### Example

In the following example, the “a” property has the values “1” and “2”, in that order, but whether the “a” property comes before the “b” property or not is not important:

```
<dl itemscope itemtype="https://md.example.com/passengers">
  <dt>Name:
  <dd itemprop="name">Express Train Passenger Car (DB Am 203)
  <dt>Product code:
  <dd itemprop="product-code">8710
  <dt>Scale:
  <dd itemprop="scale">Z
</dl>
```

The rules above disallow U+003A COLON characters in non-URL values because otherwise they could not be distinguished from URLs. Values with U+002E FULL STOP characters are reserved for future extensions. ASCII whitespace are disallowed because otherwise the values would be parsed as multiple tokens.
Thus, the following is equivalent:

```html
<div itemscope>
  <p itemprop="b">test</p>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
</div>
```

As is the following:

```html
<div itemscope>
  <p itemprop="a">1</p>
  <p itemprop="b">test</p>
  <p itemprop="a">2</p>
</div>
```

And the following:

```html
<div id="x">
  <p itemprop="a">1</p>
</div>
<div itemscope itemref="x">
  <p itemprop="b">test</p>
  <p itemprop="a">2</p>
</div>
```

5.2.4 Values

The property value of a name-value pair added by an element with an `itemprop` attribute is as given for the first matching case in the following list:

- **If the element also has an `itemscope` attribute**
  The value is the `item` created by the element.

- **If the element is a `meta` element**
  The value is the value of the element's `content` attribute, if any, or the empty string if there is no such attribute.

- **If the element is an `audio`, `embed`, `iframe`, `img`, `source`, `track`, or `video` element**
  The value is the resulting URL string that results from parsing the value of the element's `src` attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing results in an error.

- **If the element is an `a`, `area`, or `link` element**
  The value is the resulting URL string that results from parsing the value of the element's `href` attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing results in an error.

- **If the element is an `object` element**
  The value is the resulting URL string that results from parsing the value of the element's `data` attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing results in an error.
If the element is a `data` element:
The value is the value of the element's `value` attribute, if it has one, or the empty string otherwise.

If the element is a `meter` element:
The value is the value of the element's `value` attribute, if it has one, or the empty string otherwise.

If the element is a `time` element:
The value is the element's `datetime` value.

Otherwise:
The value is the element's `textContent`.

The URL property elements are the `a`, `area`, `audio`, `embed`, `iframe`, `img`, `link`, `object`, `source`, `track`, and `video` elements.

If a property's `value`, as defined by the property's definition, is an `absolute URL`, the property must be specified using a `URL property element`.

Note:
These requirements do not apply just because a property value happens to match the syntax for a URL. They only apply if the property is explicitly defined as taking such a value.

Example:
For example, a book about the first moon landing could be called "mission:moon". A "title" property from a vocabulary that defines a title as being a string would not expect the title to be given in an `a` element, even though it looks like a `URL`. On the other hand, if there was a (rather narrowly scoped!) vocabulary for "books whose titles look like URLs" which had a "title" property defined to take a `URL`, then the property would expect the title to be given in an `a` element (or one of the other URL property elements), because of the requirement above.

5.2.5 Associating names with items

To find the properties of an item defined by the element `root`, the user agent must run the following steps. These steps are also used to flag microdata errors.

1. Let `results`, `memory`, and `pending` be empty lists of elements.
2. Add the element `root` to `memory`.
3. Add the child elements of `root`, if any, to `pending`.
4. If `root` has an `itemref` attribute, split the value of that `itemref` attribute on ASCII whitespace. For each resulting token ID, if there is an element in the tree of `root` with the ID `ID`, then add the first such element to `pending`.
5. While `pending` is not empty:
   1. Remove an element from `pending` and let `current` be that element.
   2. If `current` is already in `memory`, there is a microdata error; continue.
   3. Add `current` to `memory`.
   4. If `current` does not have an `itemscope` attribute, then: add all the child elements of `current` to `pending`.
   5. If `current` has an `itemprop` attribute specified and has one or more `property names`, then add `current` to `results`.
6. Sort `results` in tree order.
7. Return `results`.

A document must not contain any `items` for which the algorithm to find the properties of an item finds any microdata errors.

An `item` is a top-level microdata item if its element does not have an `itemprop` attribute.
All `itemref` attributes in a Document must be such that there are no cycles in the graph formed from representing each `item` in the Document as a node in the graph and each `property` of an item whose `value` is another item as an edge in the graph connecting those two items.

A document must not contain any elements that have an `itemprop` attribute that would not be found to be a property of any of the `items` in that document were their `properties` all to be determined.

Example

In this example, a single license statement is applied to two works, using `itemref` from the items representing the works:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
<title>Photo gallery</title>
</head>
<body>
<h1>My photos</h1>
<figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
  <img itemprop="work" src="images/house.jpeg" alt="A white house, boarded up, sits in a forest.">
  <figcaption itemprop="title">The house I found.</figcaption>
</figure>
<figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
  <img itemprop="work" src="images/mailbox.jpeg" alt="Outside the house is a mailbox. It has a leaflet inside.">
  <figcaption itemprop="title">The mailbox.</figcaption>
</figure>
<footer>
  <p id="licenses">All images licensed under the <a itemprop="license" href="http://www.opensource.org/licenses/mit-license.php">MIT license</a>.</p>
</footer>
</body>
</html>
```

The above results in two items with the type "http://n.whatwg.org/work", one with:

`work` images/house.jpeg

`title` The house I found.

`license` http://www.opensource.org/licenses/mit-license.php

...and one with:

`work` images/mailbox.jpeg

`title` The mailbox.

`license` http://www.opensource.org/licenses/mit-license.php

5.2.6 Microdata and other namespaces

Currently, the `itemscope`, `itemprop`, and other microdata attributes are only defined for HTML elements. This means that attributes with the literal names "itemscope", "itemprop", etc, do not cause microdata processing to occur on elements in other namespaces, such as SVG.
5.3 Sample microdata vocabularies

The vocabularies in this section are primarily intended to demonstrate how a vocabulary is specified, though they are also usable in their own right.

5.3.1 vCard

An item with the item type `http://microformats.org/profile/hcard` represents a person's or organization's contact information.

This vocabulary does not support global identifiers for items.

The following are the type's defined property names. They are based on the vocabulary defined in the vCard 4.0 specification and its extensions, where more information on how to interpret the values can be found. ([RFC6350](https://example.com/rfc6350)).

**kind**

Describes what kind of contact the item represents.

The value must be text that, when compared in a case-sensitive manner, is equal to one of the kind strings.

A single property with the name `kind` may be present within each item with the type `http://microformats.org/profile/hcard`.

**fn**

Gives the formatted text corresponding to the name of the person or organization.

Exactly one property with the name `fn` must be present within each item with the type `http://microformats.org/profile/hcard`.

**n**

Gives the structured name of the person or organization.

Exactly one property with the name `n` must be present within each item with the type `http://microformats.org/profile/hcard`.

**family-name**

Gives the family name of the person, or the full name of the organization.

Any number of properties with the name `family-name` may be present within the item that forms the value of the `n` property of an item with the type `http://microformats.org/profile/hcard`.

**given-name**

Gives the given-name of the person.
The `value` must be text.

Any number of properties with the name `given-name` may be present within the `item` that forms the `value` of the `item` property of an `item` with the type `http://microformats.org/profile/hcard`.

**additional-name (inside n)**

Gives the any additional names of the person.

The `value` must be text.

Any number of properties with the name `additional-name` may be present within the `item` that forms the `value` of the `n` property of an `item` with the type `http://microformats.org/profile/hcard`.

**honorific-prefix (inside n)**

Gives the honorific prefix of the person.

The `value` must be text.

Any number of properties with the name `honorific-prefix` may be present within the `item` that forms the `value` of the `n` property of an `item` with the type `http://microformats.org/profile/hcard`.

**honorific-suffix (inside n)**

Gives the honorific suffix of the person.

The `value` must be text.

Any number of properties with the name `honorific-suffix` may be present within the `item` that forms the `value` of the `n` property of an `item` with the type `http://microformats.org/profile/hcard`.

**nickname**

Gives the nickname of the person or organization.

The `value` must be text.

Any number of properties with the name `nickname` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**photo**

Gives a photograph of the person or organization.

The `value` must be an **absolute URL**.

Any number of properties with the name `photo` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**bday**

Gives the birth date of the person or organization.

The `value` must be a **valid date string**.

A single property with the name `bday` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**anniversary**

Gives the birth date of the person or organization.

The `value` must be a **valid date string**.

A single property with the name `anniversary` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

---

**Note**

The nickname is the descriptive name given instead of or in addition to the one belonging to a person, place, or thing. It can also be used to specify a familiar form of a proper name specified by the `fn` or `n` properties.
sex

Gives the biological sex of the person.

The value must be one of F, meaning "female", M, meaning "male", N, meaning "none or not applicable", O, meaning "other", or U, meaning "unknown".

A single property with the name sex may be present within each item with the type http://microformats.org/profile/hcard.

gender-identity

Gives the gender identity of the person.

The value must be text.

A single property with the name gender-identity may be present within each item with the type http://microformats.org/profile/hcard.

adr

Gives the delivery address of the person or organization.

The value must be an item with zero or more type, post-office-box, extended-address, and street-address properties, and optionally a locality property, optionally a region property, optionally a postal-code property, and optionally a country-name property.

If no type properties are present within an item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard, then the address type string work is implied.

Any number of properties with the name adr may be present within each item with the type http://microformats.org/profile/hcard.

type (inside adr)

Gives the type of delivery address.

The value must be text that, when compared in a case-sensitive manner, is equal to one of the address type strings.

Any number of properties with the name type may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard, but within each suchadr property item there must only be one type property per distinct value.

post-office-box (inside adr)

Gives the post office box component of the delivery address of the person or organization.

The value must be text.

Any number of properties with the name post-office-box may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard.

Note

The vCard specification urges authors not to use this field.

extended-address (inside adr)

Gives an additional component of the delivery address of the person or organization.

The value must be text.

Any number of properties with the name extended-address may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard.

Note

The vCard specification urges authors not to use this field.

street-address (inside adr)

Gives the street address component of the delivery address of the person or organization.
The value must be text.

Any number of properties with the name `street-address` may be present within the `item` that forms the value of an `adr` property of an `item` with the type `http://microformats.org/profile/hcard`.

**locality (inside `adr`)**

Gives the locality component (e.g. city) of the delivery address of the person or organization.

The value must be text.

A single property with the name `locality` may be present within the `item` that forms the value of an `adr` property of an `item` with the type `http://microformats.org/profile/hcard`.

**region (inside `adr`)**

Gives the region component (e.g. state or province) of the delivery address of the person or organization.

The value must be text.

A single property with the name `region` may be present within the `item` that forms the value of an `adr` property of an `item` with the type `http://microformats.org/profile/hcard`.

**postal-code (inside `adr`)**

Gives the postal code component of the delivery address of the person or organization.

The value must be text.

A single property with the name `postal-code` may be present within the `item` that forms the value of an `adr` property of an `item` with the type `http://microformats.org/profile/hcard`.

**country-name (inside `adr`)**

Gives the country name component of the delivery address of the person or organization.

The value must be text.

A single property with the name `country-name` may be present within the `item` that forms the value of an `adr` property of an `item` with the type `http://microformats.org/profile/hcard`.

**tel**

Gives the telephone number of the person or organization.

The value must be either text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121, or an `item` with zero or more `type` properties and exactly one `value` property. [E163][1223] [X121][1228]

If no `type` properties are present within an `item` that forms the value of a `tel` property of an `item` with the type `http://microformats.org/profile/hcard`, or if the `value` of such a `tel` property is text, then the telephone type string `voice` is implied.

Any number of properties with the name `tel` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**type (inside `tel`)**

Gives the type of telephone number.

The value must be text that, when compared in a case-sensitive manner, is equal to one of the telephone type strings.

Any number of properties with the name `type` may be present within the `item` that forms the value of a `tel` property of an `item` with the type `http://microformats.org/profile/hcard`, but within each such `tel` property `item` there must only be one `type` property per distinct value.

**value (inside `tel`)**

Gives the actual telephone number of the person or organization.

The value must be text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121. [E163][1223] [X121][1228]
Exactly one property with the name `value` must be present within the `item` that forms the `value` of a `tel` property of an `item` with the type `http://microformats.org/profile/hcard`.

**email**

Gives the e-mail address of the person or organization.

The `value` must be text.

Any number of properties with the name `email` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**impp**

Gives a URL for instant messaging and presence protocol communications with the person or organization.

The `value` must be an absolute URL.

Any number of properties with the name `impp` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**lang**

Gives a language understood by the person or organization.

The `value` must be a valid BCP 47 language tag. [BCP47]

Any number of properties with the name `lang` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**tz**

Gives the time zone of the person or organization.

The `value` must be text and must match the following syntax:

1. Either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. A valid non-negative integer that is exactly two digits long and that represents a number in the range 00..23.
3. A U+003A COLON character (:).
4. A valid non-negative integer that is exactly two digits long and that represents a number in the range 00..59.

Any number of properties with the name `tz` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**geo**

Gives the geographical position of the person or organization.

The `value` must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. A U+003B SEMICOLON character (;).
5. Optionally*, a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

**Note**

The value specifies latitude and longitude, in that order (i.e., “LAT LON” ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the...
Any number of properties with the name `geo` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**title**

Gives the job title, functional position or function of the person or organization.

The `value` must be text.

Any number of properties with the name `title` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**role**

Gives the role, occupation, or business category of the person or organization.

The `value` must be text.

Any number of properties with the name `role` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**logo**

Gives the logo of the person or organization.

The `value` must be an absolute URL.

Any number of properties with the name `logo` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**agent**

Gives the contact information of another person who will act on behalf of the person or organization.

The `value` must be either an `item` with the type `http://microformats.org/profile/hcard`, or an absolute URL, or text.

Any number of properties with the name `agent` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**org**

Gives the name and units of the organization.

The `value` must be either text or an `item` with one `organization-name` property and zero or more `organization-unit` properties.

Any number of properties with the name `org` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**organization-name** (inside `org`)

Gives the name of the organization.

The `value` must be text.

Exactly one property with the name `organization-name` must be present within the `item` that forms the `value` of an `org` property of an `item` with the type `http://microformats.org/profile/hcard`.

**organization-unit** (inside `org`)

Gives the name of the organization unit.

The `value` must be text.

Any number of properties with the name `organization-unit` may be present within the `item` that forms the `value` of the `org` property of an `item` with the type `http://microformats.org/profile/hcard`.
**member**

Gives a URL that represents a member of the group.

The *value* must be an absolute URL.

Any number of properties with the name `member` may be present within each `item` if the `item` also has a property with the name `kind` whose value is "group".

**related**

Gives a relationship to another entity.

The *value* must be an `item` with one `url` property and one `rel` properties.

Any number of properties with the name `related` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**url (inside related)**

Gives the URL for the related entity.

The *value* must be an absolute URL.

Exactly one property with the name `url` must be present within the `item` that forms the *value* of a `related` property of an `item` with the type `http://microformats.org/profile/hcard`.

**rel (inside related)**

Gives the relationship between the entity and the related entity.

The *value* must be text that, when compared in a case-sensitive manner, is equal to one of the relationship strings.

Exactly one property with the name `rel` must be present within the `item` that forms the *value* of a `related` property of an `item` with the type `http://microformats.org/profile/hcard`.

**categories**

Gives the name of a category or tag that the person or organization could be classified as.

The *value* must be text.

Any number of properties with the name `categories` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**note**

Gives supplemental information or a comment about the person or organization.

The *value* must be text.

Any number of properties with the name `note` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**rev**

Gives the revision date and time of the contact information.

The *value* must be text that is a valid global date and time string.

Note: The value distinguishes the current revision of the information for other renditions of the information.

Any number of properties with the name `rev` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**sound**

Gives a sound file relating to the person or organization.

The *value* must be an absolute URL.
Any number of properties with the name sound may be present within each item with the type http://microformats.org/profile/hcard.

**uid**

Gives a globally unique identifier corresponding to the person or organization.

The value must be text.

A single property with the name uid may be present within each item with the type http://microformats.org/profile/hcard.

**url**

Gives a URL relating to the person or organization.

The value must be an absolute URL.

Any number of properties with the name url may be present within each item with the type http://microformats.org/profile/hcard.

The kind strings are:

**individual**

Indicates a single entity (e.g. a person).

**group**

Indicates multiple entities (e.g. a mailing list).

**org**

Indicates a single entity that is not a person (e.g. a company).

**location**

Indicates a geographical place (e.g. an office building).

The address type strings are:

**home**

Indicates a delivery address for a residence.

**work**

Indicates a delivery address for a place of work.

The telephone type strings are:

**home**

Indicates a residential number.

**work**

Indicates a telephone number for a place of work.

**text**

Indicates that the telephone number supports text messages (SMS).

**voice**

Indicates a voice telephone number.

**fax**

Indicates a facsimile telephone number.

**cell**

Indicates a cellular telephone number.

**video**

Indicates a video conferencing telephone number.
pager
Indicates a paging device telephone number.

textphone
Indicates a telecommunication device for people with hearing or speech difficulties.

The relationship strings are:

emergency
An emergency contact.

agent
Another entity that acts on behalf of this entity.

contact
acquaintance
friend
met
worker
colleague
resident
neighbor
child
parent
sibling
spouse
kin
muse
crush
date
sweetheart
me
Has the meaning defined in XFN. [XFN]

5.3.1.1 Conversion to vCard

Given a list of nodes nodes in a Document, a user agent must run the following algorithm to extract any vCard data represented by those nodes (only the first vCard is returned):

1. If none of the nodes in nodes are items with the item type http://microformats.org/profile/hcard, then there is no vCard. Abort the algorithm, returning nothing.
2. Let node be the first node in nodes that is an item with the item type http://microformats.org/profile/hcard.
3. Let output be an empty string.
4. Add a vCard line with the type "BEGIN" and the value "VCARD" to output.
5. Add a vCard line with the type "PROFILE" and the value "VCARD" to output.
6. Add a vCard line with the type "VERSION" and the value "4.0" to output.
7. Add a vCard line with the type "SOURCE" and the result of escaping the vCard text string that is the document's URL as the value to output.
8. If the title element is not null, add a vCard line with the type "NAME" and with the result of escaping the vCard text string obtained from the textContent of the title element as the value to output.
9. Let sex be the empty string.
10. Let gender-identity be the empty string.
11. For each element `element` that is a property of the item node: for each name `name` in `element`'s property names, run the following substeps:

   1. Let `parameters` be an empty set of name-value pairs.
   2. Run the appropriate set of substeps from the following list. The steps will set a variable `value`, which is used in the next step.

   **If the property's value is an item subitem and name is `n`**
   
   1. Let `value` be the empty string.
   2. Append to `value` the result of collecting the first vCard subproperty named `family-name` in subitem.
   3. Append a U+003B SEMICOLON character (;) to `value`.
   4. Append to `value` the result of collecting the first vCard subproperty named `given-name` in subitem.
   5. Append a U+003B SEMICOLON character (;) to `value`.
   6. Append to `value` the result of collecting the first vCard subproperty named `additional-name` in subitem.
   7. Append a U+003B SEMICOLON character (;) to `value`.
   8. Append to `value` the result of collecting the first vCard subproperty named `honorific-prefix` in subitem.
   9. Append a U+003B SEMICOLON character (;) to `value`.
   10. Append to `value` the result of collecting the first vCard subproperty named `honorific-suffix` in subitem.

   **If the property's value is an item subitem and name is `adr`**
   
   1. Let `value` be the empty string.
   2. Append to `value` the result of collecting vCard subproperties named `post-office-box` in subitem.
   3. Append a U+003B SEMICOLON character (;) to `value`.
   4. Append to `value` the result of collecting vCard subproperties named `extended-address` in subitem.
   5. Append a U+003B SEMICOLON character (;) to `value`.
   6. Append to `value` the result of collecting vCard subproperties named `street-address` in subitem.
   7. Append a U+003B SEMICOLON character (;) to `value`.
   8. Append to `value` the result of collecting the first vCard subproperty named `locality` in subitem.
   9. Append a U+003B SEMICOLON character (;) to `value`.
   10. Append to `value` the result of collecting the first vCard subproperty named `region` in subitem.
   11. Append a U+003B SEMICOLON character (;) to `value`.
   12. Append to `value` the result of collecting the first vCard subproperty named `postal-code` in subitem.
   13. Append a U+003B SEMICOLON character (;) to `value`.
   14. Append to `value` the result of collecting the first vCard subproperty named `country-name` in subitem.
15. If there is a property named \textit{type} that is not an \textit{item} and whose value consists only of ASCII alphanumerics, then add a parameter named "TYPE" whose value is the \textit{value} of that property to \textit{parameters}.

If the property's \textit{value} is an \textit{item} subitem and name is \textit{org}

1. Let \textit{value} be the empty string.
2. Append to \textit{value} the result of collecting the first vCard subproperty named \textit{organization-name} in subitem.
3. For each property named \textit{organization-unit} in subitem, run the following steps:
   1. If the \textit{value} of the property is an \textit{item}, then skip this property.
   2. Append a U+003B SEMICOLON character (;) to \textit{value}.
   3. Append the result of \textit{escaping the vCard text string} given by the \textit{value} of the property to \textit{value}.

If the property's \textit{value} is an \textit{item} subitem with the \textit{item type} \textit{http://microformats.org/profile/hcard} and name is \textit{related}

1. Let \textit{value} be the empty string.
2. If there is a property named \textit{url} in subitem, and its element is a URL property element, then append the result of \textit{escaping the vCard text string} given by the \textit{value} of the first such property to \textit{value}, and add a parameter with the name "VALUE" and the value "URI" to \textit{parameters}.
3. If there is a property named \textit{rel} in subitem, and the first such property has a \textit{value} that is not an \textit{item} and whose value consists only of ASCII alphanumerics, then add a parameter named "RELATION" whose value is the \textit{value} of that property to \textit{parameters}.

If the property's \textit{value} is an \textit{item} and name is none of the above

1. Let \textit{value} be the result of collecting the first vCard subproperty named \textit{value} in subitem.
2. If there is a property named \textit{type} in subitem, and the first such property has a \textit{value} that is not an \textit{item} and whose value consists only of ASCII alphanumerics, then add a parameter named "TYPE" whose value is the \textit{value} of that property to \textit{parameters}.

If the property's \textit{value} is not an \textit{item} and its name is \textit{sex}

If this is the first such property to be found, set \textit{sex} to the property's \textit{value}.

If the property's \textit{value} is not an \textit{item} and its name is \textit{gender-identity}

If this is the first such property to be found, set \textit{gender-identity} to the property's \textit{value}.

Otherwise (the property's \textit{value} is not an \textit{item})

1. Let \textit{value} be the property's \textit{value}.
2. If \textit{element} is one of the URL property elements, add a parameter with the name "VALUE" and the value "URI" to \textit{parameters}.
3. Otherwise, if \textit{name} is \textit{bday} or \textit{anniversary} and the \textit{value} is a valid date string, add a parameter with the name "VALUE" and the value "DATE" to \textit{parameters}.
4. Otherwise, if \textit{name} is \textit{rev} and the \textit{value} is a valid global date and time string, add a parameter with the name "VALUE" and the value "DATE-TIME" to \textit{parameters}.
5. Prefix every U+005C REVERSE SOLIDUS character (\) in \textit{value} with another U+005C REVERSE SOLIDUS character (\).
6. Prefix every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in \textit{value} with a
U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in value with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

3. Add a vCard line\(^728\) with the type name, the parameters parameters, and the value value to output.

12. If either sex or gender-identity has a value that is not the empty string, add a vCard line\(^728\) with the type "GENDER" and the value consisting of the concatenation of sex, a U+003B SEMICOLON character (;), and gender-identity to output.

13. Add a vCard line\(^728\) with the type "END" and the value "VCARD" to output.

When the above algorithm says that the user agent is to add a vCard line consisting of a type type, optionally some parameters, and a value value to a string output, it must run the following steps:

1. Let line be an empty string.
2. Append type, converted to ASCII uppercase, to line.
3. If there are any parameters, then for each parameter, in the order that they were added, run these substeps:
   1. Append a U+003B SEMICOLON character (;) to line.
   2. Append the parameter's name to line.
   3. Append a U+003D EQUALS SIGN character (=) to line.
   4. Append the parameter's value to line.
4. Append a U+003A COLON character (:) to line.
5. Append value to line.
6. Let maximum length be 75.
7. While line's length is greater than maximum length:
   1. Append the first maximum length code points of line to output.
   2. Remove the first maximum length code points from line.
   3. Append a U+000D CARRIAGE RETURN character (CR) to output.
   4. Append a U+000A LINE FEED character (LF) to output.
   5. Append a U+0020 SPACE character to output.
   6. Let maximum length be 74.
8. Append (what remains of) line to output.
9. Append a U+000D CARRIAGE RETURN character (CR) to output.
10. Append a U+000A LINE FEED character (LF) to output.

When the steps above require the user agent to obtain the result of collecting vCard subproperties named subname in subitem, the user agent must run the following steps:

1. Let value be the empty string.
2. For each property named subname in the item subitem, run the following substeps:
   1. If the value\(^714\) of the property is itself an item\(^710\), then skip this property.
   2. If this is not the first property named subname in subitem (ignoring any that were skipped by the previous step), then append a U+002C COMMA character (,) to value.
   3. Append the result of escaping the vCard text string\(^729\) given by the value\(^714\) of the property to value.
3. Return value.
When the steps above require the user agent to obtain the result of collecting the first vCard subproperty named `subname` in `subitem`, the user agent must run the following steps:

1. If there are no properties named `subname` in `subitem`, then return the empty string.
2. If the `value` of the first property named `subname` in `subitem` is an `item`, then return the empty string.
3. Return the result of escaping the vCard text string given by the `value` of the first property named `subname` in `subitem`.

When the above algorithms say that the user agent is to escape the vCard text string `value`, the user agent must use the following steps:

1. Prefix every U+005C REVERSE SOLIDUS character (`\`) in `value` with another U+005C REVERSE SOLIDUS character (`\`).
2. Prefix every U+002C COMMA character (`,`) in `value` with a U+005C REVERSE SOLIDUS character (`\`).
3. Prefix every U+003B SEMICOLON character (`;`) in `value` with a U+005C REVERSE SOLIDUS character (`\`).
4. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in `value` with a U+005C REVERSE SOLIDUS character (`\`) followed by a U+006E LATIN SMALL LETTER N character (n).
5. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in `value` with a U+005C REVERSE SOLIDUS character (`\`) followed by a U+006E LATIN SMALL LETTER N character (n).
6. Return the mutated `value`.

*Note:
This algorithm can generate invalid vCard output, if the input does not conform to the rules described for the [http://microformats.org/profile/hcard](http://microformats.org/profile/hcard) item type and defined property names.*

### 5.3.1.2 Examples

This section is non-normative.

Here is a long example vCard for a fictional character called "Jack Bauer":

```html
<section id="jack" itemscope itemtype="http://microformats.org/profile/hcard">
  <h1 itemprop="fn">
    <span itemprop="n" itemscope>Jack</span>/<span itemprop="family-name">Bauer</span>
  </h1>
  <img itemprop="photo" alt="" src="jack-bauer.jpg">
  <p itemprop="org">Counter-Terrorist Unit</p>
  <p itemprop="adr">
    10201 W. Pico Blvd.<br>
    Los Angeles<br>
    CA<br>
    90064<br>
    United States<br>
  </p>
  <span itemprop="geo">34.052339;-118.410623</span>
</section>
```

Example 729
The odd line wrapping is needed because newlines are meaningful in microdata: newlines would be preserved in a conversion to, for example, the vCard format.

Example

This example shows a site's contact details (using the address element) containing an address with two street components:

```
<address itemscope itemtype="http://microformats.org/profile/hcard">
  <strong itemprop="fn"><span itemprop="n"><span itemprop="given-name">Alfred</span></span></strong>
  <span itemprop="family-name">Person</span>
  <br>
  <span itemprop="adr">
    <span itemprop="street-address">1600 Amphitheatre Parkway</span>
    <br>
    <span itemprop="street-address">Building 43, Second Floor</span>
    <br>
    <span itemprop="locality">Mountain View</span>,
    <span itemprop="region">CA</span>
    <span itemprop="postal-code">94043</span>
  </span>
</address>
```

Example

The vCard vocabulary can be used to just mark up people's names:

```
<span itemscope itemtype="http://microformats.org/profile/hcard" itemprop="fn"><span itemprop="n"><span itemprop="given-name">George</span></span></span> <span itemprop="family-name">Washington</span>
```

This creates a single item with a two name-value pairs, one with the name "fn" and the value "George Washington", and the other with the name "n" and a second item as its value, the second item having the two name-value pairs "given-name" and "family-name" with the values "George" and "Washington" respectively. This is defined to map to the following vCard:

```
BEGIN:VCARD
PROFILE:VCARD
VERSION:4.0
SOURCE:document's address
FN:George Washington
```
5.3.2 vEvent

An item with the item type \texttt{http://microformats.org/profile/hcalendar#vevent} represents an event.

This vocabulary does not support global identifiers for items.

The following are the type's defined property names. They are based on the vocabulary defined in the iCalendar specification, where more information on how to interpret the values can be found. [RFC5545]

\begin{note}
\textit{Only the parts of the iCalendar vocabulary relating to events are used here; this vocabulary cannot express a complete iCalendar instance.}
\end{note}

\textbf{attach}

Gives the address of an associated document for the event.

The value must be an absolute URL.

Any number of properties with the name attach may be present within each item with the type \texttt{http://microformats.org/profile/hcalendar#vevent}.

\textbf{categories}

Gives the name of a category or tag that the event could be classified as.

The value must be text.

Any number of properties with the name categories may be present within each item with the type \texttt{http://microformats.org/profile/hcalendar#vevent}.

\textbf{class}

Gives the access classification of the information regarding the event.

The value must be text with one of the following values:

- public
- private
- confidential

\begin{warning}
\textit{This is merely advisory and cannot be considered a confidentiality measure.}
\end{warning}

A single property with the name class may be present within each item with the type \texttt{http://microformats.org/profile/hcalendar#vevent}.

\textbf{comment}

Gives a comment regarding the event.

The value must be text.

Any number of properties with the name comment may be present within each item with the type \texttt{http://microformats.org/profile/hcalendar#vevent}.

\textbf{description}

Gives a detailed description of the event.

The value must be text.
A single property with the name `description` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.

**geo**

Gives the geographical position of the event.

The `value` must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

**location**

Gives the location of the event.

The `value` must be text.

A single property with the name `location` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.

**resources**

Gives a resource that will be needed for the event.

The `value` must be text.

Any number of properties with the name `resources` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.

**status**

Gives the confirmation status of the event.

The `value` must be text with one of the following values:

- tentative
- confirmed
- cancelled

A single property with the name `status` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.

**summary**

Gives a short summary of the event.

The `value` must be text.

User agents should replace U+000A LINE FEED (LF) characters in the `value` by U+0020 SPACE characters when using the value.
A single property with the name `summary` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.

**dtend**

Gives the date and time by which the event ends.

If the property with the name `dtend` is present within an `item` with the type `http://microformats.org/profile/hcalendar#vevent` that has a property with the name `dtstart` whose value is a `valid date string`, then the value of the property with the name `dtend` must be text that is a `valid date string` also. Otherwise, the value of the property must be text that is a `valid global date and time string`.

In either case, the value be later in time than the value of the `dtstart` property of the same `item`.

---

**Note**

The time given by the `dtend` property is not inclusive. For day-long events, therefore, the `dtend` property's value will be the day after the end of the event.

---

A single property with the name `dtend` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`, so long as that `http://microformats.org/profile/hcalendar#vevent` does not have a property with the name `duration`.

**dtstart**

Gives the date and time at which the event starts.

The value must be text that is either a `valid date string` or a `valid global date and time string`.

Exactly one property with the name `dtstart` must be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.

**duration**

Gives the duration of the event.

The value must be text that is a `valid vevent duration string`.

The duration represented is the sum of all the durations represented by integers in the value.

A single property with the name `duration` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`, so long as that `http://microformats.org/profile/hcalendar#vevent` does not have a property with the name `dtend`.

**transp**

Gives whether the event is to be considered as consuming time on a calendar, for the purpose of free-busy time searches.

The value must be text with one of the following values:

- opaque
- transparent

A single property with the name `transp` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.

**contact**

Gives the contact information for the event.

The value must be text.

Any number of properties with the name `contact` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.

**url**

Gives a URL for the event.

The value must be an absolute URL.

A single property with the name `url` may be present within each `item` with the type `http://microformats.org/profile/hcalendar#vevent`.
uid
Gives a globally unique identifier corresponding to the event.

The value must be text.

A single property with the name uid may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

exdate
Gives a date and time at which the event does not occur despite the recurrence rules.

The value must be text that is either a valid date string or a valid global date and time string.

Any number of properties with the name exdate may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

rdate
Gives a date and time at which the event recurs.

The value must be text that is one of the following:

- A valid date string.
- A valid global date and time string.
- A valid global date and time string followed by a U+002F SOLIDUS character (/) followed by a second valid global date and time string representing a later time.
- A valid global date and time string followed by a U+002F SOLIDUS character (/) followed by a valid vevent duration string.

Any number of properties with the name rdate may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

rrule
Gives a rule for finding dates and times at which the event occurs.

The value must be text that matches the RECUR value type defined in the iCalendar specification. [RFC5545]

A single property with the name rrule may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

created
Gives the date and time at which the event information was first created in a calendaring system.

The value must be text that is a valid global date and time string.

A single property with the name created may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

last-modified
Gives the date and time at which the event information was last modified in a calendaring system.

The value must be text that is a valid global date and time string.

A single property with the name last-modified may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

sequence
Gives a revision number for the event information.

The value must be text that is a valid non-negative integer.
A single property with the name sequence may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

A string is a valid vevent duration string if it matches the following pattern:

1. A U+0050 LATIN CAPITAL LETTER P character (P).
2. One of the following:
   - A valid non-negative integer followed by a U+0057 LATIN CAPITAL LETTER W character (W). The integer represents a duration of that number of weeks.
   - At least one, and possible both in this order, of the following:
     1. A valid non-negative integer followed by a U+0044 LATIN CAPITAL LETTER D character (D). The integer represents a duration of that number of days.
     2. A U+0054 LATIN CAPITAL LETTER T character (T) followed by any one of the following, or the first and second of the following in that order, or the second and third of the following in that order, or all three of the following in this order:
        1. A valid non-negative integer followed by a U+0048 LATIN CAPITAL LETTER H character (H). The integer represents a duration of that number of hours.
        2. A valid non-negative integer followed by a U+0053 LATIN CAPITAL LETTER S character (S). The integer represents a duration of that number of seconds.

5.3.2.1 Conversion to iCalendar

Given a list of nodes in a Document, a user agent must run the following algorithm to extract any vEvent data represented by those nodes:

1. If none of the nodes in nodes are items with the type http://microformats.org/profile/hcalendar#vevent, then there is no vEvent data. Abort the algorithm, returning nothing.
2. Let output be an empty string.
3. Add an iCalendar line with the type "BEGIN" and the value "VCALENDAR" to output.
4. Add an iCalendar line with the type "PRODID" and the value equal to a user-agent-specific string representing the user agent to output.
5. Add an iCalendar line with the type "VERSION" and the value "2.0" to output.
6. For each node node in nodes that is an item with the type http://microformats.org/profile/hcalendar#vevent, run the following steps:
   1. Add an iCalendar line with the type "BEGIN" and the value "VEVENT" to output.
   2. Add an iCalendar line with the type "DTSTAMP" and a value consisting of an iCalendar DATE-TIME string representing the current date and time, with the annotation "VALUE=DATE-TIME", to output. [RFC5545]
   3. For each element element that is a property of the item node: for each name name in element's property names, run the appropriate set of substeps from the following list:
      - If the property's value is an item
        - Skip the property.
      - If the property is dtend
      - If the property is dtstart
      - If the property is exdate
      - If the property is rdate
      - If the property is created
      - If the property is last-modified
        - Let value be the result of stripping all U+002D HYPHEN-MINUS (-) and U+003A COLON (:) characters from the property's value.
If the property's \texttt{value} is a valid date string then add an iCalendar line with the type \texttt{name} and the value to \texttt{output}, with the annotation "\texttt{VALUE=DATE}".

Otherwise, if the property's \texttt{value} is a valid global date and time string then add an iCalendar line with the type \texttt{name} and the value to \texttt{output}, with the annotation "\texttt{VALUE=DATE-TIME}".

Otherwise skip the property.

Otherwise add an iCalendar line with the type \texttt{name} and the property's \texttt{value} to \texttt{output}.

4. Add an iCalendar line with the type "\texttt{END}" and the value "\texttt{VEVENT}" to \texttt{output}.

7. Add an iCalendar line with the type "\texttt{END}" and the value "\texttt{VCALENDAR}" to \texttt{output}.

When the above algorithm says that the user agent is to add an iCalendar line consisting of a type \texttt{type}, a value \texttt{value}, and optionally an annotation, to a string \texttt{output}, it must run the following steps:

1. Let \texttt{line} be an empty string.
2. Append \texttt{type}, converted to ASCII uppercase, to \texttt{line}.
3. If there is an annotation:
   1. Append a U+003B SEMICOLON character (;) to \texttt{line}.
   2. Append the annotation to \texttt{line}.
4. Append a U+003A COLON character (:) to \texttt{line}.
5. Prefix every U+005C REVERSE SOLIDUS character (\) in \texttt{value} with another U+005C REVERSE SOLIDUS character (\).
6. Prefix every U+002C COMMA character (,) in \texttt{value} with a U+005C REVERSE SOLIDUS character (\).
7. Prefix every U+003B SEMICOLON character (;) in \texttt{value} with a U+005C REVERSE SOLIDUS character (\).
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in \texttt{value} with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in \texttt{value} with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
10. Append \texttt{value} to \texttt{line}.
11. Let \texttt{maximum length} be 75.
12. While \texttt{line}'s length is greater than \texttt{maximum length}:
   1. Append the first \texttt{maximum length} code points of \texttt{line} to \texttt{output}.
   2. Remove the first \texttt{maximum length} code points from \texttt{line}.
   3. Append a U+000D CARRIAGE RETURN character (CR) to \texttt{output}.
   4. Append a U+000A LINE FEED character (LF) to \texttt{output}.
   5. Append a U+0020 SPACE character to \texttt{output}.
   6. Let \texttt{maximum length} be 74.
13. Append (what remains of) \texttt{line} to \texttt{output}.
14. Append a U+000D CARRIAGE RETURN character (CR) to \texttt{output}.
15. Append a U+000A LINE FEED character (LF) to \texttt{output}.

\textbf{Note}

This algorithm can generate invalid iCalendar output, if the input does not conform to the rules described for the \texttt{http://microformats.org/profile/hcalendar#vevent} item type and \texttt{defined property names}.
5.3.2.2 Examples §

This section is non-normative.

Here is an example of a page that uses the vEvent vocabulary to mark up an event:

```html
<body itemscope itemtype="http://microformats.org/profile/hcalendar#vevent">
  ...
  <h1 itemprop="summary">Bluesday Tuesday: Money Road</h1>
  ...
  <time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th @ 7pm</time>
  (until <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>)
  ...
  <a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
      rel="bookmark" itemprop="url">Link to this page</a>
  ...
  <p>Location: <span itemprop="location">The RoadHouse</span></p>
  ...
  <p><input type="button" value="Add to Calendar"
      onclick="location = getCalendar(this)"></p>
  ...
  <meta itemprop="description" content="via livebrum.co.uk">
</body>
```

The `getCalendar()` function is left as an exercise for the reader.

The same page could offer some markup, such as the following, for copy-and-pasting into blogs:

```html
<div itemscope itemtype="http://microformats.org/profile/hcalendar#vevent">
  <p>I’m going to</p>
  <strong itemprop="summary">Bluesday Tuesday: Money Road</strong>,
  <time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th at 7pm</time>
  to <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>,
  at <span itemprop="location">The RoadHouse</span>!
  <p><a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
      itemprop="url">See this event on livebrum.co.uk</a>.</p>
  <meta itemprop="description" content="via livebrum.co.uk">
</div>
```

5.3.3 Licensing works §

An item with the `item type` `http://n.whatwg.org/work` represents a work (e.g. an article, an image, a video, a song, etc). This type is primarily intended to allow authors to include licensing information for works.

The following are the type's `defined property names`:

**work**

Identifies the work being described.

The `value` must be an `absolute URL`.

Exactly one property with the name `work` must be present within each `item` with the type `http://n.whatwg.org/work`.

**title**

 Gives the name of the work.

A single property with the name `title` may be present within each `item` with the type `http://n.whatwg.org/work`. 
**author**

Gives the name or contact information of one of the authors or creators of the work.

The value must be either an item with the type `http://microformats.org/profile/hcard`, or text.

Any number of properties with the name `author` may be present within each item with the type `http://n.whatwg.org/work`.

**license**

Identifies one of the licenses under which the work is available.

The value must be an absolute URL.

Any number of properties with the name `license` may be present within each item with the type `http://n.whatwg.org/work`.

---

5.3.3.1 Examples

This section is non-normative.

**Example**

This example shows an embedded image entitled *My Pond*, licensed under the Creative Commons Attribution-Share Alike 4.0 International License and the MIT license simultaneously.

```html
<figure itemscope itemtype="http://n.whatwg.org/work">
  <img itemprop="work" src="mypond.jpeg">
  <figcaption>
    <p><cite itemprop="title">My Pond</cite></p>
    <p><small>Licensed under the <a itemprop="license" href="https://creativecommons.org/licenses/by-sa/4.0/">Creative Commons Attribution-Share Alike 4.0 International License</a> and the <a itemprop="license" href="http://www.opensource.org/licenses/mit-license.php">MIT license</a>.</small>
  </figcaption>
</figure>
```

5.4 Converting HTML to other formats

5.4.1 JSON

Given a list of nodes `nodes` in a Document, a user agent must run the following algorithm to extract the microdata from those nodes into a JSON form:

1. Let `result` be an empty object.
2. Let `items` be an empty array.
3. For each `node` in `nodes`, check if the element is a top-level microdata item, and if it is then get the object for that element and add it to `items`.
4. Add an entry to `result` called "items" whose value is the array `items`.
5. Return the result of serializing `result` to JSON in the shortest possible way (meaning no whitespace between tokens, no unnecessary zero digits in numbers, and only using Unicode escapes in strings for characters that do not have a dedicated escape sequence), and with a lowercase "e" used, when appropriate, in the representation of any numbers. [JSON]
When the user agent is to get the object for an item item, optionally with a list of elements memory, it must run the following substeps:

1. Let result be an empty object.
2. If no memory was passed to the algorithm, let memory be an empty list.
3. Add item to memory.
4. If the item has any item types, add an entry to result called "type" whose value is an array listing the item types of item, in the order they were specified on the itemtype attribute.
5. If the item has a global identifier, add an entry to result called "id" whose value is the global identifier of item.
6. Let properties be an empty object.
7. For each element element that has one or more property names and is one of the properties of the item item, in the order those elements are given by the algorithm that returns the properties of an item, run the following substeps:
   1. Let value be the property value of element.
   2. If value is an item, then: If value is in memory, then let value be the string "ERROR". Otherwise, get the object for value, passing a copy of memory, and then replace value with the object returned from those steps.
   3. For each name name in element's property names, run the following substeps:
      1. If there is no entry named name in properties, then add an entry named name to properties whose value is an empty array.
      2. Append value to the entry named name in properties.
8. Add an entry to result called "properties" whose value is the object properties.
9. Return result.

Example

For example, take this markup:

```html
<!DOCTYPE HTML>
<html lang="en">
<title>My Blog</title>
<article itemscope itemtype="http://schema.org/BlogPosting">
  <header>
    <h1 itemprop="headline">Progress report</h1>
    <p><time itemprop="datePublished" datetime="2013-08-29">today</time></p>
    <link itemprop="url" href="?comments=0"></link>
  </header>
  <p>All in all, he's doing well with his swim lessons. The biggest thing was he had trouble putting his head in, but we got it down.</p>
  <section>
    <h1 itemprop="headline">Comments</h1>
    <article itemscope itemtype="http://schema.org/UserComments" id="c1">
      <link itemprop="url" href="#c1"></link>
      <footer>
        <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
          <span itemprop="name">Greg</span>
        </span></p>
        <p><time itemprop="commentTime" datetime="2013-08-29">15 minutes ago</time></p>
      </footer>
      <p>Ha!</p>
    </article>
  </section>
</article>
```
When you say "we got it down"...
6 User interaction

6.1 The hidden attribute

All HTML elements may have the `hidden` content attribute set. The `hidden` attribute is a boolean attribute. When specified on an element, it indicates that the element is not yet, or is no longer, directly relevant to the page's current state, or that it is being used to declare content to be reused by other parts of the page as opposed to being directly accessed by the user. User agents should not render elements that have the `hidden` attribute specified. This requirement may be implemented indirectly through the style layer. For example, an HTML+CSS user agent could implement these requirements using the rules suggested in the Rendering section.

**Note**

Because this attribute is typically implemented using CSS, it's also possible to override it using CSS. For instance, a rule that applies `display: block` to all elements will cancel the effects of the `hidden` attribute. Authors therefore have to take care when writing their style sheets to make sure that the attribute is still styled as expected.

**Example**

In the following skeletal example, the attribute is used to hide the Web game's main screen until the user logs in:

```html
<h1>The Example Game</h1>
<section id="login">
<h2>Login</h2>
<form>
  ...
  <!-- calls login() once the user's credentials have been checked -->
  ...
</form>
<script>
  function login() {
    // switch screens
    document.getElementById('login').hidden = true;
    document.getElementById('game').hidden = false;
  }
</script>
</section>
<section id="game" hidden>
  ...
</section>
```

The `hidden` attribute must not be used to hide content that could legitimately be shown in another presentation. For example, it is incorrect to use `hidden` to hide panels in a tabbed dialog, because the tabbed interface is merely a kind of overflow presentation — one could equally well just show all the form controls in one big page with a scrollbar. It is similarly incorrect to use this attribute to hide content just from one presentation — if something is marked `hidden`, it is hidden from all presentations, including, for instance, screen readers.

Elements that are not themselves `hidden` must not `href` to elements that are `hidden`. The `for` attributes of `label` and `output` elements that are not themselves `hidden` must similarly not refer to elements that are `hidden`. In both cases, such references would cause user confusion.

Elements and scripts may, however, refer to elements that are `hidden` in other contexts.

**Example**

For example, it would be incorrect to use the `href` attribute to link to a section marked with the `hidden` attribute. If the content is not applicable or relevant, then there is no reason to link to it.

It would be fine, however, to use the ARIA `aria-describedby` attribute to refer to descriptions that are themselves `hidden`. While hiding the descriptions implies that they are not useful alone, they could be written in such a way that they are useful in the...
specific context of being referenced from the images that they describe.

Similarly, a canvas element with the hidden attribute could be used by a scripted graphics engine as an off-screen buffer, and a form control could refer to a hidden form element using its form attribute.

Elements in a section hidden by the hidden attribute are still active, e.g. scripts and form controls in such sections still execute and submit respectively. Only their presentation to the user changes.

The hidden IDL attribute must reflect the content attribute of the same name.

6.2 Inert subtrees

A node (in particular elements and text nodes) can be marked as inert. When a node is inert, then the user agent must act as if the node was absent for the purposes of targeting user interaction events, may ignore the node for the purposes of text search user interfaces (commonly known as "find in page"), and may prevent the user from selecting text in that node. User agents should allow the user to override the restrictions on search and text selection, however.

For example, consider a page that consists of just a single paragraph positioned in the middle of a body. If a user moves their pointing device from the body over to the paragraph and clicks on the paragraph, no mouseover event would be fired, and themousemove and click events would be fired on the body element rather than the paragraph.

While a browsing context container is marked as inert, its nested browsing context’s active document, and all nodes in that Document, must be marked as inert.

An element is expressly inert if it is inert and its node document is not inert.

A Document document is blocked by a modal dialog subject if subject is the topmost element in document’s top layer. While document is so blocked, every node that is connected to document, with the exception of the subject element and its shadow-including descendants, must be marked inert. (The elements excepted by this paragraph can additionally be marked inert through other means; being part of a modal dialog does not "protect" a node from being marked inert.)

The dialog element’s showModal() method causes this mechanism to trigger, by adding the dialog element to its node document’s top layer.

6.3 Activation

Certain elements in HTML have an activation behavior, which means that the user can activate them. This is always caused by a click event.

The user agent should allow the user to manually trigger elements that have an activation behavior, for instance using keyboard or voice input, or through mouse clicks. When the user triggers an element with a defined activation behavior in a manner other than clicking it, the default action of the interaction event must be to fire a click event at the element.

An algorithm is triggered by user activation if any of the following conditions is true:
• The task in which the algorithm is running is currently processing an activation behavior whose click event’s isTrusted attribute is true.

• The task in which the algorithm is running is currently running the event listener for an event whose isTrusted attribute is true and whose type is one of:
  - change
  - click
  - contextmenu
  - dblclick
  - mouseup
  - pointerup
  - reset
  - submit
  - touchend

• The task in which the algorithm is running was queued by an algorithm that was triggered by user activation, and the chain of such algorithms started within a user-agent defined timeframe.

For example, if a user clicked a button, it might be acceptable for a popup to result from that after 4 seconds, but it would likely not be acceptable for a popup to result from that after 4 hours.

For web developers (non-normative)

```javascript
  element.click()
  Acts as if the element was clicked.
```

Each element has an associated click in progress flag, which is initially unset.

The click() method must run the following steps:

1. If this element is a form control that is disabled, then return.
2. If this element's click in progress flag is set, then return.
3. Set this element's click in progress flag.
4. Fire a synthetic mouse event at this element, with the trusted flag set.
5. Unset this element's click in progress flag.

6.4 Focus

6.4.1 Introduction

This section is non-normative.

An HTML user interface typically consists of multiple interactive widgets, such as form controls, scrollable regions, links, dialog boxes, browser tabs, and so forth. These widgets form a hierarchy, with some (e.g. browser tabs, dialog boxes) containing others (e.g. links, form controls).

When interacting with an interface using a keyboard, key input is channeled from the system, through the hierarchy of interactive widgets, to an active widget, which is said to be focused.

Example

Consider an HTML application running in a browser tab running in a graphical environment. Suppose this application had a page with some text controls and links, and was currently showing a modal dialog, which itself had a text control and a button.

The hierarchy of focusable widgets, in this scenario, would include the browser window, which would have, amongst its children, the browser tab containing the HTML application. The tab itself would have as its children the various links and text controls, as
Keyboard events are always targeted at this focused element.

### 6.4.2 Data model

The term **focusable area** is used to refer to regions of the interface that can become the target of keyboard input. Focusable areas can be elements, parts of elements, or other regions managed by the user agent.

Each focusable area has a **DOM anchor**, which is a Node object that represents the position of the focusable area in the DOM. (When the focusable area is itself a Node, it is its own DOM anchor.) The DOM anchor is used in some APIs as a substitute for the focusable area when there is no other DOM object to represent the focusable area.

The following table describes what objects can be focusable areas. The cells in the left column describe objects that can be focusable areas; the cells in the right column describe the DOM anchors for those elements. (The cells that span both columns are non-normative examples.)

<table>
<thead>
<tr>
<th>Focusable area</th>
<th>DOM anchor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Elements that have their tabindex focus flag set, that are not actually disabled, that are not expressly inert, and that are either being rendered or being used as relevant canvas fallback content.</td>
<td>The element itself.</td>
</tr>
<tr>
<td>iframe, input type=text, sometimes a href=“..” (depending on platform conventions).</td>
<td>The iframe element.</td>
</tr>
<tr>
<td>The shapes of area elements in an image map associated with an img element that is being rendered and is not expressly inert.</td>
<td>The img element.</td>
</tr>
</tbody>
</table>

In the following example, the area element creates two shapes, one on each image. The DOM anchor of the first shape is the first img element, and
The DOM anchor\(^{744}\) of the second shape is the second `img` element.

```
<map id="wallmap"><area alt="Enter Door" coords="10,10,100,200" href="door.html"></map>
...<img src="images/innerwall.jpeg" alt="There is a white wall here, with a door." usemap="#wallmap">
...<img src="images/outerwall.jpeg" alt="There is a red wall here, with a door." usemap="#wallmap">
```

The user-agent provided subwidgets of elements that are being rendered\(^{1133}\) and are not actually disabled\(^{846}\) or expressly inert\(^{2742}\).

The controls in the user interface that is exposed to the user\(^{403}\) for a `video` element, the up and down buttons in a spin-control version of `<input type=number>`\(^{492}\), the two range control widgets in a `<input type=range multiple>`\(^{591}\), the part of a `details`\(^{584}\) element's rendering that enabled the element to be opened or closed using keyboard input.

The CSS `overflow` property's `scroll` value typically creates a scrollable region.

The contents of an `iframe`\(^{347}\).

Any other element or part of an element, especially to aid with accessibility or to better match platform conventions.

Example

A user agent could make all list item bullets focusable, so that a user can more easily navigate lists.

Example

Similarly, a user agent could make all elements with `title`\(^{135}\) attributes focusable, so that their advisory information can be accessed.

**Note**

A browsing context container\(^{781}\) (e.g. an `iframe`\(^{347}\)) is a focusable area\(^{744}\), but key events routed to a browse context container\(^{781}\) get immediately routed to a nested browsing context\(^{581}\)’s active document\(^{5780}\). Similarly, in sequential focus navigation a browsing context container\(^{781}\) essentially acts merely as a placeholder for its nested browsing context\(^{581}\)’s active document\(^{5780}\).

One focusable area\(^{744}\) in each Document\(^{611}\) is designated the **focused area of the document**. Which control is so designated changes over time, based on algorithms in this specification.

Focusable areas\(^{744}\) in a Document\(^{611}\) are ordered relative to the tree order of their DOM anchors\(^{744}\). Focusable areas\(^{744}\) with the same DOM anchor\(^{744}\) in a Document\(^{611}\) are ordered relative to their CSS boxes’ relative positions in a pre-order, depth-first traversal of the box tree. [CSS]\(^{1221}\).

The **currently focused area of a top-level browsing context** at any particular time is the focusable area\(^{744}\) returned by this algorithm:

1. Let candidate be the Document\(^{611}\) of the top-level browsing context\(^{5783}\).
2. If the designated focusable area of the document\(^{745}\) is a browsing context container\(^{781}\) with a non-null nested browsing context\(^{581}\), then let candidate be the active document\(^{5780}\) of that browsing context container\(^{581}\)’s nested browsing context\(^{581}\), and redo this step.
3. If candidate has a focusable area\(^{745}\), set candidate to candidate’s focusable area\(^{745}\).
4. Return candidate.

An element that is the DOM anchor\(^{744}\) of a focusable area\(^{744}\) is said to **gain focus** when that focusable area\(^{744}\) becomes the currently focused area of a top-level browsing context\(^{5745}\). When an element is the DOM anchor\(^{744}\) of a focusable area\(^{744}\) of the currently focused area of a top-level browsing context\(^{5745}\), it is **focused**.
The focus chain of a focusable area\textsuperscript{p744} subject is the ordered list constructed as follows:

1. Let current object be subject.
2. Let output be an empty list.
3. Loop: Append current object to output.
4. If current object is an area\textsuperscript{p428} element's shape, append that area\textsuperscript{p428} element to output.
   Otherwise, if current object is a focusable area\textsuperscript{p744}, whose DOM anchor\textsuperscript{p744} is an element that is not current object itself, append that DOM anchor\textsuperscript{p744} element to output.
5. If current object is a Document\textsuperscript{p110} in a nested browsing context\textsuperscript{p781}, let current object be its browsing context container\textsuperscript{p781}, and return to the step labeled loop.
6. Return output.

The tabindex content attribute allows authors to indicate that an element is supposed to be focusable\textsuperscript{p744}, and whether it is supposed to be reachable using sequential focus navigation\textsuperscript{p750} and, if so, what is to be the relative order of the element for the purposes of sequential focus navigation. The name "tab index" comes from the common use of the "tab" key to navigate through the focusable elements. The term "tabbing" refers to moving forward through the focusable elements that can be reached using sequential focus navigation.

When the attribute is omitted, the user agent applies defaults. (There is no way to make an element that is being rendered\textsuperscript{p1133} be not focusable at all without disabling\textsuperscript{p699} it or making it inert\textsuperscript{p742}.)

The tabindex\textsuperscript{p746} attribute, if specified, must have a value that is a valid integer\textsuperscript{p66}. Positive numbers specify the relative position of the element's focusable areas\textsuperscript{p744} in the sequential focus navigation order\textsuperscript{p750}, and negative numbers indicate that the control is to be unreachable by sequential focus navigation\textsuperscript{p750}.

Developers should use caution when using values other than 0 or −1 for their tabindex\textsuperscript{p746} attributes as this is complicated to do correctly.

Each element can have a tabindex focus flag set, as defined below. This flag is a factor that contributes towards determining whether an element is a focusable area\textsuperscript{p744}, as described in the previous section.

If the tabindex\textsuperscript{p746} attribute is specified on an element, it must be parsed using the rules for parsing integers\textsuperscript{p66}. The attribute's values, or lack thereof, must be interpreted as follows:

If the attribute is omitted or parsing the value returns an error

The user agent should follow platform conventions to determine if the element's tabindex focus flag\textsuperscript{p746} is set and, if so, whether the element and any focusable areas\textsuperscript{p744} that have the element as their DOM anchor\textsuperscript{p744} can be reached using sequential focus navigation\textsuperscript{p750}, and if so, what their relative position in the sequential focus navigation order\textsuperscript{p750} is to be.

Modulo platform conventions, it is suggested that for the following elements, the tabindex focus flag\textsuperscript{p746} be set:

- a\textsuperscript{p230} elements that have an href\textsuperscript{p274} attribute
- link\textsuperscript{p153} elements that have an href\textsuperscript{p154} attribute
- button\textsuperscript{p518} elements
- input\textsuperscript{p476} elements whose type\textsuperscript{p478} attribute are not in the Hidden\textsuperscript{p482} state
- select\textsuperscript{p528} elements
- textarea\textsuperscript{p530} elements

---

Notes:

6.4.3 The tabindex\textsuperscript{p746} attribute

The tabindex content attribute allows authors to indicate that an element is supposed to be focusable\textsuperscript{p744}, and whether it is supposed to be reachable using sequential focus navigation\textsuperscript{p750} and, if so, what is to be the relative order of the element for the purposes of sequential focus navigation. The name "tab index" comes from the common use of the "tab" key to navigate through the focusable elements. The term "tabbing" refers to moving forward through the focusable elements that can be reached using sequential focus navigation.

The chain starts with subject and (if subject is or can be the currently focused area of a top-level browsing context\textsuperscript{p745}) continues up the focus hierarchy up to the Document\textsuperscript{p110} of the top-level browsing context\textsuperscript{p782}.

Support:

- Chrome for Android
- Chrome
- iOS Safari
- Firefox
- IE
- Safari
- Edge
- Opera
- Others

Source:

746
• **summary** elements that are the first **summary** element child of a **details** element

• Elements with a **draggable** attribute set, if that would enable the user agent to allow the user to begin a drag operation for those elements without the use of a pointing device

• **Editing hosts**

• **Browsing context containers**

If the value is a negative integer

The user agent must set the element's **tabindex** flag, but should omit the element from the sequential focus navigation order.

**Note**

One valid reason to ignore the requirement that sequential focus navigation not allow the author to lead to the element would be if the user's only mechanism for moving the focus is sequential focus navigation. For instance, a keyboard-only user would be unable to click on a text control with a negative **tabindex**, so that user's user agent would be well justified in allowing the user to tab to the control regardless.

If the value is a zero

The user agent must set the element's **tabindex** flag, should allow the element and any focusable areas that have the element as their **DOM anchor** to be reached using sequential focus navigation, following platform conventions to determine the element's relative position in the sequential focus navigation order.

If the value is greater than zero

The user agent must set the element's **tabindex** flag, should allow the element and any focusable areas that have the element as their **DOM anchor** to be reached using sequential focus navigation, and should place the element — referenced as candidate below — and the aforementioned focusable areas in the sequential focus navigation order so that, relative to other focusable areas in the sequential focus navigation order, they are:

• before any focusable area whose **DOM anchor** is an element whose **tabindex** attribute has been omitted or whose value, when parsed, returns an error,

• before any focusable area whose **DOM anchor** is an element whose **tabindex** attribute has a value equal to or less than zero,

• after any focusable area whose **DOM anchor** is an element whose **tabindex** attribute has a value greater than zero but less than the value of the candidate's **tabindex** attribute on candidate,

• after any focusable area whose **DOM anchor** is an element whose **tabindex** attribute has a value equal to the value of the candidate's **tabindex** attribute on candidate but that is earlier in the document in tree order than candidate,

• before any focusable area whose **DOM anchor** is an element whose **tabindex** attribute has a value greater than the value of the candidate's **tabindex** attribute on candidate.

An element with the **tabindex** attribute specified is interactive content.

The **tabIndex** IDL attribute must reflect the value of the **tabindex** content attribute. Its default value is 0 for elements that are focusable and −1 for elements that are not focusable.

#### 6.4.4 Processing model

The focusing steps for an object new focus target that is either a focusable area, or an element that is not a focusable area, or a browsing context, are as follows. They can optionally be run with a fallback target.

1. If new focus target is not a focusable area, then run the first matching set of steps from the following list:

   → If new focus target is an area element with one or more shapes that are focusable areas

      Let new focus target be the shape corresponding to the first img element in tree order that uses the image map to which the area element belongs.
→ If **new focus target** is an element with one or more scrollable regions that are **focusable areas**
   Let new focus target be the element's first scrollable region, according to a pre-order, depth-first traversal of the box tree. [CSS]¹²²¹

→ If **new focus target** is the **document element** of its **Document**
   Let new focus target be the **Document**'s viewport.

→ If **new focus target** is a **browsing context**
   Let new focus target be the **browsing context**'s **active document**.

→ If **new focus target** is a **browsing context container** with a non-null nested **browsing context**
   Let new focus target be the **browsing context container**'s nested **browsing context**'s **active document**.

→ Otherwise
   If no fallback target was specified, abort the focusing steps.
   Otherwise, let new focus target be the fallback target.

1. If new focus target is **null**, then return.
2. If new focus target is a **browsing context container** with non-null nested **browsing context**, then let new focus target be the nested **browsing context**'s **active document**, and redo this step.
3. If new focus target is a **focusable area** and its **DOM anchor** is **inert**, then return.
4. If new focus target is the currently focused area of a top-level browsing context, then return.
5. Let old chain be the **focus chain** of the currently focused area of the top-level browsing context in which new focus target finds itself.
6. Let new chain be the **focus chain** of new focus target.
7. Run the focusing steps with old chain, new chain, and new focus target respectively.

User agents must immediately run the focusing steps for a **focusable area** or **browsing context** candidate whenever the user attempts to move the focus to a candidate.

The unfocusing steps for an object **old focus target** that is either a **focusable area** or an element that is not a **focusable area** are as follows:

1. If **old focus target** is **inert**, then return.
2. If **old focus target** is an area element and one of its shapes is the currently focused area of a top-level browsing context, or, if **old focus target** is an element with one or more scrollable regions, and one of them is the currently focused area of a top-level browsing context, then let **old focus target** be that currently focused area of a top-level browsing context.
3. Let old chain be the **focus chain** of the currently focused area of a top-level browsing context.
4. If **old focus target** is not one of the entries in old chain, then return.
5. If **old focus target** is a **focusable area**, then let new focus target be its **Document**'s viewport.
   Otherwise, let new focus target be null.
6. If **new focus target** is not null, then run the focusing steps for new focus target.

When the currently focused area of a top-level browsing context is somehow unfocused without another element being explicitly focused in its stead, the user agent must immediately run the unfocusing steps for that object.

**Note** The unfocusing steps do not always result in the focus changing, even when applied to the currently focused area of a top-level browsing context. For example, if the currently focused area of a top-level browsing context is a viewport, then it will usually keep its focus regardless until another focusable area is explicitly focused with the focusing steps.

**Focus fixup rule:** When the designated **focused area of the document** is removed from that Document in some way (e.g. it stops being a focusable area, it is removed from the DOM, it becomes expressly inert, etc.), designate the Document's...
viewport to be the new focused area of the document

For example, this might happen because an element is removed from its Document, or has a hidden or disabled.

Example

In a Document whose focused area is a button element, removing, disabling, or hiding that button would cause the page's new focused area to be the viewport of the Document. This would, in turn, be reflected through the activeElement API as the body element.

The focus update steps, given an old chain, a new chain, and a new focus target respectively, are as follows:

1. If the last entry in old chain and the last entry in new chain are the same, pop the last entry from old chain and redo this step.

2. For each entry entry in old chain, in order, run these substeps:

   1. If entry is an input element, and the change event applies to the element, and the element does not have a defined activation behavior, and the user has changed the element's value, or its list of selected files while the control was focused without committing that change (such that it is different to what it was when the control was first focused), then fire an event named change at the element, with the bubbles attribute initialized to true.

   2. If entry is an element, let blur event target be entry.

      If entry is a Document object, let blur event target be that Document object's Window object.

      Otherwise, let blur event target be null.

   3. If entry is the last entry in old chain, and entry is an Element, and the last entry in new chain is also an Element, then let related blur target be the last entry in new chain. Otherwise, let related blur target be null.

   4. If blur event target is not null, fire a focus event named blur at blur event target, with related blur target as the related target.

      In some cases, e.g. if entry is an area element's shape, a scrollable region, or a viewport, no event is fired.

3. Apply any relevant platform-specific conventions for focusing new focus target. (For example, some platforms select the contents of a text control when that control is focused.)

4. For each entry entry in new chain, in reverse order, run these substeps:

   1. If entry is a focusable area: designate entry as the focused area of the document.

   2. If entry is an element, let focus event target be entry.

      If entry is a Document object, let focus event target be that Document object's Window object.

      Otherwise, let focus event target be null.

   3. If entry is the last entry in new chain, and entry is an Element, and the last entry in old chain is also an Element, then let related focus target be the last entry in old chain. Otherwise, let related focus target be null.

   4. If focus event target is not null, fire a focus event named focus at focus event target, with related focus target as the related target.

      In some cases, e.g. if entry is an area element's shape, a scrollable region, or a viewport, no event is fired.

To fire a focus event named e at an element t with a given related target r, fire an event named e at t, using FocusEvent, with the relatedTarget attribute initialized to r, the view attribute initialized to t's node document's Window object, and the composed flag set.
When a key event is to be routed in a top-level browsing context, the user agent must run the following steps:

1. Let target area be the currently focused area of the top-level browsing context.
2. If target area is a focusable area, let target node be target area’s DOM anchor. Otherwise, target area is a dialog; let target node be target area.
3. If target node is a Document that has a body element, then let target node be the body element of that Document. Otherwise, if target node is a Document object that has a non-null document element, then let target node be that document element.
4. If target node is not inert, then:
   1. Let canHandle be the result of dispatching the key event at target node.
   2. If canHandle is true, then let target area handle the key event. This might include firing a click event at target node.

The has focus steps, given a Document object target, are as follows:

1. Let candidate be the Document of the top-level browsing context, if the user requested to move focus sequentially from there, or else the top-level browsing context itself, if the user instead requested to move focus from outside the top-level browsing context.
2. While true:
   1. If candidate is target, then return true.
   2. If the focused area of candidate is a browsing context container with a non-null nested browsing context, then set candidate to the active document of that browsing context container’s nested browsing context.
3. Otherwise, return false.

6.4.5 Sequential focus navigation

Each Document has a sequential focus navigation order, which orders some or all of the focusable areas in the Document relative to each other. The order in the sequential focus navigation order does not have to be related to the tree order in the Document itself. If a focusable area is omitted from the sequential focus navigation order of its Document, then it is unreachable via sequential focus navigation.

There can also be a sequential focus navigation starting point. It is initially unset. The user agent may set it when the user indicates that it should be moved.

Example

For example, the user agent could set it to the position of the user’s click if the user clicks on the document contents.

When the user requests that focus move from the currently focused area of a top-level browsing context to the next or previous focusable area (e.g. as the default action of pressing the tab key), or when the user requests that focus sequentially move to a top-level browsing context in the first place (e.g. from the browser’s location bar), the user agent must use the following algorithm:

1. Let starting point be the currently focused area of a top-level browsing context, if the user requested to move focus sequentially from there, or else the top-level browsing context itself, if the user instead requested to move focus from outside the top-level browsing context.
2. If there is a sequential focus navigation starting point defined and it is inside starting point, then let starting point be the sequential focus navigation starting point instead.
3. Let direction be forward if the user requested the next control, and backward if the user requested the previous control.
Loop: Let selection mechanism be sequential if the starting point is a browsing context or if starting point is in its Document's sequential focus navigation order.

Otherwise, starting point is not in its Document's sequential focus navigation order; let selection mechanism be DOM.

Let candidate be the result of running the sequential navigation search algorithm with starting point, direction, and selection mechanism as the arguments.

If candidate is not null, then run the focusing steps for candidate and return.

Otherwise, unset the sequential focus navigation starting point.

If starting point is the top-level browsing context, or a focusable area in the top-level browsing context, the user agent should transfer focus to its own controls appropriately (if any), honouring direction, and then return.

The sequential navigation search algorithm consists of the following steps. This algorithm takes three arguments: starting point, direction, and selection mechanism.

1. Pick the appropriate cell from the following table, and follow the instructions in that cell.

<table>
<thead>
<tr>
<th>starting point is a browsing context</th>
<th>direction is forward</th>
<th>direction is backward</th>
</tr>
</thead>
<tbody>
<tr>
<td>candidate be the first suitable sequentially focusable area in starting point's active document, if any; or else null</td>
<td>Let candidate be the first suitable sequentially focusable area in starting point's active document, if any; or else null</td>
<td>Let candidate be the last suitable sequentially focusable area in starting point's active document, if any; or else null</td>
</tr>
<tr>
<td>selection mechanism is DOM</td>
<td>Let candidate be the first suitable sequentially focusable area in the home document following starting point, if any; or else null</td>
<td>Let candidate be the last suitable sequentially focusable area in the home document preceding starting point, if any; or else null</td>
</tr>
<tr>
<td>selection mechanism is sequential</td>
<td>Let candidate be the first suitable sequentially focusable area in the home sequential focus navigation order following starting point, if any; or else null</td>
<td>Let candidate be the last suitable sequentially focusable area in the home sequential focus navigation order preceding starting point, if any; or else null</td>
</tr>
</tbody>
</table>

A suitable sequentially focusable area is a focusable area whose DOM anchor is not inert and that is in its Document's sequential focus navigation order.

The home document is the Document to which starting point belongs.

The home sequential focus navigation order is the sequential focus navigation order to which starting point belongs.

Note: The home sequential focus navigation order is the home document's sequential focus navigation order, but is only used when the starting point is in that sequential focus navigation order (when it's not, selection mechanism will be DOM).

2. If candidate is a browsing context container with a non-null nested browsing context, then let new candidate be the result of running the sequential navigation search algorithm with candidate's nested browsing context as the first argument, direction as the second, and sequential as the third.

If new candidate is null, then let starting point be candidate, and return to the top of this algorithm. Otherwise, let candidate be new candidate.

3. Return candidate.
6.4.6 Focus management APIs

IDL
dictionary FocusOptions {
  boolean preventScroll = false;
};

For web developers (non-normative)

document.activeElement

Returns the deepest element in the document through which or to which key events are being routed. This is, roughly speaking, the focused element in the document.

For the purposes of this API, when a child browsing context is focused, its browsing context container is focused in the parent browsing context. For example, if the user moves the focus to a text control in an iframe, the iframe is the element returned by the activeElement API in the iframe's node document.

document.hasFocus()

Returns true if key events are being routed through or to the document; otherwise, returns false. Roughly speaking, this corresponds to the document, or a document nested inside this one, being focused.

window.focus()

Moves the focus to the window's browsing context, if any.

element.focus([ { preventScroll: true } ])

Moves the focus to the element.

If the element is a browsing context container, moves the focus to the nested browsing context instead.

By default, this method also scrolls the element into view. Providing the preventScroll option and setting it to true prevents this behavior.

element.blur()

Moves the focus to the viewport. Use of this method is discouraged; if you want to focus the viewport, call the focus() method on the Document's document element.

Do not use this method to hide the focus ring if you find the focus ring unsightly. Instead, use a CSS rule to override the 'outline' property, and provide a different way to show what element is focused. Be aware that if an alternative focusing style isn't made available, the page will be significantly less usable for people who primarily navigate pages using a keyboard, or those with reduced vision who use focus outlines to help them navigate the page.

Example

For example, to hide the outline from links and instead use a yellow background to indicate focus, you could use:

CSS
:link:focus, :visited:focus { outline: none; background: yellow; color: black; }

The activeElement attribute's getter must run these steps:

1. Let candidate be the DOM anchor of the focused area of this Document object.
2. If candidate is not a Document object, then return candidate.
3. If candidate has a body element, then return that body element.
4. If candidate's document element is non-null, then return that document element.
5. Return null.

The hasFocus() method on the Document object, when invoked, must return the result of running the has focus steps with the Document object as the argument.

The focus() method on the Window object, when invoked, must run the focusing steps with the Window object's browsing context. Additionally, if this browsing context is a top-level browsing context, user agents are encouraged to trigger some sort of notification to indicate to the user that the page is attempting to gain focus.
The `blur()` method on the `Window` object, when invoked, provides a hint to the user agent that the script believes the user probably is not currently interested in the contents of the `browsing context` of the `Window` object on which the method was invoked, but that the contents might become interesting again in the future.

User agents are encouraged to ignore calls to this `blur()` method entirely.

---

**Note**

Historically, the `focus()` and `blur()` methods actually affected the system-level focus of the system widget (e.g. tab or window) that contained the `browsing context`, but hostile sites widely abuse this behavior to the user's detriment.

---

The `focus(options)` method on elements, when invoked, must run the following steps:

1. If the element is marked as `locked for focus`, then return.
2. Mark the element as `locked for focus`.
3. Run the focusing steps for the element.
4. If the value of the `preventScroll` dictionary member of `options` is false, then scroll the element into view with scroll behavior "auto", block flow direction position set to a UA-defined value, and inline base direction position set to a UA-defined value.
5. Unmark the element as `locked for focus`.

The `blur()` method, when invoked, should run the unfocusing steps for the element on which the method was called. User agents may selectively or uniformly ignore calls to this method for usability reasons.

---

**Example**

For example, if the `blur()` method is unwisely being used to remove the focus ring for aesthetics reasons, the page would become unusable by keyboard users. Ignoring calls to this method would thus allow keyboard users to interact with the page.

---

### 6.5 Assigning keyboard shortcuts

#### 6.5.1 Introduction

This section is non-normative.

Each element that can be activated or focused can be assigned a single key combination to activate it, using the `accesskey` attribute.

The exact shortcut is determined by the user agent, based on information about the user's keyboard, what keyboard shortcuts already exist on the platform, and what other shortcuts have been specified on the page, using the information provided in the `accesskey` attribute as a guide.

In order to ensure that a relevant keyboard shortcut is available on a wide variety of input devices, the author can provide a number of alternatives in the `accesskey` attribute.

Each alternative consists of a single character, such as a letter or digit.

User agents can provide users with a list of the keyboard shortcuts, but authors are encouraged to do so also. The `accessKeyLabel` IDL attribute returns a string representing the actual key combination assigned by the user agent.

---

**Example**

In this example, an author has provided a button that can be invoked using a shortcut key. To support full keyboards, the author has provided "C" as a possible key. To support devices equipped only with numeric keypads, the author has provided "1" as another possibly key.

```html
<input type=button value=Collect onclick="collect()"
accesskey="C 1" id=c>
```
To tell the user what the shortcut key is, the author has this script here opted to explicitly add the key combination to the button’s label:

```javascript
function addShortcutKeyLabel(button) {
  if (button.accessKeyLabel != '')
    button.value += ' (' + button.accessKeyLabel + ')';
}
addShortcutKeyLabel(document.getElementById('c'));
```

Browsers on different platforms will show different labels, even for the same key combination, based on the convention prevalent on that platform. For example, if the key combination is the Control key, the Shift key, and the letter C, a Windows browser might display "Ctrl+Shift+C", whereas a Mac browser might display "^⇧C", while an Emacs browser might just display "C-C". Similarly, if the key combination is the Alt key and the Escape key, Windows might use "Alt+Esc", Mac might use "⌥⎋", and an Emacs browser might use "M-ESC" or "ESC ESC".

In general, therefore, it is unwise to attempt to parse the value returned from the `accessKeyLabel` IDL attribute.

### 6.5.2 The `accesskey` attribute

All HTML elements may have the `accesskey` content attribute set. The `accesskey` attribute’s value is used by the user agent as a guide for creating a keyboard shortcut that activates or focuses the element.

If specified, the value must be an ordered set of unique space-separated tokens that are case-sensitive, each of which must be exactly one code point in length.

In the following example, a variety of links are given with access keys so that keyboard users familiar with the site can more quickly navigate to the relevant pages:

```html
<nav>
  <p>
    <a title="Consortium Activities" accesskey="A" href="/Consortium/activities">Activities</a> | 
    <a title="Technical Reports and Recommendations" accesskey="T" href="/TR/">Technical Reports</a> | 
    <a title="Alphabetical Site Index" accesskey="S" href="/Consortium/siteindex">Site Index</a> | 
    <a title="About This Site" accesskey="B" href="/Consortium/">About Consortium</a> | 
    <a title="Contact Consortium" accesskey="C" href="/Consortium/contact">Contact</a>
  </p>
</nav>
```

In the following example, the search field is given two possible access keys, "s" and "0" (in that order). A user agent on a device with a full keyboard might pick Ctrl+Alt+S as the shortcut key, while a user agent on a small device with just a numeric keypad might pick just the plain unadorned key 0:

```html
<form action="/search">
  <label>Search: <input type="search" name="q" accesskey="s 0"></label>
  <input type="submit">
</form>
```
In the following example, a button has possible access keys described. A script then tries to update the button’s label to advertise the key combination the user agent selected.

```html
<input type='submit' accesskey='N @ 1' value='Compose'>

<script>
    function labelButton(button) {
        if (button.accessKeyLabel)
            button.value += ' (' + button.accessKeyLabel + ')';
    }
    var inputs = document.getElementsByTagName('input');
    for (var i = 0; i < inputs.length; i += 1) {
        if (inputs[i].type == "submit")
            labelButton(inputs[i]);
    }
</script>
```

On one user agent, the button’s label might become "Compose (⌘N)". On another, it might become "Compose (Alt+⇧+1)". If the user agent doesn’t assign a key, it will be just "Compose". The exact string depends on what the **assigned access key** is, and on how the user agent represents that key combination.

### 6.5.3 Processing model

An element’s **assigned access key** is a key combination derived from the element’s **accesskey** content attribute. Initially, an element must not have an **assigned access key**.

Whenever an element’s **accesskey** attribute is set, changed, or removed, the user agent must update the element’s **assigned access key** by running the following steps:

1. If the element has no **accesskey** attribute, then skip to the *fallback* step below.
2. Otherwise, *split the attribute’s value on ASCII whitespace*, and let *keys* be the resulting tokens.
3. For each value in *keys* in turn, in the order the tokens appeared in the attribute’s value, run the following substeps:
   1. If the value is not a string exactly one code point in length, then skip the remainder of these steps for this value.
   2. If the value does not correspond to a key on the system’s keyboard, then skip the remainder of these steps for this value.
   3. If the user agent can find a mix of zero or more modifier keys that, combined with the key that corresponds to the value given in the attribute, can be used as the access key, then the user agent may assign that combination of keys as the element’s **assigned access key** and return.

4. **Fallback**: Optionally, the user agent may assign a key combination of its choosing as the element’s **assigned access key** and then return.

5. If this step is reached, the element has no **assigned access key**.

Once a user agent has selected and assigned an access key for an element, the user agent should not change the element’s **assigned access key** unless the **accesskey** content attribute is changed or the element is moved to another Document.

When the user presses the key combination corresponding to the **assigned access key** for an element, if the element *defines a command*, the command’s **Hidden State** facet is false (visible), the command’s **Disabled State** facet is also false (enabled), the element is in a document that has a **browsing context**, and neither the element nor any of its ancestors has a **hidden** attribute specified, then the user agent must trigger the **Action** of the command.

---

**Note**

User agents *might expose* elements that have an **accesskey** attribute in other ways as well, e.g. in a menu displayed in...
The accessKey IDL attribute must reflect the accesskey content attribute.

The accessKeyLabel IDL attribute must return a string that represents the element's assigned access key, if any. If the element does not have one, then the IDL attribute must return the empty string.

6.6 Editing

6.6.1 Making document regions editable: The contenteditable content attribute

IDL interface mixin ElementContentEditable {
    [CEReactions] attribute DOMString contentEditable;
    readonly attribute boolean isContentEditable;
    [CEReactions] attribute DOMString inputMode;
};

The contenteditable content attribute is an enumerated attribute whose keywords are the empty string, true, and false. The empty string and the true keyword map to the true state. The false keyword maps to the false state. In addition, there is a third state, the inherit state, which is the missing value default and the invalid value default.

The true state indicates that the element is editable. The inherit state indicates that the element is editable if its parent is. The false state indicates that the element is not editable.

Example

For example, consider a page that has a form and a textarea to publish a new article, where the user is expected to write the article using HTML:

```html
<form method=POST>
    <fieldset>
        <legend>New article</legend>
        <textarea name=article>Hello world.</textarea>
    </fieldset>
    <p><button>Publish</button></p>
</form>
```

When scripting is enabled, the textarea element could be replaced with a rich text control instead, using the contenteditable attribute:

```html
<form method=POST>
    <fieldset>
        <legend>New article</legend>
        <textarea id=textarea name=article>Hello world.</textarea>
        <div id=div style="white-space: pre-wrap" hidden>Hello world.</div>
        <script>
            let textarea = document.getElementById("textarea");
            let div = document.getElementById("div");
            textarea.hidden = true;
            div.hidden = false;
            div.contentEditable = "true";
            div.oninput = (e) => {
                textarea.value = div.innerHTML;
            };
        </script>
    </fieldset>
```
The `contentEditable` IDL attribute, on getting, must return the string "$true" if the content attribute is set to the true state, "$false" if the content attribute is set to the false state, and "$inherit" otherwise. On setting, if the new value is an ASCII case-insensitive match for the string "$true" then the content attribute must be set to the string "$true", if the new value is an ASCII case-insensitive match for the string "$false" then the content attribute must be set to the string "$false", and otherwise the attribute setter must throw a "$SyntaxError": DOMException if the new value isn't one of those strings.

The `isContentEditable` IDL attribute, on getting, must return true if the element is editable; otherwise, returns false.

The `designMode` IDL attribute on the `Document` object takes two values, "on" and "off". On setting, the new value must be compared in an ASCII case-insensitive manner to these two values; if it matches the "on" value, then `designMode` must be enabled, and if it matches the "off" value, then `designMode` must be disabled. Other values must be ignored.
On getting, if `designMode` is enabled, the IDL attribute must return the value "on"; otherwise it is disabled, and the attribute must return the value "off".

The last state set must persist until the document is destroyed or the state is changed. Initially, documents must have their `designMode` disabled.

When the `designMode` changes from being disabled to being enabled, the user agent must immediately reset the document’s `active range`’s start and end boundary points to be at the start of the Document and then run the focusing steps for the `document element` of the Document, if non-null.

### 6.6.3 Best practices for in-page editors

Authors are encouraged to set the `white-space` property on editing hosts and on markup that was originally created through these editing mechanisms to the value 'pre-wrap'. Default HTML whitespace handling is not well suited to WYSIWYG editing, and line wrapping will not work correctly in some corner cases if 'white-space' is left at its default value.

As an example of problems that occur if the default 'normal' value is used instead, consider the case of the user typing "yellow␣␣ball", with two spaces (here represented by "␣") between the words. With the editing rules in place for the default value of 'white-space' ('normal'), the resulting markup will either consist of "yellow &nbsp; ball" or "yellow &nbsp; ball"; i.e., there will be a non-breaking space between the two words in addition to the regular space. This is necessary because the 'normal' value for 'white-space' requires adjacent regular spaces to be collapsed together.

In the former case, "yellow␣␣" might wrap to the next line ("␣␣" being used here to represent a non-breaking space) even though "yellow" alone might fit at the end of the line; in the latter case, "␣␣ball", if wrapped to the start of the line, would have visible indentation from the non-breaking space.

When 'white-space' is set to 'pre-wrap', however, the editing rules will instead simply put two regular spaces between the words, and should the two words be split at the end of a line, the spaces would be neatly removed from the rendering.

### 6.6.4 Editing APIs

The definition of the terms `active range`, `editing host`, `editing host of`, and `editable`, the user interface requirements of elements that are `editing hosts` or `editable`, the `execCommand()`, `queryCommandEnabled()`, `queryCommandIndeterm()`, `queryCommandState()`, `queryCommandSupported()`, and `queryCommandValue()` methods, text selections, and the `delete the selection` algorithm are defined in `execCommand`. [EXECCOMMAND]

### 6.6.5 Spelling and grammar checking

User agents can support the checking of spelling and grammar of editable text, either in form controls (such as the value of `textarea` elements), or in elements in an `editing host` (e.g. using `contenteditable`).

For each element, user agents must establish a default behavior, either through defaults or through preferences expressed by the user. There are three possible default behaviors for each element:

**true-by-default**

The element will be checked for spelling and grammar if its contents are editable and spellchecking is not explicitly disabled through the `spellcheck` attribute.

**false-by-default**

The element will never be checked for spelling and grammar unless spellchecking is explicitly enabled through the `spellcheck` attribute.

**inherit-by-default**

The element's default behavior is the same as its parent element's. Elements that have no parent element cannot have this as their
The `spellcheck` attribute is an enumerated attribute whose keywords are the empty string, `true` and `false`. The empty string and the `true` keyword map to the `true` state. The `false` keyword maps to the `false` state. In addition, there is a third state, the `default` state, which is the missing value default and the invalid value default.

**Note**

The true state indicates that the element is to have its spelling and grammar checked. The default state indicates that the element is to act according to a default behavior, possibly based on the parent element’s own `spellcheck` state, as defined below. The false state indicates that the element is not to be checked.

**For web developers (non-normative)**

```
(element).spellcheck[ = value ]
```

Returns true if the element is to have its spelling and grammar checked; otherwise, returns false.

Can be set, to override the default and set the `spellcheck` content attribute.

The `spellcheck` IDL attribute, on getting, must return true if the element’s `spellcheck` content attribute is in the `true` state, or if the element’s `spellcheck` content attribute is in the `default` state and the element’s `default behavior` is `true-by-default`, or if the element’s `spellcheck` content attribute is in the `default` state and the element’s `default behavior` is `inherit-by-default` and the element’s parent element’s `spellcheck` IDL attribute would return true; otherwise, if none of those conditions applies, then the attribute must instead return false.

**Note**

The `spellcheck` IDL attribute is not affected by user preferences that override the `spellcheck` content attribute, and therefore might not reflect the actual spellchecking state.

On setting, if the new value is true, then the element’s `spellcheck` content attribute must be set to the literal string "true", otherwise it must be set to the literal string "false".

User agents must only consider the following pieces of text as checkable for the purposes of this feature:

- The `value` of `input` elements whose `type` attributes are in the `Text`, `Search`, `URL`, or `E-mail` states and that are `mutable` (i.e. that do not have the `readonly` attribute specified and that are not `disabled`).
- The `value` of `textarea` elements that do not have a `readonly` attribute and that are not `disabled`.
- Text in `Text` nodes that are children of `editing hosts` or `editable` elements.
- Text in attributes of `editable` elements.

For text that is part of a `Text` node, the element with which the text is associated is the element that is the immediate parent of the first character of the word, sentence, or other piece of text. For text in attributes, it is the attribute’s element. For the values of `input` and `textarea` elements, it is the element itself.

To determine if a word, sentence, or other piece of text in an applicable element (as defined above) is to have spelling- and grammar-checking enabled, the UA must use the following algorithm:

1. If the user has disabled the checking for this text, then the checking is disabled.
2. Otherwise, if the user has forced the checking for this text to always be enabled, then the checking is enabled.
3. Otherwise, if the element with which the text is associated has a `spellcheck` content attribute, then: if that attribute is in the true state, then checking is enabled; otherwise, if that attribute is in the false state, then checking is disabled.
4. Otherwise, if there is an ancestor element with a `spellcheck` content attribute that is not in the `default` state, then: if the nearest such ancestor’s `spellcheck` content attribute is in the true state, then checking is enabled; otherwise, checking is disabled.
5. Otherwise, if the element’s `default behavior` is `true-by-default`, then checking is enabled.
6. Otherwise, if the element's default behavior is false-by-default, then checking is disabled.

7. Otherwise, if the element's parent element has its checking enabled, then checking is enabled.

8. Otherwise, checking is disabled.

If the checking is enabled for a word/sentence/text, the user agent should indicate spelling and grammar errors in that text. User agents should take into account the other semantics given in the document when suggesting spelling and grammar corrections. User agents may use the language of the element to determine what spelling and grammar rules to use, or may use the user's preferred language settings. UAs should use input element attributes such as pattern to ensure that the resulting value is valid, where possible.

If checking is disabled, the user agent should not indicate spelling or grammar errors for that text.

Example

The element with ID "a" in the following example would be the one used to determine if the word "Hello" is checked for spelling errors. In this example, it would not be.

```
<div contenteditable="true">
  <span spellcheck="false" id="a">Hell</span><em>o!</em>
</div>
```

The element with ID "b" in the following example would have checking enabled (the leading space character in the attribute's value on the input element causes the attribute to be ignored, so the ancestor's value is used instead, regardless of the default).

```
<p spellcheck="true">
  <label>Name: <input spellcheck="false" id="b"></label>
</p>
```

Note

This specification does not define the user interface for spelling and grammar checkers. A user agent could offer on-demand checking, could perform continuous checking while the checking is enabled, or could use other interfaces.

6.6.6 Autocapitalization

Some methods of entering text, for example virtual keyboards on mobile devices, and also voice input, often assist users by automatically capitalizing the first letter of sentences (when composing text in a language with this convention). A virtual keyboard that implements autocapitalization might automatically switch to showing uppercase letters (but allow the user to toggle it back to lowercase) when a letter that should be autocapitalized is about to be typed. Other types of input, for example voice input, may perform autocapitalization in a way that does not give users an option to intervene first. The autocapitalize attribute allows authors to control such behavior.

The autocapitalize attribute, as typically implemented, does not affect behavior when typing on a physical keyboard. (For this reason, as well as the ability for users to override the autocapitalization behavior in some cases or edit the text after initial input, the attribute must not be relied on for any sort of input validation.)

The autocapitalize attribute can be used on an editing host to control autocapitalization behavior for the hosted editable region, on an input or textarea element to control the behavior for inputting text into that element, or on a form element to control the default behavior for all autocapitalize-inheriting elements associated with the form element.

The autocapitalize attribute never causes autocapitalization to be enabled for input elements whose type attribute is in one of the URI, E-mail, or Password states. (This behavior is included in the used autocapitalization hint algorithm below.)

The autocapitalization processing model is based on selecting among five autocapitalization hints, defined as follows:

**default**

The user agent and input method should use make their own determination of whether or not to enable autocapitalization.
None
No autocapitalization should be applied (all letters should default to lowercase).

Sentences
The first letter of each sentence should default to a capital letter; all other letters should default to lowercase.

Words
The first letter of each word should default to a capital letter; all other letters should default to lowercase.

Characters
All letters should default to uppercase.

The autocapitalize attribute is an enumerated attribute whose states are the possible autocapitalization hints. The autocapitalization hint specified by the attribute’s state combines with other considerations to form the used autocapitalization hint, which informs the behavior of the user agent. The keywords for this attribute and their state mappings are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>none</td>
</tr>
<tr>
<td>none</td>
<td>none</td>
</tr>
<tr>
<td>on</td>
<td>sentences</td>
</tr>
<tr>
<td>sentences</td>
<td>words</td>
</tr>
<tr>
<td>words</td>
<td>characters</td>
</tr>
<tr>
<td>characters</td>
<td></td>
</tr>
</tbody>
</table>

The invalid value default is the sentences state. The missing value default is the default state.

For web developers (non-normative)

```
  element.autocapitalize [ = value ]
```

Returns the current autocapitalization state for the element, or an empty string if it hasn't been set. Note that for input and textarea elements that inherit their state from a form element, this will return the autocapitalization state of the form element, but for an element in an editable region, this will not return the autocapitalization state of the editing host (unless this element is, in fact, the editing host).

Can be set, to set the autocapitalize content attribute (and thereby change the autocapitalization behavior for the element).

To compute the own autocapitalization hint of an element element, run the following steps:

1. If the autocapitalize content attribute is present on element, and its value is not the empty string, return the state of the attribute.
2. If element is an autocapitalize-inheriting element and has a non-null form owner, return the own autocapitalization hint of element's form owner.
3. Return default.

The autocapitalize IDL attribute, on getting, must return the string value corresponding to own autocapitalization hint of the element, with the exception that the default state maps to the empty string. On setting, it must set the autocapitalize content attribute to the given new value.

User agents that support customizable autocapitalization behavior for a text input method and wish to allow web developers to control this functionality should, during text input into an element, compute the used autocapitalization hint for the element. This will be an autocapitalization hint that describes the recommended autocapitalization behavior for text input into the element.

User agents or input methods may choose to ignore or override the used autocapitalization hint in certain circumstances.

The used autocapitalization hint for an element element is computed using the following algorithm:

1. If element is an input element whose type attribute is in one of the URL, E-mail, or Password states, then return default.
2. If element is an `input` element or a `textarea` element, then return element's own autocapitalization hint.

3. If element is an `editing host` or an `editable` element, then return the own autocapitalization hint of the editing host of element.

4. Assert: this step is never reached, since text input only occurs in elements that meet one of the above criteria.

6.6.7 Input modalities: the `inputmode` attribute

User agents can support the `inputmode` attribute on form controls (such as the value of `textarea` elements), or in elements in an `editing host` (e.g., using `contenteditable`).

The `inputmode` content attribute is an enumerated attribute that specifies what kind of input mechanism would be most helpful for users entering content.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>The user agent should not display a virtual keyboard. This keyword is useful for content that renders its own keyboard control.</td>
</tr>
<tr>
<td>text</td>
<td>The user agent should display a virtual keyboard capable of text input in the user's locale.</td>
</tr>
<tr>
<td>tel</td>
<td>The user agent should display a virtual keyboard capable of telephone number input. This should include keys for the digits 0 to 9, the “#” character, and the “*” character. In some locales, this can also include alphabetic mnemonic labels (e.g., in the US, the key labeled “2” is historically also labeled with the letters A, B, and C).</td>
</tr>
<tr>
<td>url</td>
<td>The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of URLs, such as that for the “/” and “.” characters and for quick input of strings commonly found in domain names such as “www.” or “.com”.</td>
</tr>
<tr>
<td>email</td>
<td>The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of e-mail addresses, such as that for the “@” character and the “.” character.</td>
</tr>
<tr>
<td>numeric</td>
<td>The user agent should display a virtual keyboard capable of numeric input. This keyword is useful for PIN entry.</td>
</tr>
<tr>
<td>decimal</td>
<td>The user agent should display a virtual keyboard capable of fractional numeric input. Numeric keys and the format separator for the locale should be shown.</td>
</tr>
<tr>
<td>search</td>
<td>The user agent should display a virtual keyboard optimized for search.</td>
</tr>
</tbody>
</table>

The `inputMode` IDL attribute must reflect the `inputmode` content attribute, limited to only known values.

When `inputmode` is unspecified (or is in a state not supported by the user agent), the user agent should determine the default virtual keyboard to be shown. Contextual information such as the input `type` or `pattern` attributes should be used to determine which type of virtual keyboard should be presented to the user.

6.7 Drag and drop

This section defines an event-based drag-and-drop mechanism.

This specification does not define exactly what a drag-and-drop operation actually is.

On a visual medium with a pointing device, a drag operation could be the default action of a `mousedown` event that is followed by a series of `mousemove` events, and the drop could be triggered by the mouse being released.

When using an input modality other than a pointing device, users would probably have to explicitly indicate their intention to perform a drag-and-drop operation, stating what they wish to drag and where they wish to drop it, respectively.

However it is implemented, drag-and-drop operations must have a starting point (e.g. where the mouse was clicked, or the start of the selection or element that was selected for the drag), may have any number of intermediate steps (elements that the mouse moves over during a drag, or elements that the user picks as possible drop points as they cycle through possibilities), and must either have an end point (the element above which the mouse button was released, or the element that was finally selected), or be canceled. The end point must be the last element selected as a possible drop point before the drop occurs (so if the operation is not canceled, there must be at least one element in the middle step).
To make an element draggable, give the element a `draggable` attribute, and set an event listener for `dragstart` that stores the data being dragged.

The event handler typically needs to check that it’s not a text selection that is being dragged, and then needs to store data into the `DataTransfer` object and set the allowed effects (copy, move, link, or some combination).

For example:

```html
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)"
    ondragover="dragOverHandler(event)"
    ondrop="dropHandler(event)"
</ol>
<script>
    var internalDNDType = 'text/x-example'; // set this to something specific to your site
    function dragStartHandler(event) {
        if (event.target instanceof HTMLLIElement) {
            // use the element's data-value="" attribute as the value to be moving:
            event.dataTransfer.setData(internalDNDType, event.target.dataset.value);
            event.dataTransfer.effectAllowed = 'move'; // only allow moves
        } else {
            event.preventDefault(); // don't allow selection to be dragged
        }
    }
</script>
```

To accept a drop, the drop target has to listen to the following events:

1. The `dragenter` event handler reports whether or not the drop target is potentially willing to accept the drop, by canceling the event.
2. The `dragover` event handler specifies what feedback will be shown to the user, by setting the `dropEffect` attribute of the `DataTransfer` associated with the event. This event also needs to be canceled.
3. The `drop` event handler has a final chance to accept or reject the drop. If the drop is accepted, the event handler must perform the drop operation on the target. This event needs to be canceled, so that the `dropEffect` attribute's value can be used by the source. Otherwise, the drop operation is rejected.

For example:

```html
<p>Drop your favorite fruits below:</p>
<ol ondragenter="dragEnterHandler(event)"
    ondragover="dragOverHandler(event)"
    ondrop="dropHandler(event)"
</ol>
<script>
    var internalDNDType = 'text/x-example'; // set this to something specific to your site
    function dragEnterHandler(event) {
        var items = event.dataTransfer.items;
        for (var i = 0; i < items.length; ++i) {
            var item = items[i];
            if (item.kind === 'string' && item.type === internalDNDType) {
                event.preventDefault();
                return;
            }
        }
    }
    function dragOverHandler(event) {
```
To remove the original element (the one that was dragged) from the display, the `dragend` event can be used.

For our example here, that means updating the original markup to handle that event:

```html
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)" ondragend="dragEndHandler(event)"
    ...as before...
</ol>

<script>
    function dragStartHandler(event) {
        // ...as before...
    }
    function dragEndHandler(event) {
        if (event.dataTransfer.dropEffect == 'move') {
            // remove the dragged element
            event.target.parentNode.removeChild(event.target);
        }
    }
</script>
```

### 6.7.2 The drag data store

The data that underlies a drag-and-drop operation, known as the **drag data store**, consists of the following information:

- A **drag data store item list**, which is a list of items representing the dragged data, each consisting of the following information:

  - **The drag data item kind**
    - The kind of data:
      - **Plain Unicode string**
        - Text.
      - **File**
        - Binary data with a file name.

  - **The drag data item type string**
    - A Unicode string giving the type or format of the data, generally given by a MIME type. Some values that are not MIME types are special-cased for legacy reasons. The API does not enforce the use of MIME types; other values can be used as well. In all cases, however, the values are all converted to ASCII lowercase by the API.
There is a limit of one Plain Unicode string item per item type string.

The actual data
A Unicode or binary string, in some cases with a file name (itself a Unicode string), as per the drag data item kind.

The drag data store item list is ordered in the order that the items were added to the list; most recently added last.

- The following information, used to generate the UI feedback during the drag:
  - User-agent-defined default feedback information, known as the drag data store default feedback.
  - Optionally, a bitmap image and the coordinate of a point within that image, known as the drag data store bitmap and drag data store hot spot coordinate.

- A drag data store mode, which is one of the following:
  - **Read/write mode**
    For the dragstart event. New data can be added to the drag data store.
  - **Read-only mode**
    For the drop event. The list of items representing dragged data can be read, including the data. No new data can be added.
  - **Protected mode**
    For all other events. The formats and kinds in the drag data store list of items representing dragged data can be enumerated, but the data itself is unavailable and no new data can be added.

- A drag data store allowed effects state, which is a string.

When a drag data store is created, it must be initialized such that its drag data store item list is empty, it has no drag data store default feedback, it has no drag data store bitmap and drag data store hot spot coordinate, its drag data store mode is protected mode, and its drag data store allowed effects state is the string "uninitialized".

6.7.3 The DataTransfer interface

DataTransfer objects are used to expose the drag data that underlies a drag-and-drop operation.

```
IDL [Exposed=Window, Constructor]
interface DataTransfer {
    attribute DOMString dropEffect;
    attribute DOMString effectAllowed;

    [SameObject] readonly attribute DataTransferItemList items;

    void setDragImage(Element image, long x, long y);

    /* old interface */
    readonly attribute FrozenArray<DOMString> types;
    DOMString getData(DOMString format);
    void setData(DOMString format, DOMString data);
    void clearData(optional DOMString format);
    [SameObject] readonly attribute FileList files;
};
```

For web developers (non-normative)
```
dataTransfer = new DataTransfer()
```

Creates a new DataTransfer object with an empty drag data store.
DataTransfer\.__dropEffect\[ = value \]
Returns the kind of operation that is currently selected. If the kind of operation isn’t one of those that is allowed by the effectAllowed\[ attribute, then the operation will fail.
Can be set, to change the selected operation.
The possible values are "\.none\", "copy\", "link\", and "move\".

DataTransfer\.__effectAllowed\[ = value \]
Returns the kinds of operations that are to be allowed.
Can be set (during the dragstart\[ event), to change the allowed operations.
The possible values are "\.none\", "copy\", "copyLink\", "copyMove\", "link\", "linkMove\", "move\", "all\", and "uninitialized\".

DataTransfer\.__items\]
Returns a DataTransferItemList\ object, with the drag data.

DataTransfer\.__setDragImage\(\(element, x, y\)\)
Uses the given element to update the drag feedback, replacing any previously specified feedback.

DataTransfer\.__types\]
Returns a frozen array listing the formats that were set in the dragstart\[ event. In addition, if any files are being dragged, then one of the types will be the string "Files".

\(data = dataTransfer\.__getDragData\(\(format\)\)
Returns the specified data. If there is no such data, returns the empty string.

DataTransfer\.__setData\(\(format, data\)\)
Adds the specified data.

DataTransfer\.__clearData\[\(\{\ format \}\)\]
Removes the data of the specified formats. Removes all data if the argument is omitted.

DataTransfer\.__files\]
Returns a FileList of the files being dragged, if any.

DataTransfer\ objects that are created as part of drag-and-drop events\ are only valid while those events are being fired.

A DataTransfer\ object is associated with a drag data store while it is valid.

A DataTransfer\ object has an associated types array, which is a FrozenArray\<DOMString\>, initially empty. When the contents of the DataTransfer\ object’s drag data store item list change, or when the DataTransfer\ object becomes no longer associated with a drag data store, run the following steps:

1. Let L be an empty sequence.
2. If the DataTransfer\ object is still associated with a drag data store, then:
   1. For each item in the DataTransfer\ object’s drag data store item list whose kind is Plain Unicode string, add an entry to L consisting of the item’s type string.
   2. If there are any items in the DataTransfer\ object’s drag data store item list whose kind is File, then add an entry to L consisting of the string "Files". (This value can be distinguished from the other values because it is not lowercase.)
3. Set the DataTransfer\ object’s types array to the result of creating a frozen array from L.

The DataTransfer\ constructor, when invoked, must return a newly created DataTransfer\ object initialized as follows:

1. Set the drag data store’s item list to be an empty list.
2. Set the drag data store's mode to read/write.

3. Set the dropEffect and effectAllowed to "none".

The dropEffect attribute controls the drag-and-drop feedback that the user is given during a drag-and-drop operation. When the DataTransfer object is created, the dropEffect attribute is set to a string value. On getting, it must return its current value. On setting, if the new value is one of "none", "copy", "link", or "move", then the attribute's current value must be set to the new value. Other values must be ignored.

The effectAllowed attribute is used in the drag-and-drop processing model to initialize the dropEffect attribute during the dragenter and dragover events. When the DataTransfer object is created, the effectAllowed attribute is set to a string value. On getting, it must return its current value. On setting, if drag data store's mode is the read/write mode and the new value is one of "none", "copy", "copyLink", "copyMove", "link", "linkMove", "move", "all", or "uninitialized", then the attribute's current value must be set to the new value. Otherwise it must be left unchanged.

The items attribute must return a DataTransferItemList object associated with the DataTransfer object.

The setDragImage(element, x, y) method must run the following steps:

1. If the DataTransfer object is no longer associated with a drag data store, return. Nothing happens.
2. If the drag data store's mode is not the read/write mode, return. Nothing happens.
3. If element is an img element, then set the drag data store bitmap to the element's image (at its intrinsic size); otherwise, set the drag data store bitmap to an image generated from the given element (the exact mechanism for doing so is not currently specified).
4. Set the drag data store hot spot coordinate to the given x, y coordinate.

The types attribute must return this DataTransfer object's types array.

The getData(format) method must run the following steps:

1. If the DataTransfer object is no longer associated with a drag data store, then return the empty string.
2. If the drag data store's mode is the protected mode, then return the empty string.
3. Let format be the first argument, converted to ASCII lowercase.
4. Let convert-to-URL be false.
5. If format equals "text", change it to "text/plain".
6. If format equals "url", change it to "text/uri-list" and set convert-to-URL to true.
7. If there is no item in the drag data store item list whose kind is Plain Unicode string and whose type string is equal to format, return the empty string.
8. Let result be the data of the item in the drag data store item list whose kind is Plain Unicode string and whose type string is equal to format.
9. If convert-to-URL is true, then parse result as appropriate for text/uri-list data, and then set result to the first URL from the list, if any, or the empty string otherwise. [RFC2483]
10. Return result.

The setData(format, data) method must run the following steps:

1. If the DataTransfer object is no longer associated with a drag data store, return. Nothing happens.
2. If the drag data store's mode is not the read/write mode, return. Nothing happens.
3. Let format be the first argument, converted to ASCII lowercase.
4. If format equals "text", change it to "text/plain".
   If format equals "url", change it to "text/uri-list".
5. Remove the item in the drag data store item list whose kind is Plain Unicode string and whose type string is equal
6. Add an item to the drag data store item list whose kind is Plain Unicode string, whose type string is equal to format, and whose data is the string given by the method’s second argument.

The clearData() method must run the following steps:

1. If the DataTransfer object is no longer associated with a drag data store, return. Nothing happens.
2. If the drag data store’s mode is not the read/write mode, return. Nothing happens.
3. If the method was called with no arguments, remove each item in the drag data store item list whose kind is Plain Unicode string, and whose type string is equal to format, if there is one.
4. Let format be the first argument, converted to ASCII lowercase.
5. If format equals "text", change it to "text/plain".
6. Remove the item in the drag data store item list whose kind is Plain Unicode string and whose type string is equal to format, if there is one.

The files attribute must return a live FileList sequence consisting of File objects representing the files found by the following steps. Furthermore, for a given FileList object and a given underlying file, the same File object must be used each time.

1. Start with an empty list L.
2. If the DataTransfer object is no longer associated with a drag data store, the FileList is empty. Return the empty list L.
3. If the drag data store’s mode is the protected mode, Return the empty list L.
4. For each item in the drag data store item list whose kind is File, add the item’s data (the file, in particular its name and contents, as well as its type) to the list L.
5. The files found by these steps are those in the list L.

Note: This version of the API does not expose the types of the files during the drag.

6.7.3.1 The DataTransferItemList interface

Each DataTransfer object is associated with a DataTransferItemList object.

```idl
[Exposed=Window]
interface DataTransferItemList {
  readonly attribute unsigned long length;
  getter DataTransferItem (unsigned long index);
  DataTransferItem? add(DOMString data, DOMString type);
  DataTransferItem? add(File data);
  void remove(unsigned long index);
  void clear();
};
```

For web developers (non-normative)

items . length

Returns the number of items in the drag data store.
**items[index]**

Returns the DataTransferItem object representing the indexth entry in the drag data store.

**items.remove(index)**

Removes the indexth entry in the drag data store.

**items.clear()**

Removes all the entries in the drag data store.

**items.add(data)**

Adds a new entry for the given data to the drag data store. If the data is plain text then a type string has to be provided also.

While the DataTransferItemList object's DataTransfer object is associated with a drag data store, the DataTransferItemList object's mode is the same as the drag data store mode. When the DataTransferItemList object's DataTransfer object is not associated with a drag data store, the DataTransferItemList object's mode is the disabled mode. The drag data store referenced in this section (which is used only when the DataTransferItemList object is not in the disabled mode) is the drag data store with which the DataTransferItemList object's DataTransfer object is associated.

The length attribute must return zero if the object is in the disabled mode; otherwise it must return the number of items in the drag data store item list.

When a DataTransferItemList object is not in the disabled mode, its supported property indices are the numbers in the range 0..n-1, where n is the number of items in the drag data store item list.

To determine the value of an indexed property of a DataTransferItemList object, the user agent must return a DataTransferItem object representing the ith item in the drag data store. The same object must be returned each time a particular item is obtained from this DataTransferItemList object. The DataTransferItem object must be associated with the same DataTransfer object as the DataTransferItemList object when it is first created.

The add() method must run the following steps:

1. If the DataTransferItemList object is not in the read/write mode, return null.
2. Jump to the appropriate set of steps from the following list:
   - **If the first argument to the method is a string**
     - If there is already an item in the drag data store item list whose kind is Plain Unicode string and whose type string is equal to the value of the method's second argument, converted to ASCII lowercase, then throw a "NotSupportedError" DOMException.
     - Otherwise, add an item to the drag data store item list whose kind is Plain Unicode string, whose type string is equal to the value of the method's second argument, converted to ASCII lowercase, and whose data is the string given by the method's first argument.
   - **If the first argument to the method is a File**
     - Add an item to the drag data store item list whose kind is File, whose type string is the type of the File, converted to ASCII lowercase, and whose data is the same as the File's data.
     - Determine the value of the indexed property corresponding to the newly added item, and return that value (a newly created DataTransferItem object).

The remove() method, when invoked with the argument i, must run these steps:

1. If the DataTransferItemList object is not in the read/write mode, throw an "InvalidStateError" DOMException.
2. Remove the ith item from the drag data store.

The clear() method, if the DataTransferItemList object is in the read/write mode, must remove all the items from the drag data store. Otherwise, it must do nothing.
Each `DataTransferItem` object is associated with a `DataTransfer` object.

```idl
[Exposed=Window]
interface DataTransferItem {
  readonly attribute DOMString kind;
  readonly attribute DOMString type;
  void getAsString(FunctionStringCallback? _callback);
  File? getAsFile();
};
```

**For web developers (non-normative)**

```
item . kind
  Returns the drag data item kind, one of: "string", "file".

item . type
  Returns the drag data item type string.

item . getAsString(callback)
  Invokes the callback with the string data as the argument, if the drag data item kind is Plain Unicode string.

file = item . getAsFile()
  Returns a File object, if the drag data item kind is File.
```

While the `DataTransferItem` object's `DataTransfer` object is associated with a `drag data store` and that `drag data store`'s `drag data store item list` still contains the item that the `DataTransferItem` object represents, the `DataTransferItem` object's `mode` is the same as the `drag data store mode`. When the `DataTransferItem` object's `DataTransfer` object is not associated with a `drag data store`, or if the item that the `DataTransferItem` object represents has been removed from the relevant `drag data store item list`, the `DataTransferItem` object's `mode` is the `disabled mode`. The `drag data store` referenced in this section (which is used only when the `DataTransferItem` object is not in the `disabled mode`) is the `drag data store`, with which the `DataTransferItem` object's `DataTransfer` object is associated.

The `kind` attribute must return the empty string if the `DataTransferItem` object is in the `disabled mode`; otherwise it must return the string given in the cell from the second column of the following table from the row whose cell in the first column contains the `drag data item kind` of the item represented by the `DataTransferItem` object:

<table>
<thead>
<tr>
<th>Kind</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plain Unicode string</td>
<td>&quot;string&quot;</td>
</tr>
<tr>
<td>File</td>
<td>&quot;file&quot;</td>
</tr>
</tbody>
</table>

The `type` attribute must return the empty string if the `DataTransferItem` object is in the `disabled mode`; otherwise it must return the `drag data item type string` of the item represented by the `DataTransferItem` object.

The `getAsString(callback)` method must run the following steps:

1. If the `callback` is null, return.
2. If the `DataTransferItem` object is not in the `read/write mode` or the `read-only mode`, return. The callback is never invoked.
3. If the `drag data item kind` is not `Plain Unicode string`, then return. The callback is never invoked.
4. Otherwise, `queue a task` to invoke `callback`, passing the actual data of the item represented by the `DataTransferItem` object as the argument.

The `getAsFile()` method must run the following steps:

1. If the `DataTransferItem` object is not in the `read/write mode` or the `read-only mode`, then return null.
2. If the drag data item kind is not File, then return null.

3. Return a new File object representing the actual data of the item represented by the DataTransferItem object.

6.7.4 The DragEvent interface

The drag-and-drop processing model involves several events. They all use the DragEvent interface.

```idl
[Exposed=Window,
 Constructor(DOMString type, optional DragEventInit eventInitDict)]
interface DragEvent : MouseEvent {
    readonly attribute DataTransfer? dataTransfer;
};

dictionary DragEventInit : MouseEventInit {
    DataTransfer? dataTransfer = null;
};
```

For web developers (non-normative)

event . dataTransfer

Returns the DataTransfer object for the event.

Note

Although, for consistency with other event interfaces, the DragEvent interface has a constructor, it is not particularly useful. In particular, there's no way to create a useful DataTransfer object from script, as DataTransfer objects have a processing and security model that is coordinated by the browser during drag-and-drops.

The dataTransfer attribute of the DragEvent interface must return the value it was initialized to. It represents the context information for the event.

When a user agent is required to fire a DND event named e at an element, using a particular drag data store, and optionally with a specific related target, the user agent must run the following steps:

1. Let dataDragStoreWasChanged be false.
2. If no specific related target was provided, set related target to null.
3. Let window be the Window object of the Document object of the specified target element.
4. If e is dragstart, then set the drag data store mode to the read/write mode and set dataDragStoreWasChanged to true.
   If e is drop, set the drag data store mode to the read-only mode.
5. Let dataTransfer be a newly created DataTransfer object associated with the given drag data store.
6. Set the effectAllowed attribute to the drag data store's drag data store allowed effects state.
7. Set the dropEffect attribute to "none" if e is dragstart, drag, dragexit, or dragleave; or to the value corresponding to the current drag operation if e is drop or dragend; and to a value based on the effectAllowed attribute's value and the drag-and-drop source, as given by the following table, otherwise (i.e. if e is dragenter or dragover):

<table>
<thead>
<tr>
<th>effectAllowed</th>
<th>dropEffect</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;none&quot;</td>
<td>&quot;none&quot;</td>
</tr>
<tr>
<td>&quot;copy&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
<tr>
<td>&quot;copyLink&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
<tr>
<td>&quot;copyMove&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
<tr>
<td>&quot;all&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
</tbody>
</table>

Note

For web developers (non-normative)

Although, for consistency with other event interfaces, the DragEvent interface has a constructor, it is not particularly useful. In particular, there's no way to create a useful DataTransfer object from script, as DataTransfer objects have a processing and security model that is coordinated by the browser during drag-and-drops.

The dataTransfer attribute of the DragEvent interface must return the value it was initialized to. It represents the context information for the event.

When a user agent is required to fire a DND event named e at an element, using a particular drag data store, and optionally with a specific related target, the user agent must run the following steps:

1. Let dataDragStoreWasChanged be false.
2. If no specific related target was provided, set related target to null.
3. Let window be the Window object of the Document object of the specified target element.
4. If e is dragstart, then set the drag data store mode to the read/write mode and set dataDragStoreWasChanged to true.
   If e is drop, set the drag data store mode to the read-only mode.
5. Let dataTransfer be a newly created DataTransfer object associated with the given drag data store.
6. Set the effectAllowed attribute to the drag data store's drag data store allowed effects state.
7. Set the dropEffect attribute to "none" if e is dragstart, drag, dragexit, or dragleave; or to the value corresponding to the current drag operation if e is drop or dragend; and to a value based on the effectAllowed attribute's value and the drag-and-drop source, as given by the following table, otherwise (i.e. if e is dragenter or dragover):

<table>
<thead>
<tr>
<th>effectAllowed</th>
<th>dropEffect</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;none&quot;</td>
<td>&quot;none&quot;</td>
</tr>
<tr>
<td>&quot;copy&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
<tr>
<td>&quot;copyLink&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
<tr>
<td>&quot;copyMove&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
<tr>
<td>&quot;all&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
</tbody>
</table>
When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent’s purview.

1. Determine what is being dragged, as follows:

   If the drag operation was invoked on a selection, then it is the selection that is being dragged.

   Otherwise, if the drag operation was invoked on a document, it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute `droaggable` set to true. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.

   Otherwise, the drag operation was invoked outside the user agent’s purview. What is being dragged is defined by the document or application where the drag was started.

### 6.7.5 Processing model

When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent’s purview.

1. Determine what is being dragged, as follows:

   If the drag operation was invoked on a selection, then it is the selection that is being dragged.

   Otherwise, if the drag operation was invoked on a `Document`, it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute `draggable` set to true. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.

   Otherwise, the drag operation was invoked outside the user agent’s purview. What is being dragged is defined by the document or application where the drag was started.

<table>
<thead>
<tr>
<th><code>effectAllowed</code></th>
<th><code>dropEffect</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;move&quot;</td>
<td>&quot;move&quot;</td>
</tr>
<tr>
<td>&quot;link&quot;</td>
<td>&quot;link&quot;</td>
</tr>
<tr>
<td>&quot;linkMove&quot;</td>
<td>&quot;link&quot;, or, if appropriate &quot;move&quot;</td>
</tr>
<tr>
<td>&quot;move&quot;</td>
<td>&quot;move&quot;</td>
</tr>
<tr>
<td>&quot;initialized&quot;</td>
<td>&quot;move&quot;, or, if appropriate either &quot;copy&quot; or &quot;move&quot;</td>
</tr>
<tr>
<td>&quot;initialized&quot;</td>
<td>&quot;move&quot;, or, if appropriate either &quot;link&quot; or &quot;move&quot;</td>
</tr>
<tr>
<td>&quot;initialized&quot;</td>
<td>&quot;move&quot;, or, if appropriate either &quot;link&quot; or &quot;move&quot;</td>
</tr>
<tr>
<td>Any other case</td>
<td>&quot;copy&quot;, or, if appropriate either &quot;link&quot; or &quot;move&quot;</td>
</tr>
</tbody>
</table>

Where the table above provides **possibly appropriate alternatives**, user agents may instead use the listed alternative values if platform conventions dictate that the user has requested those alternate effects.

---

**Example**

For example, Windows platform conventions are such that dragging while holding the "alt" key indicates a preference for linking the data, rather than moving or copying it. Therefore, on a Windows system, if "link" is an option according to the table above while the "alt" key is depressed, the user agent could select that instead of "copy" or "move".

---

6.7.5 Processing model

When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent’s purview.

1. Determine what is being dragged, as follows:

   If the drag operation was invoked on a selection, then it is the selection that is being dragged.

   Otherwise, if the drag operation was invoked on a `Document`, it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute `draggable` set to true. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.

   Otherwise, the drag operation was invoked outside the user agent’s purview. What is being dragged is defined by the document or application where the drag was started.

---

**Note**

`img` elements and `a` elements with an `href` attribute have their `draggable` attribute set to true by default.
2. Create a drag data store. All the DND events fired subsequently by the steps in this section must use this drag data store.

3. Establish which DOM node is the source node, as follows:
   - If it is a selection that is being dragged, then the source node is the Text node that the user started the drag on (typically the Text node that the user originally clicked). If the user did not specify a particular node, for example if the user just told the user agent to begin a drag of “the selection”, then the source node is the first Text node containing a part of the selection.
   - Otherwise, if it is an element that is being dragged, then the source node is the element that is being dragged.
   - Otherwise, the source node is part of another document or application. When this specification requires that an event be dispatched at the source node in this case, the user agent must instead follow the platform-specific conventions relevant to that situation.

4. Determine the list of dragged nodes, as follows:
   - If it is a selection that is being dragged, then the list of dragged nodes contains, in tree order, every node that is partially or completely included in the selection (including all their ancestors).
   - Otherwise, the list of dragged nodes contains only the source node, if any.

5. If it is a selection that is being dragged, then add an item to the drag data store item list, with its properties set as follows:
   - The drag data item type string
     - text/plain
   - The drag data item kind
     - Plain Unicode string
   - The actual data
     - The text of the selection
   - Otherwise, if any files are being dragged, then add one item per file to the drag data store item list, with their properties set as follows:
     - The drag data item type string
       - The MIME type of the file, if known, or "application/octet-stream" otherwise.
     - The drag data item kind
       - File
     - The actual data
       - The file's contents and name.

6. If the list of dragged nodes is not empty, then extract the microdata from those nodes into a JSON form, and add one item to the drag data store item list, with its properties set as follows:
   - The drag data item type string
     - application/microdata+json

Note: Multiple events are fired on the source node during the course of the drag-and-drop operation.

Note: Dragging files can currently only happen from outside a browsing context, for example from a file system manager application.

User agents may also add one or more items representing the selection or dragged element(s) in other forms, e.g. as HTML.

If the drag initiated outside of the application, the user agent must add items to the drag data store item list as appropriate for the data being dragged, honoring platform conventions where appropriate; however, if the platform conventions do not use MIME types to label dragged data, the user agent must make a best-effort attempt to map the types to MIME types, and, in any case, all the drag data item type strings must be converted to ASCII lowercase.
The drag data item kind
Plain Unicode string

The actual data
The resulting JSON string.

7. Run the following substeps:

1. Let urls be an empty list of absolute URLs.
2. For each node in the list of dragged nodes:
   - If the node is an `a` element with an `href` attribute
     Add to urls the result of parsing the element's `href` content attribute relative to the element's node document.
   - If the node is an `img` element with a `src` attribute
     Add to urls the result of parsing the element's `src` content attribute relative to the element's node document.
3. If urls is still empty, then return.
4. Let url string be the result of concatenating the strings in urls, in the order they were added, separated by a U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF).
5. Add one item to the drag data store item list, with its properties set as follows:

<table>
<thead>
<tr>
<th>The drag data item type string</th>
<th>text/uri-list</th>
</tr>
</thead>
<tbody>
<tr>
<td>The drag data item kind</td>
<td>Plain Unicode string</td>
</tr>
</tbody>
</table>

The actual data
url string

8. Update the drag data store default feedback as appropriate for the user agent (if the user is dragging the selection, then the selection would likely be the basis for this feedback; if the user is dragging an element, then that element's rendering would be used; if the drag began outside the user agent, then the platform conventions for determining the drag feedback should be used).

9. Fire a DND event named dragstart at the source node.

If the event is canceled, then the drag-and-drop operation should not occur; return.

**Note:** Since events with no event listeners registered are, almost by definition, never canceled, drag-and-drop is always available to the user if the author does not specifically prevent it.

10. Initiate the drag-and-drop operation in a manner consistent with platform conventions, and as described below.

The drag-and-drop feedback must be generated from the first of the following sources that is available:

1. The drag data store bitmap, if any. In this case, the drag data store hot spot coordinate should be used as hints for where to put the cursor relative to the resulting image. The values are expressed as distances in CSS pixels from the left side and from the top side of the image respectively. [CSS]
2. The drag data store default feedback.

From the moment that the user agent is to initiate the drag-and-drop operation, until the end of the drag-and-drop operation, device input events (e.g. mouse and keyboard events) must be suppressed.

During the drag operation, the element directly indicated by the user as the drop target is called the immediate user selection. (Only elements can be selected by the user; other nodes must not be made available as drop targets.) However, the immediate user selection is not necessarily the current target element, which is the element currently selected for the drop part of the drag-and-drop operation.

The immediate user selection changes as the user selects different elements (either by pointing at them with a pointing device, or
by selecting them in some other way). The current target element changes when the immediate user selection changes, based on the results of event listeners in the document, as described below.

Both the current target element and the immediate user selection can be null, which means no target element is selected. They can also both be elements in other (DOM-based) documents, or other (non-Web) programs altogether. (For example, a user could drag text to a word-processor.) The current target element is initially null.

In addition, there is also a current drag operation, which can take on the values "none", "copy", "link", and "move". Initially, it has the value "none". It is updated by the user agent as described in the steps below.

User agents must, as soon as the drag operation is initiated, and every 350ms (±200ms) thereafter for as long as the drag operation is ongoing, queue a task to perform the following steps in sequence:

1. If the user agent is still performing the previous iteration of the sequence (if any) when the next iteration becomes due, return for this iteration (effectively "skipping missed frames" of the drag-and-drop operation).

2. Fire a DND event, named drag at the source node. If this event is canceled, the user agent must set the current drag operation to "none" (no drag operation).

3. If the drag event was not canceled and the user has not ended the drag-and-drop operation, check the state of the drag-and-drop operation, as follows:
   
   1. If the user is indicating a different immediate user selection than during the last iteration (or if this is the first iteration), and if this immediate user selection is not the same as the current target element, then fire a DND event, named dragexit at the current target element, and then update the current target element as follows:
      
      → If the new immediate user selection is null
        Set the current target element to null also.

      → If the new immediate user selection is in a non-DOM document or application
        Set the current target element to the immediate user selection.

      → Otherwise
        Fire a DND event named dragenter at the immediate user selection.

        If the event is canceled, then set the current target element to the immediate user selection.

      Otherwise, run the appropriate step from the following list:

      → If the immediate user selection is a text control (e.g., textarea, or an input element whose type attribute is in the Text state) or an editing host or editable element, and the drag data store item list has an item with the drag data item type string "text/plain" and the drag data item kind Plain Unicode string
        Set the current target element to the immediate user selection anyway.

      → If the immediate user selection is the body element
        Leave the current target element unchanged.

      → Otherwise
        Fire a DND event named dragenter at the body element, if there is one, or at the Document object, if not. Then, set the current target element to the body element, regardless of whether that event was canceled or not.

   2. If the previous step caused the current target element to change, and if the previous target element was not null or a part of a non-DOM document, then fire a DND event named dragleave at the previous target element, with the new current target element as the specific related target.  

   3. If the current target element is a DOM element, then fire a DND event named dragover at this current target element.

   If the dragover event is not canceled, run the appropriate step from the following list:

   → If the current target element is a text control (e.g., textarea, or an input element whose type attribute is in the Text state) or an editing host or editable element, and the drag data
store item list has an item with the drag data item type string 
and the drag data item kind Plain Unicode string

Set the current drag operation to either "copy" or "move", as appropriate given the platform conventions.

Otherwise

Reset the current drag operation to "none".

Otherwise (if the dragover event is canceled), set the current drag operation based on the values of the effectAllowed and dropEffect attributes of the DragEvent object's dataTransfer object as they stood after the event dispatched, as per the following table:

<table>
<thead>
<tr>
<th>effectAllowed</th>
<th>dropEffect</th>
<th>Drag operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;uninitialized&quot;</td>
<td>&quot;copy&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
<tr>
<td>&quot;uninitialized&quot;</td>
<td>&quot;link&quot;</td>
<td>&quot;link&quot;</td>
</tr>
<tr>
<td>&quot;uninitialized&quot;</td>
<td>&quot;move&quot;, &quot;copyMove&quot;</td>
<td>&quot;move&quot;</td>
</tr>
<tr>
<td>&quot;uninitialized&quot;</td>
<td>&quot;all&quot;</td>
<td>&quot;all&quot;</td>
</tr>
</tbody>
</table>

Any other case

"none"

Otherwise, if the current target element is not a DOM element, use platform-specific mechanisms to determine what drag operation is being performed (none, copy, link, or move), and set the current drag operation accordingly.

5. Update the drag feedback (e.g. the mouse cursor) to match the current drag operation, as follows:

<table>
<thead>
<tr>
<th>Drag operation</th>
<th>Feedback</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;copy&quot;</td>
<td>Data will be copied if dropped here.</td>
</tr>
<tr>
<td>&quot;link&quot;</td>
<td>Data will be linked if dropped here.</td>
</tr>
<tr>
<td>&quot;move&quot;</td>
<td>Data will be moved if dropped here.</td>
</tr>
<tr>
<td>&quot;none&quot;</td>
<td>No operation allowed, dropping here will cancel the drag-and-drop operation.</td>
</tr>
</tbody>
</table>

4. Otherwise, if the user ended the drag-and-drop operation (e.g. by releasing the mouse button in a mouse-driven drag-and-drop interface), or if the drag event was canceled, then this will be the last iteration. Run the following steps, then stop the drag-and-drop operation:

1. If the current drag operation is "none" (no drag operation), or, if the user ended the drag-and-drop operation by canceling it (e.g. by hitting the Escape key), or if the current target element is null, then the drag operation failed. Run these substeps:

   1. Let dropped be false.

   2. If the current target element is a DOM element, fire a DND event named dragleave at it; otherwise, if it is not null, use platform-specific conventions for drag cancelation.

   3. Set the current drag operation to "none".

Otherwise, the drag operation might be a success; run these substeps:

1. Let dropped be true.

2. If the current target element is a DOM element, fire a DND event named drop at it; otherwise, use platform-specific conventions for indicating a drop.

3. If the event is canceled, set the current drag operation to the value of the dropEffect attribute of the DragEvent object's dataTransfer object as it stood after the event dispatched.

Otherwise, the event is not canceled; perform the event's default action, which depends on the exact target as follows:

   1. If the current target element is a text control (e.g., textarea, or an input element whose type attribute is in the Text state) or an editing host or editable element, and the drag data store item list has an item with the drag data item type string "text/plain" and the drag data item kind Plain Unicode string

Insert the actual data of the first item in the drag data store item list to have a drag data item type string of "text/plain" and a drag data item kind that is Plain Unicode string into the text control or editing host or editable element in a manner consistent with platform-specific conventions.
conventions (e.g. inserting it at the current mouse cursor position, or inserting it at the end of the field).

**Otherwise**

Reset the current drag operation to "none".

2. Fire a DND event named `dragend` at the source node.

3. Run the appropriate steps from the following list as the default action of the `dragend` event:

   - If `dropped` is true, the current target element is a text control (see below), the current drag operation is "move", and the source of the drag-and-drop operation is a selection in the DOM that is entirely contained within an editing host.
     
     Delete the selection.

   - If `dropped` is true, the current target element is a text control (see below), the current drag operation is "move", and the source of the drag-and-drop operation is a selection in a text control.
     
     The user agent should delete the dragged selection from the relevant text control.

   - If `dropped` is false or if the current drag operation is "none".
     
     The drag was canceled. If the platform conventions dictate that this be represented to the user (e.g. by animating the dragged selection going back to the source of the drag-and-drop operation), then do so.

   - The event has no default action.

For the purposes of this step, a text control is a `textarea` element or an `input` element whose `type` attribute is in one of the `Text`, `Search`, `Tel`, `Tel`, `URL`, `E-mail`, `Password`, or `Number` states.

**Note**

User agents are encouraged to consider how to react to drags near the edge of scrollable regions. For example, if a user drags a link to the bottom of the viewport on a long page, it might make sense to scroll the page so that the user can drop the link lower on the page.

**Note**

This model is independent of which `Document` object the nodes involved are from; the events are fired as described above and the rest of the processing model runs as described above, irrespective of how many documents are involved in the operation.

### 6.7.6 Events summary

This section is non-normative.

The following events are involved in the drag-and-drop model.

<table>
<thead>
<tr>
<th>Event name</th>
<th>Target</th>
<th>Cancelable?</th>
<th>Drag data store mode</th>
<th>dropEffect</th>
<th>Default Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>dragstart</td>
<td>Source node</td>
<td>✓ Cancelable</td>
<td>Read/Write mode</td>
<td>&quot;none&quot;</td>
<td>Initiate the drag-and-drop operation</td>
</tr>
<tr>
<td>drag</td>
<td>Source node</td>
<td>✓ Cancelable</td>
<td>Protected mode</td>
<td>&quot;none&quot;</td>
<td>Continue the drag-and-drop operation</td>
</tr>
<tr>
<td>dragenter</td>
<td>Immediate user selection or the body element</td>
<td>✓ Cancelable</td>
<td>Protected mode</td>
<td>Based on effectAllowed value</td>
<td>Reject immediate user selection as potential target element</td>
</tr>

<td>Varies</td>
</tr>
</tbody>
</table>
6.7.7 The `draggable` attribute

All HTML elements may have the `draggable` content attribute set. The `draggable` attribute is an enumerated attribute. It has three states. The first state is `true` and it has the keyword `true`. The second state is `false` and it has the keyword `false`. The third state is `auto`; it has no keywords but it is the missing value default and the invalid value default.

The `true` state means the element is draggable; the `false` state means that it is not. The `auto` state uses the default behavior of the user agent.

An element with a `draggable` attribute should also have a `title` attribute that names the element for the purpose of non-visual interactions.

**For web developers (non-normative)**

```

element . draggable [ = value ]

  Returns true if the element is draggable; otherwise, returns false.
  Can be set, to override the default and set the `draggable` content attribute.
```

The `draggable` IDL attribute, whose value depends on the content attribute’s in the way described below, controls whether or not the element is draggable. Generally, only text selections are draggable, but elements whose `draggable` IDL attribute is true become draggable as well.

If an element’s `draggable` content attribute has the state `true`, the `draggable` IDL attribute must return true.

Otherwise, if the element’s `draggable` content attribute has the state `false`, the `draggable` IDL attribute must return false.

Otherwise, the element’s `draggable` content attribute has the state `auto`. If the element is an `<img>` element, an `<object>` element that represents an image, or an `<a>` element with an `<href>` content attribute, the `draggable` IDL attribute must return true; otherwise, the `draggable` IDL attribute must return false.

If the `draggable` IDL attribute is set to the value false, the `draggable` content attribute must be set to the literal value "false". If the `draggable` IDL attribute is set to the value true, the `draggable` content attribute must be set to the literal value "true".

6.7.8 Security risks in the drag-and-drop model

User agents must not make the data added to the `DataTransfer` object during the `dragstart` event available to scripts until the `drop` event, because otherwise, if a user were to drag sensitive information from one document to a second document, crossing a hostile third document in the process, the hostile document could intercept the data.

For the same reason, user agents must consider a drop to be successful only if the user specifically ended the drag operation — if any scripts end the drag operation, it must be considered unsuccessful (canceled) and the `drop` event must not be fired.

User agents should take care to not start drag-and-drop operations in response to script actions. For example, in a mouse-and-window environment, if a script moves a window while the user has their mouse button depressed, the UA would not consider that to start a drag. This is important because otherwise UAs could cause data to be dragged from sensitive sources and dropped into hostile documents without the user's consent.

User agents should filter potentially active (scripted) content (e.g. HTML) when it is dragged and when it is dropped, using a safelist of known-safe features. Similarly, relative URLs should be turned into absolute URLs to avoid references changing in unexpected ways. This specification does not specify how this is performed.
Consider a hostile page providing some content and getting the user to select and drag and drop (or indeed, copy and paste) that content to a victim page's *contenteditable* region. If the browser does not ensure that only safe content is dragged, potentially unsafe content such as scripts and event handlers in the selection, once dropped (or pasted) into the victim site, get the privileges of the victim site. This would thus enable a cross-site scripting attack.
7 Loading Web pages

This section describes features that apply most directly to Web browsers. Having said that, except where specified otherwise, the requirements defined in this section do apply to all user agents, whether they are Web browsers or not.

7.1 Browsing contexts

A browsing context is an environment in which Document objects are presented to the user.

A browsing context has a corresponding WindowProxy object.

A browsing context has a session history, which lists the Document objects that the browsing context has presented, is presenting, or will present. A browsing context's active document is its WindowProxy object's [[Window]] internal slot value's associated Document. A Document's browsing context is the browsing context whose session history contains the Document, if any such browsing context exists and has not been discarded.

To set the active document of a browsing context browsingContext to a Document object document, optionally with a Window object window, run these steps:

1. If window is not given, let window be document's relevant global object.

Per this standard document can be created before window, which does not make much sense. See issue #2688.

2. Set browsingContext's WindowProxy object's [[Window]] internal slot value to window.

4. Set window's relevant settings object's execution ready flag.

A browsing context can have a creator browsing context, the browsing context that was responsible for its creation. If a browsing context has a parent browsing context, then that is its creator browsing context. Otherwise, if the browsing context has an opener browsing context, then that is its creator browsing context. Otherwise, the browsing context has no creator browsing context.

If a browsing context context has a creator browsing context creator, it also has the following properties. In what follows, let creator document be creator's active document at the time context is created:

Note

In general, there is a 1-to-1 mapping from the Window object to the Document object, as long as the Document object has a browsing context. There are two exceptions. First, a Window can be reused for the presentation of a second Document in the same browsing context, such that the mapping is then 1-to-2. This occurs when a browsing context is navigated from the initial about:blank Document, to another, with replacement enabled. Second, a Document can end up being reused for several Window objects when the document.open(type, replace) method is used, such that the mapping is then many-to-1.

Note

A Document does not necessarily have a browsing context associated with it. In particular, data mining tools are likely to never instantiate browsing contexts. A Document created using an API such as createDocument() never has a browsing context. And the Document originally created for an iframe element, which has since been removed from the document, has no associated browsing context, since that browsing context was discarded.

Note

A tab or window in a Web browser typically contains a browsing context, as does an iframe or frame's in a frameset.

Note

A browsing context has a session history, which lists the Document objects that the browsing context has presented, is presenting, or will present. A browsing context's active document is its WindowProxy object's [[Window]] internal slot value's associated Document. A Document's browsing context is the browsing context whose session history contains the Document, if any such browsing context exists and has not been discarded.

7.2 Navigation

A document's browsing context is the browsing context whose session history contains the Document, if any such browsing context exists and has not been discarded.

Note

A Document does not necessarily have a browsing context associated with it. In particular, data mining tools are likely to never instantiate browsing contexts. A Document created using an API such as createDocument() never has a browsing context. And the Document originally created for an iframe element, which has since been removed from the document, has no associated browsing context, since that browsing context was discarded.

To set the active document of a browsing context browsingContext to a Document object document, optionally with a Window object window, run these steps:

1. If window is not given, let window be document's relevant global object.

Per this standard document can be created before window, which does not make much sense. See issue #2688.

2. Set browsingContext's WindowProxy object's [[Window]] internal slot value to window.

4. Set window's relevant settings object's execution ready flag.

A browsing context can have a creator browsing context, the browsing context that was responsible for its creation. If a browsing context has a parent browsing context, then that is its creator browsing context. Otherwise, if the browsing context has an opener browsing context, then that is its creator browsing context. Otherwise, the browsing context has no creator browsing context.

If a browsing context context has a creator browsing context creator, it also has the following properties. In what follows, let creator document be creator's active document at the time context is created:
To create a new browsing context, optionally given noopen:

1. If noopen was not given, let it be false.
2. Let `browsingContext` be a new browsing context.
3. Let `realm execution context` be the result of creating a new JavaScript realm with the following customizations:
   ◦ For the global object, create a new `Window` object.
   ◦ For the global `this` binding, use `browsingContext`'s `WindowProxy` object.
4. Set up a window environment settings object with `realm execution context`, and let `settingsObject` be the result.
5. Let `document` be a new `Document`, marked as an HTML document in quirks mode, whose content type is "text/html", and which is both ready for post-load tasks and completely loaded immediately.
6. Ensure that `document` has a single child `html` node, which itself has two empty child nodes: a `head` element, and a `body` element.
7. Set the active document of `browsingContext` to `document`.
8. Set the `origin` of `document`:
   ◦ If `browsingContext` has a creator browsing context, then the `origin` of `document` is the creator origin.
   ◦ Otherwise, the `origin` of `document` is a unique opaque origin.
9. If `browsingContext` has a creator browsing context, then set `document`'s referrer to the serialization of creator URL.
10. If `browsingContext` has a creator browsing context, then set `document`'s referrer policy to the creator referrer policy.
11. Implement the sandboxing for `document`.
12. Execute the Initialize document's Feature Policy algorithm on `document`. [FEATUREPOLICY]
13. Add `document` to `browsingContext`'s session history.
14. If noopen is false, `browsingContext` is a top-level browsing context, and creator origin is same origin with `document`'s origin, then copy the sessionStorage storage area of the creator origin from the creator browsing context into `browsingContext`'s set of session storage areas. These areas must be considered separate, not affecting each other in any way.
15. Return `browsingContext`.

7.1.1 Nested browsing contexts

Certain elements (for example, `iframe` elements) can instantiate further browsing contexts. These elements are called browsing context containers.

Each browsing context container has a nested browsing context, which is either a browsing context or null.

If a browsing context is the nested browsing context of a browsing context container, then the browsing context is said to be nested through the browsing context container's node document.
A browsing context\(^\text{780}\) child is said to be a child browsing context of another browsing context\(^\text{780}\) parent, if all of the following conditions hold:

- child is a nested browsing context\(^\text{781}\) of a browsing context container\(^\text{781}\) element
- element is connected
- element's shadow-including root's browsing context\(^\text{780}\) is parent

A browsing context\(^\text{780}\) child is then a document-tree child browsing context of parent if it is a child browsing context\(^\text{782}\) and its browsing context container\(^\text{781}\) is not just connected, but also in a document tree.

A browsing context\(^\text{780}\) child may have a parent browsing context. This is the unique browsing context\(^\text{780}\) that has child as a child browsing context\(^\text{782}\), if any such browsing context exists. Otherwise, the browsing context\(^\text{780}\) has no parent browsing context\(^\text{782}\).

A browsing context\(^\text{780}\) A is said to be an ancestor of a browsing context B if there exists a browsing context A' that is a child browsing context\(^\text{782}\) of A and that is itself an ancestor\(^\text{782}\) of B, or if the browsing context A is the parent browsing context\(^\text{782}\) of B.

A browsing context\(^\text{780}\) that is not a nested browsing context\(^\text{781}\) has no parent browsing context\(^\text{782}\), and is the top-level browsing context of all the browsing contexts for which it is an ancestor browsing context\(^\text{782}\).

The list of the descendant browsing contexts of a Document\(^\text{780}\) d is the (ordered) list returned by the following algorithm:

1. Let list be an empty list.
2. For each child browsing context\(^\text{782}\) of d that is nested through\(^\text{781}\) an element that is in the Document\(^\text{780}\) d, in the tree order of the elements nesting those browsing contexts\(^\text{780}\), run these substeps:
   1. Append that child browsing context\(^\text{782}\) to the list list.
   2. Append the list of the descendant browsing contexts\(^\text{782}\) of the active document\(^\text{780}\) of that child browsing context\(^\text{782}\) to the list list.
3. Return the constructed list.

A Document\(^\text{780}\) is said to be fully active when it has a browsing context\(^\text{780}\) and it is the active document\(^\text{780}\) of that browsing context\(^\text{780}\), and either its browsing context is a top-level browsing context\(^\text{782}\), or it has a parent browsing context\(^\text{782}\) and the Document\(^\text{780}\) through which\(^\text{781}\) it is nested\(^\text{781}\) is itself fully active\(^\text{782}\).

Because they are associated with an element, child browsing contexts\(^\text{782}\) are always tied to a specific Document\(^\text{780}\) in their parent browsing context\(^\text{782}\). User agents must not allow the user to interact with child browsing contexts\(^\text{782}\) of elements that are in Document\(^\text{780}\)'s that are not themselves fully active\(^\text{782}\).

### Example

The following example illustrates the differences between active\(^\text{780}\) and fully active\(^\text{782}\) Document\(^\text{780}\) objects. Here a.html is loaded into a browser window, b-1.html starts out loaded into an iframe\(^\text{784}\) as shown, and b-2.html and c.html are omitted (they can simply be an empty document).

```html
<!- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Browsing context A</title>

<iframe src="b-1.html"></iframe>
<button onclick="frames[0].location.href = 'b-2.html'">Click me</button>

<!- b-1.html -->
<!DOCTYPE html>
<html lang="en">
<title>Browsing context B</title>
```

782
At this point, the documents given by a.html, b-1.html, and c.html are all the [active documents][780] of their respective [browsing contexts][780]. They are also all [fully active][782].

After clicking on the [button][518], and thus loading a new [Document][716] from b-2.html into browsing context B, we have the following results:

- The a.html [Document][716] remains both the [active document][780] of browsing context A, and [fully active][782].
- The b-1.html [Document][716] is now not the [active document][780] of browsing context B. As such it is also not [fully active][782].
- The new b-2.html [Document][716] is now the [active document][780] of browsing context B, and is also [fully active][782].
- The c.html [Document][716] is still the [active document][780] of browsing context C. However, since it is [nested through][781] the b-1.html [Document][716], which is itself not [fully active][782], this means the c.html [Document][716] is now not [fully active][782] (even though it is [active][780]).

For more explorations of the complexities involved here, especially as it impacts the [session history][809], see A Model of Navigation History. [NAVMODEL][1225]

A [browsing context][780] that is a [nested browsing context][781] can be put into a delaying [load events mode][782]. This is used when it is [navigated][825], to delay the load event[1107] of its [browsing context container][781] before the new [Document][716] is created.

The [content document][784] of a [browsing context container][782] container is the result of the following algorithm:

1. If container's [nested browsing context][781] is null, then return null.
2. Let context be container's [nested browsing context][781].
3. Let document be context's [active document][780].
4. If document's origin[803] and the origin[869] specified by the [current settings object][884] are not [same origin-domain][885], then return null.
5. Return document.

### 7.1.1.1 Navigating nested browsing contexts in the DOM

For web developers (non-normative)

- **window . top**[783]
  
  Returns the [WindowProxy][800] for the [top-level browsing context][782].

- **window . parent**[784]
  
  Returns the [WindowProxy][800] for the [parent browsing context][782].

- **window . frameElement**[784]
  
  Returns the [Element] for the [browsing context container][781].

  Returns null if there isn’t one, and in cross-origin situations.

The top IDL attribute, on getting, must run the following algorithm:

2. If there is no browsing context with windowProxy as its WindowProxy object, then return null.

3. Let context be that browsing context.

4. If context is a top-level browsing context, then return context's WindowProxy object.

5. Otherwise, context must have a top-level browsing context (i.e. an ancestor browsing context with no parent browsing context). Return that top-level browsing context's WindowProxy object.

The parent IDL attribute, on getting, must run the following algorithm:

1. Let windowProxy be this Window object's WindowProxy object.

2. If there is no browsing context with windowProxy as its WindowProxy object, then return null.

3. Let context be that browsing context.

4. If context is a child browsing context of another browsing context parent, then return parent's WindowProxy object.

5. Otherwise, context must be a top-level browsing context. Return context's WindowProxy object.

The frameElement IDL attribute, on getting, must run the following algorithm:

1. Let windowProxy be this Window object's WindowProxy object.

2. If there is no browsing context with windowProxy as its WindowProxy object, then return null.

3. Let context be that browsing context.

4. If context is not a nested browsing context, then return null.

5. Let container be context's browsing context container.

6. If container's node document's origin is not same origin-domain with the current settings object's origin, then return null.

7. Return container.

Example

An example of when these IDL attributes can return null is as follows:

```html
<!DOCTYPE html>
<iframe></iframe>
<script>
"use strict";
const element = document.querySelector("iframe");
const iframeWindow = element.contentWindow;
element.remove();

console.assert(iframeWindow.top === null);
console.assert(iframeWindow.parent === null);
console.assert(iframeWindow.frameElement === null);
</script>
```

Here the browsing context corresponding to iframeWindow was discarded when element was removed from the document.

### 7.1.2 Auxiliary browsing contexts

It is possible to create new browsing contexts that are related to a top-level browsing context without being nested through an element. Such browsing contexts are called auxiliary browsing contexts. Auxiliary browsing contexts are always top-level browsing contexts.
An **auxiliary browsing context** has an **opener browsing context**, which is the **browsing context** from which the auxiliary browsing context was created.

### 7.1.2.1 Navigating auxiliary browsing contexts in the DOM

An **auxiliary browsing context**, can be **disowned**.

The **opener** attribute’s getter must run these steps:

1. If the current **browsing context** is **disowned**, then return null.
2. If the current **browsing context** has no **opener browsing context**, then return null.
3. Return the current **browsing context**’s **opener browsing context**’s **WindowProxy** object.

The **opener** attribute’s setter, must run these steps:

1. If the given value is null, then **disown** the current **browsing context** and return.
2. Return the result of calling **OrdinaryDefineOwnProperty**(this **Window** object, "opener", { ![Writable]: true, ![Enumerable]: true, ![Configurable]: true }). Rethrow any exceptions.

**Note**  
If a **browsing context** is **disowned**, its **window.opener** attribute is null. That prevents scripts in the **browsing context** from changing any properties of its **opener browsing context**’s **Window** object (i.e., the **Window** object from which the browsing context was created).

Otherwise, if a **browsing context** is not **disowned**, then scripts in that **browsing context** can use **window.opener** to change properties of its **opener browsing context**’s **Window** object. For example, a script running in the **browsing context** can change the value of **window.opener.location**, causing the **opener browsing context** to navigate to a completely different document.

### 7.1.3 Security

A **browsing context** is **familiar with** a second **browsing context** if one of the following conditions is true:

- Either the **origin** of the **active document** of A is the same as the **origin** of the **active document** of B, or
- The browsing context A is a **nested browsing context** with a **top-level browsing context**, and its **top-level browsing context** is B, or
- The browsing context B is an **auxiliary browsing context** and A is **familiar with** B’s **opener browsing context**, or
- The browsing context B is not a **top-level browsing context**, but there exists an **ancestor browsing context** of B whose **active document** has the same **origin** as the **active document** of A (possibly in fact being A itself).

A **browsing context** is **allowed to navigate** a second **browsing context** if the following algorithm returns true:

1. If A is not the same **browsing context** as B, and A is not one of the **ancestor browsing contexts** of B, and B is not a **top-level browsing context**, and A’s **active document**’s **active sandboxing flag set** has its **sandboxed navigation browsing context flag** set, then return false.
2. Otherwise, if B is a **top-level browsing context**, and is one of the **ancestor browsing contexts** of A, then:
   1. If this algorithm is triggered by user activation and A’s **active document**’s **active sandboxing flag set** has its **sandboxed top-level navigation with user activation browsing context flag** set, then return false.
   2. Otherwise, if this algorithm is not triggered by user activation and A’s **active document**’s **active sandboxing flag set** has its **sandboxed top-level navigation without user activation browsing context flag** set, then return false.
false.

3. Otherwise, if \( B \) is a top-level browsing context\(^{782} \), and is neither \( A \) nor one of the ancestor browsing contexts\(^{782} \) of \( A \), and \( A \)'s Document\(^{311}\)'s active sandboxing flag set\(^{906} \) has its sandboxed navigation browsing context flag\(^{906} \) set, and \( A \) is not the one permitted sandboxed navigator\(^{906} \) of \( B \), then return false.

4. Return true.

An element has a browsing context scope origin if its Document\(^{110}\)'s browsing context\(^{780} \) is a top-level browsing context\(^{782} \) or if all of its Document\(^{311}\)'s ancestor browsing contexts\(^{782} \) all have active documents\(^{780} \) whose origin\(^{803} \) are the same origin\(^{805} \) as the element's node document's origin\(^{903} \). If an element has a browsing context scope origin\(^{786} \), then its value is the origin\(^{903} \) of the element's node document.

### 7.1.4 Groupings of browsing contexts \(^{5978} \)

Each browsing context\(^{978} \) is defined as having a list of one or more directly reachable browsing contexts. These are:

- The browsing context\(^{978} \) itself.
- All the child browsing contexts\(^{782} \).
- The parent browsing context\(^{978} \).
- All the browsing contexts\(^{780} \) that have the browsing context\(^{780} \) as their opener browsing context\(^{978} \).
- The opener browsing context\(^{780} \).

The transitive closure of all the browsing contexts\(^{780} \) that are directly reachable browsing contexts\(^{978} \) forms a unit of related browsing contexts.

Each unit of related browsing contexts\(^{978} \) is then further divided into the smallest number of groups such that every member of each group has an active document\(^{780} \) with an origin\(^{903} \) that, through appropriate manipulation of the document.domain\(^{606} \) attribute, could be made to be same origin-domain\(^{605} \) with other members of the group, but could not be made the same as members of any other group. Each such group is a unit of related similar-origin browsing contexts.

#### Note

There is also at most one event loop\(^{983} \) per unit of related similar-origin browsing contexts\(^{978} \) (though several units of related similar-origin browsing contexts\(^{978} \) can have a shared event loop\(^{983} \)).

### 7.1.5 Browsing context names \(^{5978} \)

Browsing contexts can have a browsing context name. Unless stated otherwise, it is the empty string.

A valid browsing context name is any string with at least one character that does not start with a U+005F LOW LINE character. (Names starting with an underscore are reserved for special keywords.)

A valid browsing context name or keyword is any string that is either a valid browsing context name\(^{978} \) or that is an ASCII case-insensitive match for one of: _blank, _self, _parent, or _top.

These values have different meanings based on whether the page is sandboxed or not, as summarized in the following (non-normative) table. In this table, "current" means the browsing context\(^{780} \) that the link or script is in, "parent" means the parent browsing context\(^{782} \) of the one the link or script is in, "top" means the top-level browsing context\(^{782} \) of the one the link or script is in, "new" means a new top-level browsing context\(^{782} \) or auxiliary browsing context\(^{784} \) is to be created, subject to various user preferences and user agent policies, "none" means that nothing will happen, and "maybe new" means the same as "new" if the allow-popups\(^{908} \) keyword is also specified on the sandbox\(^{352} \) attribute (or if the user overrode the sandboxing), and the same as "none" otherwise.
<table>
<thead>
<tr>
<th>Keyword</th>
<th>Ordinary effect</th>
<th>Effect in an iframe with...</th>
</tr>
</thead>
<tbody>

<tr>
<td>name that exists with different top, not familiar</td>
<td>new</td>
<td>maybe new</td>
</tr>
</tbody>
</table>

Most of the restrictions on sandboxed browsing contexts are applied by other algorithms, e.g. the navigation algorithm, not the rules for choosing a browsing context given below.

### The rules for choosing a browsing context

Given a browsing context name, a browsing context current, and a boolean noopenner are as follows:

1. Let chosen be null.
2. Let new be false.
3. If name is the empty string or an ASCII case-insensitive match for "_self", then set chosen to current.
4. If name is an ASCII case-insensitive match for "_parent", then set chosen to current’s parent browsing context, if any, and current otherwise.
5. If name is an ASCII case-insensitive match for "_top", then set chosen to current’s top-level browsing context, if any, and current otherwise.
6. If name is not an ASCII case-insensitive match for "_blank" and there exists a browsing context whose name is the same as name, and current is familiar with that browsing context, and the user agent determines that the two browsing contexts are related enough that it is ok if they reach each other, then set chosen to that browsing context. If there are multiple matching browsing contexts, the user agent should set chosen to one in some arbitrary consistent manner, such as the most recently opened, most recently focused, or more closely related.

This will be made more precise in issue #1440.

7. Otherwise, a new browsing context is being requested, and what happens depends on the user agent’s configuration and abilities — it is determined by the rules given for the first applicable option from the following list:

   - If the algorithm is not triggered by user activation and the user agent has been configured to not show popups (i.e. the user agent has a "popup blocker" enabled)
     The user agent may inform the user that a popup has been blocked.

   - If current’s active document’s active sandboxing flag set has the sandboxed auxiliary navigation browsing context flag set.
     The user agent may offer the user one of:
1. Set `chosen` to a new top-level browsing context given `noopenner`, and set `new` to true.

2. Set `chosen` to an existing top-level browsing context.

⚠ Warning: If this case occurs, it means that an author has explicitly sandboxed the document that is trying to open a link.

† Note: If the user declines or the user agent doesn’t offer the above, the variables remain unchanged.

→ If the user agent has been configured such that in this instance it will create a new browsing context:

Set `chosen` to a new auxiliary browsing context given `noopenner` with the opener browsing context being current, and set `new` to true. If `name` is not an ASCII case-insensitive match for "_blank", then `chosen`'s `name` must be set to `name`.

† Note: If the newly created browsing context is immediately navigated, then the navigation will be done with replacement enabled.

→ If the user agent has been configured such that in this instance it will reuse current

Set `chosen` to `current`.

→ If the user agent has been configured such that in this instance it will not find a browsing context

Do nothing.

† Note: User agents are encouraged to provide a way for users to configure the user agent to always reuse current.

8. If `new` is true, then:

1. Let `flagSet` be `current`'s active document's active sandboxing flag set.

2. If `flagSet`'s sandboxed navigation browsing context flag is set, then `current` must be set as `chosen`'s one permitted sandboxed navigator.

3. If `flagSet`'s sandbox propagates to auxiliary browsing contexts flag is set, then all the flags that are set in `flagSet` must be set in `chosen`'s popup sandboxing flag set.

9. Return `chosen` and `new`.

7.2 Security infrastructure for `Window`, `WindowProxy`, and `Location` objects

Although typically objects cannot be accessed across origins, the web platform would not be true to itself if it did not have some legacy exceptions to that rule that the web depends upon.

7.2.1 Integration with IDL

When perform a security check is invoked, with a `platformObject`, `identifier`, and `type`, run these steps:

1. If `platformObject` is a `Window` or `Location` object, then:

   1. Repeat for each `e` that is an element of `CrossOriginProperties`(platformObject):

      1. If `SameValue(e.[[Property]], identifier)` is true, then:

         1. If `type` is "method" and `e` has neither `[[NeedsGet]]` nor `[[NeedsSet]]`, then return.

         2. Otherwise, if `type` is "getter" and `e.[[NeedsGet]]` is true, then return.
3. Otherwise, if type is "setter" and e.[[NeedsSet]] is true, then return.

2. If ! IsPlatformObjectSameOrigin(platformObject) is false, then throw a "SecurityError" DOMException.

7.2.2 Shared internal slot: [[CrossOriginPropertyDescriptorMap]]

Window and Location objects both have a [[CrossOriginPropertyDescriptorMap]] internal slot, whose value is initially an empty map.

**Note**
The [[CrossOriginPropertyDescriptorMap]] internal slot contains a map with entries whose keys are (currentGlobal, objectGlobal, propertyKey)-tuples and values are property descriptors, as a memoization of what is visible to scripts when currentGlobal inspects a Window or Location object from objectGlobal. It is filled lazily by CrossOriginGetOwnPropertyHelper, which consults it on future lookups.

User agents should allow a value held in the map to be garbage collected along with its corresponding key when nothing holds a reference to any part of the value. That is, as long as garbage collection is not observable.

**Example**
For example, with const href = Object.getOwnPropertyDescriptor(crossOriginLocation, "href").set the value and its corresponding key in the map cannot be garbage collected as that would be observable.

User agents may have an optimization whereby they remove key-value pairs from the map when document.domain is set. This is not observable as document.domain cannot revisit an earlier value.

**Example**
For example, setting document.domain to "example.com" on www.example.com means user agents can remove all key-value pairs from the map where part of the key is www.example.com, as that can never be part of the origin again and therefore the corresponding value could never be retrieved from the map.

7.2.3 Shared abstract operations

7.2.3.1 CrossOriginProperties ( O )

1. Assert: O is a Location or Window object.

2. If O is a Location object, then return « { [[Property]]: "href", [[NeedsGet]]: false, [[NeedsSet]]: true }, { [[Property]]: "replace" } ».

4. Repeat for each e that is an element of O's document-tree child browsing context name property set:

   1. Add { [[Property]]: e, [[HideFromKeys]]: true } as the last element of crossOriginWindowProperties.

5. Return crossOriginWindowProperties.

**Note**
Indexed properties do not need to be safelisted as they are handled directly by the WindowProxy object.
7.2.3.2 IsPlatformObjectSameOrigin (O)

1. Return true if the current settings object's origin is same origin-domain with O's relevant settings object's origin, and false otherwise.

7.2.3.3 CrossOriginGetOwnPropertyHelper (O, P)

Note

If this abstract operation returns undefined and there is no custom behavior, the caller needs to throw a "SecurityError" DOMException.

1. Let crossOriginKey be a tuple consisting of the current settings object, O's relevant settings object, and P.

2. Repeat for each e that is an element of ! CrossOriginProperties(O):
   1. If SameValue(e.:[Property], P) is true, then:
      1. If the value of the [[CrossOriginPropertyDescriptorMap]] internal slot of O contains an entry whose key is crossOriginKey, then return that entry's value.
      2. Let originalDesc be OrdinaryGetOwnProperty(O, P).
      3. Let crossOriginDesc be undefined.
      4. If e.:[NeedsGet] and e.:[NeedsSet] are absent, then:
         1. Let value be originalDesc.:[Value].
         2. If ! IsCallable(value) is true, then set value to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the IDL operation P on object O.
         3. Set crossOriginDesc to PropertyDescriptor( [[Value]]: value, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true ).
      5. Otherwise:
         1. Let crossOriginGet be undefined.
         2. If e.:[NeedsGet] is true, then set crossOriginGet to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the getter of the IDL attribute P on object O.
         3. Let crossOriginSet be undefined.
         4. If e.:[NeedsSet] is true, then set crossOriginSet to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the setter of the IDL attribute P on object O.
         5. Set crossOriginDesc to PropertyDescriptor( [[Get]]: crossOriginGet, [[Set]]: crossOriginSet, [[Enumerable]]: false, [[Configurable]]: true ).
      6. Create an entry in the value of the [[CrossOriginPropertyDescriptorMap]] internal slot of O with key crossOriginKey and value crossOriginDesc.
    7. Return crossOriginDesc.

3. If P is "then", @@toStringTag, @@hasInstance, or @@isConcatSpreadable, then return PropertyDescriptor( [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true ).

4. Return undefined.

Note

The reason that the property descriptors produced here are configurable is to preserve the invariants of the essential internal methods required by the JavaScript specification. In particular, since the value of the property can change as a consequence of navigation, it is required that the property be configurable. (However, see tc39/ecma262 issue #672 and references to it elsewhere in this specification for cases where we are not able to preserve these invariants, for compatibility with existing Web content.)
2. Assert: desc is not undefined.
3. If ! IsDataDescriptor(desc) is true, then return desc.[[Value]].
4. Assert: IsAccessorDescriptor(desc) is true.
5. Let getter be desc.[[Get]].
6. If getter is undefined, then throw a "SecurityError" DOMException.

7.2.3.5 CrossOriginSet ( O, P, V, Receiver ) §p79
2. Assert: desc is not undefined.
3. If desc.[[Set]] is present and its value is not undefined, then:
   1. Perform ? Call(setter, Receiver, « V »).
   2. Return true.
4. Throw a "SecurityError" DOMException.

7.2.3.6 CrossOriginOwnPropertyKeys ( O ) §p79
1. Let keys be a new empty List.
2. Repeat for each e that is an element of ! CrossOriginProperties(O):
   1. If e.[[HideFromKeys]] is not true, append e.[[Property]] to keys.
3. If keys does not contain "then", then append "then" to keys.
4. Return the concatenation of keys and « @@toStringTag, @@hasInstance, @@isConcatSpreadable ».

7.3 The Window object §p79

IDL
[Global=Window,
Exposed=Window,
LegacyUnenumerableNamedProperties]
interface Window : EventTarget {
   // the current browsing context
   [Unforgeable] readonly attribute WindowProxy window;
   [Replaceable] readonly attribute WindowProxy self;
   [Unforgeable] readonly attribute Document document;
attribute DOMString name;
  [PutForwards=href, Unforgeable] readonly attribute Location location;
readonly attribute History history;
readonly attribute CustomElementRegistry customElements;
[Replaceable] readonly attribute BarProp locationbar;
[Replaceable] readonly attribute BarProp menubar;
[Replaceable] readonly attribute BarProp personalbar;
[Replaceable] readonly attribute BarProp scrollbars;
[Replaceable] readonly attribute BarProp statusbar;
[Replaceable] readonly attribute BarProp toolbar;
attribute DOMString status;
void close();
readonly attribute boolean closed;

DOMString? prompt(optional DOMString message = "", optional DOMString default = "");
void print();

unsigned long requestAnimationFrame(FrameRequestCallback callback);
void cancelAnimationFrame(unsigned long handle);

void postMessage(any message, USVString targetOrigin, optional sequence<object> transfer = []);
};
Window includes GlobalEventHandlers;
Window includes WindowEventHandlers;

callback FrameRequestCallback = void (DOMHighResTimeStamp time);

---

For web developers (non-normative)

```
window . window
window . frames
window . self
```

These attributes all return `window`. 
The `Window` object has an associated `Document`, which is a `Document` object. It is set when the `Window` object is created, and only ever changed during navigation from the initial about:blank document.

The `window`, `frames`, and `self` IDL attributes, on getting, must all return this `Window` object's `browsing context`'s `WindowProxy` object.

The `document` IDL attribute, on getting, must return this `Window` object's associated `Document`.

Note: The `Document` object associated with a `Window` object can change in exactly one case: when the `navigate` algorithm initializes a new `Document` object for the first page loaded in a `browsing context`. In that specific case, the `Window` object of the original about:blank page is reused and gets a new `Document` object.

The `defaultView` IDL attribute of the `Document` interface, on getting, must return this `Document`'s `browsing context`'s `WindowProxy` object, if this `Document` has an associated browsing context, or null otherwise.

For historical reasons, `Window` objects must also have a writable, configurable, non-enumerable property named `HTMLDocument` whose value is the `Document` interface object.

### 7.3.1 APIs for creating and navigating browsing contexts by name

For web developers (non-normative)

```javascript
window.open([url [, target [, features ]]]
```

Opens a window to show `url` (defaults to about:blank), and returns it. The `target` argument gives the name of the new window. If a window exists with that name already, it is reused. The `features` argument can be used to influence the rendering of the new window.

```javascript
window.name = value
```

Returns the name of the window.

Can be set, to change the name.

```javascript
window.close()
```

Closes the window.

```javascript
window.closed
```

Returns true if the window has been closed, false otherwise.

```javascript
window.stop()
```

 Cancels the document load.

The `window open steps`, given a string `url`, a string `target`, and a string `features`, are as follows:

1. Let `entry settings` be the `entry settings object`.
2. Let `source browsing context` be the `responsible browsing context` specified by `entry settings`.
3. If `target` is the empty string, then set `target` to "_blank".
4. Let \( \text{tokenizedFeatures} \) be the result of tokenizing features.

5. Let \( \text{noopener} \) be true if \( \text{tokenizedFeatures} \) contains an entry with the key "noopener".

6. Let target browsing context and new be the result of applying the rules for choosing a browsing context given target, source browsing context, and \( \text{noopener} \).

Example

If there is a user agent that supports control-clicking a link to open it in a new tab, and the user control-clicks on an element whose onclick handler uses the window.open API to open a page in an iframe element, the user agent could override the selection of the target browsing context to instead target a new tab.

7. If target browsing context is null, then return null.

8. If new is true, then set up browsing context features for target browsing context given \( \text{tokenizedFeatures} \). [CSSOMVIEW]

9. Let resource be the URL "about:blank".

10. If url is not the empty string or new is true, then:
    1. If url is not the empty string, then parse url relative to entry settings, and set resource to the resulting URL record, if any. If the parse a URL algorithm failed, then throw a "SyntaxError" DOMException.
    2. If resource is "about:blank" and new is true, then queue a task to fire an event named load at target browsing context's Window object, with the legacy target override flag set.
    3. Otherwise, navigate target browsing context to resource, with the exceptions enabled flag set. If new is true, then replacement must be enabled. The source browsing context is source browsing context. Rethrow any exceptions.

11. If \( \text{noopener} \) is true, then disown target browsing context and return null.

12. Return target browsing context's WindowProxy object.

The open\((url, target, features)\) method on Window objects provides a mechanism for navigating an existing browsing context or opening and navigating an auxiliary browsing context.

When the method is invoked, the user agent must run the window open steps with url, target, and features.

To tokenize the features argument:

1. Let \( \text{tokenizedFeatures} \) be a new ordered map.

2. Let position point at the first code point of features.

3. While position is not past the end of features:
   1. Let \( \text{name} \) be the empty string.
   2. Let \( \text{value} \) be the empty string.
   3. Collect a sequence of code points that are feature separators from features given position. This skips past leading separators before the name.
   4. Collect a sequence of code points that are not feature separators from features given position. Set \( \text{name} \) to the collected characters, converted to ASCII lowercase.
   5. Set \( \text{name} \) to the result of normalizing the feature name\( \text{name} \).
   6. While position is not past the end of features and the code point at position in features is not U+003D (=):
      1. If the code point at position in features is U+002C (,), or if it is not a feature separator, then break.
      2. Advance position by 1.

Note

This skips to the first U+003D (=) but does not skip past a U+002C (,) or a non-separator.
7. If the code point at position in features is a feature separator:
   1. While position is not past the end of features and the code point at position in features is a feature separator:
      1. If the code point at position in features is U+002C (,), then break.
      2. Advance position by 1.

   2. Collect a sequence of code points that are not feature separators code points from features given position. Set value to the collected code points, converted to ASCII lowercase.

4. Return tokenizedFeatures.

A code point is a feature separator if it is ASCII whitespace, U+003D (=), or U+002C (,).

For legacy reasons, there are some aliases of some feature names. To normalize a feature name name, switch on name:

↪ "screenx"
   Return "left".

↪ "screeny"
   Return "top".

↪ "innerwidth"
   Return "width".

↪ "innerheight"
   Return "height".

↪ Anything else
   Return name.

The name attribute of the Window object must, on getting, return the current name of the browsing context; and, on setting, set the name of the browsing context to the new value.

The closed attribute on Window objects must return true if the Window object's browsing context has been discarded, and false otherwise.

The stop() method on Window objects should, if there is an existing attempt to navigate the browsing context and that attempt is not currently running the unload a document algorithm, cancel that navigation; then, it must abort the active document of the browsing context of the Window object on which it was invoked.
### 7.3.2 Accessing other browsing contexts

For web developers (non-normative)

- `window.length`
  
  Returns the number of document-tree child browsing contexts.

- `window[index]`
  
  Returns the indicated document-tree child browsing context.

The number of document-tree child browsing contexts of a `Window` object `W` is the number of document-tree child browsing contexts of `W`'s associated `Document`'s browsing context.

The `length` IDL attribute’s getter must return the number of document-tree child browsing contexts of this `Window` object.

---

### 7.3.3 Named access on the `Window` object

For web developers (non-normative)

- `window[name]`
  
  Returns the indicated element or collection of elements.

  As a general rule, relying on this will lead to brittle code. Which IDs end up mapping to this API can vary over time, as new features are added to the Web platform, for example. Instead of this, use `document.getElementById()` or `document.querySelector()`.

The document-tree child browsing context name property set of a `Window` object `window` is the return value of running these steps:

1. Let `activeDocument` be `window`'s `browsing context`'s `active document`.
2. Let `childBrowsingContexts` be all document-tree child browsing contexts of `activeDocument`'s `browsing context` whose `browsing context name` is not the empty string, in order, and including only the first document-tree child browsing context with a given name if multiple document-tree child browsing contexts have the same one.
3. Remove each `browsing context` from `childBrowsingContexts` whose `active document`'s `origin` is not `same origin` with activeDocument's `origin` and whose `browsing context name` does not match the name of its `browsing context container`'s name content attribute value.
4. Return the `browsing context names` of `childBrowsingContexts`, in the same order.

---

Example

This means that in the following example, hosted on `https://example.org/`, assuming `https://elsewhere.example/` sets `window.name` to "spices", evaluating `window.spices` after everything has loaded will yield undefined:

```html
<iframe src="https://elsewhere.example.com/>
<iframe name="spices"></iframe>
```

---

The `Window` object supports named properties. The supported property names of a `Window` object `window` at any moment consist of the following, in tree order according to the element that contributed them, ignoring later duplicates:

- `window`'s document-tree child browsing context name property set.
- the value of the name content attribute for all `embed`, `form`, `frameset`, `img`, and `object` elements that have a
non-empty name content attribute and are in a document tree with window's browsing context's active document as their root; and

• the value of the id content attribute for all HTML elements that have a non-empty id content attribute and are in a document tree with window's browsing context's active document as their root.

To determine the value of a named property name in a Window, the user agent must return the value obtained using the following steps:

1. Let objects be the list of named objects with the name name.

   There will be at least one such object, by definition.

2. If objects contains a nested browsing context, then return the WindowProxy object of the nested browsing context corresponding to the first browsing context container in tree order whose nested browsing context is in objects.

3. Otherwise, if objects has only one element, return that element.

4. Otherwise return an HTMLCollection rooted at the Document node, whose filter matches only named objects with the name name. (By definition, these will all be elements.)

Named objects with the name name, for the purposes of the above algorithm, consist of the following:

• document-tree child browsing contexts of the active document whose name is name;

• embed, form, frameset, img, or object elements that have a name content attribute whose value is name and are in a document tree with the active document as their root; and

• HTML elements that have an id content attribute whose value is name and are in a document tree with the active document as their root.

7.3.4 Garbage collection and browsing contexts

A browsing context has a strong reference to each of its Document's and its WindowProxy object, and the user agent itself has a strong reference to its top-level browsing contexts.

A Document has a strong reference to its Window object.

A Window object has a strong reference to its Document object through its document attribute. Thus, references from other scripts to either of those objects will keep both alive. Similarly, both Document and Window objects have implied strong references to the WindowProxy object.

Each script has a strong reference to its settings object and each environment settings object has strong references to its global object, responsible browsing context, and responsible document (if any).

To discard a Document document:

1. Set document's salvageable state to false.

2. Run any unloading document cleanup steps for document that are defined by this specification and other applicable specifications.

3. Abort document.

4. Remove any tasks associated with document in any task source, without running those tasks.

5. Discard all the child browsing contexts of document.

6. Lose the strong reference from document's browsing context to document.

7. Remove document from the owner set of each WorkerGlobalScope object whose set contains document.
When a browsing context is discarded, the strong reference from the user agent itself to the browsing context must be severed, and all the Document objects for all the entries in the browsing context’s session history must be discarded as well.

User agents may discard top-level browsing contexts at any time (typically, in response to user requests, e.g. when a user force-closes a window containing one or more top-level browsing contexts). Other browsing contexts must be discarded once their WindowProxy object is eligible for garbage collection, in addition to the other places where this specification requires them to be discarded.

A WindowProxy does not have a strong reference to the browsing context it was created alongside. In particular, it is possible for a nested browsing context to be discarded even if JavaScript code holds a reference to its WindowProxy object.

7.3.5 Closing browsing contexts

To close a browsing context, run these steps:

1. Prompt to unload browsingContext's active document. If the user refused to allow the document to be unloaded, then return.
2. Unload browsingContext's active document with the recycle parameter set to false.
3. Remove browsingContext from the user interface (e.g., close or hide its tab in a tabbed browser).

User agents should offer users the ability to arbitrarily close any top-level browsing context.

7.3.6 Browser interface elements

To allow Web pages to integrate with Web browsers, certain Web browser interface elements are exposed in a limited way to scripts in Web pages.

Each interface element is represented by a BarProp object:

```
IDL [Exposed=Window]
interface BarProp {
  readonly attribute boolean visible;
};
```

For web developers (non-normative)

```
window . locationbar . visible
Returns true if the location bar is visible; otherwise, returns false.

window . menubar . visible
Returns true if the menu bar is visible; otherwise, returns false.

window . personalbar . visible
Returns true if the personal bar is visible; otherwise, returns false.

window . scrollbars . visible
Returns true if the scroll bars are visible; otherwise, returns false.

window . statusbar . visible
Returns true if the status bar is visible; otherwise, returns false.

window . toolbar . visible
Returns true if the toolbar is visible; otherwise, returns false.
```
The `visible` attribute, on getting, must return either true or a value determined by the user agent to most accurately represent the visibility state of the user interface element that the object represents, as described below.

The following `BarProp` objects exist for each `Document` object in a browsing context. Some of the user interface elements represented by these objects might have no equivalent in some user agents; for those user agents, except when otherwise specified, the object must act as if it was present and visible (i.e. its `visible` attribute must return true).

**The location bar `BarProp` object**

Represents the user interface element that contains a control that displays the URL of the active document, or some similar interface concept.

**The menu bar `BarProp` object**

Represents the user interface element that contains a list of commands in menu form, or some similar interface concept.

**The personal bar `BarProp` object**

Represents the user interface element that contains links to the user's favorite pages, or some similar interface concept.

**The scrollbar `BarProp` object**

Represents the user interface element that contains a scrolling mechanism, or some similar interface concept.

**The status bar `BarProp` object**

Represents a user interface element found immediately below or after the document, as appropriate for the user's media, which typically provides information about ongoing network activity or information about elements that the user's pointing device is current indicating. If the user agent has no such user interface element, then the object may act as if the corresponding user interface element was absent (i.e. its `visible` attribute may return false).

**The toolbar `BarProp` object**

Represents the user interface element found immediately above or before the document, as appropriate for the user's media, which typically provides session history traversal controls (back and forward buttons, reload buttons, etc). If the user agent has no such user interface element, then the object may act as if the corresponding user interface element was absent (i.e. its `visible` attribute may return false).

The `locationbar` attribute must return the location bar `BarProp` object.

The `menubar` attribute must return the menu bar `BarProp` object.

The `personalbar` attribute must return the personal bar `BarProp` object.

The `scrollbars` attribute must return the scrollbar `BarProp` object.

The `statusbar` attribute must return the status bar `BarProp` object.

The `toolbar` attribute must return the toolbar `BarProp` object.

For historical reasons, the `status` attribute on the `Window` object, on getting, return the last string it was set to, and on setting, must set itself to the new value. When the `Window` object is created, the attribute must be set to the empty string. It does not do anything else.

### 7.3.7 Script settings for `Window` objects

When the user agent is required to set up a window environment settings object, given a JavaScript execution context and an optional reserved environment, it must run the following steps:

1. Let `realm` be the value of `execution context`'s Realm component.
2. Let `window` be `realm`'s `global object`.
3. Let `url` be a copy of the URL of `window`'s `associated Document`.
4. Let `settings object` be a new environment settings object whose algorithms are defined as follows:

   **The `realm execution context`**

   Return `execution context`.

799
The **module map**
Return the **module map** of window's associated Document.

The **responsible browsing context**
Return the **browsing context** with which window is associated.

The **responsible event loop**
Return the **event loop** that is associated with the unit of related similar-origin browsing contexts to which window's browsing context belongs.

The **responsible document**
Return window's associated Document.

The **API URL character encoding**
Return the current character encoding of window's associated Document.

The **API base URL**
Return the current base URL of window's associated Document.

The **origin**
Return the **origin** of window's associated Document.

The **HTTPS state**
Return the HTTPS state of window's associated Document.

The **referrer policy**

1. Let document be the Document with which window is currently associated.
2. While document is an iframe srcdoc document and document's referrer policy is the empty string, set document to document's browsing context's browsing context container's node document.

5. If reserved environment is given, then:

1. Set settings object's id to reserved environment's id, settings object's creation URL to reserved environment's creation URL, settings object's target browsing context to reserved environment's target browsing context, and settings object's active service worker to reserved environment's active service worker.
2. Set reserved environment's id to the empty string.

6. Otherwise, set settings object's id to a new unique opaque string, settings object's creation URL to url, settings object's target browsing context to null, and settings object's active service worker to null.

7. Set realm's [[HostDefined]] field to settings object.

8. Return settings object.

---

### 7.4 The **WindowProxy** exotic object

A **WindowProxy** is an exotic object that wraps a **Window** ordinary object, indireecting most operations through to the wrapped object. Each **browsing context** has an associated **WindowProxy** object. When the **browsing context** is navigated, the **Window** object wrapped by the **browsing context**'s associated **WindowProxy** object is changed.

There is no **WindowProxy** interface object.
Every `WindowProxy` object has a `[[Window]]` internal slot representing the wrapped `Window` object.

The `WindowProxy` object internal methods are described in the subsections below.

**Note** Although `WindowProxy` is named as a "proxy", it does not do polymorphic dispatch on its target's internal methods as a real proxy would, due to a desire to reuse machinery between `WindowProxy` and `Location` objects. As long as the `Window` object remains an ordinary object this is unobservable and can be implemented either way.

### 7.4.1 `[[GetPrototypeOf]]()`

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. If `IsPlatformObjectSameOrigin(W)` is true, then return `OrdinaryGetPrototypeOf(W)`.  
3. Return null.

### 7.4.2 `[[SetPrototypeOf]]`( `V` )

1. Return `SetImmutablePrototype(this, V)`.

### 7.4.3 `[[IsExtensible]]()`

1. Return true.

### 7.4.4 `[[PreventExtensions]]()`

1. Return false.

### 7.4.5 `[[GetOwnProperty]]`( `P` )

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. If `P` is an array index property name, then:
   1. Let `index` be `ToUint32(P)`.
   2. Let `maxProperties` be the number of document-tree child browsing contexts of `W`.
   3. Let `value` be undefined.
   4. If `maxProperties` is greater than 0 and `index` is less than `maxProperties`, then:
      2. Set `value` to the `WindowProxy` object of the `index`th document-tree child browsing context of document's browsing context, sorted in the order that their browsing context container elements were most recently inserted into document, the `WindowProxy` object of the most recently inserted browsing context container's nested browsing context being last.
   5. If `value` is undefined, then return undefined.
   6. Return `PropertyDescriptor({[[Value]]: value, [[Writable]]: false, [[Enumerable]]: true, [[Configurable]]: true })`.
3. If \( \text{IsPlatformObjectSameOrigin}\) is true, then return \( \text{OrdinaryGetOwnProperty}(W, P) \).

**Note**
This is a willful violation of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing Web content. See tc39/ecma262 issue #672 for more information.

[JavaScript]

4. Let property be \( \text{CrossOriginGetOwnPropertyHelper}(W, P) \).

5. If property is not undefined, then return property.

6. If property is undefined and \( P \) is in \( W \)'s document-tree child browsing context name property set, then:
   1. Let value be the \( \text{WindowProxy} \) object of the named \( \text{object} \) with the name \( P \).
   2. Return \( \text{PropertyDescriptor} \{ \text{[[Value]]}: \text{value}, \text{[[Enumerable]]}: \text{false}, \text{[[Writable]]}: \text{false}, \text{[[Configurable]]}: \text{true} \} \).

**Note**
The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing Web content. See issue #3183 for details.

7. Throw a "SecurityError" \( \text{DOMException} \).

**7.4.6 \([\text{DefineOwnProperty}] (P, \text{Desc})\)**

1. Let \( W \) be the value of the \( \text{[[Window]]} \) internal slot of this.

2. If \( \text{IsPlatformObjectSameOrigin}(W) \) is true, then:
   1. If \( P \) is an array index property name, return false.
   2. Return ? \( \text{OrdinaryDefineOwnProperty}(W, P, \text{Desc}) \).

**Note**
This is a willful violation of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing Web content. See tc39/ecma262 issue #672 for more information.

[JavaScript]

3. Throw a "SecurityError" \( \text{DOMException} \).

**7.4.7 \([\text{Get}] (P, \text{Receiver})\)**

1. Let \( W \) be the value of the \( \text{[[Window]]} \) internal slot of this.

2. If \( \text{IsPlatformObjectSameOrigin}(W) \) is true, then return ? \( \text{OrdinaryGet}(\text{this}, P, \text{Receiver}) \).

3. Return ? \( \text{CrossOriginGet}(\text{this}, P, \text{Receiver}) \).

**7.4.8 \([\text{Set}] (P, V, \text{Receiver})\)**

1. Let \( W \) be the value of the \( \text{[[Window]]} \) internal slot of this.

2. If \( \text{IsPlatformObjectSameOrigin}(W) \) is true, then return ? \( \text{OrdinarySet}(W, \text{this}, \text{Receiver}) \).

3. Return ? \( \text{CrossOriginSet}(\text{this}, P, V, \text{Receiver}) \).
7.4.9 [[Delete]] (P) §803

1. Let \( W \) be the value of the \([\text{Window}]\) internal slot of \text{this}.

2. If ! IsPlatformObjectSameOrigin\( ^{790} (W) \) is true, then:
   1. If \( P \) is an array index property name, then:
      1. Let \( \text{desc} \) be \text{this}[[GetOwnProperty]](\( P \)).
      2. If \( \text{desc} \) is undefined, then return true.
      3. Return false.
   2. Return ? OrdinaryDelete\( (W, P) \).

3. Throw a "SecurityError" DOMException.

7.4.10 [[OwnPropertyKeys]] ( ) §803

1. Let \( W \) be the value of the \([\text{Window}]\) internal slot of \text{this}.

2. Let keys be a new empty List.

3. Let \( \text{maxProperties} \) be the number of document-tree child browsing contexts\( ^{796} \) of \( W \).

4. Let index be 0.

5. Repeat while index < maxProperties,
   1. Add ! ToString\( (\text{index}) \) as the last element of keys.
   2. Increment index by 1.

6. If ! IsPlatformObjectSameOrigin\( ^{790} (W) \) is true, then return the concatenation of keys and ! OrdinaryOwnPropertyKeys\( (W) \).

7. Return the concatenation of keys and ! CrossOriginOwnPropertyKeys\( ^{791} (W) \).

7.5 Origin §803

Origins are the fundamental currency of the Web's security model. Two actors in the Web platform that share an origin are assumed to trust each other and to have the same authority. Actors with differing origins are considered potentially hostile versus each other, and are isolated from each other to varying degrees.

Example

For example, if Example Bank's Web site, hosted at bank.example.com, tries to examine the DOM of Example Charity's Web site, hosted at charity.example.org, a "SecurityError" DOMException will be raised.

An origin is one of the following:

An opaque origin

An internal value, with no serialization it can be recreated from (it is serialized as "null" per serialization of an origin\( ^{805} \)), for which the only meaningful operation is testing for equality.

A tuple origin

A tuple\( ^{803} \) consists of:

- A scheme (a scheme).
- A host (a host).
- A port (a port).
- A domain (null or a domain). Null unless stated otherwise.
The effective domain of an origin is computed as follows:

1. If origin is an opaque origin, then return null.
2. If origin's domain is non-null, then return origin's domain.
3. Return origin's host.

Various specification objects are defined to have an origin. These origins are determined as follows:

For Document objects
- If the Document's active sandboxing flag set has its sandboxed origin browsing context flag set
- If the Document was generated from a data: URL
  A unique opaque origin assigned when the Document is created.
- If the Document's URL's scheme is a network scheme
  A copy of the Document's URL's origin assigned when the Document is created.
- If the Document is the initial "about:blank" document
  The one it was assigned when its browsing context was created.
- If the Document is a non-initial "about:blank" document
  The origin of the incumbent settings object when the navigate algorithm was invoked, or, if no script was involved, the origin of the node document of the element that initiated the navigation to that URL.
- If the Document was created as part of the processing for javascript: URLs
  The origin of the active document of the browsing context being navigated when the navigate algorithm was invoked.
- If the Document is an iframe srcdoc document
  The origin of the Document's browsing context's browsing context container's node document.
- If the Document was obtained in some other manner (e.g. a Document created using the createDocument() API, etc)
  The default behavior as defined in the WHATWG DOM standard applies. [DOM].

For images of elements
- If the image data is CORS-cross-origin
  A unique opaque origin assigned when the image is created.
- If the image data is CORS-same-origin
  The img element's node document's origin.

For audio and video elements
- If the media data is CORS-cross-origin
  A unique opaque origin assigned when the media data is fetched.
- If the media data is CORS-same-origin
  The media element's node document's origin.

Other specifications can override the above definitions by themselves specifying the origin of a particular Document object, image, or media element.
The serialization of an origin is the string obtained by applying the following algorithm to the given origin:

1. If origin is an opaque origin, then return "null".
2. Otherwise, let result be origin's scheme.
3. Append "://" to result.
4. Append origin's host, serialized, to result.
5. If origin's port is non-null, append a U+003A COLON character (:), and origin's port, serialized, to result.
6. Return result.

Example

The serialization of ("https", "xn--maraa-rta.example", null, null) is "https://xn--maraa-rta.example".

Note

There used to also be a Unicode serialization of an origin. However, it was never widely adopted.

Two origins, A and B, are said to be same origin if the following algorithm returns true:

1. If A and B are the same opaque origin, then return true.
2. If A and B are both tuple origins and their schemes, hosts, and port are identical, then return true.
3. Return false.

Two origins, A and B, are said to be same origin-domain if the following algorithm returns true:

1. If A and B are the same opaque origin, then return true.
2. If A and B are both tuple origins, run these substeps:
   1. If A and B's schemes are identical and their domains are identical and non-null, then return true.
   2. Otherwise, if A and B are same origin and their domains are identical and null, then return true.
3. Return false.

Example

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>same origin</th>
<th>same origin-domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>(&quot;https&quot;, &quot;example.org&quot;, null, null)</td>
<td>(&quot;https&quot;, &quot;example.org&quot;, null, null)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>(&quot;https&quot;, &quot;example.org&quot;, 314, null)</td>
<td>(&quot;https&quot;, &quot;example.org&quot;, 420, null)</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>(&quot;https&quot;, &quot;example.org&quot;, 314, &quot;example.org&quot;)</td>
<td>(&quot;https&quot;, &quot;example.org&quot;, 420, &quot;example.org&quot;)</td>
<td>X</td>
<td>✓</td>
</tr>
<tr>
<td>(&quot;https&quot;, &quot;example.org&quot;, null, null)</td>
<td>(&quot;https&quot;, &quot;example.org&quot;, null, &quot;example.org&quot;)</td>
<td>✓</td>
<td>X</td>
</tr>
<tr>
<td>(&quot;https&quot;, &quot;example.org&quot;, null, &quot;example.org&quot;)</td>
<td>(&quot;http&quot;, &quot;example.org&quot;, null, &quot;example.org&quot;)</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

7.5.1 Relaxing the same-origin restriction

For web developers (non-normative)

document . domain [ = domain ]

Returns the current domain used for security checks.

Can be set to a value that removes subdomains, to change the origin's domain, to allow pages on other subdomains of the same domain (if they do the same thing) to access each other. (Can't be set in sandboxed iframes.)

To determine if a string hostSuffixString is a registrable domain suffix of or is equal to a host originalHost, run these steps:

1. If hostSuffixString is the empty string, then return false.
2. Let host be the result of parsing hostSuffixString.

3. If host is failure, then return false.

4. If host does not equal originalHost, then:
   1. If host or originalHost is not a domain, then return false.
   2. If host, prefixed by a U+002E FULL STOP (.), does not exactly match the end of originalHost, then return false.
   3. If host equals host’s public suffix, then return false. [URL]

5. Return true.

The domain attribute’s getter must run these steps:

1. Let effectiveDomain be this Document object’s origin’s effective domain.
2. If effectiveDomain is null, then return the empty string.
3. Return effectiveDomain, serialized.

The domain attribute’s setter must run these steps:

1. If this Document object has no browsing context, then throw a "SecurityError" DOMException.
2. If this Document object’s active sandboxing flag has its sandboxed document domain browsing context flag set, then throw a "SecurityError" DOMException.
3. Let effectiveDomain be this Document object’s origin’s effective domain.
4. If effectiveDomain is null, then throw a "SecurityError" DOMException.
5. If the given value is not a registrable domain suffix of and is not equal to effectiveDomain, then throw a "SecurityError" DOMException.
6. Set this Document object’s origin’s domain to the result of parsing the given value.

Note: The document.domain attribute is used to enable pages on different hosts of a domain to access each other’s DOMs.

⚠️ Warning! Do not use the document.domain attribute when using shared hosting. If an untrusted third party is able to host an HTTP server at the same IP address but on a different port, then the same-origin protection that normally protects two different sites on the same host will fail, as the ports are ignored when comparing origins after the document.domain attribute has been used.

### 7.6 Sandboxing

A sandboxing flag set is a set of zero or more of the following flags, which are used to restrict the abilities that potentially untrusted resources have:

The sandboxed navigation browsing context flag

This flag prevents content from navigating browsing contexts other than the sandboxed browsing context itself, (or browsing contexts further nested inside it), auxiliary browsing contexts (which are protected by the sandboxed auxiliary navigation browsing context flag, defined next), and the top-level browsing context (which is protected by the sandboxed top-level navigation without user activation browsing context flag and sandboxed top-level navigation with user activation browsing context flag, defined below).

If the sandboxed auxiliary navigation browsing context flag is not set, then in certain cases the restrictions nonetheless allow popups (new top-level browsing contexts) to be opened. These browsing contexts always have one permitted sandboxed
navigator, set when the browsing context is created, which allows the browsing context that created them to actually navigate them. (Otherwise, the sandboxed navigation browsing context flag would prevent them from being navigated even if they were opened.)

The sandboxed auxiliary navigation browsing context flag
This flag prevents content from creating new auxiliary browsing contexts, e.g. using the target attribute or the method.

The sandboxed top-level navigation without user activation browsing context flag
This flag prevents content from navigating their top-level browsing context and prevents content from closing their top-level browsing context. It is consulted only from algorithms that are not triggered by user activation.

When the sandboxed top-level navigation without user activation browsing context flag is not set, content can navigate its top-level browsing context, but other browsing contexts are still protected by the sandboxed navigation browsing context flag and possibly the sandboxed auxiliary navigation browsing context flag.

The sandboxed top-level navigation with user activation browsing context flag
This flag prevents content from navigating their top-level browsing context and prevents content from closing their top-level browsing context. It is consulted only from algorithms that are triggered by user activation.

As with the sandboxed top-level navigation without user activation browsing context flag, this flag only affects the top-level browsing context; if it is not set, other browsing contexts might still be protected by other flags.

The sandboxed plugins browsing context flag
This flag prevents content from instantiating plugins, whether using the embed element, the object element, or through navigation of a nested browsing context, unless those plugins can be secured.

The sandboxed origin browsing context flag
This flag forces content into a unique origin, thus preventing it from accessing other content from the same origin.

This flag also prevents script from reading from or writing to the document.cookie IDL attribute, and blocks access to the localstorage.

The sandboxed forms browsing context flag
This flag blocks form submission.

The sandboxed pointer lock browsing context flag
This flag disables the Pointer Lock API.

The sandboxed scripts browsing context flag
This flag blocks script execution.

The sandboxed automatic features browsing context flag
This flag blocks features that trigger automatically, such as automatically playing a video or automatically focusing a form control.

The sandboxed storage area URLs flag
This flag prevents URL schemes that use storage areas from being able to access the origin's data.

The sandboxed document.domain browsing context flag
This flag prevents content from using the document.domain setter.

The sandbox propagates to auxiliary browsing contexts flag
This flag prevents content from escaping the sandbox by ensuring that any auxiliary browsing context creates inherits the content's active sandboxing flag set.

The sandboxed modals flag
This flag prevents content from using any of the following features to produce modal dialogs:

- window.alert()
- window.confirm()
• `window.print()`
• `window.prompt()`
• the `beforeunload` event

**The sandboxed orientation lock browsing context flag**

This flag disables the ability to lock the screen orientation. [SCREENORIENTATION]

**The sandboxed presentation browsing context flag**

This flag disables the Presentation API. [PRESENTATION]

When the user agent is to **parse a sandboxing directive**, given a string `input`, a `sandboxing flag set` output, it must run the following steps:

1. Split `input` on ASCII whitespace, to obtain `tokens`.
2. Let `output` be empty.
3. Add the following flags to `output`:
   - The `sandboxed navigation browsing context flag`.
   - The `sandboxed auxiliary navigation browsing context flag`, unless `tokens` contains the `allow-popups` keyword.
   - The `sandboxed top-level navigation without user activation browsing context flag`, unless `tokens` contains the `allow-top-navigation` keyword.
   - The `sandboxed top-level navigation with user activation browsing context flag`, unless `tokens` contains either the `allow-top-navigation-by-user-activation` keyword or the `allow-top-navigation` keyword.
   - The `sandboxed plugins browsing context flag`.
   - The `sandboxed origin browsing context flag`, unless the `tokens` contains the `allow-same-origin` keyword.
   - The `sandboxed forms browsing context flag`, unless `tokens` contains the `allow-forms` keyword.
   - The `sandboxed pointer lock browsing context flag`, unless `tokens` contains the `allow-pointer-lock` keyword.
   - The `sandboxed scripts browsing context flag`, unless `tokens` contains the `allow-scripts` keyword.
   - The `sandboxed automatic features browsing context flag`, unless `tokens` contains the `allow-scripts` keyword (defined above).
   - The `sandboxed storage area URLs flag`.
   - The `sandboxed document, domain browsing context flag`.

**Note**

This means that if the `allow-top-navigation` is present, the `allow-top-navigation-by-user-activation` keyword will have no effect. For this reason, specifying both is a document conformance error.

**Note**

The `allow-same-origin` keyword is intended for two cases.

First, it can be used to allow content from the same site to be sandboxed to disable scripting, while still allowing access to the DOM of the sandboxed content.

Second, it can be used to embed content from a third-party site, sandboxed to prevent that site from opening pop-up windows, etc, without preventing the embedded page from communicating back to its originating site, using the database APIs to store data, etc.

**Note**

This flag is relaxed by the same keyword as scripts, because when scripts are enabled these features are trivially possible anyway, and it would be unfortunate to force authors to use script to do them when sandboxed rather than allowing them to use the declarative features.
The sandbox propagates to auxiliary browsing contexts flag\(^{807}\), unless tokens contains the allow-popups-to-escape-sandbox keyword.

The sandboxed modals flag\(^{807}\), unless tokens contains the allow-modals keyword.

The sandboxed orientation lock browsing context flag\(^{808}\), unless tokens contains the allow-orientation-lock keyword.

The sandboxed presentation browsing context flag\(^{808}\), unless tokens contains the allow-presentation keyword.

Every top-level browsing context\(^{782}\) has a popup sandboxing flag set, which is a sandboxing flag set\(^{806}\). When a browsing context\(^{780}\) is created, its popup sandboxing flag set\(^{806}\) must be empty. It is populated by the rules for choosing a browsing context\(^{787}\).

Every browsing context\(^{780}\) that is a nested browsing context\(^{781}\) has an iframe sandboxing flag set, which is a sandboxing flag set\(^{806}\). Which flags in a nested browsing context\(^{781}\)’s iframe sandboxing flag set\(^{806}\) are set at any particular time is determined by the iframe\(^{344}\) element’s sandbox\(^{331}\) attribute.

Every Document\(^{118}\) has an active sandboxing flag set, which is a sandboxing flag set\(^{806}\). When the Document\(^{116}\) is created, its active sandboxing flag set\(^{806}\) must be empty. It is populated by the navigation algorithm\(^{825}\).

Every resource that is obtained by the navigation algorithm\(^{825}\) has a forced sandboxing flag set, which is a sandboxing flag set\(^{806}\). A resource by default has no flags set in its forced sandboxing flag set\(^{809}\), but other specifications can define that certain flags are set.

Note

In particular, the forced sandboxing flag set\(^{809}\) is used by Content Security Policy. [CSP]\(^{8122}\)

To implement the sandboxing for a Document\(^{118}\) object document, populate document’s active sandboxing flag set\(^{809}\) with the union of the flags that are present in the following sandboxing flag sets\(^{806}\):

- If document’s browsing context\(^{780}\) is a top-level browsing context\(^{782}\), then: the flags set on the browsing context\(^{780}\)’s popup sandboxing flag set\(^{806}\).
- If document’s browsing context\(^{780}\) is a nested browsing context\(^{781}\), then: the flags set on the browsing context\(^{780}\)’s iframe sandboxing flag set\(^{809}\).
- If document’s browsing context\(^{780}\) is a nested browsing context\(^{781}\), then: the flags set on the browsing context\(^{780}\)’s parent browsing context\(^{782}\)’s active document\(^{780}\)’s active sandboxing flag set\(^{809}\).
- The flags set on document’s resource’s forced sandboxing flag set\(^{809}\), if it has one.

7.7 Session history and navigation \(^{80}\)

7.7.1 The session history of browsing contexts \(^{80}\)

The sequence of Document\(^{118}\)’s in a browsing context\(^{780}\) is its session history. Each browsing context\(^{780}\), including nested browsing contexts\(^{781}\), has a distinct session history. A browsing context\(^{780}\)’s session history consists of a flat list of session history entries\(^{809}\). Each session history entry consists, at a minimum, of a URL, and each entry may in addition have serialized state\(^{810}\), a title, a Document\(^{116}\) object, form data, a scroll restoration mode\(^{816}\), a scroll position, a browsing context name\(^{786}\), and other information associated with it.

Note

Each entry, when first created, has a Document\(^{118}\). However, when a Document\(^{118}\) is not active\(^{782}\), it’s possible for it to be discarded\(^{792}\) to free resources. The URL and other data in a session history entry\(^{809}\) is then used to bring a new Document\(^{116}\) into being to take the place of the original, in case the user agent finds itself having to reactivate that Document\(^{116}\).

Note

Titles associated with session history entries\(^{809}\) need not have any relation with the current title\(^{816}\) of the Document\(^{116}\). The title of a session history entry\(^{809}\) is intended to explain the state of the document at that point, so that the user can navigate the document’s history.
URLs without associated serialized state\textsuperscript{818} are added to the session history as the user (or script) navigates from page to page.

Each Document\textsuperscript{p116} object in a browsing context\textsuperscript{p780} is session history\textsuperscript{a809} is associated with a unique History\textsuperscript{p811} object which must all model the same underlying session history\textsuperscript{a809}.

The history attribute of the Window\textsuperscript{p791} interface must return the object implementing the History\textsuperscript{p811} interface for this Window\textsuperscript{p791} object's associated Document\textsuperscript{p793}.

Serialized state is a serialization (via StructuredSerializeForStorage\textsuperscript{p104}) of an object representing a user interface state. We sometimes informally refer to "state objects", which are the objects representing user interface state supplied by the author, or alternately the objects created by deserializing (via StructuredDeserialize\textsuperscript{p104}) serialized state.

Pages can add serialized state\textsuperscript{p810} to the session history. These are then deserialized and returned to the script\textsuperscript{p1217} when the user (or script) goes back in the history, thus enabling authors to use the "navigation" metaphor even in one-page applications.

At any point, one of the entries in the session history is the current entry. This is the entry representing the active document\textsuperscript{p770} of the browsing context\textsuperscript{p780}. Which entry is the current entry\textsuperscript{p810} is changed by the algorithms defined in this specification, e.g. during session history traversal\textsuperscript{p837}.

An entry with persisted user state is one that also has user-agent defined state. This specification does not specify what kind of state can be stored.

An entry's scroll restoration mode indicates whether the user agent should restore the persisted scroll position (if any) when traversing to it. The scroll restoration mode may be one of the following:

"auto"

The user agent is responsible for restoring the scroll position upon navigation.

"manual"

The page is responsible for restoring the scroll position and the user agent does not attempt to do so automatically.

If unspecified, the scroll restoration mode\textsuperscript{p810} of a new entry must be set to "auto\textsuperscript{p810}".

Entries that contain serialized state\textsuperscript{p810} share the same Document\textsuperscript{p110} as the entry for the page that was active when they were added.
Contiguous entries that differ just by their URLs' fragments also share the same Document.

Note

All entries that share the same Document (and that are therefore merely different states of one particular document) are contiguous by definition.

Each Document in a browsing context can also have a latest entry. This is the entry for that Document to which the browsing context's session history was most recently traversed. When a Document is created, it initially has no latest entry.

User agents may discard the Document objects of entries other than the current entry that are not referenced from any script, reloading the pages afresh when the user or script navigates back to such pages. This specification does not specify when user agents should discard Document objects and when they should cache them.

Entries that have had their Document objects discarded must, for the purposes of the algorithms given below, act as if they had not. When the user or script navigates back or forwards to a page which has no in-memory DOM objects, any other entries that shared the same Document object with it must share the new object as well.

### 7.7.2 The History interface

```idl
enum ScrollRestoration {
  "auto", "manual";

[Exposed=Window]
interface History {
  readonly attribute unsigned long length;
  attribute ScrollRestoration scrollRestoration;
  readonly attribute any state;
  void go(optional long delta = 0);
  void back();
  void forward();
  void pushState(any data, DOMString title, optional USVString? url = null);
  void replaceState(any data, DOMString title, optional USVString? url = null);
};
```

**For web developers (non-normative)**

`window.history.length`  
Returns the number of entries in the joint session history.

`window.history.scrollRestoration[ = value ]`  
Returns the scroll restoration mode of the current entry in the session history. Can be set, to change the scroll restoration mode of the current entry in the session history.

`window.history.state`  
Returns the current serialized state, deserialized into an object.

`window.history.go([ delta ])`  
Goes back or forward the specified number of steps in the joint session history. A zero delta will reload the current page. If the delta is out of range, does nothing.

`window.history.back()`  
Goes back one step in the joint session history. If there is no previous page, does nothing.

`window.history.forward()`  
Goes forward one step in the joint session history. If there is no next page, does nothing.
The **joint session history** of a **top-level browsing context** is the union of all the **session histories** of all **browsing contexts** of all the **fully active** objects that share that **top-level browsing context**, with all the entries that are **current entries** in their respective **session histories**, removed except for the current entry of the joint session history.

The **current entry of the joint session history** is the entry that most recently became a current entry in its **session history**.

Entries in the joint session history are ordered chronologically by the time they were added to their respective **session histories**. Each entry has an index; the earliest entry has index 0, and the subsequent entries are numbered with consecutively increasing integers (1, 2, 3, etc.).

**Note** Since each **Document** in a **browsing context** might have a different **event loop**, the actual state of the joint session history can be somewhat nebulous. For example, two sibling **iframe** elements could both **traverse** from one unique origin to another at the same time, so their precise order might not be well-defined; similarly, since they might only find out about each other later, they might disagree about the length of the joint session history.

The **length** attribute of the **History** interface, on getting, must return the number of entries in the **top-level browsing context**'s joint session history. If this **History** object is associated with a **Document** that is not **fully active**, getting must instead throw a "**SecurityError**" **DOMException**.

The actual entries are not accessible from script.

The **scrollRestoration** attribute of the History interface, on getting, must return the **scroll restoration mode** of the current entry in the **session history**. On setting, the **scroll restoration mode** of the current entry in the **session history** must be set to the new value. If this **History** object is associated with a **Document** that is not **fully active**, both getting and setting must instead throw a "**SecurityError**" **DOMException**.

The **state** attribute of the **History** interface, on getting, must return the last value it was set to by the user agent. If this **History** object is associated with a **Document** that is not **fully active**, getting must instead throw a "**SecurityError**" **DOMException**. Initially, its value must be null.

When the **go(delta)** method is invoked, if delta is zero, the user agent must act as if the **location.reload()** method was called instead. Otherwise, the user agent must **traverse the history by a delta** whose value is delta. If this **History** object is associated with a **Document** that is not **fully active**, invoking must instead throw a "**SecurityError**" **DOMException**.

When the **back()** method is invoked, the user agent must **traverse the history by a delta** −1. If this **History** object is associated with a **Document** that is not **fully active**, invoking must instead throw a "**SecurityError**" **DOMException**.

When the **forward()** method is invoked, the user agent must **traverse the history by a delta** +1. If this **History** object is associated with a **Document** that is not **fully active**, invoking must instead throw a "**SecurityError**" **DOMException**.

Each **top-level browsing context** has a **session history traversal queue**, initially empty, to which **tasks** can be added.

Each **top-level browsing context**, when created, must begin running the following algorithm, known as the **session history event loop** for that **top-level browsing context**, in parallel:

1. Wait until this **top-level browsing context**'s **session history traversal queue** is not empty.
2. Pull the first **task** from this **top-level browsing context**'s **session history traversal queue**, and execute it.
3. Return to the first step of this algorithm.

The **session history event loop** helps coordinate cross-browsing-context transitions of the **joint session history**, since each **browsing context** might, at any particular time, have a different **event loop** (this can happen if the user agent has more than one
To traverse the history by a delta \( \delta \), the user agent must append a task to this top-level browsing context's session history traversal queue, the task consisting of running the following steps:

1. If the index of the current entry of the joint session history plus \( \delta \) is less than zero or greater than or equal to the number of items in the joint session history, then return.
2. Let specified entry be the entry in the joint session history whose index is the sum of \( \delta \) and the index of the current entry of the joint session history.
3. Let specified browsing context be the browsing context of the specified entry.
4. If the specified browsing context's active document's unload a document algorithm is currently running, return.
5. Queue a task that consists of running the following substeps. The relevant event loop is that of the specified browsing context's active document. The task source for the queued task is the history traversal task source.
   1. If there is an ongoing attempt to navigate specified browsing context that has not yet matured (i.e. it has not passed the point of making its Document the active document), then cancel that attempt to navigate the browsing context.
   2. If the specified browsing context's active document is not the same Document as the Document of the specified entry, then run these substeps:
      1. Prompt to unload the active document of the specified browsing context. If the user refused to allow the document to be unloaded, then return.
      2. Unload the active document of the specified browsing context with the recycle parameter set to false.
   3. Traverse the history of the specified browsing context to the specified entry with the history-navigation flag set.

When the user navigates through a browsing context, e.g. using a browser's back and forward buttons, the user agent must traverse the history by a delta equivalent to the action specified by the user.

The pushState(data, title, url) method adds a state object entry to the history.

The replaceState(data, title, url) method updates the state object, title, and optionally the URL of the current entry in the history.

When either of these methods is invoked, the user agent must run the following steps:

1. Let document be the unique Document object this History object is associated with.
2. If document is not fully active, throw a "SecurityError" DOMException.
3. Optionally, return. (For example, the user agent might disallow calls to these methods that are invoked on a timer, or from event listeners that are not triggered in response to a clear user action, or that are invoked in rapid succession.)
4. Let targetRealm be this History object's relevant Realm.
5. Let serializedData be StructuredSerializeForStorage(data). Rethrow any exceptions.
6. If the third argument is not null, run these substeps:
   1. Parse the value of the third argument, relative to the relevant settings object of this History object.
   2. If that fails, throw a "SecurityError" DOMException.
   3. Let new URL be the resulting URL record.
   4. Compare new URL to document's URL. If any component of these two URL records differ other than the path, query, and fragment components, then throw a "SecurityError" DOMException.
   5. If the origin of new URL is not same origin with the origin of document, and either the path or query...
components of the two URL records compared in the previous step differ, throw a "SecurityError"
DOMException. (This prevents sandboxed content from spoofing other pages on the same origin.)

7. If the third argument is null, then let new URL be the URL of the current entry.

8. If the method invoked was the pushState() method:
   1. Remove all the entries in the browsing context's session history after the current entry. If the current entry is the last entry in the session history, then no entries are removed.
   
   **Note**
   
   This doesn't necessarily have to affect the user agent's user interface.

   2. Remove any tasks queued by the history traversal task source that are associated with any Document objects in the top-level browsing context's document family.

   3. If appropriate, update the current entry to reflect any state that the user agent wishes to persist. The entry is then said to be an entry with persisted user state.

   4. Add a session history entry entry to the session history, after the current entry, with serializedData as the serialized state, the given title as the title, new URL as the URL of the entry, and the scroll restoration mode of the current entry in the session history as the scroll restoration mode.

   5. Update the current entry to be this newly added entry.

Otherwise, if the method invoked was the replaceState() method:
   1. Update the current entry in the session history so that serializedData is the entry's new serialized state, the given title is the new title, and new URL is the entry's new URL.

9. If the current entry in the session history represents a non-GET request (e.g. it was the result of a POST submission) then update it to instead represent a GET request.

10. Set document's URL to new URL.

   **Note**
   
   Since this is neither a navigation of the browsing context nor a history traversal, it does not cause a hashchange event to be fired.

11. Let state be StructuredDeserialize(serializedData, targetRealm). If this throws an exception, catch it, ignore the exception, and set state to null.

12. Set history.state to state.

13. Set the current entry's Document object's latest entry to the current entry.

   **Note**
   
   The title is purely advisory. User agents might use the title in the user interface.

User agents may limit the number of state objects added to the session history per page. If a page hits the UA-defined limit, user agents must remove the entry immediately after the first entry for that Document object in the session history after having added the new entry. (Thus the state history acts as a FIFO buffer for eviction, but as a LIFO buffer for navigation.)

**Example**

Consider a game where the user can navigate along a line, such that the user is always at some coordinate, and such that the user can bookmark the page corresponding to a particular coordinate, to return to it later.

A static page implementing the x=5 position in such a game could look like the following:

```html
<!DOCTYPE HTML>
<!-- this is https://example.com/line?x=5 -->
<html lang="en">
  <title>Line Game - 5</title>
  <p>You are at coordinate 5 on the line.</p>
</html>
```
The problem with such a system is that each time the user clicks, the whole page has to be reloaded. Here instead is another way of doing it, using script:

```html
<!DOCTYPE HTML>
<!-- this starts off as https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate <span id="coord">5</span> on the line.</p>
<p>
<a href="?x=6" onclick="go(1); return false;">Advance to 6</a> or
<a href="?x=4" onclick="go(-1); return false;">retreat to 4</a>?
</p>
<script>
var currentPage = 5; // prefilled by server
function go(d) {
    setupPage(currentPage + d);
    history.pushState(currentPage, document.title, '?x=' + currentPage);
}
onpopstate = function(event) {
    setupPage(event.state);
}
function setupPage(page) {
    currentPage = page;
    document.title = 'Line Game - ' + currentPage;
    document.getElementById('coord').textContent = currentPage;
    document.links[0].href = '?x=' + (currentPage+1);
    document.links[0].textContent = 'Advance to ' + (currentPage+1);
    document.links[1].href = '?x=' + (currentPage-1);
    document.links[1].textContent = 'retreat to ' + (currentPage-1);
}
</script>

In systems without script, this still works like the previous example. However, users that do have script support can now navigate much faster, since there is no network access for the same experience. Furthermore, contrary to the experience the user would have with just a naïve script-based approach, bookmarking and navigating the session history still work.

In the example above, the data argument to the `pushState()` method is the same information as would be sent to the server, but in a more convenient form, so that the script doesn’t have to parse the URL each time the user navigates.

Applications might not use the same title for a `session history entry` as the value of the document’s `title` element at that time. For example, here is a simple page that shows a block in the `title` element. Clearly, when navigating backwards to a previous state the user does not go back in time, and therefore it would be inappropriate to put the time in the session history title.

```html
<!DOCTYPE HTML>
<html lang="en">
<title>Line</title>
<script>
setInterval(function () { document.title = 'Line - ' + new Date(); }, 1000);
var i = 1;
function inc() {
    set(i=1);
}
</script>
</html>
```
This section is non-normative.

The History interface is not meant to place restrictions on how implementations represent the session history to the user. For example, session history could be implemented in a tree-like manner, with each page having multiple "forward" pages. This specification doesn't define how the linear list of pages in the history object are derived from the actual session history as seen from the user's perspective.

Similarly, a page containing two iframes has a history object distinct from the iframes’ history objects, despite the fact that typical Web browsers present the user with just one "Back" button, with a session history that interleaves the navigation of the two inner frames and the outer page.

Security: It is suggested that to avoid letting a page "hijack" the history navigation facilities of a UA by abusing pushState() attribute as soon as possible (e.g., in the first script element in the document's head element) to ensure that any entry added to the history session gets the desired scroll restoration mode.

Example

Most applications want to use the same scroll restoration mode value for all of their history entries. To achieve this they can set the scrollRestoration attribute as soon as possible (e.g., in the first script element in the document's head element) to ensure that any entry added to the history session gets the desired scroll restoration mode.

```
function set(newI) {
    i = newI;
    document.forms.F.I.value = newI;
}

</SCRIPT>

<BODY ONPOPSTATE="set(event.state)">

<FORM NAME="F">
    State: <OUTPUT NAME="I">1</OUTPUT> <INPUT VALUE="Increment" TYPE=BUTTON ONCLICK="inc()">
</FORM>
```

7.7.3 Implementation notes for session history

This section is non-normative.

The History interface is not meant to place restrictions on how implementations represent the session history to the user.

For example, session history could be implemented in a tree-like manner, with each page having multiple "forward" pages. This specification doesn't define how the linear list of pages in the history object are derived from the actual session history as seen from the user's perspective.

Similarly, a page containing two iframes has a history object distinct from the iframes' history objects, despite the fact that typical Web browsers present the user with just one "Back" button, with a session history that interleaves the navigation of the two inner frames and the outer page.

Security: It is suggested that to avoid letting a page "hijack" the history navigation facilities of a UA by abusing pushState() attribute as soon as possible (e.g., in the first script element in the document's head element) to ensure that any entry added to the history session gets the desired scroll restoration mode.

For both pushState() and replaceState(), user agents are encouraged to prevent abuse of these APIs via too-frequent calls or over-large state objects. As detailed above, the algorithm explicitly allows user agents to ignore any such calls when appropriate.

7.7.4 The Location interface

Each Window object is associated with a unique instance of a Location object, allocated when the Window object is created.

⚠Warning! The Location exotic object is defined through a mishmash of IDL, invocation of JavaScript internal methods post-
To create a Location object, run these steps:

1. Let location be a new Location platform object.
2. Perform `! location.[[DefineOwnProperty]]("valueOf", { [[Value]]: %ObjProto_valueOf%, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false });`.
3. Perform `! location.[[DefineOwnProperty]](@@toPrimitive, { [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false });`.
4. Set the value of the [[DefaultProperties]] internal slot of location to location.[[OwnPropertyKeys]]().
5. Return location.

The Document object's location attribute's getter must return this Document object's relevant global object's Location object, if this Document object is fully active, and null otherwise.

The Window object's location attribute's getter must return this Window object's Location object.

Location objects provide a representation of the URL of the active document's browsing context, and allow the current entry of the browsing context's session history to be changed, by adding or replacing entries in the history object.

Note: The addition of valueOf and @@toPrimitive own data properties, as well as the fact that all of Location's IDL attributes are marked [Unforgeable], is required by legacy code that consulted the Location interface, or stringified it, to determine the document URL, and then used it in a security-sensitive way. In particular, the valueOf, @@toPrimitive, and [Unforgeable] stringifier mitigations ensure that code such as `foo[location] = bar` or `location + ""` cannot be misdirected.

For web developers (non-normative)

```javascript
document.location[817] [ = value ]
window.location[817] [ = value ]
```

Returns a Location object with the current page's location.

Can be set, to navigate to another page.

The Document object's location attribute's getter must return this Document object's relevant global object's Location object, if this Document object is fully active, and null otherwise.

The Window object's location attribute's getter must return this Window object's Location object.

Location objects provide a representation of the URL of the active document's browsing context, and allow the current entry of the browsing context's session history to be changed, by adding or replacing entries in the history object.

IDL [Exposed=Window]

```javascript
interface Location { // but see also additional creation steps and overridden internal methods
  [Unforgeable] stringifier attribute USVString href;
  [Unforgeable] readonly attribute USVString origin;
  attribute USVString protocol;
  [Unforgeable] attribute USVString host;
  [Unforgeable] attribute USVString hostname;
  attribute USVString port;
  attribute USVString pathname;
  attribute USVString search;
  attribute USVString hash;
  void assign(USVString url);
  void replace(USVString url);
  void reload();

  [Unforgeable, SameObject] readonly attribute DOMStringList ancestorOrigins;
};
```
A `Location` object has an associated relevant `Document`, which is this `Location` object's associated `Document` object's browsing context's active document.

A `Location` object has an associated `url`, which is this `Location` object's relevant `Document` object's URL.

A `Location` object has an associated ancestor origins list. When a `Location` object is created, its ancestor origins list must be set to a `DOMStringList` object whose associated list is the list of strings that the following steps would produce:

```
location.toString()
location.href
Returns the `Location` object's URL.
Can be set, to navigate to the given URL.

location.origin
Returns the `Location` object's URL's origin.

location.protocol
Returns the `Location` object's URL's scheme.
Can be set, to navigate to the same URL with a changed scheme.

location.host
Returns the `Location` object's URL's host and port (if different from the default port for the scheme).
Can be set, to navigate to the same URL with a changed host and port.

location.hostname
Returns the `Location` object's URL's host.
Can be set, to navigate to the same URL with a changed host.

location.port
Returns the `Location` object's URL's port.
Can be set, to navigate to the same URL with a changed port.

location.pathname
Returns the `Location` object's URL's path.
Can be set, to navigate to the same URL with a changed path.

location.search
Returns the `Location` object's URL's query (includes leading "?" if non-empty).
Can be set, to navigate to the same URL with a changed query (ignores leading "?").

location.hash
Returns the `Location` object's URL's fragment (includes leading "#" if non-empty).
Can be set, to navigate to the same URL with a changed fragment (ignores leading ").

location.assign(url)
Navigates to the given URL.

location.replace(url)
Removes the current page from the session history and navigates to the given URL.

location.reload()
Reloads the current page.

location.ancestorOrigins
Returns a `DOMStringList` object listing the origins of the ancestor browsing contexts, from the parent browsing context to the top-level browsing context.

A `Location` object has an associated relevant `Document`, which is this `Location` object's associated `Document` object's browsing context's active document.

A `Location` object has an associated `url`, which is this `Location` object's relevant `Document` object's URL.

A `Location` object has an associated ancestor origins list. When a `Location` object is created, its ancestor origins list must be set to a `DOMStringList` object whose associated list is the list of strings that the following steps would produce:
Let output be a new list of strings.

Let current be the browsing context of the Document, with which this Location object is associated.

Loop: If current has no parent browsing context, jump to the step labeled end.

Let current be current's parent browsing context.

Append the serialization of current's active document's origin to output.

Return to the step labeled loop.

End: Return output.

A Location object has an associated Location-object-setter navigate algorithm, which given a url, runs these steps:

1. If any of the following conditions are met, let replacement flag be unset; otherwise, let it be set:
   - This Location object's relevant Document has completely loaded, or
   - In the task in which the algorithm is running, an activation behavior is currently being processed whose click event's isTrusted attribute is true, or
   - In the task in which the algorithm is running, the event listener for a click event, whose isTrusted attribute is true, is being handled.

2. Location-object-setter.navigate, given url and replacement flag.

To Location-object-navigate, given a url and replacement flag, run these steps:

1. The source browsing context is the responsible browsing context specified by the incumbent settings object.

2. Navigate the browsing context to url, with the exceptions enabled flag set. Rethrow any exceptions.

   If the replacement flag is set or the browsing context's session history contains only one Document, and that was the about:blank Document created when the browsing context was created, then the navigation must be done with replacement enabled.

The href attribute's getter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain, with the entry settings object's origin, then throw a SecurityError DOMException.

2. Return this Location object's url, serialized.

The href attribute's setter must run these steps:

1. Parse the given value relative to the entry settings object. If that failed, throw a TypeError exception.

2. Location-object-setter.navigate to the resulting URL record.

Note: The href attribute setter intentionally has no security check.

The origin attribute's getter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain, with the entry settings object's origin, then throw a SecurityError DOMException.

2. Return the serialization of this Location object's url's origin.

The protocol attribute's getter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain, with the entry settings object's origin, then throw a SecurityError DOMException.

2. Return this Location object's url's scheme, followed by ".".

The protocol attribute's setter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain, with the entry settings object's origin, then throw a SecurityError DOMException.
object's origin, then throw a "SecurityError" DOMException.

2. Let copyURL be a copy of this Location object's url.

3. Let possibleFailure be the result of basic URL parsing the given value, followed by ";", with copyURL as url and scheme start state as state override.

```plaintext
Note
Because the URL parser ignores multiple consecutive colons, providing a value of "https:" (or even "https:::") is the same as providing a value of "https".
```

4. If possibleFailure is failure, then throw a "SyntaxError" DOMException.

5. If copyURL's scheme is not an HTTP(S) scheme, then terminate these steps.

6. Location-object-setter navigate to copyURL.

The host attribute's getter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain with the entry settings object's origin, then throw a "SecurityError" DOMException.

2. Let url be this Location object's url.

3. If url's host is null, return the empty string.

4. If url's port is null, return url's host, serialized.

5. Return url's host, serialized, followed by ";" and url's port, serialized.

The hostname attribute's getter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain with the entry settings object's origin, then throw a "SecurityError" DOMException.

2. Let copyURL be a copy of this Location object's url.

3. If copyURL's cannot-be-a-base-URL flag is set, terminate these steps.

4. Basic URL parse the given value, with copyURL as url and host state as state override.

5. Location-object-setter navigate to copyURL.

The port attribute's getter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain with the entry settings object's origin, then throw a "SecurityError" DOMException.
2. If this `Location` object's `url`'s `port` is null, return the empty string.
3. Return this `Location` object's `url`'s `port`, serialized.

The `port` attribute's setter must run these steps:

1. If this `Location` object's relevant `Document`'s `origin` is not `same-origin-domain` with the entry settings object's `origin`, then throw a "`SecurityError`" DOMException.
2. Let `copyURL` be a copy of this `Location` object's `url`.
3. If `copyURL` cannot have a `username`/`password`/`port`, then return.
4. If the given value is the empty string, then set `copyURL`'s `port` to null.
5. Otherwise, basic URL parse the given value, with `copyURL` as `url` and `port state` as state override.
6. `Location-object-setter navigate` to `copyURL`.

The `pathname` attribute's getter must run these steps:

1. If this `Location` object's relevant `Document`'s `origin` is not `same-origin-domain` with the entry settings object's `origin`, then throw a "`SecurityError`" DOMException.
2. Let `url` be this `Location` object's `url`.
3. If `url`'s `cannot-be-a-base-URL flag` is set, return the first string in `url`'s `path`.
4. If `url`'s `path` is empty, then return the empty string.
5. Return "/", followed by the strings in `url`'s `path` (including empty strings), separated from each other by "/".

The `pathname` attribute's setter must run these steps:

1. If this `Location` object's relevant `Document`'s `origin` is not `same-origin-domain` with the entry settings object's `origin`, then throw a "`SecurityError`" DOMException.
2. Let `copyURL` be a copy of this `Location` object's `url`.
3. If `copyURL`'s `cannot-be-a-base-URL flag` is set, terminate these steps.
4. Set `copyURL`'s `path` to the empty list.
5. Basic URL parse the given value, with `copyURL` as `url` and `path start state` as state override.
6. `Location-object-setter navigate` to `copyURL`.

The `search` attribute's getter must run these steps:

1. If this `Location` object's relevant `Document`'s `origin` is not `same-origin-domain` with the entry settings object's `origin`, then throw a "`SecurityError`" DOMException.
2. If this `Location` object's `url`'s `query` is either null or the empty string, return the empty string.
3. Return "+?", followed by this `Location` object's `url`'s `query`.

The `search` attribute's setter must run these steps:

1. If this `Location` object's relevant `Document`'s `origin` is not `same-origin-domain` with the entry settings object's `origin`, then throw a "`SecurityError`" DOMException.
2. Let `copyURL` be a copy of this `Location` object's `url`.
3. If the given value is the empty string, set `copyURL`'s `query` to null.
4. Otherwise, run these substeps:
   1. Let `input` be the given value with a single leading "?" removed, if any.
   2. Set `copyURL`'s `query` to the empty string.
3. Basic URL parse input, with copyURL as url and query state as state override, and the relevant Document’s character encoding as encoding override.

5. Location-object-setter navigate to copyURL.

The hash attribute's getter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain with the entry settings object's origin, then throw a "SecurityError" DOMException.
2. If this Location object's url's fragment is either null or the empty string, return the empty string.
3. Return "#", followed by this Location object's url's fragment.

The hash attribute's setter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain with the entry settings object's origin, then throw a "SecurityError" DOMException.
2. Let copyURL be a copy of this Location object's url.
3. Let input be the given value with a single leading "#" removed, if any.
4. Set copyURL's fragment to the empty string.
5. Basic URL parse input, with copyURL as url and fragment state as state override.
6. Location-object-setter navigate to copyURL.

When the assign(url) method is invoked, the user agent must run the following steps:

1. If this Location object's relevant Document's origin is not same origin-domain with the entry settings object's origin, then throw a "SecurityError" DOMException.
2. Parse url relative to the entry settings object. If that failed, throw a "SyntaxError" DOMException.
3. Location-object navigate to the resulting URL record.

When the replace(url) method is invoked, the user agent must run the following steps:

1. Parse url relative to the entry settings object. If that failed, throw a "SyntaxError" DOMException.
2. Location-object navigate to the resulting URL record with the replacement flag set.

Note
Unlike the equivalent API for the a and area elements, the hash attribute's setter does not special case the empty string to remain compatible with deployed scripts.

When the reload() method is invoked, the user agent must run the appropriate steps from the following list:

↪ If this Location object's relevant Document's origin is not same origin-domain with the entry settings object's origin, Throw a "SecurityError" DOMException.

↪ If the currently executing task is the dispatch of a resize event in response to the user resizing the browsing context, Repaint the browsing context and return.

↪ If the browsing context's active document is an iframe srcdoc document, Reprocess the iframe attributes of the browsing context's browsing context container.
If the browsing context's active document has its reload override flag set
Perform an overridden reload, with the browsing context being navigated as the responsible browsing context.
Rethrow any exceptions.

Otherwise
Navigate the browsing context to this Location object's relevant Document's URL to perform an entry update of the browsing context's current entry, with the exceptions enabled flag set. The source browsing context must be the browsing context being navigated. This is a reload-triggered navigation. Rethrow any exceptions.

When a user requests that the active document of a browsing context be reloaded through a user interface element, the user agent should navigate the browsing context to the same resource as that Document's current entry. This is a reload-triggered navigation. In the case of non-idempotent methods (e.g. HTTP POST), the user agent should prompt the user to confirm the operation first, since otherwise transactions (e.g. purchases or database modifications) could be repeated. User agents may allow the user to explicitly override any caches when reloading. If browsing context's active document's reload override flag is set, then the user agent may instead perform an overridden reload rather than the navigation described in this paragraph (with the browsing context being reloaded as the source browsing context).

The ancestorOrigins attribute's getter must run these steps:

1. If this Location object's relevant Document's origin is not same origin-domain with the entry settings object's origin, then throw a "SecurityError" DOMException.
2. Otherwise, return this Location object's ancestor origins list.

⚠Warning!
The details of how the ancestorOrigins attribute works are still controversial and might change. See issue #1918 for more information.

As explained earlier, the Location exotic object requires additional logic beyond IDL for security purposes. The internal slot and internal methods Location objects must implement are defined below.

Every Location object has a [[DefaultProperties]] internal slot representing its own properties at time of its creation.

7.7.4.1 [[GetPrototypeOf]] ( )

1. If ! IsPlatformObjectSameOrigin(this) is true, then return ! OrdinaryGetPrototypeOf(this).
2. Return null.

7.7.4.2 [[SetPrototypeOf]] ( V )

1. Return ! SetImmutablePrototype(this, V).

7.7.4.3 [[IsExtensible]] ( )

1. Return true.

7.7.4.4 [[PreventExtensions]] ( )

1. Return false.
7.7.4.5 [[GetOwnProperty]] (P) §82
1. If ! IsPlatformObjectSameOrigin\(^{790}\)(this) is true, then:
   1. Let desc be \texttt{OrdinaryGetOwnProperty}(this, P).
   2. If the value of the \[[DefaultProperties]\]\(^{823}\) internal slot of this contains P, then set desc.[[Configurable]] to true.
   3. Return desc.
2. Let property be \texttt{CrossOriginGetOwnPropertyHelper}\(^{790}\)(this, P).
3. If property is not undefined, return property.
4. Throw a "SecurityError" DOMException.

7.7.4.6 [[DefineOwnProperty]] (P, Desc) §82
1. If ! IsPlatformObjectSameOrigin\(^{790}\)(this) is true, then:
   1. If the value of the \[[DefaultProperties]\]\(^{823}\) internal slot of this contains P, then return false.
   2. Return ? \texttt{OrdinaryDefineOwnProperty}(this, P, Desc).
2. Throw a "SecurityError" DOMException.

7.7.4.7 [[Get]] (P, Receiver) §82
1. If ! IsPlatformObjectSameOrigin\(^{790}\)(this) is true, then return ? \texttt{OrdinaryGet}(this, P, Receiver).

7.7.4.8 [[Set]] (P, V, Receiver) §82
1. If ! IsPlatformObjectSameOrigin\(^{790}\)(this) is true, then return ? \texttt{OrdinarySet}(this, P, Receiver).

7.7.4.9 [[Delete]] (P) §82
1. If ! IsPlatformObjectSameOrigin\(^{790}\)(this) is true, then return ? \texttt{OrdinaryDelete}(this, P).
2. Throw a "SecurityError" DOMException.

7.7.4.10 [[OwnPropertyKeys]] () §82
1. If ! IsPlatformObjectSameOrigin\(^{790}\)(this) is true, then return ! \texttt{OrdinaryOwnPropertyKeys}(this).
2. Return ! \texttt{CrossOriginOwnPropertyKeys}\(^{791}\)(this).
7.8 Browsing the Web

7.8.1 Navigating across documents

Certain actions cause the browsing context to navigate to a new resource. A user agent may provide various ways for the user to explicitly cause a browsing context to navigate, in addition to those defined in this specification.

Example

For example, following a hyperlink, form submission, and the window.open() and location.assign() methods can all cause a browsing context to navigate.

Note

A resource has a URL, but that might not be the only information necessary to identify it. For example, a form submission that uses HTTP POST would also have the HTTP method and payload. Similarly, an iframe srcdoc document needs to know the data it is to use.

Navigation always involves source browsing context, which is the browsing context which was responsible for starting the navigation.

As explained in issue #1130 the use of a browsing context as source might not be the correct architecture.

To navigate a browsing context browsingContext to a resource resource, optionally with an exceptions enabled flag, the user agent must run these steps:

1. If resource is a URL, then set resource to a new request whose url is resource.
2. If resource is a request and this is a reload-triggered navigation, then set resource's reload-navigation flag.
3. If the source browsing context is not allowed to navigate browsingContext, then:
   1. If the exceptions enabled flag is set, then throw a "SecurityError" DOMException.
   2. Otherwise, the user agent may instead offer to open resource in a new top-level browsing context or in the top-level browsing context of the source browsing context, at the user's option, in which case the user agent must navigate that designated top-level browsing context to resource as if the user had requested it independently.

Note

Doing so, however, can be dangerous, as it means that the user is overriding the author's explicit request to sandbox the content.

4. If there is a preexisting attempt to navigate browsingContext, and the source browsing context is not allowed to navigate browsingContext, then:
   1. If the prompt to unload algorithm is being run for the active document of browsingContext, then return without affecting the preexisting attempt to navigate browsingContext.

5. If the prompt to unload algorithm is being run for the active document of browsingContext, then return without affecting the prompt to unload algorithm.

6. If this is not a reload-triggered navigation, resource is a request, resource's url equals browsingContext's active document's URL with exclude fragments flag set, and resource's url's fragment is non-null, then navigate to that fragment with replacement enabled if this was invoked with replacement enabled, and return.

7. Cancel any preexisting but not yet mature attempt to navigate browsingContext, including canceling any instances of the fetch algorithm started by those attempts. If one of those attempts has already created and initialized a new document object, abort that Document also. (Navigation attempts that have matured already have session history entries, and are therefore handled during the update the session history with the new page algorithm, later.)

8. Prompt to unload the active document of browsingContext. If the user refused to allow the document to be unloaded, then return.

   If this instance of the navigation algorithm gets canceled while this step is running, the prompt to unload algorithm must nonetheless be run to completion.

10. If `browsingContext` is a nested browsing context\[p781\], then put it in the delaying load events mode\[p783\].

The user agent must take this nested browsing context\[p781\] out of the delaying load events mode\[p783\] when this navigation\[p825\] algorithm later matures\[p832\], or when it terminates (whether due to having run all the steps, or being canceled, or being aborted), whichever happens first.

11. Let `navigationType` be "form-submission" if the navigation algorithm\[p825\] was invoked as a result of the form submission algorithm\[p578\], and "other" otherwise.

12. Return to whatever algorithm invoked the navigation steps and continue running these steps in parallel\[p42\].

13. This is the step that attempts to obtain resource, if necessary. Jump to the first appropriate substep:

If resource is a response

Run process a navigate response\[p828\] with null, resource, `navigationType`, the `source browsing context`\[p825\], and `browsingContext`, and then return.

If resource is a request whose `url`'s `scheme` is "javascript"\[p424\]a

Queue a task\[p803\] to run these `javascript: URL` steps, associated with the active document\[p780\] of `browsingContext`:

1. Let `result` be undefined, and jump to the step labeled process result below if either of the following are true:
   - The `source browsing context`\[p825\]'s active document\[p780\]'s `origin`\[p803\] is not the same origin\[p805\] as `browsingContext`'s active document\[p780\]'s `origin`\[p803\].

   As explained in issue #2591 this step does not work and presents a security issue.

   - The Should navigation request of type from source in target be blocked by Content Security Policy? algorithm returns "Blocked" when executed upon resource, "other", the `source browsing context`\[p825\], and `browsingContext`. [CSP][p1221]  

2. Let `urlString` be the result of running the URL serializer on resource's `url`.

3. Remove the leading "javascript:" string from `urlString`.

4. Let `script source` be the result of string percent decoding `urlString`.

5. Replace `script source` with the result of applying the UTF-8 decode algorithm to `script source`.

6. Let `address` be the URL of the active document\[p780\] of `browsingContext`.

7. Let `settings` be the relevant settings object\[p884\] for the active document\[p780\] of `browsingContext`.

8. Let `base URL` be settings object's API base URL\[p869\].

9. Let `script` be the result of creating a classic script\[p875\] given `script source`, `settings`, `base URL`, and the default classic script fetch options\[p870\].

10. Let `evaluationStatus` be the result of running the classic script\[p876\] `script`.

11. Let `result` be undefined if `evaluationStatus` is an abrupt completion, or evaluationStatus.([Value]) otherwise.

12. Let `response` be null.

13. Process result: If `Type(result)` is not String, then set `response` to a `response` whose `status` is 204.

   Otherwise, set `response` a `response` whose `header list` consists of `Content-Type`/"text/html"\[p1189\] and `Referrer-Policy`/settings's `referrer policy`, whose `body` is `result`, and whose HTTPS state is settings's HTTPS state\[p869\].

   ⚠Warning!

   The exact conversion between the JavaScript string result and the bytes that comprise a response body is not yet specified, pending further investigation into user agent behavior. See issue #1129.

   When it comes time to set the document's address\[p829\], use `address` as the override URL\[p829\].

14. Run process a navigate response\[p828\] with `resource`, `response`, `navigationType`, the `source browsing context`\[p825\],
and `browsingContext`, and then return.

The `task source` for this `task` is the DOM manipulation task source.

**Example**

So for example a `javascript: URL` attribute of an element would only be evaluated when the link was followed, while such a URL in the `src` attribute of an element would be evaluated in the context of the `iframe`'s own `nested browsing context` when the `iframe` is being set up; once evaluated, its return value (if it was a string) would replace that `browsing context`'s `Document`, thus also changing the `Window` object of that `browsing context`.

If `resource` is to be fetched using `GET`, and there are relevant application caches that are identified by a URL with the same origin as the URL in question, and that have this URL as one of their entries, excluding entries marked as foreign, and whose mode is fast, and the user agent is not in a mode where it will avoid using application caches, fetch resource from the most appropriate application cache of those that match.

**Example**

For example, imagine an HTML page with an associated application cache displaying an image and a form, where the image is also used by several other application caches. If the user right-clicks on the image and chooses "View Image", then the user agent could decide to show the image from any of those caches, but it is likely that the most useful cache for the user would be the one that was used for the aforementioned HTML page. On the other hand, if the user submits the form, and the form does a POST submission, then the user agent will not use an application cache at all; the submission will be made to the network.

This still needs to be integrated with the Fetch standard. [FETCH]

If `resource` is a request whose url's scheme is a fetch scheme

Run process a navigate fetch, given resource, the `source browsing context`, and `browsing context`, and `navigationType`.

Otherwise, `resource` is a request whose url's scheme is neither `javascript` nor a fetch scheme

Run process a navigate URL scheme, given resource's url and `browsingContext`.

To process a navigate fetch, given a request request, `browsing context` sourceBrowsingContext, `browsing context` browsingContext, and string `navigationType`, run these steps:

1. Let response be null.
2. Set request's `client` to sourceBrowsingContext's `active document`'s relevant settings object, destination to "document", mode to "navigate", credentials mode to "include", use-URL-credentials flag, redirect mode to "manual", and target client id to browsingContext's `active document`'s relevant settings object's id.
3. If browsingContext is a child browsing context and the browsing context container of browsingContext has a browsing context scope origin, then set request's origin to that browsing context scope origin.
4. Create a new environment reservedEnvironment, and set its id to a new unique opaque string, its creation URL to request's url, and its target browsing context to browsingContext.

**Note**

The created environment's active service worker is set in the handle fetch algorithm during the fetch if its creation URL matches a service worker registration. [SW]

5. Set request's reserved client to reservedEnvironment.
6. If the Should navigation request of type from source in target be blocked by Content Security Policy algorithm returns "Blocked" when executed upon request, `navigationType`, sourceBrowsingContext, and `browsingContext`, then set response to a network error. [CSP]

Otherwise:

1. Fetch request.
2. Wait for the task \[^{893}\] on the networking task source \[^{893}\] to process response and set response to the result.

7. If response has a location URL and it is either failure or a URL whose scheme is an HTTP(S) scheme, then set response to the result of performing HTTP-redirect fetch using request and response and then run this step again.

---

**Note**

Navigation handles redirects manually as navigation is the only place in the web platform that cares for redirects to mailto: URLs and such.

---

8. Otherwise, if response has a location URL that is a URL whose scheme is "blob", "file", "filesystem", or "javascript", then set response to a network error.

9. Otherwise, if response has a location URL that is a URL whose scheme is a fetch scheme, then run process a navigate fetch\[^{827}\] with a new request whose url is response's location URL, sourceBrowsingContext, browsingContext, and navigationType.

10. Otherwise, if response has a location URL that is a URL, run the process a navigate URL scheme\[^{831}\], given response's location URL and browsingContext.

11. **Fallback in prefer-online mode**: If response was not fetched from an application cache\[^{846}\], and was to be fetched using 'GET', and there are relevant application caches\[^{847}\] that are identified by a URL with the same origin\[^{845}\] as the URL in question, and that have this URL as one of their entries, excluding entries marked as foreign\[^{846}\] and whose mode\[^{846}\] is prefer-online\[^{846}\], and the user didn't cancel the navigation attempt during the earlier step, and response is either a network error or its status is not an ok status, then:

Let candidate be the response identified by the URL in question from the most appropriate application cache\[^{847}\] of those that match.

If candidate is not marked as foreign\[^{846}\], then the user agent must discard the failed load and instead continue along these steps using candidate as response. The user agent may indicate to the user that the original page load failed, and that the page used was a previously cached response.

12. **Fallback for fallback entries**: If response was not fetched from an application cache\[^{846}\], and was to be fetched using 'GET', and its URL matches the fallback namespace\[^{847}\] of one or more relevant application caches\[^{847}\], and the most appropriate application cache\[^{847}\] of those that match does not have an entry in its online safelist\[^{846}\] that has the same origin\[^{845}\] as response's URL and that is a prefix match\[^{844}\] for response's URL, and the user didn't cancel the navigation attempt during the earlier step, and response is either a network error or its status is not an ok status, then:

Let candidate be the fallback response\[^{846}\] specified for the fallback namespace\[^{846}\] in question. If multiple application caches match, the user agent must use the fallback of the most appropriate application cache\[^{847}\] of those that match.

If candidate is not marked as foreign\[^{846}\], then the user agent must discard the failed load and instead continue along these steps using candidate as response. The document's URL, if appropriate, will still be the originally requested URL, not the fallback URL, but the user agent may indicate to the user that the original page load failed, that the page used was a fallback response, and what the URL of the fallback response actually is.

13. Run process a navigate response\[^{828}\] given request, response, navigationType, the source browsing context\[^{825}\], browsingContext, and reservedEnvironment.

To process a navigate response, given null or a request request, a response response, a string navigationType, two browsing contexts\[^{916}\] source and browsingContext, and an optional environment\[^{896}\] reservedEnvironment, run these steps:

1. If any of the following are true, then display the inline content with an appropriate error shown to the user\[^{835}\], with the newly created Document\[^{916}\] object's origin\[^{801}\] set to a new opaque origin\[^{898}\], run the environment discarding steps\[^{968}\] for reservedEnvironment, and return.

   - response is a network error.

   - **TODO: Define X-Frame-Options processing here** \[^{whatwg/html#1230}\].

   - The Should navigation response to navigation request of type from source in target be blocked by Content Security Policy\[^{2}\] algorithm returns "Blocked" when executed upon request, response, navigationType, source, and browsingContext. \[^{[CSP]}\[^{912}\].

---

**Note**

This is where the network errors defined and propagated by the WHATWG Fetch standard, such as DNS or TLS errors,
2. If response's status is 204 or 205, then return.

3. If response has an `Content-Disposition` header specifying the attachment disposition type, then handle it as a download and return.

4. Let type be the computed type of response.

5. If the user agent has been configured to process resources of the given type using some mechanism other than rendering the content in a browsing context, then skip this step. Otherwise, if the type is one of the following types, jump to the appropriate entry in the following list, and process response as described there:

   - An HTML MIME type
     Follow the steps given in the HTML document section, and then, once they have completed, return.

   - An XML MIME type that is not an explicitly supported XML MIME type
     Follow the steps given in the XML document section. If that section determines that the content is not to be displayed as a generic XML document, then proceed to the next step in this overall set of steps. Otherwise, once the steps in the XML document section have completed, return.

   - A JSON MIME type that is not an explicitly supported JSON MIME type
     Follow the steps given in the plain text file section, and then, once they have completed, return.

   - "multipart/x-mixed-replace"
     Follow the steps given in the multipart/x-mixed-replace section, and then, once they have completed, return.

   - A supported image, video, or audio type
     Follow the steps given in the media section, and then, once they have completed, return.

   - A type that will use an external application to render the content in browsingContext
     Follow the steps given in the plugin section, and then, once they have completed, return.

An explicitly supported XML MIME type is an XML MIME type for which the user agent is configured to use an external application to render the content (either a plugin rendering directly in browsingContext, or a separate application), or one for which the user agent has dedicated processing rules (e.g. a Web browser with a built-in Atom feed viewer would be said to explicitly support the application/atom+xml MIME type), or one for which the user agent has a dedicated handler.

An explicitly supported JSON MIME type is a JSON MIME type for which the user agent is configured to use an external application to render the content (either a plugin rendering directly in browsingContext, or a separate application), or one for which the user agent has dedicated processing rules, or one for which the user agent has a dedicated handler.

Setting the document's address: If there is no override URL, then any Document created by these steps must have its URL set to the URL that was originally to be fetched, ignoring any other data that was used to obtain the resource. However, if there is an override URL, then any Document created by these steps must have its URL set to that URL instead.

Setting the document's address: If there is no override URL, then any Document created by these steps must have its URL set to the URL that was originally to be fetched, ignoring any other data that was used to obtain the resource. However, if there is an override URL, then any Document created by these steps must have its URL set to that URL instead.

Initializing a new Document object: when a Document is created as part of the above steps, the user agent will be required to additionally run the following algorithm after creating the new object:

1. If browsingContext's only entry in its session history is the about:blank Document that was added when browsingContext was created, and navigation is occurring with replacement enabled, and that Document has the same origin as the new Document, then do nothing.

2. Otherwise:

   1. Let realm execution context be the result of creating a new JavaScript realm with the following
customizations:

- For the global object, create a new `Window` object.
- For the global `this` binding, use `browsingContext`'s `WindowProxy` object.

2. **Set up a window environment settings object** with `realm execution context` and `reservedEnvironment`, if present.

4. Set the `Document`'s `referrer policy` to the result of parsing the ``Referrer-Policy` header` of response. [REFERRERPOLICY]

5. Execute the `Initialize a Document's CSP list` algorithm on the `Document` object and the `response` used to generate the document. [CSP]

6. If `request` is non-null, then set the `document's referrer` to the serialization of `request's referrer`, if `request's referrer` is a `URL record`, and the empty string otherwise.

   **Note**

   Per the WHATWG Fetch standard a `request's referrer` will be either a `URL record` or "no-referrer" at this point.

7. **Implement the sandboxing** for the `Document`.

8. Execute the `Initialize document's Feature Policy from response` algorithm on the `Document` object and the `response` used to generate the document. [FEATUREPOLICY]

   **Note**

   The `Initialize document's Feature Policy from response` algorithm makes use of the `Document`'s `origin`. If `document.domain` has been used for the `browsing context container`'s `node document`, then its `origin` cannot be `same origin-domain` with `document's origin`, because these steps run when document is initialized, so it cannot itself yet have used `document.domain`. Note that this means that Feature Policy checks are less permissive compared to doing a `same origin` check instead.

**Example**

In this example, the child document is not allowed to use `PaymentRequest`, despite being `same origin-domain` at the time the child document tries to use it. At the time the child document is initialized, only the parent document has set `document.domain`, and the child document has not.

```html
<!doctype html>
<script>
    document.domain = 'example.com';
</script>
<iframe src='b.html'></iframe>

<!doctype html>
<script>
    document.domain = 'example.com'; // This happens after the document is initialized
    new PaymentRequest(...); // Not allowed to use
</script>
```

**Example**

In this example, the child document is allowed to use `PaymentRequest`, despite not being `same origin-domain` at the time the child document tries to use it. At the time the child document is initialized, none of the documents have set `document.domain`, yet `same origin-domain` falls back to a normal `same origin` check.

```html
<!doctype html>
```
9. If response has a `Refresh` header, then:
   1. **Multiple `Refresh` headers**.
   2. Let value be the value of the header with each byte mapped to a code point of equal value.
   3. Run the shared declarative refresh steps with the Document and value.

6. **Non-document content**: If, given type, the new resource is to be handled by displaying some sort of inline content, e.g., a native rendering of the content or an error message because the specified type is not supported, then display the inline content, and then return.

7. Otherwise, the document's type is such that the resource will not affect browsingContext, e.g., because the resource is to be handed to an external application or because it is an unknown type that will be processed as a download. Process the resource appropriately.

To process a navigate URL scheme, given a URL url and browsing context browsingContext, run these steps:

1. If url is to be handled using a mechanism that does not affect browsingContext, e.g., because url's scheme is handled externally, then proceed with that mechanism instead.

2. Otherwise, url is to be handled by displaying some sort of inline content, e.g., an error message because the specified scheme is not one of the supported protocols, or an inline prompt to allow the user to select a registered handler for the given scheme. Display the inline content.

**Note**

In the case of a registered handler being used, navigate will be invoked with a new URL.

When a resource is handled by passing its URL or data to an external software package separate from the user agent (e.g. handing a mailto: URL to a mail client, or a Word document to a word processor), user agents should attempt to mitigate the risk that this is an attempt to exploit the target software, e.g. by prompting the user to confirm that the source browsing context's active document's origin is to be allowed to invoke the specified software. In particular, if the navigate algorithm, when it was invoked, was not triggered by user activation, the user agent should not invoke the external software package without prior user confirmation.

**Example**

For example, there could be a vulnerability in the target software's URL handler which a hostile page would attempt to exploit by tricking a user into clicking a link.

Some of the sections below, to which the above algorithm defers in certain cases, require the user agent to update the session history with the new page. When a user agent is required to do this, it must queue a task (associated with the Document object of the current entry, not the new one) to run the following steps:

1. **Unload** the Document object of the current entry, with the recycle parameter set to false.

   If this instance of the navigation algorithm is canceled while this step is running the unload a document algorithm, then the unload a document algorithm must be allowed to run to completion, but this instance of the navigation algorithm.
algorithm must not run beyond this step. (In particular, for instance, the cancelation of this algorithm does not abort any event dispatch or script execution occurring as part of unloading the document or its descendants.)

2. **If the navigation was initiated for entry update of an entry**
   1. Replace the `Document` of the entry being updated, and any other entries that referenced the same document as that entry, with the new `Document`.
   2. **Traverse the history** to the new entry.

   **If the navigation was initiated with a URL that equals the browsing context’s active document’s URL**
   1. Replace the current entry with a new entry representing the new resource and its `Document` object, related state, and the default `scroll restoration mode` of "auto".
   2. **Traverse the history** to the new entry.

   **Otherwise**
   1. Remove all the entries in the browsing context’s session history after the current entry. If the current entry is the last entry in the session history, then no entries are removed.

     **Note**
     *This doesn't necessarily have to affect the user agent's user interface.*

   2. Append a new entry at the end of the `History` object representing the new resource and its `Document` object, related state, and the default `scroll restoration mode` of "auto".
   3. **Traverse the history** to the new entry. If the navigation was initiated with replacement enabled, then the traversal must itself be initiated with replacement enabled.

3. The navigation algorithm has now matured.

4. **Fragment loop**: Spin the event loop for a user-agent-defined amount of time, as desired by the user agent implementer. (This is intended to allow the user agent to optimize the user experience in the face of performance concerns.)

5. If the `Document` object has no parser, or its parser has stopped parsing, or the user agent has reason to believe the user is no longer interested in scrolling to the fragment, then return.

6. **Scroll to the fragment** given in the document’s URL. If this fails to find an indicated part of the document, then return to the fragment loop step.

The task source for this task is the networking task source.

### 7.8.2 Page load processing model for HTML files

When an HTML document is to be loaded in a browsing context, the user agent must queue a task to create a `Document` object, mark it as being an HTML document, set its `content type` to "text/html", initialize the `Document` object, and finally create an HTML parser and associate it with the `Document`. Each task that the networking task source places on the task queue while fetching runs must then fill the parser’s input byte stream with the fetched bytes and cause the HTML parser to perform the appropriate processing of the input stream.

**Note**
*The input byte stream converts bytes into characters for use in the tokenizer. This process relies, in part, on character encoding information found in the real Content-Type metadata of the resource; the computed type is not used for this purpose.*

When no more bytes are available, the user agent must queue a task for the parser to process the implied EOF character, which eventually causes a load event to be fired.

After creating the `Document` object, but before any script execution, certainly before the parser stops, the user agent must update the session history with the new page.

**Note**
*Application cache selection happens in the HTML parser.*
The task source for the two tasks mentioned in this section must be the networking task source.

### 7.8.3 Page load processing model for XML files

When faced with displaying an XML file inline, user agents must follow the requirements defined in the XML and Namespaces in XML recommendations, RFC 7303, DOM, and other relevant specifications to create a Document object and a corresponding XML parser, [XML][5128] [XMLNS][5128] [RFC7303][5128] [DOM][5122].

**Note**

At the time of writing, the XML specification community had not actually yet specified how XML and the DOM interact.

After the Document is created, the user agent must initialize the Document object.

The actual HTTP headers and other metadata, not the headers as mutated or implied by the algorithms given in this specification, are the ones that must be used when determining the character encoding according to the rules given in the above specifications. Once the character encoding is established, the document's character encoding must be set to that character encoding.

If the document element, as parsed according to the XML specifications cited above, is found to be an html element with an attribute manifest, whose value is not the empty string, then, as soon as the element is inserted into the document, the user agent must parse the value of that attribute relative to that element's node document, and if that is successful, must apply the URL serializer algorithm to the resulting URL record with the exclude fragment flag set to obtain manifest URL, and then run the application cache selection algorithm with manifest URL as the manifest URL, passing in the newly-created Document. Otherwise, if the attribute is absent, its value is the empty string, or parsing its value fails, then as soon as the document element is inserted into the document, the user agent must run the application cache selection algorithm with no manifest, and passing in the Document.

**Note**

Because the processing of the manifest attribute happens only once the document element is parsed, any URLs referenced by processing instructions before the document element (such as <?xml-stylesheet?> PIs) will be fetched from the network and cannot be cached.

User agents may examine the namespace of the root Element node of this Document object to perform namespace-based dispatch to alternative processing tools, e.g. determining that the content is actually a syndication feed and passing it to a feed handler. If such processing is to take place, abort the steps in this section, and jump to the next step (labeled non-document content) in the navigate steps above.

Otherwise, then, with the newly created Document, the user agent must update the session history with the new page. User agents may do this before the complete document has been parsed (thus achieving incremental rendering), and must do this before any scripts are to be executed.

Error messages from the parse process (e.g. XML namespace well-formedness errors) may be reported inline by mutating the Document.

### 7.8.4 Page load processing model for text files

When a plain text document is to be loaded in a browsing context, the user agent must queue a task to create a Document object, mark it as being an HTML document, set its content type to the computed MIME type of the resource (type in the navigate algorithm), initialize the Document object, create an HTML parser, associate it with the Document, act as if the tokenizer had emitted a start tag token with the tag name "pre" followed by a single U+000A LINE FEED (LF) character, and switch the HTML parser's tokenizer to the PLAINTEXT state. Each task that the networking task source places on the task queue while fetching runs must then fill the parser's input byte stream with the fetched bytes and cause the HTML parser to perform the appropriate processing of the input stream.

The rules for how to convert the bytes of the plain text document into actual characters, and the rules for actually rendering the text to the user, are defined by the specifications for the computed MIME type of the resource (type in the navigate algorithm).

The document's character encoding must be set to the character encoding used to decode the document.

Upon creation of the Document object, the user agent must run the application cache selection algorithm with no manifest, and
passing in the newly-created Document.

When no more bytes are available, the user agent must queue a task for the parser to process the implied EOF character, which eventually causes a load event to be fired.

After creating the Document object, but potentially before the page has finished parsing, the user agent must update the session history with the new page.

User agents may add content to the head element of the Document, e.g., linking to a style sheet, providing script, or giving the document a title.

Note

In particular, if the user agent supports the Format=Flowed feature of RFC 3676 then the user agent would need to apply extra styling to cause the text to wrap correctly and to handle the quoting feature. This could be performed using, e.g., a CSS extension.

The task source for the two tasks mentioned in this section must be the networking task source.

7.8.5 Page load processing model for multipart/x-mixed-replace resources

When a resource with the type multipart/x-mixed-replace is to be loaded in a browsing context, the user agent must parse the resource using the rules for multipart types. [RFC2046]

For each body part obtained from the resource, the user agent must run process a navigate response using the new body part and the same browsing context, with replacement enabled if a previous body part from the same resource resulted in a Document object being created and initialized, and otherwise using the same setup as the navigate attempt that caused this section to be invoked in the first place.

For the purposes of algorithms processing these body parts as if they were complete stand-alone resources, the user agent must act as if there were no more bytes for those resources whenever the boundary following the body part is reached.

Note

Thus, load events (and for that matter unload events) do fire for each body part loaded.

7.8.6 Page load processing model for media

When an image, video, or audio resource is to be loaded in a browsing context, the user agent should create a Document object, mark it as being an HTML document, set its content type to the computed MIME type of the resource (type in the navigate algorithm), initialize the Document object, append an html element to the Document, append a head element and a body element to the html element, append an element host element for the media, as described below, to the address of the image, video, or audio resource.

The element host element to create for the media is the element given in the table below in the second cell of the row whose first cell describes the media. The appropriate attribute to set is the one given by the third cell in that same row.

<table>
<thead>
<tr>
<th>Type of media</th>
<th>Element for the media</th>
<th>Appropriate attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>Image</td>
<td>img</td>
<td>src</td>
</tr>
<tr>
<td>Video</td>
<td>video</td>
<td>src</td>
</tr>
<tr>
<td>Audio</td>
<td>audio</td>
<td>src</td>
</tr>
</tbody>
</table>

Then, the user agent must act as if it had stopped parsing.

Upon creation of the Document object, the user agent must run the application cache selection algorithm with no manifest, and passing in the newly-created Document.

After creating the Document object, but potentially before the page has finished fully loading, the user agent must update the session history with the new page.
User agents may add content to the `head` element of the `Document`, or attributes to the element `host element`, e.g., to link to a style sheet, to provide a script, to give the document a `title`, or to make the media `autoplay`.

### 7.8.7 Page load processing model for content that uses plugins

When a resource that requires an external resource to be rendered is to be loaded in a `browsing context`, the user agent should create a `Document` object, mark it as being an `HTML document` and mark it as being a `plugin document`, set its `content type` to the computed MIME type of the resource (type in the `navigate` algorithm), initialize the `Document object`, append an `html` element to the `Document`, append a `head` element and a `body` element to the `html` element, append an `embed` to the `body` element, and set the `src` attribute of the `embed` element to the address of the resource.

**Note**

The term `plugin document` is used by Content Security Policy as part of the mechanism that ensures `iframe`s can't be used to evade plugin-types directives. [CSP]

Then, the user agent must act as if it had `stopped parsing`.

Upon creation of the `Document` object, the user agent must run the `application cache selection algorithm` with no manifest, and passing in the newly-created `Document`.

After creating the `Document` object, but potentially before the page has finished fully loading, the user agent must `update the session history with the new page`.

User agents may add content to the `head` element of the `Document`, or attributes to the `embed` element, e.g. to link to a style sheet or to give the document a `title`.

**Note**

If the `Document`'s active sandboxing flag set has its sandboxed plugins browsing context flag set, the synthesized `embed` element will fail to render the content if the relevant plugin cannot be secured.

### 7.8.8 Page load processing model for inline content that doesn’t have a DOM

When the user agent is to display a user agent page inline in a `browsing context`, the user agent should create a `Document` object, mark it as being an `HTML document`, set its `content type` to "text/html", initialize the `Document object`, and then either associate that `Document` with a custom rendering that is not rendered using the normal `Document rendering rules`, or mutate that `Document` until it represents the content the user agent wants to render.

Once the page has been set up, the user agent must act as if it had `stopped parsing`.

Upon creation of the `Document` object, the user agent must run the `application cache selection algorithm` with no manifest, passing in the newly-created `Document`.

After creating the `Document` object, but potentially before the page has been completely set up, the user agent must `update the session history with the new page`.

### 7.8.9 Navigating to a fragment

When a user agent is supposed to navigate to a `fragment`, optionally with `replacement enabled`, then the user agent must run the following steps:

1. If not with `replacement enabled`, then remove all the entries in the `browsing context`'s `session history` after the `current entry`. If the `current entry` is the last entry in the session history, then no entries are removed.

**Note**

This `doesn't necessarily have to affect` the user agent's user interface.
2. Remove any tasks queued by the history traversal task that are associated with any Document objects in the top-level browsing context's document family.

3. Append a new entry at the end of the History object representing the new resource and its Document object, related state, and current entry's scroll restoration mode. Its URL must be set to the address to which the user agent was navigating. The title must be left unset.

4. Traverse the history to the new entry, with replacement enabled if this was invoked with replacement enabled, and with the non-blocking events flag set. This will scroll to the fragment given in what is now the document's URL. The title must be left unset.

When the user agent is required to scroll to the fragment and the indicated part of the document, if any, is being rendered, the user agent must either change the scrolling position of the document using the following algorithm, or perform some other action such that the indicated part of the document is brought to the user's attention. If there is no indicated part, or if the indicated part is not being rendered, then the user agent must do nothing. The aforementioned algorithm is as follows:

1. If there is no indicated part of the document, set the Document's target element to null.

2. If the indicated part of the document is the top of the document, then:
   1. Set the Document's target element to null.
   2. Scroll to the beginning of the document for the Document. [CSSOMVIEW]

3. Otherwise:
   1. Let target be element that is the indicated part of the document.
   2. Set the Document's target element to target.
   3. Scroll target into view, with behavior set to "auto", block set to "start", and inline set to "nearest". [CSSOMVIEW]
   4. Run the focusing steps for target, with the Document's viewport as the fallback target.
   5. Move the sequential focus navigation starting point to target.

The indicated part of the document is the one that the fragment, if any, identifies. The semantics of the fragment in terms of mapping it to a node is defined by the specification that defines the MIME type used by the Document (for example, the processing of fragments for XML MIME types is the responsibility of RFC7303). [RFC7303]

There is also a target element for each Document, which is used in defining the :target pseudo-class and is updated by the above algorithm. It is initially null.

For HTML documents (and HTML MIME types), the following processing model must be followed to determine what the indicated part of the document is.

1. Let fragment be the document's URL's fragment.
2. If fragment is the empty string, then the indicated part of the document is the top of the document; return.
3. If find a potential indicated element with fragment returns non-null, then the return value is the indicated part of the document; return.
4. Let fragmentBytes be the result of string percent decoding fragment.
5. Let decodedFragment be the result of running UTF-8 decode without BOM on fragmentBytes.
6. If find a potential indicated element with decodedFragment returns non-null, then the return value is the indicated part of the document; return.
7. If decodedFragment is an ASCII case-insensitive match for the string top, then the indicated part of the document is the top of the document; return.
To find a potential indicated element given a string \textit{fragment}, run these steps:

1. If there is an element in the document tree that has an \textit{ID} equal to \textit{fragment}, then return the first such element in tree order.
2. If there is an \textit{a} element in the document tree that has a \textit{name} attribute whose value is equal to \textit{fragment}, then return the first such element in tree order.
3. Return null.

The \textit{task source} for the task mentioned in this section must be the \textit{DOM manipulation task source}.

7.8.10 History traversal

To traverse the history to a session history entry entry, optionally with \textit{replacement enabled}, Optionally with the \textit{non-blocking events flag} set, and optionally with the \textit{history-navigation flag} set:

\textbf{Note}

This algorithm is not just invoked when \textit{explicitly going back or forwards in the session history} — it is also invoked in other situations, for example when \textit{navigating a browsing context}, as part of \textit{updating the session history with the new page}.

1. If \textit{entry} no longer holds a Document object, then:
   1. Let \textit{request} be a new request whose \textit{url} is \textit{entry}'s URL.
   2. If the \textit{history-navigation flag} is set, then set \textit{request}'s \textit{history-navigation flag}.
   3. Navigate the \textit{browsing context} to \textit{request} to perform an \textit{entry update} of \textit{entry}. The navigation must be done using the same \textit{source browsing context}, as was used the first time \textit{entry} was created. (This can never happen with \textit{replacement enabled}.)

\textbf{Note}

The \textit{navigate} algorithm reinvokes this \textit{traverse} algorithm to complete the traversal, at which point \textit{entry} holds a Document object.

\textbf{Note}

If the resource was obtained using a non-idempotent action, for example a POST form submission, or if the resource is no longer available, for example because the computer is now offline and the page wasn't cached, navigating to it again might not be possible. In this case, the navigation will result in a different page than previously; for example, it might be an error message explaining the problem or offering to resubmit the form.

4. Return.

2. If the \textit{current entry}'s title was not set by the \textit{pushState()} or \textit{replaceState()} methods, then set its title to the value returned by the Document's \textit{title} IDL attribute.

3. If appropriate, update the \textit{current entry} in the \textit{browsing context}'s Document object's History object to reflect any state that the user agent wishes to persist. The entry is then said to be an entry with persisted user state.

4. If \textit{entry} has a different Document object than the \textit{current entry}, then run the following substeps:
   1. Remove any tasks queued by the history traversal task source that are associated with any Document objects in the top-level browsing context's document family.
   2. If the origin of \textit{entry}'s Document object is not the same as the origin of the \textit{current entry}'s Document object, then run the following subsubsteps:
      1. The current browsing context name must be stored with all the entries in the history that are associated with Document objects with the same origin, as the active document and that are contiguous with the current entry.
      2. If the browsing context is a top-level browsing context, but not an auxiliary browsing context, then set the browsing context's name to the empty string.
3. Set the active document\(^{9780}\) of the browsing context\(^{9780}\) to entry's Document\(^{9718}\) object.

4. If entry has a browsing context name\(^{9786}\), then run the following substeps:

   1. Set the browsing context's browsing context name\(^{9786}\) to entry's browsing context name\(^{9786}\).
   2. Clear any browsing context names\(^{9786}\) of all entries in the history that are associated with Document\(^{9718}\) objects with the same origin\(^{9805}\) as the new active document\(^{9780}\) and that are contiguous with entry.

5. If entry's Document\(^{9718}\) object has any form controls whose autofill field name\(^{9561}\) is "off\(^{9557}\)", invoke the reset algorithm\(^{9584}\) of each of those elements.

6. If the current document readiness\(^{9113}\) of entry's Document\(^{9718}\) object is "complete", then queue a task\(^{9893}\) to run the following substeps:

   1. If the Document\(^{9718}\)'s page showing\(^{9840}\) flag is true, then abort these steps.
   2. Set the Document\(^{9718}\)'s page showing\(^{9840}\) flag to true.
   3. Run any session history document visibility change steps for Document\(^{9718}\) that are defined by other applicable specifications\(^{963}\).

   \section*{Note}
   This is specifically intended for use by the Page Visibility specification. [PAGEVIS]\(^{91235}\)

4. Fire an event named pageshow\(^{9117}\) at the Document\(^{9718}\) object's Window\(^{9791}\) object, using PageTransitionEvent\(^{9848}\), with the persisted\(^{9849}\) attribute initialized to true, and legacy target override flag set.

5. Set the document's URL to entry's URL.

6. If entry has a URL whose fragment differs from that of the current entry\(^{9810}\)'s when compared in a case-sensitive\(^{964}\) manner, and the two share the same Document\(^{9718}\) object, then let hash changed be true, and let old URL be the current entry\(^{9810}\)'s URL and new URL be entry's URL. Otherwise, let hash changed be false.

7. If the traversal was initiated with replacement enabled\(^{9837}\), remove the entry immediately before the specified entry in the session history.

8. If entry is not an entry with persisted user state\(^{9810}\), but its URL's fragment is non-null, then scroll to the fragment\(^{9836}\).

9. Set the current entry\(^{9810}\) to entry.

10. Let targetRealm be the current Realm Record.

11. If entry has serialized state\(^{9810}\), then let state be StructuredDeserialize\(^{9104}\)(entry's serialized state\(^{9810}\), targetRealm). If this throws an exception, catch it, ignore the exception, and let state be null.

12. Otherwise, let state be null.

13. Set history.state\(^{9832}\) to state.

14. Let state changed be true if entry's Document\(^{9718}\) object has a latest entry\(^{9811}\), and that entry is not entry; otherwise let it be false.

15. Set entry's Document\(^{9718}\) object's latest entry\(^{9811}\) to entry.

16. If the non-blocking events flag\(^{9837}\) is not set, then run the following substeps immediately\(^{942}\). Otherwise, the non-blocking events flag\(^{9837}\) flag is set; queue a task\(^{9893}\) to run the following substeps instead.

   1. If state changed is true, then fire an event named popstate\(^{91217}\) at the Document\(^{9718}\) object's Window\(^{9791}\) object, using PopStateEvent\(^{9839}\), with the state\(^{9839}\) attribute initialized to state.
   2. If entry is an entry with persisted user state\(^{9810}\), then the user agent may restore persisted user state\(^{9839}\) and update aspects of the document and its rendering.
   3. If hash changed is true, then fire an event named hashchange\(^{91217}\) at the browsing context\(^{9780}\) 's Window\(^{9791}\) object, using HashChangeEvent\(^{9839}\), with the oldURL\(^{9840}\) attribute initialized to old URL and the newURL\(^{9846}\) attribute initialized to new URL.
The task source for the tasks mentioned above is the DOM manipulation task source.

### 7.8.10.1 Persisted user state restoration

When the user agent is to restore persisted user state from a history entry, it must run the following steps immediately:

1. If the entry has a `scroll restoration mode`, let `scrollRestoration` be that. Otherwise let `scrollRestoration` be "auto".

2. If `scrollRestoration` is "manual", the user agent should not restore the scroll position for the `Document` or any of its scrollable regions, with the exception of any nested browsing contexts whose scroll restoration is controlled by their own history entry's `scroll restoration mode`, otherwise, it may do so.

3. Optionally, update other aspects of the document and its rendering, for instance values of form fields, that the user agent had previously recorded.

**Note**

This can even include updating the `dir` attribute of `textarea` elements or `input` elements whose `type` attribute is in either the `Text` state or the `Search` state, if the persisted state includes the directionality of user input in such controls.

**Note**

Not restoring the scroll position by user agent does not imply that the scroll position will be left at any particular value (e.g., (0,0)). The actual scroll position depends on the navigation type and the user agent's particular caching strategy. So web applications cannot assume any particular scroll position but rather are urged to set it to what they want it to be.

### 7.8.10.2 The `PopStateEvent` interface

**IDL**

```idl
[Exposed=Window,]
Constructor(DOMString type, optional PopStateEventInit eventInitDict)]
interface PopStateEvent : Event {
  readonly attribute any state;
};
```

**dictionary**

```idl
PopStateEventInit : EventInit {
  any state = null;
};
```

**For web developers (non-normative)**

`event.state` Returns a copy of the information that was provided to `pushState()` or `replaceState()`.

The `state` attribute must return the value it was initialized to. It represents the context information for the event, or null, if the state represented is the initial state of the `Document`.

### 7.8.10.3 The `HashChangeEvent` interface

**IDL**

```idl
[Exposed=Window,]
Constructor(DOMString type, optional HashChangeEventInit eventInitDict)]
interface HashChangeEvent : Event {
  readonly attribute USVString oldURL;
  readonly attribute USVString newURL;
};
```

**dictionary**

```idl
HashChangeEventInit : EventInit {
  USVString oldURL = "";
};
```

The `state` attribute must return the value it was initialized to. It represents the context information for the event, or null, if the state represented is the initial state of the `Document`. 
For web developers (non-normative)

**event** `.oldURL`

Returns the URL of the session history entry that was previously current.

**event** `.newURL`

Returns the URL of the session history entry that is now current.

The `oldURL` attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the session history entry that was traversed from.

The `newURL` attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the session history entry that was traversed to.

### 7.8.10.4 The `PageTransitionEvent` interface

IDL

```
[Exposed=Window, Constructor(DOMString type, optional PageTransitionEventInit eventInitDict)]
interface PageTransitionEvent : Event {
  readonly attribute boolean persisted;
};

dictionary PageTransitionEventInit : EventInit {
  boolean persisted = false;
};
```

For web developers (non-normative)

**event** `.persisted`

For the `pageshow` event, returns false if the page is newly being loaded (and the `Load` event will fire). Otherwise, returns true.

For the `pagehide` event, returns false if the page is going away for the last time. Otherwise, returns true, meaning that (if nothing conspires to make the page unsalvageable) the page might be reused if the user navigates back to this page.

Things that can cause the page to be unsalvageable include:

- `document.open(type, replace)`
- Listening for `beforeunload` events
- Listening for `unload` events
- Having `iframe` s that are not salvageable
- Active WebSocket objects
- Aborting a Document

The `persisted` attribute must return the value it was initialized to. It represents the context information for the event.

### 7.8.11 Unloading documents

A `Document` has a salvageable state, which must initially be true, a fired `unload` flag, which must initially be false, and a page showing flag, which must initially be false. The `page showing` flag is used to ensure that scripts receive `pageshow` and `pagehide` events in a consistent manner (e.g. that they never receive two `pagehide` events in a row without an intervening `pageshow`, or vice versa).

`Event loops` have a termination nesting level counter, which must initially be 0.
To prompt to unload, given a `Document` object `document` and optionally a `recursiveFlag`, run these steps:

1. Increase the event loop's termination nesting level by 1.
2. Increase the `document`'s ignore-opens-during-unload counter by 1.
3. Let event be the result of creating an event using `BeforeUnloadEvent`.
4. Initialize event's `type` attribute to `beforeunload` and its `cancelable` attribute true.
5. Dispatch: Dispatch event at `document`'s `Window` object.
6. Decrease the event loop's termination nesting level by 1.
7. If any event listeners were triggered by the earlier dispatch step, then set `document`'s salvageable state to false.
8. If `document`'s active sandboxing flag set does not have its sandboxed modals flag set, and the `returnValue` attribute of the event object is not the empty string, or if the event was canceled, then the user agent may ask the user to confirm that they wish to unload the document.

   The message shown to the user is not customizable, but instead determined by the user agent. In particular, the actual value of the `returnValue` attribute is ignored.

   The user agent is encouraged to avoid asking the user for confirmation if it judges that doing so would be annoying, deceptive, or pointless. A simple heuristic might be that if the user has not interacted with the document, the user agent would not ask for confirmation before unloading it.

   If the user agent asks the user for confirmation, it must `pause` while waiting for the user's response.

   If the user did not confirm the page navigation, then the user agent refused to allow the document to be unloaded.

9. If the `recursiveFlag` is not set, then:
   1. Let `descendants` be the list of the descendant browsing contexts of `document`.
   2. For each `browsingContext` in `descendants`:
      1. Prompt to unload `browsingContext`'s active document with the `recursiveFlag` set. If the user refused to allow the document to be unloaded, then the user implicitly also refused to allow document to be unloaded; break.
      2. If the `salvageable` state of `browsingContext`'s active document is false, then set the `salvageable` state of `document` to false.

To unload a `Document` document, given a boolean `recycle` and optionally a `recursiveFlag`:

   The recycle argument indicates whether the `Document` object is going to be reused; it is set by the `document.open(type, replace)` method.

1. Increase the event loop's termination nesting level by one.
2. Increase `document`'s ignore-opens-during-unload counter by one.
3. If `document`'s page showing flag is false, then jump to the step labeled unload event below (i.e. skip firing the `pagehide` event and don't rerun the unloading document visibility change steps).
4. Set `document`'s page showing flag to false.
5. Fire an event named `pagehide` at `document`'s `Window` object, using `PageTransitionEvent`, with the persisted attribute initialized to true if `document`'s `salvageable` state is true, and false otherwise, and legacy target override flag set.
6. Run any unloading document visibility change steps for `document` that are defined by other applicable specifications.
7. **Unload event**: If document's `fired unload` flag is false, then fire an event named `unload` at document's `Window` object, with legacy target override flag set.

8. Decrease the event loop's termination nesting level by one.

9. If any event listeners were triggered by the earlier unload event step, then set document's `salvageable` state to false and set document's `fired unload` flag to true.

10. Run any unloading document cleanup steps for `document` that are defined by this specification and other applicable specifications.

11. If the `recursiveFlag` is not set, then:
   1. Let `descendants` be the list of the descendant browsing contexts of `document`.
   2. For each `browsingContext` in `descendants`:
      1. Unload the active document of `browsingContext` with the `recycle` parameter set to false, and the `recursiveFlag` set.
      2. If the `salvageable` state of the active document of `browsingContext` is false, then set the `salvageable` state of `document` to false also.
   3. If both `document`'s `salvageable` state and `recycle` are false, then discard `document`.

This specification defines the following unloading document cleanup steps. Other specifications can define more. Given a `Document` document:

1. Let `window` be `document`'s `Window` object.
2. For each `WebSocket` object `webSocket` whose `relevant global object` is equal to `window`, make disappear `webSocket`.
   If this affected any `WebSocket` objects, then set `document`'s `salvageable` state to false.
3. If `document`'s `salvageable` state is false, then:
   1. For each `EventSource` object `eventSource` whose `relevant global object` is equal to `window`, forcibly close `eventSource`.
   2. Empty `window`'s list of active timers.

### 7.8.11.1 The `BeforeUnloadEvent` interface

```idl
[Exposed=Window]
interface BeforeUnloadEvent : Event {
    attribute DOMString returnValue;
};
```

**Note**
There are no `BeforeUnloadEvent`-specific initialization methods.

The `BeforeUnloadEvent` interface is a legacy interface which allows prompting to unload to be controlled not only by canceling the event, but by setting the `returnValue` attribute to a value besides the empty string. Authors should use the `preventDefault()` method, or other means of canceling events, instead of using `returnValue`.

The `returnValue` attribute controls the process of prompting to unload. When the event is created, the attribute must be set to the empty string. On getting, it must return the last value it was set to. On setting, the attribute must be set to the new value.
7.8.12 Aborting a document load §84

To abort a Document document:

1. Abort the active documents of every child browsing context, if this results in any of those Document objects having their salvageable state set to false, then set document's salvageable state to false also.

2. Cancel any instances of the fetch algorithm in the context of document, discarding any tasks, queued for them, and discarding any further data received from the network for them. If this resulted in any instances of the fetch algorithm being canceled or any queued tasks or any network data getting discarded, then set document's salvageable state to false.

3. If document has an active parser, then abort that parser and set document's salvageable state to false.

User agents may allow users to explicitly invoke the abort a document algorithm for a Document. If the user does so, then, if that Document is an active document, the user agent should queue a task to fire an event named abort at that Document's Window object before invoking the abort algorithm.

7.9 Offline Web applications §84

This feature is in the process of being removed from the Web platform. (This is a long process that takes many years.) Using any of the offline Web application features at this time is highly discouraged. Use service workers instead. [SW]

7.9.1 Introduction §84

This section is non-normative.

In order to enable users to continue interacting with Web applications and documents even when their network connection is unavailable — for instance, because they are traveling outside of their ISP's coverage area — authors can provide a manifest which lists the files that are needed for the Web application to work offline and which causes the user's browser to keep a copy of the files for use offline.

To illustrate this, consider a simple clock applet consisting of an HTML page "clock1.html", a CSS style sheet "clock.css", and a JavaScript script "clock.js".

Before adding the manifest, these three files might look like this:

```
<!---- clock1.html -->
<!DOCTYPE HTML>
<html>
<head>
<meta charset="utf-8">
<title>Clock</title>
<script src="clock.js"></script>
<link rel="stylesheet" href="clock.css">
</head>
<body>
<p>The time is: <output id="clock"></output></p>
</body>
</html>
```
The time is: <output id="clock"></output>

Note

Authors are encouraged to include the main page in the manifest also, but in practice the page that referenced the manifest is automatically cached even if it isn't explicitly mentioned.

Note

With the exception of "no-store" directive, HTTP cache headers and restrictions on caching pages served over TLS (encrypted, using https:) are overridden by manifests. Thus, pages will not expire from an application cache before the user agent has updated it, and even applications served over TLS can be made to work offline.

View this example online.

7.9.1.1 Supporting offline caching for legacy applications

This section is non-normative.

The application cache feature works best if the application logic is separate from the application and user data, with the logic (markup, scripts, style sheets, images, etc) listed in the manifest and stored in the application cache, with a finite number of static HTML pages for the application, and with the application and user data stored in Web Storage or a client-side Indexed Database, updated dynamically using Web Sockets, XMLHttpRequest, server-sent events, or some other similar mechanism.

This model results in a fast experience for the user: the application immediately loads, and fresh data is obtained as fast as the network will allow it (possibly while stale data shows).

Legacy applications, however, tend to be designed so that the user data and the logic are mixed together in the HTML, with each
operation resulting in a new HTML page from the server.

For example, consider a news application. The typical architecture of such an application, when not using the application cache feature, is that the user fetches the main page, and the server returns a dynamically-generated page with the current headlines and the user interface logic mixed together.

A news application designed for the application cache feature, however, would instead have the main page just consist of the logic, and would then have the main page fetch the data separately from the server, e.g. using XMLHttpRequest.

The mixed-content model does not work well with the application cache feature: since the content is cached, it would result in the user always seeing the stale data from the previous time the cache was updated.

While there is no way to make the legacy model work as fast as the separated model, it can at least be retrofitted for offline use using the prefer-online application cache mode. To do so, list all the static resources used by the HTML page you want to have work offline in an application cache manifest, use the manifest attribute to select that manifest from the HTML file, and then add the following line at the bottom of the manifest:

```
SETTINGS:
prefer-online
NETWORK:
*
```

This causes the application cache to only be used for master entries when the user is offline, and causes the application cache to be used as an atomic HTTP cache (essentially pinning resources listed in the manifest), while allowing all resources not listed in the manifest to be accessed normally when the user is online.

### 7.9.1.2 Events summary

This section is non-normative.

When the user visits a page that declares a manifest, the browser will try to update the cache. It does this by fetching a copy of the manifest and, if the manifest has changed since the user agent last saw it, redownloading all the resources it mentions and caching them anew.

As this is going on, a number of events get fired on the ApplicationCache object to keep the script updated as to the state of the cache update, so that the user can be notified appropriately. The events are as follows:

<table>
<thead>
<tr>
<th>Event name</th>
<th>Interface</th>
<th>Fired when...</th>
<th>Next events</th>
</tr>
</thead>
<tbody>
<tr>
<td>checking</td>
<td>Event</td>
<td>The user agent is checking for an update, or attempting to download the manifest for the first time. This is always the first event in the sequence.</td>
<td>noupdate, downloading, obsolete, error</td>
</tr>
<tr>
<td>noupdate</td>
<td>Event</td>
<td>The manifest hadn't changed.</td>
<td>Last event in sequence.</td>
</tr>
<tr>
<td>downloading</td>
<td>Event</td>
<td>The user agent has found an update and is fetching it, or is downloading the resources listed by the manifest for the first time.</td>
<td>progress, error, cached, updateready</td>
</tr>
<tr>
<td>progress</td>
<td>ProgressEvent</td>
<td>The user agent is downloading resources listed by the manifest. The event object's total attribute returns the total number of files to be downloaded. The event object's loaded attribute returns the number of files processed so far.</td>
<td>progress, error, cached, updateready</td>
</tr>
<tr>
<td>cached</td>
<td>Event</td>
<td>The resources listed in the manifest have been downloaded, and the application is now cached.</td>
<td>Last event in sequence.</td>
</tr>
<tr>
<td>updateready</td>
<td>Event</td>
<td>The resources listed in the manifest have been newly redownloaded, and the script can use swapCache() to switch to the new cache.</td>
<td>Last event in sequence.</td>
</tr>
<tr>
<td>obsolete</td>
<td>Event</td>
<td>The manifest was found to have become a 404 or 410 page, so the application cache is being deleted.</td>
<td>Last event in sequence.</td>
</tr>
<tr>
<td>error</td>
<td>Event</td>
<td>The manifest was a 404 or 410 page, so the attempt to cache the application has been aborted. The manifest hadn't changed, but the page referencing the manifest failed to download properly. A fatal error occurred while fetching the resources listed in the manifest. The manifest changed while the update was being run.</td>
<td>The user agent will try fetching the files again momentarily.</td>
</tr>
</tbody>
</table>
These events are cancelable; their default action is for the user agent to show download progress information. If the page shows its own update UI, canceling the events will prevent the user agent from showing redundant progress information.

7.9.2 Application caches

An application cache is a set of cached resources consisting of:

- One or more resources (including their out-of-band metadata, such as HTTP headers, if any), identified by URLs, each falling into one (or more) of the following categories:

  **Master entries**

  These are documents that were added to the cache because a browsing context was navigated to that document and the document indicated that this was its cache, using the manifest attribute.

  **The manifest**

  This is the resource corresponding to the URL that was given in a master entry's html element's manifest attribute. The manifest is fetched and processed during the application cache download process. All the master entries have the same origin as the manifest.

  **Explicit entries**

  These are the resources that were listed in the cache's manifest in an explicit section.

  **Fallback entries**

  These are the resources that were listed in the cache's manifest in a fallback section.

  Explicit entries and Fallback entries can be marked as foreign, which means that they have a manifest attribute but that it doesn’t point at this cache’s manifest.

  A URL in the list can be flagged with multiple different types, and thus an entry can end up being categorized as multiple entries. For example, an entry can be a manifest entry and an explicit entry at the same time, if the manifest is listed within the manifest.

  Zero or more fallback namespaces, each of which is mapped to a fallback entry.

  These are URLs used as prefix match patterns for resources that are to be fetched from the network if possible, or to be replaced by the corresponding fallback entry if not. Each namespace URL has the same origin as the manifest.

- Zero or more URLs that form the online safelist namespaces.

  These are used as prefix match patterns, and declare URLs for which the user agent will ignore the application cache, instead fetching them normally (i.e. from the network or local HTTP cache as appropriate).

  An online safelist wildcard flag, which is either open or blocking.

  The open state indicates that any URL not listed as cached is to be implicitly treated as being in the online safelist namespaces; the blocking state indicates that URLs not listed explicitly in the manifest are to be treated as unavailable.

- A cache mode flag, which is either in the fast state or the prefer-online state.
Each application cache has a completeness flag, which is either complete or incomplete.

An application cache group is a group of application caches, identified by the absolute URL of a resource manifest which is used to populate the caches in the group.

An application cache is newer than another if it was created after the other (in other words, application caches in an application cache group have a chronological order).

Only the newest application cache in an application cache group can have its completeness flag set to incomplete; the others are always all complete.

Each application cache group has an update status, which is one of the following: idle, checking, downloading.

A relevant application cache is an application cache that is the newest in its group to be complete.

Each application cache group has a list of pending master entries. Each entry in this list consists of a resource and a corresponding Document object. It is used during the application cache download process to ensure that new master entries are cached even if the application cache download process was already running for their application cache group when they were loaded.

An application cache group can be marked as obsolete, meaning that it must be ignored when looking at what application cache groups exist.

A cache host is a Document object.

Each cache host has an associated ApplicationCache object.

Each cache host initially is not associated with an application cache, but can become associated with one early during the page load process, when steps in the parser and in the navigation sections cause cache selection to occur.

Multiple application caches in different application cache groups, can contain the same resource, e.g. if the manifests all reference that resource. If the user agent is to select an application cache from a list of relevant application caches that contain a resource, the user agent must use the application cache that the user most likely wants to see the resource from, taking into account the following:

- which application cache was most recently updated,
- which application cache was being used to display the resource from which the user decided to look at the new resource, and
- which application cache the user prefers.

A URL matches a fallback namespace if there exists a relevant application cache whose manifest's URL has the same origin as the URL in question, and that has a fallback namespace that is a prefix match for the URL being examined. If multiple fallback namespaces match the same URL, the longest one is the one that matches. A URL looking for a fallback namespace can match more than one application cache at a time, but only matches one namespace in each cache.

### Example

If a manifest https://example.com/appl/manifest declares that https://example.com/resources/images is a fallback namespace, and the user navigates to https://example.com:80/resources/images/cat.png, then the user agent will decide that the application cache identified by https://example.com/appl/manifest contains a namespace with a match for that URL.

### 7.9.3 The cache manifest syntax

#### 7.9.3.1 Some sample manifests

This section is non-normative.
This example manifest requires two images and a style sheet to be cached and safelists a CGI script.

CACHE MANIFEST
# the above line is required

# this is a comment
# there can be as many of these anywhere in the file
# they are all ignored
# comments can have spaces before them
# but must be alone on the line

# blank lines are ignored too

# these are files that need to be cached they can either be listed
# first, or a "CACHE:" header could be put before them, as is done
# lower down.
images/sound-icon.png
images/background.png
# note that each file has to be put on its own line

# here is a file for the online safelist -- it isn't cached, and
# references to this file will bypass the cache, always hitting the
# network (or trying to, if the user is offline).
NETWORK:
comm.cgi

# here is another set of files to cache, this time just the CSS file.
CACHE:
style/default.css

It could equally well be written as follows:

CACHE MANIFEST
NETWORK:
comm.cgi
CACHE:
style/default.css
images/sound-icon.png
images/background.png

Offline application cache manifests can use absolute paths or even absolute URLs:

CACHE MANIFEST
/main/home
/main/app.js
/settings/home
/settings/app.js
https://img.example.com/logo.png
https://img.example.com/check.png
https://img.example.com/cross.png

The following manifest defines a catch-all error page that is displayed for any page on the site while the user is offline. It also
specifies that the online safelist wildcard flag is open, meaning that accesses to resources on other sites will not be blocked.
(Resources on the same site are already not blocked because of the catch-all fallback namespace.)
So long as all pages on the site reference this manifest, they will get cached locally as they are fetched, so that subsequent hits to the same page will load the page immediately from the cache. Until the manifest is changed, those pages will not be fetched from the server again. When the manifest changes, then all the files will be redownloaded.

Subresources, such as style sheets, images, etc, would only be cached using the regular HTTP caching semantics, however.

```
CACHE MANIFEST
FALLBACK:
/ /offline.html
NETWORK:

7.9.3.2 Writing cache manifests

Manifests must be served using the text/cache-manifest MIME type. All resources served using the text/cache-manifest MIME type must follow the syntax of application cache manifests, as described in this section.

An application cache manifest is a text file, whose text is encoded using UTF-8. Data in application cache manifests is line-based. Newlines must be represented by U+000A LINE FEED (LF) characters, U+000D CARRIAGE RETURN (CR) characters, or U+000D CARRIAGE RETURN (CR) U+000A LINE FEED (LF) pairs.

The first line of an application cache manifest must consist of the string "CACHE", a single SPACE character, the string "MANIFEST", and either a SPACE character, a CHARACTER TABULATION (tab) character, a LINE FEED (LF) character, or a CARRIAGE RETURN (CR) character. The first line may optionally be preceded by a BYTE ORDER MARK (BOM) character. If any other text is found on the first line, it is ignored.

Subsequent lines, if any, must all be one of the following:

A blank line

Blank lines must consist of zero or more SPACE and CHARACTER TABULATION (tab) characters only.

A comment

Comment lines must consist of zero or more SPACE and CHARACTER TABULATION (tab) characters, followed by a single NUMBER SIGN character (#), followed by zero or more characters other than SPACE and CHARACTER TABULATION (tab) characters or LINE FEED (LF) and CARRIAGE RETURN (CR) characters.

Note

Comments need to be on a line on their own. If they were to be included on a line with a URL, the "#" would be mistaken for part of a fragment.

A section header

Section headers change the current section. There are four possible section headers:

```
CACHE MANIFEST
FALLBACK:
/ /offline.html
NETWORK:

Note

This is a willful violation of RFC 2046, which requires all text/* types to only allow CRLF line breaks. This requirement, however, is outdated; the use of CR, LF, and CRLF line breaks is commonly supported and indeed sometimes CRLF is not supported by text editors.

The first line of an application cache manifest must consist of the string "CACHE", a single SPACE character, the string "MANIFEST", and either a SPACE character, a CHARACTER TABULATION (tab) character, a LINE FEED (LF) character, or a CARRIAGE RETURN (CR) character. The first line may optionally be preceded by a BYTE ORDER MARK (BOM) character. If any other text is found on the first line, it is ignored.

Subsequent lines, if any, must all be one of the following:

A blank line

Blank lines must consist of zero or more SPACE and CHARACTER TABULATION (tab) characters only.

A comment

Comment lines must consist of zero or more SPACE and CHARACTER TABULATION (tab) characters, followed by a single NUMBER SIGN character (#), followed by zero or more characters other than SPACE and CHARACTER TABULATION (tab) characters or LINE FEED (LF) and CARRIAGE RETURN (CR) characters.

Note

Comments need to be on a line on their own. If they were to be included on a line with a URL, the "#" would be mistaken for part of a fragment.

A section header

Section headers change the current section. There are four possible section headers:

```
CACHE MANIFEST
FALLBACK:
/ /offline.html
NETWORK:

Note

This is a willful violation of RFC 2046, which requires all text/* types to only allow CRLF line breaks. This requirement, however, is outdated; the use of CR, LF, and CRLF line breaks is commonly supported and indeed sometimes CRLF is not supported by text editors.
by one of the names above (including the U+003A COLON character (:)) followed by zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

Ironically, by default, the current section is the `explicit section`.

**Data for the current section**

The format that data lines must take depends on the current section.

When the current section is the `explicit section`, data lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, a **valid URL string** identifying a resource other than the manifest itself, and then zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

When the current section is the `fallback section`, data lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, a **valid URL string** identifying a resource other than the manifest itself, one or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, another **valid URL string** identifying a resource other than the manifest itself, and then zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

When the current section is the `online safelist section`, data lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, either a single U+002A ASTERISK character (*) or a **valid URL string** identifying a resource other than the manifest itself, and then zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

When the current section is the `settings section`, data lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, a **setting** and then zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

Currently only one **setting** is defined:

**The cache mode setting**

This consists of the string "prefer-online". It sets the `cache mode` to `prefer-online`. (The `cache mode` defaults to `fast`.)

Within a `settings section`, each **setting** must occur no more than once.

Manifests may contain sections more than once. Sections may be empty.

URLs that are to be fallback pages associated with `fallback namespaces`, and those namespaces themselves, must be given in `fallback sections`, with the namespace being the first URL of the data line, and the corresponding fallback page being the second URL. All the other pages to be cached must be listed in `explicit sections`.

`Fallback namespaces` and `fallback entries` must have the **same origin**, as the manifest itself. `Fallback namespaces` must also be in the same path as the manifest's URL.

A `fallback namespace` must not be listed more than once.

Namespaces that the user agent is to put into the `online safelist` must all be specified in `online safelist sections`. (This is needed for any URL that the page is intending to use to communicate back to the server.) To specify that all URLs are automatically safelisted in this way, a U+002A ASTERISK character (*) may be specified as one of the URLs.

Authors should not include namespaces in the `online safelist` for which another namespace in the `online safelist` is a **prefix match**.

Relative URLs must be given relative to the manifest's own URL. All URLs in the manifest must have the same `scheme` as the manifest itself (either explicitly or implicitly, through the use of relative URLs).

URLs in manifests must not have **fragments** (i.e. the U+0023 NUMBER SIGN character isn't allowed in URLs in manifests).

`Fallback namespaces` and namespaces in the `online safelist` are matched by `prefix match`.

### 7.9.3.3 Parsing cache manifests

When a user agent is to **parse a manifest**, it means that the user agent must run the following steps:
1. **UTF-8 decode** the byte stream corresponding with the manifest to be parsed.

   *Note: The UTF-8 decode algorithm strips a leading BOM, if any.*

2. Let base URL be the absolute URL representing the manifest.

3. Apply the URL parser to base URL, and let manifest path be the path component thus obtained.

4. Remove all the characters in manifest path after the last U+002F SOLIDUS character (/), if any. (The first character and the last character in manifest path after this step will both be slashes, the URL path separator character.)

5. Apply the URL parser steps to the base URL, so that the components from its URL record can be used by the subsequent steps of this algorithm.

6. Let explicit URLs be an initially empty list of absolute URLs for explicit entries.

7. Let fallback URLs be an initially empty mapping of fallback namespaces to absolute URLs for fallback entries.

8. Let online safelist namespaces be an initially empty list of absolute URLs for an online safelist.

9. Let online safelist wildcard flag be blocking.

10. Let cache mode flag be fast.

11. Let input be the decoded text of the manifest's byte stream.

12. Let position be a pointer into input, initially pointing at the first character.

13. If the characters starting from position are "CACHE", followed by a U+0020 SPACE character, followed by "MANIFEST", then advance position to the next character after those. Otherwise, this isn't a cache manifest; return with a failure while checking for the magic signature.

14. If the character at position is neither a U+0020 SPACE character, a U+0009 CHARACTER TABULATION (tab) character, U+000A LINE FEED (LF) character, nor a U+000D CARRIAGE RETURN (CR) character, then this isn't a cache manifest; return with a failure while checking for the magic signature.

15. This is a cache manifest. The algorithm cannot fail beyond this point (though bogus lines can get ignored).

16. Collect a sequence of code points that are not U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters from input given position, and ignore those characters. (Extra text on the first line, after the signature, is ignored.)

17. Let mode be "explicit".

18. **Start of line**: If position is past the end of input, then jump to the last step. Otherwise, collect a sequence of code points that are U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR), U+0020 SPACE, or U+0009 CHARACTER TABULATION (tab) characters from input given position.

19. Now, collect a sequence of code points that are not U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters from input given position, and let the result be line.

20. Drop any trailing U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters at the end of line.

21. If line is the empty string, then jump back to the step labeled start of line.

22. If the first character in line is a U+0023 NUMBER SIGN character (#), then jump back to the step labeled start of line.

23. If line equals "CACHE:" (the word "CACHE" followed by a U+003A COLON character (:)), then set mode to "explicit" and jump back to the step labeled start of line.

24. If line equals "FALLBACK:" (the word "FALLBACK" followed by a U+003A COLON character (:)), then set mode to "fallback" and jump back to the step labeled start of line.

25. If line equals "NETWORK:" (the word "NETWORK" followed by a U+003A COLON character (:)), then set mode to "online safelist" and jump back to the step labeled start of line.

26. If line equals "SETTINGS:" (the word "SETTINGS" followed by a U+003A COLON character (:)), then set mode to "settings" and jump back to the step labeled start of line.

27. If line ends with a U+003A COLON character (:), then set mode to "unknown" and jump back to the step labeled start of line.
This is either a data line or it is syntactically incorrect.

Let \( \text{position} \) be a pointer into \( \text{line} \), initially pointing at the start of the string.

Let \( \text{tokens} \) be a list of strings, initially empty.

While \( \text{position} \) doesn't point past the end of \( \text{line} \):

1. Let \( \text{current token} \) be an empty string.

2. While \( \text{position} \) doesn't point past the end of \( \text{line} \) and the character at \( \text{position} \) is neither a U+0020 SPACE nor a U+0009 CHARACTER TABULATION (tab) character, add the character at \( \text{position} \) to \( \text{current token} \) and advance \( \text{position} \) to the next character in \( \text{input} \).

3. Add \( \text{current token} \) to the \( \text{tokens} \) list.

4. While \( \text{position} \) doesn't point past the end of \( \text{line} \) and the character at \( \text{position} \) is either a U+0020 SPACE or a U+0009 CHARACTER TABULATION (tab) character, advance \( \text{position} \) to the next character in \( \text{input} \).

Process \( \text{tokens} \) as follows:

→ If \( \text{mode} \) is "explicit"

Let \( \text{urlRecord} \) be the result of parsing the first item in \( \text{tokens} \) with base URL; ignore the rest.

If \( \text{urlRecord} \) is failure, then jump back to the step labeled \( \text{start of line} \).

If \( \text{urlRecord} \) has a different scheme component than base URL (the manifest's URL), then jump back to the step labeled \( \text{start of line} \).

Let new URL be the result of applying the URL serializer algorithm to \( \text{urlRecord} \), with the exclude fragment flag set.

Add new URL to the explicit URLs.

→ If \( \text{mode} \) is "fallback"

Let \( \text{part one} \) be the first token in \( \text{tokens} \), and let \( \text{part two} \) be the second token in \( \text{tokens} \).

Let \( \text{urlRecordOne} \) be the result of parsing \( \text{part one} \) with base URL.

Let \( \text{urlRecordTwo} \) be the result of parsing \( \text{part two} \) with base URL.

If either \( \text{urlRecordOne} \) or \( \text{urlRecordTwo} \) are failure, then jump back to the step labeled \( \text{start of line} \).

If the origin of either \( \text{urlRecordOne} \) or \( \text{urlRecordTwo} \) is not same origin with the manifest's URL origin, then jump back to the step labeled \( \text{start of line} \).

Let \( \text{part one path} \) be the path component of \( \text{urlRecordOne} \).

If \( \text{manifest path} \) is not a prefix match for \( \text{part one path} \), then jump back to the step labeled \( \text{start of line} \).

Let \( \text{part one} \) be the result of applying the URL serializer algorithm to \( \text{urlRecordOne} \), with the exclude fragment flag set.

Let \( \text{part two} \) be the result of applying the URL serializer algorithm to \( \text{urlRecordTwo} \), with the exclude fragment flag set.

If \( \text{part one} \) is already in the fallback URLs mapping as a fallback namespace, then jump back to the step labeled \( \text{start of line} \).

Otherwise, add \( \text{part one} \) to the fallback URLs mapping as a fallback namespace, mapped to \( \text{part two} \) as the fallback entry.

→ If \( \text{mode} \) is "online safelist"

If the first item in \( \text{tokens} \) is a U+002A ASTERISK character (*), then set online safelist wildcard flag to open and jump back to the step labeled \( \text{start of line} \).

Otherwise, let \( \text{urlRecord} \) be the result of parsing the first item in \( \text{tokens} \) with base URL.

If \( \text{urlRecord} \) is failure, then jump back to the step labeled \( \text{start of line} \).
If `urlRecord` has a different `scheme` component than `base URL` (the manifest's URL), then jump back to the step labeled `start of line`.

Let new `URL` be the result of applying the `URL serializer` algorithm to `urlRecord`, with the `exclude fragment flag` set.

Add new `URL` to the `online safelist namespaces`.

- **If mode is “settings”**

  If `tokens` contains a single token, and that token is a `case-sensitive` match for the string "prefer-online", then set `cache mode flag` to `prefer-online` and jump back to the step labeled `start of line`.

  Otherwise, the line is an unsupported setting: do nothing; the line is ignored.

- **If mode is "unknown"**

  Do nothing. The line is ignored.

33. Jump back to the step labeled `start of line`. (That step jumps to the next, and last, step when the end of the file is reached.)

34. Return the `explicit URLs` list, the `fallback URLs` mapping, the `online safelist namespaces`, the `online safelist wildcard flag`, and the `cache mode flag`.

**Note**

The resource that declares the manifest (with the `manifest` attribute) will always get taken from the cache, whether it is listed in the cache or not, even if it is listed in an `online safelist namespace`.

If a resource is listed in the `explicit section` or as a `fallback entry` in the `fallback section`, the resource will always be taken from the cache, regardless of any other matching entries in the `fallback namespaces` or `online safelist namespaces`.

When a `fallback namespace` and an `online safelist namespace` overlap, the `online safelist namespace` has priority.

The `online safelist wildcard flag` is applied last, only for URLs that match neither the `online safelist namespace` nor the `fallback namespace` and that are not listed in the `explicit section`.

---

**7.9.4 Downloading or updating an application cache**

When the user agent is required (by other parts of this specification) to start the `application cache download process` for an `absolute URL` purported to identify a `manifest`, or for an `application cache group`, potentially given a particular `cache host`, and potentially given a `master` resource, the user agent must run the steps below. These steps are always run in parallel with the `event loop`, with the `event loop` tasks.

Some of these steps have requirements that only apply if the user agent shows caching progress. Support for this is optional. Caching progress UI could consist of a progress bar or message panel in the user agent's interface, or an overlay, or something else. Certain events fired during the `application cache download process` allow the script to override the display of such an interface. (Such events are delayed until after the `load` event has fired.) The goal of this is to allow Web applications to provide more seamless update mechanisms, hiding from the user the mechanics of the application cache mechanism. User agents may display user interfaces independent of this, but are encouraged to not show prominent update progress notifications for applications that cancel the relevant events.

The `application cache download process` steps are as follows:

1. Optionally, wait until the permission to start the `application cache download process` has been obtained from the user and until the user agent is confident that the network is available. This could include doing nothing until the user explicitly opts-in to caching the site, or could involve prompting the user for permission. The algorithm might never get past this point. (This step is particularly intended to be used by user agents running on severely space-constrained devices or in highly privacy-sensitive environments).

2. Atomically, so as to avoid race conditions, perform the following substeps:

   1. Pick the appropriate substeps:
If these steps were invoked with an **absolute URL** purported to identify a **manifest**

Let **manifest URL** be that **absolute URL**.

If there is no **application cache group** identified by **manifest URL**, then create a new **application cache group** identified by **manifest URL**. Initially, it has no **application caches**. One will be created later in this algorithm.

If these steps were invoked with an **application cache group**

Let **manifest URL** be that **absolute URL**.

If there is no **application cache group** identified by **manifest URL**, then create a new **application cache group** identified by **manifest URL**. Initially, it has no **application caches**. One will be created later in this algorithm.

If these steps were invoked with a **master resource**, then add the resource, along with the resource’s **Document**, to **cache group**’s list of pending master entries.

If these steps were invoked with a **cache host**, and the **status** of **cache group** is **checking** or **downloading**, then queue a post-load task to run these steps:

1. Let **showProgress** be the result of firing an event named **checking** at the **ApplicationCache singleton** of that **cache host**, with the **cancelable** attribute initialized to true.

2. If **showProgress** is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the user agent is checking to see if it can download the application.

If these steps were invoked with a **cache host**, and the **status** of **cache group** is **downloading**, then also queue a post-load task to run these steps:

1. Let **showProgress** be the result of firing an event named **downloading** at the **ApplicationCache singleton** of that **cache host**, with the **cancelable** attribute initialized to true.

2. If **showProgress** is true and the user agent shows caching progress, then display some sort of user interface indicating to the user the application is being downloaded.

If the **status** of the **cache group** is either **checking** or **downloading**, then abort this instance of the **application cache download process**. This can happen if another instance of this algorithm found the manifest to be 404 or 410 while this algorithm was waiting in the first step above.

If **cache group** already has an **application cache** in it, then this is an **upgrade attempt**. Otherwise, this is a **cache attempt**.

If **cache group** already has an **application cache** in it, then this is an **upgrade attempt**. Otherwise, this is a **cache attempt**.

If **cache group** already has an **application cache** in it, then this is an **upgrade attempt**. Otherwise, this is a **cache attempt**.

3. If this is a **cache attempt**, then this algorithm was invoked with a **cache host**; queue a post-load task to run these steps:

1. Let **showProgress** be the result of firing an event named **checking** at the **ApplicationCache singleton** of that **cache host**, with the **cancelable** attribute initialized to true.

2. If **showProgress** is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the user agent is checking for the availability of updates.

**Note**

*The remainder of the steps run in parallel.*

If **cache group** already has an **application cache** in it, then this is an **upgrade attempt**. Otherwise, this is a **cache attempt**.

If **cache group** already has an **application cache** in it, then this is an **upgrade attempt**. Otherwise, this is a **cache attempt**.

3. If this is a **cache attempt**, then this algorithm was invoked with a **cache host**; queue a post-load task to run these steps:

1. Let **showProgress** be the result of firing an event named **checking** at the **ApplicationCache singleton** of that **cache host**, with the **cancelable** attribute initialized to true.

2. If **showProgress** is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the user agent is checking for the availability of updates.
4. Let request be a new request whose url is manifest URL, client is null, destination is the empty string, referrer is "no-referrer", synchronous flag is set, credentials mode is "include", and whose use-URL-credentials flag is set.

5. Fetching the manifest: Let manifest be the result of fetching request. HTTP caching semantics should be honored for this request.

Parse manifest's body according to the rules for parsing manifests, obtaining a list of explicit entries, fallback entries, and the fallback namespaces that map to them, entries for the online safelist, and values for the online safelist wildcard flag and the cache mode flag.

Note: The MIME type of the resource is ignored — it is assumed to be text/cache-manifest. In the future, if new manifest formats are supported, the different types will probably be distinguished on the basis of the file signatures (for the current format, that is the "CACHE MANIFEST" string at the top of the file).

6. If fetching the manifest fails due to a 404 or 410 response status, then run these substeps:

1. Mark cache group as obsolete. This cache group no longer exists for any purpose other than the processing of Document objects already associated with an application cache in the cache group.

2. Let task list be an empty list of tasks.

3. For each cache host associated with an application cache in cache group, create a task to run these steps and append it to task list:

   1. Let showProgress be the result of firing an event named obsolete at the ApplicationCache singleton of the cache host, with the cancelable attribute initialized to true.

   2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the application is no longer available for offline use.

4. For each entry in cache group's list of pending master entries, create a task to run these steps and append it to task list:

   1. Let showProgress be the result of firing an event named error (not obsolete) at the ApplicationCache singleton of the Document for this entry, if there still is one, with the cancelable attribute initialized to true.

   2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.

5. If cache group has an application cache whose completeness flag is incomplete, then discard that application cache.

6. If appropriate, remove any user interface indicating that an update for this cache is in progress.

7. Let the status of cache group be idle.

8. For each task in task list, queue that task as a post-load task.

9. Abort the application cache download process.

7. Otherwise, if fetching the manifest fails in some other way (e.g. the server returns another 4xx or 5xx response, or there is a DNS error, or the connection times out, or the user cancels the download, or the parser for manifests fails when checking the magic signature), or if the server returned a redirect, then run the cache failure steps (HTTP)

8. If this is an upgrade attempt and the newly downloaded manifest is byte-for-byte identical to the manifest found in the newest application cache in cache group, or the response status is 304, then run these substeps:

   1. Let cache be the newest application cache in cache group.

   2. Let task list be an empty list of tasks.

   3. For each entry in cache group's list of pending master entries, wait for the resource for this entry to have either completely downloaded or failed.

   If the download failed (e.g. the server returns a 4xx or 5xx response, or there is a DNS error, the connection times out, or the user cancels the download), or if the resource is labeled with the "no-store" cache directive, then create a task to run these steps and append it to task list:
1. Let `showProgress` be the result of firing an event named `error` at the `ApplicationCache` singleton of the `Document` for this entry, if there still is one, with the `cancelable` attribute initialized to true.

2. If `showProgress` is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.

   Otherwise, associate the `Document` for this entry with `cache`; store the resource for this entry in `cache`, if it isn’t already there, and categorize its entry as a master entry. If applying the URL parser algorithm to the resource’s URL results in a URL record that has a non-null fragment component, the URL used for the entry in cache must instead be the absolute URL obtained from applying the URL serializer algorithm to the URL record with the exclude fragment flag set (application caches never include fragments).

4. For each `cache host` associated with an `application cache` in cache group, create a task to run these steps and append it to task list:

   1. Let `showProgress` be the result of firing an event named `noupdate` at the `ApplicationCache` singleton of the `cache host`, with the `cancelable` attribute initialized to true.

   2. If `showProgress` is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the application is up to date.

5. Empty cache group’s list of pending master entries.

6. If appropriate, remove any user interface indicating that an update for this cache is in progress.

7. Let the `status` of cache group be idle.

8. For each task in task list, queue that task as a post-load task.

9. Abort the application cache download process.

9. Let new cache be a newly created `application cache`, in cache group. Set its completeness flag to incomplete.

10. For each entry in cache group's list of pending master entries, associate the `Document` for this entry with new cache.

11. Set the `status` of cache group to downloading.

12. For each `cache host` associated with an `application cache` in cache group, queue a post-load task to run these steps:

   1. Let `showProgress` be the result of firing an event named `noupdate` at the `ApplicationCache` singleton of the `cache host`, with the `cancelable` attribute initialized to true.

   2. If `showProgress` is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that a new version is being downloaded.

13. Let `file list` be an empty list of URLs with flags.

14. Add all the URLs in the list of explicit entries, obtained by parsing manifest to file list, each flagged with "explicit entry".

15. Add all the URLs in the list of fallback entries, obtained by parsing manifest to file list, each flagged with "fallback entry".

16. If this is an upgrade attempt, then add all the URLs of master entries in the newest application cache in cache group whose completeness flag is complete to file list, each flagged with "master entry".

17. If any URL is in file list more than once, then merge the entries into one entry for that URL, that entry having all the flags that the original entries had.

18. For each URL in file list, run the following steps. These steps may be run in parallel for two or more of the URLs at a time. If, while running these steps, the `ApplicationCache` object’s `abort()` method sends a signal to this instance of the application cache download process algorithm, then run the cache failure steps instead.

   1. If the resource URL being processed was flagged as neither an “explicit entry” nor a “fallback entry”, then the user agent may skip this URL.

   **Note:** This is intended to allow user agents to expire resources not listed in the manifest from the cache. Generally, implementers are urged to use an approach that expires lesser-used resources first.
2. For each cache host associated with an application cache in cache group, queue a progress post-load task to run these steps:

   1. Let showProgress be the result of firing an event named progress at the ApplicationCache singleton of the cache host, using ProgressEvent, with the cancelable attribute initialized to true, the LengthComputable attribute initialized to true, the total attribute initialized to the number of files in file list, and the loaded attribute initialized to the number of files in file list that have been either downloaded or skipped so far. [XHR]

   2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that a file is being downloaded in preparation for updating the application.

3. Let request be a new request whose url is URL, client is null, destination is the empty string, origin is manifest URL's origin, referer is "no-referrer", synchronous flag is set, credentials mode is "include", use-URL-credentials flag is set, and redirect mode is "manual".

4. Fetch request. If this is an upgrade attempt, then use the newest application cache in cache group as an HTTP cache, and honor HTTP caching semantics (such as expiration, ETags, and so forth) with respect to that cache. User agents may also have other caches in place that are also honored.

5. If the previous step fails (e.g. the server returns a 4xx or 5xx response, or there is a DNS error, or the connection times out, or the user cancels the download), or if the server returned a redirect, or if the resource is labeled with the "no-store" cache directive, then run the first appropriate step from the following list:

   - If the URL being processed was flagged as an "explicit entry" or a "fallback entry"
     If these steps are being run in parallel for any other URLs in file list, then abort this algorithm for those other URLs. Run the cache failure steps.

   - If the error was a 404 or 410 HTTP response
     Skip this resource. It is dropped from the cache.

   - Otherwise
     Copy the resource and its metadata from the newest application cache in cache group whose completeness flag is complete, and act as if that was the fetched resource, ignoring the resource obtained from the network.

User agents may warn the user of these errors as an aid to development.

6. Otherwise, the fetching succeeded. Store the resource in the new cache.

   If the user agent is not able to store the resource (e.g. because of quota restrictions), the user agent may prompt the user or try to resolve the problem in some other manner (e.g. automatically pruning content in other caches). If the problem cannot be resolved, the user agent must run the cache failure steps.

7. If the URL being processed was flagged as an "explicit entry" in file list, then categorize the entry as an explicit entry.

8. If the URL being processed was flagged as a "fallback entry" in file list, then categorize the entry as a fallback entry.
9. If the URL being processed was flagged as an "master entry" in file list, then categorize the entry as a master entry.

10. As an optimization, if the resource is an HTML or XML file whose document element is an html element with a manifest attribute whose value doesn't match the manifest URL of the application cache being processed, then the user agent should mark the entry as being foreign.

19. For each cache host associated with an application cache in cache group, queue a progress post-load task to run these steps:

1. Let showProgress be the result of firing an event named progress at the ApplicationCache singleton of the cache host, using ProgressEvent, with the cancelable attribute initialized to true, the lengthComputable attribute initialized to true, and the total and loaded attributes initialized to the number of files in file list.

2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that all the files have been downloaded.

20. Store the list of fallback namespaces, and the URLs of the fallback entries that they map to, in new cache.

21. Store the URLs that form the new online safelist in new cache.

22. Store the value of the new online safelist wildcard flag in new cache.

23. Store the value of the new cache mode flag in new cache.

24. For each entry in cache group's list of pending master entries, wait for the resource for this entry to have either completely downloaded or failed.

   If the download failed (e.g. the server returns a 4xx or 5xx response, or there is a DNS error, the connection times out, or the user cancels the download), or if the resource is labeled with the "no-store" cache directive, then run these substeps:

   1. Unassociate the Document for this entry from new cache.

   2. Queue a post-load task to run these steps:

      1. Let showProgress be the result of firing an event named error at the ApplicationCache singleton of the Document for this entry, if there still is one, with the cancelable attribute initialized to true.

      2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.

   3. If this is a cache attempt and this entry is the last entry in cache group's list of pending master entries, then run these further substeps:

      1. Discard cache group and its only application cache, new cache.

      2. If appropriate, remove any user interface indicating that an update for this cache is in progress.

      3. Abort the application cache download process.

   Otherwise, remove this entry from cache group's list of pending master entries.

Otherwise, store the resource for this entry in new cache, if it isn't already there, and categorize its entry as a master entry.

25. Let request be a new request whose url is manifest URL, client is null, destination is the empty string, referrer is "no-referrer", synchronous flag is set, credentials mode is "include", and whose use-URL-credentials flag is set.

26. Let second manifest be the result of fetching request. HTTP caching semantics should again be honored for this request.

Note

Since caching can be honored, authors are encouraged to avoid setting the cache headers on the manifest in such a way that the user agent would simply not contact the network for this second request; otherwise, the user agent would not notice if the cache had changed during the cache update process.

27. If the previous step failed for any reason, or if the fetching attempt involved a redirect, or if second manifest and manifest
are not byte-for-byte identical, then schedule a rerun of the entire algorithm with the same parameters after a short delay, and run the cache failure steps.

28. Otherwise, store manifest in new cache, if it’s not there already, and categorize its entry as the manifest.

29. Set the completeness flag of new cache to complete.

30. Let task list be an empty list of tasks.

31. If this is a cache attempt, then for each cache host associated with an application cache in cache group, create a task to run these steps and append it to task list:
   1. Let showProgress be the result of firing an event named cached at the ApplicationCache singleton of the cache host, with the cancelable attribute initialized to true.
   2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the application has been cached and that they can now use it offline.

Otherwise, it is an upgrade attempt. For each cache host, associated with an application cache in cache group, create a task to run these steps and append it to task list:
   1. Let showProgress be the result of firing an event named updateready at the ApplicationCache singleton of the cache host, with the cancelable attribute initialized to true.
   2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that a new version is available and that they can activate it by reloading the page.

32. If appropriate, remove any user interface indicating that an update for this cache is in progress.

33. Set the update status of cache group to idle.

34. For each task in task list, queue that task as a post-load task.

The cache failure steps are as follows:

1. Let task list be an empty list of tasks.

2. For each entry in cache group’s list of pending master entries, run the following further substeps. These steps may be run in parallel for two or more entries at a time.
   1. Wait for the resource for this entry to have either completely downloaded or failed.
   2. Unassociate the Document for this entry from its application cache, if it has one.
   3. Create a task to run these steps and append it to task list:
      1. Let showProgress be the result of firing an event named error at the ApplicationCache singleton of the Document for this entry, if there still is one, with the cancelable attribute initialized to true.
      2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.

3. For each cache host still associated with an application cache in cache group, create a task to run these steps and append it to task list:
   1. Let showProgress be the result of firing an event named error at the ApplicationCache singleton of the cache host, with the cancelable attribute initialized to true.
   2. If showProgress is true and the user agent shows caching progress, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.

4. Empty cache group’s list of pending master entries.

5. If cache group has an application cache whose completeness flag is incomplete, then discard that application cache.

6. If appropriate, remove any user interface indicating that an update for this cache is in progress.

7. Let the status of cache group be idle.
8. If this was a cache attempt, discard cache group altogether.

9. For each task in task list, queue that task as a post-load task.

10. Abort the application cache download process.

Attempts to fetch resources as part of the application cache download process may be done with cache-defeating semantics, to avoid problems with stale or inconsistent intermediary caches.

User agents may invoke the application cache download process, in the background, for any application cache group, at any time (with no cache host). This allows user agents to keep caches primed and to update caches even before the user visits a site.

Each Document has a list of pending application cache download process tasks that is used to delay events fired by the algorithm above until the document's load event has fired. When the Document is created, the list must be empty.

When the steps above say to queue a post-load task, where task is a task that dispatches an event on a target ApplicationCache object target, the user agent must run the appropriate steps from the following list:

If target's node document is ready for post-load tasks:
Queue the task.

Otherwise
Add task to target's node document's list of pending application cache download process tasks.

When the steps above say to queue a progress post-load task, where task is a task that dispatches an event on a target ApplicationCache object target, the user agent must run the following steps:

1. If there is a task in target's node document's list of pending application cache download process tasks that is labeled as a progress task, then remove that task from the list.
2. Label task as a progress task.
3. Queue a post-load task task.

The task source for these tasks is the networking task source.

7.9.5 The application cache selection algorithm

When the application cache selection algorithm is invoked with a Document document and optionally a manifest URL, the user agent must run the first applicable set of steps from the following list:

- If there is a manifest URL, and document was loaded from an application cache, and the URL of the manifest of that cache's application cache group is not the same as manifest URL
  Mark the entry for the resource from which document was taken in the application cache from which it was loaded as foreign.
  Restart the current navigation from the top of the navigation algorithm, undoing any changes that were made as part of the initial load (changes can be avoided by ensuring that the step to update the session history with the new page is only ever completed after this application cache selection algorithm is run, though this is not required).

  Note
  The navigation will not result in the same resource being loaded, because "foreign" entries are never picked during navigation.

User agents may notify the user of the inconsistency between the cache manifest and the document's own metadata, to aid in application development.

- If document was loaded from an application cache, and that application cache still exists (it is not now obsolete)
  Associate document with the application cache from which it was loaded. Invoke, in the background, the application cache

860
If document was loaded using `GET`, and, there is a manifest URL, and manifest URL has the same origin as document

Invoke, in the background, the application cache download process for manifest URL, with document as the cache host and with the resource from which document was parsed as the master resource.

If there are relevant application caches that are identified by a URL with the same origin as the URL of document, and that have this URL as one of their entries, excluding entries marked as foreign, then the user agent should use the most appropriate application cache of those that match as an HTTP cache for any subresource loads. User agents may also have other caches in place that are also honored.

Otherwise

The Document is not associated with any application cache.

If there was a manifest URL, the user agent may report to the user that it was ignored, to aid in application development.

7.9.6 Changes to the networking model

If "AppCache" is not removed as a feature this section needs to be integrated into the Fetch standard.

When a cache host is associated with an application cache whose completeness flag is complete, any and all loads for resources related to that cache host other than those for child browsing contexts must go through the following steps instead of immediately invoking the mechanisms appropriate to that resource's scheme:

1. If the resource is not to be fetched using the GET method, or if applying the URL parser algorithm to both its URL and the application cache's manifest's URL results in two URL records with different scheme components, then fetch the resource normally and return.

2. If the resource's URL is a master entry, the manifest, an explicit entry, or a fallback entry in the application cache, then get the resource from the cache (instead of fetching it), and return.

3. If there is an entry in the application cache's online safelist that has the same origin as the resource's URL and that is a prefix match for the resource's URL, then fetch the resource normally and return.

4. If the resource's URL has the same origin as the manifest's URL, and there is a fallback namespace in the application cache that is a prefix match for the resource's URL, then:

   Fetch the resource normally. If this results in a redirect to a resource with another origin (indicative of a captive portal), or a 4xx or 5xx status code, or if there were network errors (but not if the user canceled the download), then instead get, from the cache, the resource of the fallback entry corresponding to the fallback namespace. Return.

5. If the application cache's online safelist wildcard flag is open, then fetch the resource normally and return.

6. Fail the resource load as if there had been a generic network error.

The above algorithm ensures that so long as the online safelist wildcard flag is blocking, resources that are not present in the manifest will always fail to load (at least, after the application cache has been primed the first time), making the testing of offline applications simpler.

7.9.7 Expiring application caches

As a general rule, user agents should not expire application caches, except on request from the user, or after having been left unused for an extended period of time.

Application caches and cookies have similar implications with respect to privacy (e.g. if the site can identify the user when providing the cache, it can store data in the cache that can be used for cookie resurrection). Implementors are therefore encouraged to expose application caches in a manner related to HTTP cookies, allowing caches to be expunged together with cookies and other origin-
specific data.

**Example**

For example, a user agent could have a "delete site-specific data" feature that clears all cookies, application caches, local storage, databases, etc, from an origin all at once.

### 7.9.8 Disk space

User agents should consider applying constraints on disk usage of application caches, and care should be taken to ensure that the restrictions cannot be easily worked around using subdomains.

User agents should allow users to see how much space each domain is using, and may offer the user the ability to delete specific application caches.

For predictability, quotas should be based on the uncompressed size of data stored.

**Note**

How quotas are presented to the user is not defined by this specification. User agents are encouraged to provide features such as allowing a user to indicate that certain sites are trusted to use more than the default quota, e.g. by presenting a non-modal user interface while a cache is being updated, or by having an explicit safelist in the user agent's configuration interface.

### 7.9.9 Security concerns with offline applications caches

This section is non-normative.

The main risk introduced by offline application caches is that an injection attack can be escalated into persistent site-wide page replacement. This attack involves using an injection vulnerability to upload two files to the victim site. The first file is an application cache manifest consisting of just a fallback entry pointing to the second file, which is an HTML page whose manifest is declared as that first file. Once the user has been directed to that second file, all subsequent accesses to any file covered by the given fallback namespace while either the user or the site is offline will instead show that second file. Targeted denial-of-service attacks or cookie bombing attacks (where the client is made to send so many cookies that the server refuses to process the request) can be used to ensure that the site appears offline.

To mitigate this, manifests can only specify fallbacks that are in the same path as the manifest itself. This means that a content injection upload vulnerability in a particular directory on a server can only be escalated to a take-over of that directory and its subdirectories. If there is no way to inject a file into the root directory, the entire site cannot be taken over.

If a site has been attacked in this way, simply removing the offending manifest might eventually clear the problem, since the next time the manifest is updated, a 404 error will be seen, and the user agent will clear the cache. "Eventually" is the key word here, however; while the attack on the user or server is ongoing, such that connections from an affected user to the affected site are blocked, the user agent will simply assume that the user is offline and will continue to use the hostile manifest. Unfortunately, if a cookie bombing attack has also been used, merely removing the manifest is insufficient; in addition, the server has to be configured to return a 404 or 410 response instead of the 413 "Request Entity Too Large" response.

TLS does not inherently protect a site from this attack, since the attack relies on content being served from the server itself. Not using application caches also does not prevent this attack, since the attack relies on an attacker-provided manifest.

### 7.9.10 Application cache API

```idl
[Exposed=Window]
interface ApplicationCache : EventTarget {
    // update status
    const unsigned short UNCACHED = 0;
    const unsigned short IDLE = 1;
    const unsigned short CHECKING = 2;
}```
const unsigned short DOWNLOADING = 3;
const unsigned short UPDATEREADY = 4;
const unsigned short OBSOLETE = 5;
readonly attribute unsigned short status;

// updates
void update();
void abort();
void swapCache();

// events
attribute EventHandler onchecking;
attribute EventHandler onerror;
attribute EventHandler onnoupdate;
attribute EventHandler ondownloading;
attribute EventHandler onprogress;
attribute EventHandler onupdateready;
attribute EventHandler oncached;
attribute EventHandler onobsolete;

 For web developers (non-normative)

cache = window.applicationCache;

Returns the ApplicationCache object that applies to the active document of that Window.

cache.status

Returns the current status of the application cache, as given by the constants defined below.

cache.update()

Invokes the application cache download process.

Throws an "InvalidStateError" DOMException if there is no application cache to update.

Calling this method is not usually necessary, as user agents will generally take care of updating application caches automatically.

The method can be useful in situations such as long-lived applications. For example, a Web mail application might stay open in a browser tab for weeks at a time. Such an application could want to test for updates each day.

cache.abort()

Cancels the application cache download process.

This method is intended to be used by Web application showing their own caching progress UI, in case the user wants to stop the update (e.g. because bandwidth is limited).

cache.swapCache()

Switches to the most recent application cache, if there is a newer one. If there isn’t, throws an "InvalidStateError" DOMException.

This does not cause previously-loaded resources to be reloaded; for example, images do not suddenly get reloaded and style sheets and scripts do not get reparsed or reevaluated. The only change is that subsequent requests for cached resources will obtain the newer copies.

The updateready event will fire before this method can be called. Once it fires, the Web application can, at its leisure, call this method to switch the underlying cache to the one with the more recent updates. To make proper use of this, applications have to be able to bring the new features into play; for example, reloading scripts to enable new features.

An easier alternative to swapCache() is just to reload the entire page at a time suitable for the user, using location.reload().

There is a one-to-one mapping from cache hosts to ApplicationCache objects. The applicationCache attribute on Window objects must return the ApplicationCache object associated with the Window object’s active document.
The status attribute, on getting, must return the current state of the application cache that the ApplicationCache object's cache host is associated with, if any. This must be the appropriate value from the following list:

**UNCACHED** (numeric value 0)

The ApplicationCache object's cache host is not associated with an application cache at this time.

**IDLE** (numeric value 1)

The ApplicationCache object's cache host is associated with an application cache whose application cache group's update status is idle, and that application cache is the newest in its application cache group, and the application cache group is not marked as obsolete.

**CHECKING** (numeric value 2)

The ApplicationCache object's cache host is associated with an application cache whose application cache group's update status is checking.

**DOWNLOADING** (numeric value 3)

The ApplicationCache object's cache host is associated with an application cache whose application cache group's update status is downloading.

**UPDATEREADY** (numeric value 4)

The ApplicationCache object's cache host is associated with an application cache whose application cache group's update status is idle, and whose application cache group is not marked as obsolete, but that application cache is not the newest cache in its group.

**OBsolete** (numeric value 5)

The ApplicationCache object's cache host is associated with an application cache whose application cache group is marked as obsolete.

If the update() method is invoked, the user agent must invoke the application cache download process, in the background, for the application cache group of the application cache, with which the ApplicationCache object's cache host is associated, but without giving that cache host to the algorithm. If there is no such application cache, or if its application cache group is marked as obsolete, then the method must throw an "InvalidStateError" DOMException instead.

If the abort() method is invoked, the user agent must send a signal to the current application cache download process for the application cache group of the application cache, with which the ApplicationCache object's cache host is associated, if any. If there is no such application cache, or it does not have a current application cache download process, then do nothing.

If the swapCache() method is invoked, the user agent must run the following steps:

1. Check that ApplicationCache object's cache host is associated with an application cache. If it is not, then throw an "InvalidStateError" DOMException.
2. Let cache be the application cache with which the ApplicationCache object's cache host is associated. (By definition, this is the same as the one that was found in the previous step.)
3. If cache's application cache group is marked as obsolete, then unassociate the ApplicationCache object's cache host from cache and return. (Resources will now load from the network instead of the cache.)
4. Check that there is an application cache in the same application cache group, as cache whose completeness flag is complete and that is newer than cache. If there is not, then throw an "InvalidStateError" DOMException exception.
5. Let new cache be the newest application cache in the same application cache group as cache whose completeness flag is complete.
6. Unassociate the ApplicationCache object's cache host from cache and instead associate it with new cache.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the ApplicationCache interface:
### Event handler event type

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onchecking</td>
<td>checking</td>
</tr>
<tr>
<td>onerror</td>
<td>error</td>
</tr>
<tr>
<td>onnoupdate</td>
<td>noupdate</td>
</tr>
<tr>
<td>ondownloading</td>
<td>downloading</td>
</tr>
<tr>
<td>onprogress</td>
<td>progress</td>
</tr>
<tr>
<td>onupdaterready</td>
<td>updaterready</td>
</tr>
<tr>
<td>oncached</td>
<td>cached</td>
</tr>
<tr>
<td>onobsolete</td>
<td>obsolete</td>
</tr>
</tbody>
</table>

### 7.9.11 Browser state

IDL

```plaintext
interface mixin NavigatorOnline {  
    readonly attribute boolean onLine;
};
```

For web developers (non-normative)

```plaintext
self.navigator.onLine
```

Returns false if the user agent is definitely offline (disconnected from the network). Returns true if the user agent might be online.

The events `online` and `offline` are fired when the value of this attribute changes.

The `navigator.onLine` attribute must return false if the user agent will not contact the network when the user follows links or when a script requests a remote page (or knows that such an attempt would fail), and must return true otherwise.

When the value that would be returned by the `navigator.onLine` attribute of a `Window` or `WorkerGlobalScope` changes from true to false, the user agent must queue a task to fire an event named `offline` at the `Window` or `WorkerGlobalScope` object.

On the other hand, when the value that would be returned by the `navigator.onLine` attribute of a `Window` or `WorkerGlobalScope` changes from false to true, the user agent must queue a task to fire an event named `online` at the `Window` or `WorkerGlobalScope` object.

The `task source` for these tasks is the `networking task source`.

**Note**

This attribute is inherently unreliable. A computer can be connected to a network without having Internet access.

Example

In this example, an indicator is updated as the browser goes online and offline.

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
    <title>Online status</title>
    <script>
        function updateIndicator() {
            document.getElementById('indicator').textContent = navigator.onLine ? 'online' : 'offline';
        }
    </script>
</head>
<body onload="updateIndicator()" ononline="updateIndicator()" onoffline="updateIndicator()">
    <p>The network is: <span id="indicator">(state unknown)</span></p>
</body>
```
8 Web application APIs

8.1 Scripting

8.1.1 Introduction
Various mechanisms can cause author-provided executable code to run in the context of a document. These mechanisms include, but are probably not limited to:

- Processing of script elements.
- Navigating to javascript: URLs.
- Event handlers, whether registered through the DOM using addEventListener(), by explicit event handler content attributes, by event handler IDL attributes, or otherwise.
- Processing of technologies like SVG that have their own scripting features.

8.1.2 Enabling and disabling scripting

Scripting is enabled in a browsing context when all of the following conditions are true:

- The user agent supports scripting.
- The user has not disabled scripting for this browsing context at this time. (User agents may provide users with the option to disable scripting globally, or in a finer-grained manner, e.g. on a per-origin basis.)
- The browsing context's active document's active sandboxing flag set does not have its sandboxed scripts browsing context flag set.

Scripting is disabled in a browsing context when any of the above conditions are false (i.e. when scripting is not enabled).

Scripting is enabled for a node if the node's node document has a browsing context, and scripting is enabled in that browsing context.

Scripting is disabled for a node if there is no such browsing context, or if scripting is disabled in that browsing context.

8.1.3 Processing model

8.1.3.1 Definitions

A script is one of two possible structs. All scripts have:

A settings object
An environment settings object, containing various settings that are shared with other scripts in the same context.

A record
Either a Script Record, for classic scripts; a Source Text Module Record, for module scripts; or null. In the former two cases, it represents a parsed script; null represents a failure parsing.

A parse error
A JavaScript value, which has meaning only if the record is null, indicating that the corresponding script source text could not be parsed.

An error to rethrow
A JavaScript value representing an error that will prevent evaluation from succeeding. It will be re-thrown by any attempts to run.
the script.

**Note**

*Since this exception value is provided by the JavaScript specification, we know that it is never null, so we use null to signal that no error has occurred.*

**Fetch options**

A script fetch options\(^{p869}\), containing various options related to fetching this script or module scripts\(^{p869}\) that it imports.

**A base URL**

A base URL used for resolving module specifiers\(^{p868}\). This will either be the URL from which the script was obtained, for external scripts, or the document base URL\(^{p868}\) of the containing document, for inline scripts.

**A classic script** is a type of script\(^{p867}\) that has the following additional *item*:

**A muted errors boolean**

A boolean which, if true, means that error information will not be provided for errors in this script. This is used to mute errors for cross-origin scripts, since that can leak private information.

**A module script** is another type of script\(^{p867}\). It has no additional *items*.

The active script is determined by the following algorithm:

1. Let record be GetActiveScriptOrModule().
2. If record is null, return null.
3. Return record.[[HostDefined]].

**An environment** is an object that identifies the settings of a current or potential execution environment. An environment\(^{p868}\) has the following fields:

**An id**

An opaque string that uniquely identifies the environment\(^{p868}\).

**A creation URL**

A URL record that represents the location of the resource with which the environment\(^{p868}\) is associated.

**Note**

*In the case of an environment settings object\(^{p868}\), this URL might be distinct from the environment settings object\(^{p868}\)’s responsible document\(^{p869}\)’s URL, due to mechanisms such as history.pushState()\(^{p813}\).*

**A target browsing context**

Null or a target browsing context\(^{p780}\) for a navigation request.

**An active service worker**

Null or a service worker that controls the environment\(^{p868}\).

**An execution ready flag**

A flag that indicates whether the environment setup is done. It is initially unset.

Specifications may define environment discarding steps for environments. The steps take an environment\(^{p868}\) as input.

**Note**

The environment discarding steps\(^{p868}\) are run for only a select few environments: the ones that will never become execution ready because, for example, they failed to load.

**An environment settings object** is an environment\(^{p868}\) that additionally specifies algorithms for:

**A realm execution context**

A JavaScript execution context shared by all scripts\(^{p594}\) that use this settings object, i.e. all scripts in a given JavaScript realm. When we run a classic script\(^{p876}\) or run a module script\(^{p877}\), this execution context becomes the top of the JavaScript execution context.
A module map
A module map\textsuperscript{866} that is used when importing JavaScript modules.

A responsible browsing context
A browsing context\textsuperscript{780} that is assigned responsibility for actions taken by the scripts that use this environment settings object\textsuperscript{868}.

A responsible event loop
An event loop\textsuperscript{863} that is used when it would not be immediately clear what event loop to use.

A responsible document
A Document\textsuperscript{110} that is assigned responsibility for actions taken by the scripts that use this environment settings object\textsuperscript{868}.

An API URL character encoding
An API URL character encoding used to encode URLs by APIs called by scripts that use this environment settings object\textsuperscript{868}.

An API base URL
A URL used by APIs called by scripts that use this environment settings object\textsuperscript{868} to parse URLs\textsuperscript{588}.

An origin
An origin\textsuperscript{803} used in security checks.

An HTTPS state
An HTTPS state value representing the security properties of the network channel used to deliver the resource with which the environment settings object\textsuperscript{868} is associated.

A referrer policy
The default referrer policy for fetches performed using this environment settings object\textsuperscript{868} as a request client. \textsuperscript{[REFERRERPOLICY]}\textsuperscript{51225}

An environment settings object\textsuperscript{868} also has an outstanding rejected promises weak set and an about-to-be-notified rejected promises list, used to track unhandled promise rejections\textsuperscript{5891}. The outstanding rejected promises weak set\textsuperscript{868} must not create strong references to any of its members, and implementations are free to limit its size, e.g. by removing old entries from it when new ones are added.

8.1.3.2 Fetching scripts \textsuperscript{586}
This section introduces a number of algorithms for fetching scripts, taking various necessary inputs and resulting in classic\textsuperscript{868} or module scripts\textsuperscript{868}.

Script fetch options is a struct with the following items:

**Cryptographic nonce**
The cryptographic nonce metadata used for the initial fetch and for fetching any imported modules
**integrity metadata**

The integrity metadata used for the initial fetch

**parser metadata**

The parser metadata used for the initial fetch and for fetching any imported modules

**credentials mode**

The credentials mode used for the initial fetch (for module scripts) and for fetching any imported modules (for both module scripts and classic scripts)

**referrer policy**

The referrer policy used for the initial fetch and for fetching any imported modules

---

The **default classic script fetch options** are a script fetch options whose cryptographic nonce is the empty string, integrity metadata is the empty string, parser metadata is "not-parser-inserted", credentials mode is "omit", and referrer policy is the empty string.

Given a request request and a script fetch options options, we define:

**set up the classic script request**

Set request's cryptographic nonce metadata to options's cryptographic nonce, its integrity metadata to options's integrity metadata, its parser metadata to options's parser metadata, and its referrer policy to options's referrer policy.

**set up the module script request**

Set request's cryptographic nonce metadata to options's cryptographic nonce, its integrity metadata to options's integrity metadata, its parser metadata to options's parser metadata, its credentials mode to options's credentials mode, and its referrer policy to options's referrer policy.

For any given script fetch options options, the descendant script fetch options are a new script fetch options whose items all have the same values, except for the integrity metadata, which is instead the empty string.

The algorithms below can be customized by optionally supplying a custom perform the fetch hook, which takes a request and an is top-level flag. The algorithm must complete with a response (which may be a network error), either synchronously (when using fetch a classic worker-imported script) or asynchronously (otherwise). The is top-level flag will be set for all classic script fetches, and for the initial fetch when fetching a module script graph or fetching a module worker script graph, but not for the fetches resulting from import statements encountered throughout the graph.

**Note**

By default, not supplying the perform the fetch will cause the below algorithms to simply fetch the given request, with algorithm-specific customizations to the request and validations of the resulting response.

To layer your own customizations on top of these algorithm-specific ones, supply a perform the fetch hook that modifies the given request, fetches it, and then performs specific validations of the resulting response (completing with a network error if the validations fail).

The hook can also be used to perform more subtle customizations, such as keeping a cache of responses and avoiding performing a fetch at all.

**Note**

Service Workers is an example of a specification that runs these algorithms with its own options for the hook. [SW]1227

Now for the algorithms themselves.

**To fetch a classic script** given a url, a settings object, some options, a CORS setting, and a character encoding, run these steps. The algorithm will asynchronously complete with either null (on failure) or a new classic script (on success).
1. Let request be the result of creating a potential-CORS request\textsuperscript{87} given url, "script", and CORS setting.

2. Set request's client to settings object.

3. Set up the classic script request\textsuperscript{9870} given request and options.

4. If the caller specified custom steps to perform the fetch\textsuperscript{9870}, perform them on request, with the is top-level\textsuperscript{9870} flag set. Return from this algorithm, and when the custom perform the fetch\textsuperscript{9870} steps complete with response response, run the remaining steps.

   Otherwise, fetch request. Return from this algorithm, and run the remaining steps as part of the fetch's process response for the response response.

   \textbf{Note}\textsuperscript{87} \textit{response can be either CORS-same-origin\textsuperscript{87} or CORS-cross-origin\textsuperscript{87}. This only affects how error reporting happens.}

5. Let response be response's unsafe response\textsuperscript{87}.

6. If response's type is "error", or response's status is not an ok status, asynchronously complete this algorithm with null, and abort these steps.

7. If response's Content Type metadata\textsuperscript{87}, if any, specifies a character encoding, and the user agent supports that encoding, then set character encoding to that encoding (ignoring the passed-in value).

8. Let source text be the result of decoding response's body to Unicode, using character encoding as the fallback encoding.

   \textbf{Note}\textsuperscript{87} \textit{The decode algorithm overrides character encoding if the file contains a BOM.}

9. Let muted errors be true if response was CORS-cross-origin\textsuperscript{87}, and false otherwise.

10. Let script be the result of creating a classic script\textsuperscript{9875} given source text, settings object, response's url, options, and muted errors.

11. Asynchronously complete this algorithm with script.

To fetch a classic worker script given a url, a fetch client settings object, a destination, and a script settings object, run these steps. The algorithm will asynchronously complete with either null (on failure) or a new classic script\textsuperscript{878} on success).

1. Let request be a new request whose url is url, client is fetch client settings object, destination is destination, mode is "same-origin", credentials mode is "same-origin", parser metadata is "not parser-inserted", and whose use-URL-credentials flag is set.

2. If the caller specified custom steps to perform the fetch\textsuperscript{9870}, perform them on request, with the is top-level\textsuperscript{9870} flag set. Return from this algorithm, and when the custom perform the fetch\textsuperscript{9870} steps complete with response response, run the remaining steps.

   Otherwise, fetch request. Return from this algorithm, and run the remaining steps as part of the fetch's process response for the response response.

3. Let response be response's unsafe response\textsuperscript{87}.

4. If response's type is "error", or response's status is not an ok status, asynchronously complete this algorithm with null, and abort these steps.

5. Let source text be the result of UTF-8 decoding response's body.

6. Let script be the result of creating a classic script\textsuperscript{9875} using source text, script settings object, response's url, and the default classic script fetch options\textsuperscript{9870}.

7. Asynchronously complete this algorithm with script.

To fetch a classic worker-imported script given a url and a settings object, run these steps. The algorithm will synchronously complete with a classic script\textsuperscript{878} on success, or throw an exception on failure.

1. Let request be a new request whose url is url, client is settings object, destination is "script", parser metadata is "not parser-inserted", synchronous flag is set, and whose use-URL-credentials flag is set.
2. If the caller specified custom steps to perform the fetch, perform them on request, with the is top-level flag set. Let response be the result.

Otherwise, fetch request, and let response be the result.

**Note**
Unlike other algorithms in this section, the fetching process is synchronous here. Thus any perform the fetch steps will also finish their work synchronously.

3. Let response be response's unsafe response.

4. If response's type is "error", or response's status is not an ok status, throw a NetworkError DOMException.

5. Let source text be the result of UTF-8 decoding response's body.

6. Let muted errors be true if response was CORS-cross-origin, and false otherwise.

7. Let script be the result of creating a classic script given source text, settings object, response's url, the default classic script fetch options, and muted errors.

8. Return script.

To fetch a module script graph given a url, a settings object, a destination, and some options, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script (on success).

1. Let visited set be « url ».

2. Perform the internal module script graph fetching procedure given url, settings object, destination, options, settings object, visited set, "client", and with the top-level module fetch flag set. If the caller of this algorithm specified custom perform the fetch steps, pass those along as well.

3. When the internal module script graph fetching procedure asynchronously completes with result, asynchronously complete this algorithm with result.

To fetch a module worker script graph given a url, a fetch client settings object, a destination, a credentials mode, and a module map settings object, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script (on success).

1. Let visited set be « url ».

2. Let options be a script fetch options whose cryptographic nonce is the empty string, integrity metadata is the empty string, parser metadata is "not-parser-inserted", credentials mode is credentials mode, and referrer policy is the empty string.

3. Perform the internal module script graph fetching procedure given url, fetch client settings object, destination, options, module map settings object, visited set, "client", and with the top-level module fetch flag set. If the caller of this algorithm specified custom perform the fetch steps, pass those along as well.

4. When the internal module script graph fetching procedure asynchronously completes with result, asynchronously complete this algorithm with result.

The following algorithms are meant for internal use by this specification only as part of fetching a module script graph or preparing a script, and should not be used directly by other specifications.

To perform the internal module script graph fetching procedure given a url, a fetch client settings object, a destination, some options, a module map settings object, a visited set, a referrer, and a top-level module fetch flag, perform these steps. The algorithm will asynchronously complete with either null (on failure) or a module script (on success).

2. Fetch a single module script given url, fetch client settings object, destination, options, module map settings object, referrer, and the top-level module fetch flag. If the caller of this algorithm specified custom perform the fetch steps, pass those along while fetching a single module script.

3. Return from this algorithm, and run the following steps when fetching a single module script asynchronously completes with result:
4. If result is null, asynchronously complete this algorithm with null, and abort these steps.

5. If the top-level module fetch flag is set, fetch the descendants of and instantiate result given fetch client settings object, destination, and visited set. Otherwise, fetch the descendants of result given the same arguments.

6. When the appropriate algorithm asynchronously completes with final result, asynchronously complete this algorithm with final result.

To fetch a single module script, given a url, a fetch client settings object, a destination, some options, a module map settings object, a referrer, and a top-level module fetch flag, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script (on success).

1. Let moduleMap be module map settings object's module map.

2. If moduleMap[url] is "fetching", wait in parallel until that entry's value changes, then queue a task on the networking task source to proceed with running the following steps.

3. If moduleMap[url] exists, asynchronously complete this algorithm with moduleMap[url], and abort these steps.

4. Set moduleMap[url] to "fetching".

5. Let request be a new request whose url is url, destination is destination, mode is "cors", referrer is referrer, and client is fetch client settings object.

6. Set up the module script request given request and options.

7. If the caller specified custom steps to perform the fetch, perform them on request, setting the is top-level flag if the top-level module fetch flag is set. Return from this algorithm, and when the custom perform the fetch steps complete with response, run the remaining steps. Otherwise, fetch request. Return from this algorithm, and run the remaining steps as part of the fetch's process response for the response.

8. If any of the following conditions are met, set moduleMap[url] to null, asynchronously complete this algorithm with null, and abort these steps:
   - response's type is "error"
   - response's status is not an ok status
   - The result of extracting a MIME type from response's header list is not a JavaScript MIME type

9. Let source text be the result of UTF-8 decoding response's body.

10. Let module script be the result of creating a module script given source text, module map settings object, response's url, and options.

11. Set moduleMap[url] to module script, and asynchronously complete this algorithm with module script.

   Note: response is always CORS-same-origin.

9. Let source text be the result of UTF-8 decoding response's body.

10. Let module script be the result of creating a module script given source text, module map settings object, response's url, and options.

11. Set moduleMap[url] to module script, and asynchronously complete this algorithm with module script.

   Note: It is intentional that the module map is keyed by the request URL, whereas the base URL for the module script is set to the response URL. The former is used to deduplicate fetches, while the latter is used for URL resolution.

To fetch the descendants of a module script module script, given a fetch client settings object, a destination, and a visited set, run these steps. The algorithm will asynchronously complete with either null (on failure) or with module script (on success).

1. If module script's record is null, then asynchronously complete this algorithm with module script and abort these steps.

2. Let record be module script's record.

3. If record.[[RequestedModules]] is empty, asynchronously complete this algorithm with module script.
4. Let urls be a new empty list.

5. For each string requested of record.[[RequestedModules]],
   1. Let url be the result of resolving a module specifier given module script's base URL and requested.
   2. Assert: url is never failure, because resolving a module specifier must have been previously successful with these same two arguments.
   3. If visited set does not contain url, then:
      1. Append url to urls.
      2. Append url to visited set.

6. Let options be the descendant script fetch options for module script's fetch options.

7. For each url in urls, perform the internal module script graph fetching procedure given url, fetch client settings object, destination, options, module script's settings object, visited set, module script's base URL, and with the top-level module fetch flag unset. If the caller of this algorithm specified custom perform the fetch steps, pass those along while performing the internal module script graph fetching procedure. These invocations of the internal module script graph fetching procedure should be performed in parallel to each other.

   If any of the invocations of the internal module script graph fetching procedure asynchronously complete with null, asynchronously complete this algorithm with null, aborting these steps.

   Otherwise, wait until all of the internal module script graph fetching procedure invocations have asynchronously completed. Asynchronously complete this algorithm with module script.

To fetch the descendants of and instantiate a module script module script, given a fetch client settings object, a destination, and an optional visited set, run these steps. The algorithm will asynchronously complete with either null (on failure) or with module script (on success).

1. If visited set was not given, let it be an empty set.
2. Fetch the descendants of module script, given fetch client settings object, destination, and visited set.
3. Return from this algorithm, and run the following steps when fetching the descendants of a module script asynchronously completes with result.
4. If result is null, then asynchronously complete this algorithm with result.

   Note
   In this case, there was an error fetching one or more of the descendants. We will not attempt to instantiate.

5. Let parse error be the result of finding the first parse error given result.
6. If parse error is null, then:
   1. Let record be result's record.
   2. Perform record.Instantiate().

   Note
   This step will recursively call Instantiate on all of the module's uninstantiated dependencies.

   If this throws an exception, set result's error to rethrow to that exception.

7. Otherwise, set result's error to rethrow to parse error.
8. Asynchronously complete this algorithm with result.

To find the first parse error given a root moduleScript and an optional discoveredSet:

1. Let moduleMap be moduleScript's settings object's module map.
2. If discoveredSet was not given, let it be an empty set.
3. Append moduleScript to discoveredSet.
4. If `moduleScript`'s `record`'s `parse error` is null, then return `moduleScript`'s `parse error`.

5. Let `childSpecifiers` be the value of `moduleScript`'s `record`'s [[RequestedModules]] internal slot.

6. Let `childURLs` be the list obtained by calling `resolve a module specifier` once for each item of `childSpecifiers`, given `moduleScript`'s `base URL` and that item. (None of these will ever fail, as otherwise `moduleScript` would have been marked as itself having a parse error.)

7. Let `childModules` be the list obtained by getting each value in `moduleMap` whose key is given by an item of `childURLs`.

8. For each `childModule` of `childModules`:
   1. Assert: `childModule` is a module script (i.e., it is not "fetching" or null); by now all module scripts in the graph rooted at `moduleScript` will have successfully been fetched.
   2. If `discoveredSet` already contains `childModule`, continue.
   3. Let `childParseError` be the result of finding the first parse error given `childModule` and `discoveredSet`.
   4. If `childParseError` is not null, return `childParseError`.

8.1.3.3 Creating scripts

To create a classic script, given a JavaScript string `source`, an environment settings object `settings`, a URL `baseURL`, and some script fetch options:

1. If `muted errors` was not provided, let it be false.
2. If scripting is disabled for `settings`'s responsible browsing context, then set `source` to the empty string.
3. Let `script` be a new classic script that this algorithm will subsequently initialize.
4. Set `script`'s `settings object` to `settings`.
5. Set `script`'s `base URL` to `baseURL`.
6. Set `script`'s `fetch options` to `options`.
7. Set `script`'s `muted errors` to `muted errors`.
8. Set `script`'s `parse error` and `error to rethrow` to null.
9. Let result be `ParseScript(source, settings'`'s `Realm, script).

Passing `script` as the last parameter here ensures result.[[HostDefined]] will be `script`.

10. If result is a list of errors, then:
    1. Set `script`'s `parse error` and its `error to rethrow` to result[0].
    2. Return `script`.

11. Set `script`'s `record` to result.

12. Return `script`.

To create a module script, given a JavaScript string `source`, an environment settings object `settings`, a URL `baseURL`, and some script fetch options:

1. If scripting is disabled for `settings`'s responsible browsing context, then set `source` to the empty string.
2. Let `script` be a new module script that this algorithm will subsequently initialize.
3. Set `script`'s `settings object` to `settings`.

Note: Passing `script` as the last parameter here ensures result.[[HostDefined]] will be `script`. 
4. Set script's base URL to baseURL.
5. Set script's fetch options to options.
6. Set script's parse error and error to rethrow to null.
7. Let result be ParseModule(source, settings's Realm, script).

**Note**

Passing script as the last parameter here ensures result.[[HostDefined]] will be script.

8. If result is a list of errors, then:
   1. Set script's parse error to result[0].
   2. Return script.
9. For each string requested of result.[[RequestedModules]]:
   1. Let url be the result of resolving a module specifier, given script's base URL and requested.
   2. If url is failure, then:
      1. Let error be a new TypeError exception.
      2. Set script's parse error to error.
      3. Return script.

**Note**

This step is essentially validating all of the requested module specifiers. We treat a module with unresolvable module specifiers the same as one that cannot be parsed; in both cases, a syntactic issue makes it impossible to ever contemplate instantiating the module later.

10. Set script's record to result.
11. Return script.

### 8.1.3.4 Calling scripts

To run a classic script given a classic script script and an optional rethrow errors boolean:

1. If rethrow errors is not given, let it be false.
2. Let settings be the settings object of script.
3. Check if we can run script with settings. If this returns "do not run" then return NormalCompletion(undefined).
4. Prepare to run script given settings.
5. Let evaluationStatus be null.
6. If script's error to rethrow is not null, then set evaluationStatus to Completion { [[Type]]: throw, [[Value]]: script's error to rethrow, [[Target]]: empty }.
7. Otherwise, set evaluationStatus to ScriptEvaluation(script's record).
   If ScriptEvaluation does not complete because the user agent has aborted the running script, leave evaluationStatus as null.
8. If evaluationStatus is an abrupt completion, then:
   1. If rethrow errors is true and script's muted errors is false, then:
      1. Clean up after running script with settings.
      2. Rethrow evaluationStatus.[[Value]].
2. If rethrow errors is true and script's muted errors is true, then:
   1. Clean up after running script with settings.
   2. Throw a "NetworkError" DOMException.
3. Otherwise, rethrow errors is false. Perform the following steps:
   1. Report the exception given by evaluationStatus.\([\text{Value}]\) for script.
   2. Clean up after running script with settings.
3. Return evaluationStatus.

9. Clean up after running script with settings.

10. If evaluationStatus is a normal completion, return evaluationStatus.

Note: This value is only ever used by the javascript: URL steps.

11. If we've reached this point, evaluationStatus was left as null because the script was aborted prematurely during evaluation. Return Completion \(\{ [[\text{Type}]]: \text{throw}, [[\text{Value}]]: \text{a new } \text{"QuotaExceededError" DOMException}, [[\text{Target}]]: \text{empty }\}."

To run a module script given a module script script, with an optional rethrow errors boolean:

1. If rethrow errors is not given, let it be false.
2. Let settings be the settings object of script.
3. Check if we can run script with settings. If this returns "do not run" then return NormalCompletion(undefined).
4. Prepare to run script given settings.
5. Let evaluationStatus be null.
6. If script's error to rethrow is not null, then set evaluationStatus to Completion \(\{ [[\text{Type}]]: \text{throw}, [[\text{Value}]]: \text{script's error to rethrow}, [[\text{Target}]]: \text{empty }\}."
7. Otherwise:
   1. Let record be script's record.
   2. Set evaluationStatus to record.Eval().

Note: This step will recursively evaluate all of the module's dependencies.

If Eval fails to complete as a result of the user agent aborting the running script, then set evaluationStatus to Completion \(\{ [[\text{Type}]]: \text{throw}, [[\text{Value}]]: \text{a new } \text{"QuotaExceededError" DOMException}, [[\text{Target}]]: \text{empty }\}."

8. If evaluationStatus is an abrupt completion, then:
   1. If rethrow errors is true, rethrow the exception given by evaluationStatus.\([\text{Value}]\).
   2. Otherwise, report the exception given by evaluationStatus.\([\text{Value}]\) for script.
9. Clean up after running script with settings.
10. Return evaluationStatus.

The steps to check if we can run script with an environment settings object specified by settings are as follows. They return either "run" or "do not run".

1. If the global object specified by settings is a Window object whose Document object is not fully active, then return "do not run".
2. If scripting is disabled for the responsible browsing context specified by settings, then return "do not run".
3. Return "run".
The steps to **prepare to run script** with an **environment settings object** settings are as follows:

1. Push settings's realm execution context onto the JavaScript execution context stack; it is now the running JavaScript execution context.

The steps to **clean up after running script** with an **environment settings object** settings are as follows:

1. Assert: settings's realm execution context is the running JavaScript execution context.
2. Remove settings's realm execution context from the JavaScript execution context stack.
3. If the JavaScript execution context stack is now empty, perform a microtask checkpoint. (If this runs scripts, these algorithms will be invoked reentrantly.)

**Note**

These algorithms are not invoked by one script directly calling another, but they can be invoked reentrantly in an indirect manner, e.g. if a script dispatches an event which has event listeners registered.

The **running script** is the script in the [[HostDefined]] field in the ScriptOrModule component of the running JavaScript execution context.

### 8.1.3.5 Realms, settings objects, and global objects

A **global object** is a JavaScript object that is the [[GlobalObject]] field of a **JavaScript realm**.

**Note**

In this specification, all **JavaScript realms** are created with **global objects** that are either **Window** or **WorkerGlobalScope** objects.

There is always a 1-to-1-to-1 mapping between **JavaScript realms**, **global objects**, and **environment settings objects**.

- A **JavaScript realm** has a [[HostDefined]] field, which contains the **Realm's settings object**.
- A **JavaScript realm** has a [[GlobalObject]] field, which contains the **Realm's global object**.
- Each **global object** in this specification is created during the creation of a corresponding **JavaScript realm**, known as the **global object's Realm**.
- Each **global object** in this specification is created alongside a corresponding **environment settings object**, known as its **relevant settings object**.
- An **environment settings object**'s realm execution context's Realm component is the **environment settings object's Realm**.
- An **environment settings object**'s **Realm** then has a [[GlobalObject]] field, which contains the **environment settings object's global object**.

To **create a new JavaScript realm**, optionally with instructions to create a global object or a global this binding (or both), the following steps are taken:

1. Perform `InitializeHostDefinedRealm()` with the provided customizations for creating the global object and the global this binding.
2. Let realm execution context be the running JavaScript execution context.
   **Note**
   This is the JavaScript execution context created in the previous step.
3. Remove realm execution context from the JavaScript execution context stack.
4. Return realm execution context.

When defining algorithm steps throughout this specification, it is often important to indicate what **JavaScript realm** is to be used—or,
equivalently, what `global object` or `environment settings object` is to be used. In general, there are at least four possibilities:

**Entry**
This corresponds to the script that initiated the currently running script action: i.e., the function or script that the user agent called into when it called into author code.

**Incumbent**
This corresponds to the most-recently-entered author function or script on the stack, or the author function or script that originally scheduled the currently-running callback.

**Current**
This corresponds to the currently-running function object, including built-in user-agent functions which might not be implemented as JavaScript. (It is derived from the current JavaScript realm.)

**Relevant**
Every platform object has a relevant Realm, which is roughly the JavaScript realm in which it was created. When writing algorithms, the most prominent platform object whose relevant Realm might be important is the this value of the currently-running function object. In some cases, there can be other important relevant Realms, such as those of any arguments.

Note how the entry, incumbent, and current concepts are usable without qualification, whereas the relevant concept must be applied to a particular platform object.

**Example**

Consider the following pages, with a.html being loaded in a browser window, b.html being loaded in an iframe as shown, and c.html and d.html omitted (they can simply be empty documents):

```html
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Entry page</title>

<iframe src="b.html"></iframe>
<button onclick="frames[0].hello()">Hello</button>

<!-- b.html -->
<!DOCTYPE html>
<html lang="en">
<title>Incumbent page</title>

<iframe src="c.html" id="c"></iframe>
<iframe src="d.html" id="d"></iframe>

<script>
const c = document.querySelector("#c").contentWindow;
const d = document.querySelector("#d").contentWindow;

window.hello = () => {
  c.print.call(d);
};
</script>

Each page has its own browsing context, and thus its own JavaScript realm, global object, and environment settings object.

When the `print()` method is called in response to pressing the button in a.html, then:

- The entry Realm is that of a.html.
- The incumbent Realm is that of b.html.
- The current Realm is that of c.html (since it is the `print()` method from c.html whose code is running).
- The relevant Realm of the object on which the `print()` method is being called is that of d.html.
The incumbent and entry concepts should not be used by new specifications, as they are excessively complicated and unintuitive to work with. We are working to remove almost all existing uses from the platform: see issue #1430 for incumbent, and issue #1431 for entry.

In general, web platform specifications should use the relevant concept, applied to the object being operated on (usually the this value of the current method). This mismatches the JavaScript specification, where current is generally used as the default (e.g. in determining the JavaScript realm whose Array constructor should be used to construct the result in Array.prototype.map). But this inconsistency is so embedded in the platform that we have to accept it going forward.

Note that in constructors, where there is no this value yet, the current concept is the appropriate default.

⚠️ Warning! The relevant concept is generally a better default choice than the current concept is that it is more suitable for creating an object that is to be persisted and returned multiple times. For example, the navigator.getBattery() method creates promises in the relevant Realm for the Navigator object on which it is invoked. This has the following impact:

```html
<!-- outer.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant Realm demo: outer page</title>
<script>
  function doTest() {
    const promise = navigator.getBattery.call(frames[0].navigator);
    console.log(promise instanceof Promise); // logs false
    console.log(promise instanceof frames[0].Promise); // logs true
    frames[0].hello();
  }
</script>
<iframe src="inner.html" onload="doTest()"></iframe>

<!-- inner.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant Realm demo: inner page</title>
<script>
  function hello() {
    const promise = navigator.getBattery();
    console.log(promise instanceof Promise); // logs true
    console.log(promise instanceof parent.Promise); // logs false
  }
</script>

If the algorithm for the getBattery() method had instead used the current concept, all the results would be reversed. That is, after the first call to getBattery() in outer.html, the Navigator object in inner.html would be permanently storing a Promise object created in outer.html's JavaScript realm, and calls like that inside the hello() function would thus return a promise from the "wrong" realm. Since this is undesirable, the algorithm instead uses the relevant Realm, giving the sensible results indicated in the comments above.

The rest of this section deals with formally defining the entry, incumbent, current, and relevant concepts.
8.1.3.5.1 Entry

The process of calling scripts will push or pop realm execution contexts onto the JavaScript execution context stack, interspersed with other execution contexts.

With this in hand, we define the entry execution context to be the most recently pushed item in the JavaScript execution context stack that is a realm execution context. The entry Realm is the entry execution context's Realm component.

Then, the entry settings object is the environment settings object of the entry Realm. Similarly, the entry global object is the global object of the entry Realm.

8.1.3.5.2 Incumbent

All JavaScript execution contexts must contain, as part of their code evaluation state, a skip-when-determining-incumbent counter value, which is initially zero. In the process of preparing to run a callback and cleaning up after running a callback, this value will be incremented and decremented.

Every event loop has an associated backup incumbent settings object stack, initially empty. Roughly speaking, it is used to determine the incumbent settings object when no author code is on the stack, but author code is responsible for the current algorithm having been run in some way. The process of preparing to run a callback and cleaning up after running a callback manipulate this stack.

When Web IDL is used to invoke author code, or when EnqueueJob invokes a promise job, they use the following algorithms to track relevant data for determining the incumbent settings object:

To prepare to run a callback with an environment settings object settings:

1. Push settings onto the backup incumbent settings object stack.
2. Let context be the topmost script-having execution context.
3. If context is not null, increment context's skip-when-determining-incumbent counter.

To clean up after running a callback with an environment settings object settings:

1. Let context be the topmost script-having execution context.
2. If context is not null, decrement context's skip-when-determining-incumbent counter.
3. Assert: the topmost entry of the backup incumbent settings object stack is settings.
4. Remove settings from the backup incumbent settings object stack.

Here, the topmost script-having execution context is the topmost entry of the JavaScript execution context stack that has a non-null ScriptOrModule component, or null if there is no such entry in the JavaScript execution context stack.

With all this in place, the incumbent settings object is determined as follows:

1. Let context be the topmost script-having execution context.
2. If context is null, or if context's skip-when-determining-incumbent counter is greater than zero, then:
   1. Assert: the backup incumbent settings object stack is not empty.

Note

This assert would fail if you try to obtain the incumbent settings object from inside an algorithm that was triggered neither by calling scripts nor by Web IDL invoking a callback. For example, it would trigger if you tried to obtain the incumbent settings object inside an algorithm that ran periodically as part of the event loop with no involvement of author code. In such cases the incumbent concept cannot be used.
2. Return the topmost entry of the backup incumbent settings object stack.

3. Return context’s Realm component’s settings object.

Then, the incumbent Realm is the Realm of the incumbent settings object.

Similarly, the incumbent global object is the global object of the incumbent settings object.

The following series of examples is intended to make it clear how all of the different mechanisms contribute to the definition of the incumbent concept:

**Example**

Consider the following very simple example:

```html
<!DOCTYPE html>
<iframe></iframe>
<script>
    new frames[0].MessageChannel();
</script>
```

When the `MessageChannel()` constructor looks up the incumbent settings object to use as the owner of the new `MessagePort` objects, the topmost script-having execution context will be that corresponding to the `script` element: it was pushed onto the JavaScript execution context stack as part of ScriptEvaluation during the run a classic script algorithm. Since there are no Web IDL callback invocations involved, the context’s skip-when-determining-incumbent counter is zero, so it is used to determine the incumbent settings object; the result is the environment settings object of `window`.

(In this example, the environment settings object of `frames[0]` is not involved at all. It is the current settings object, but the `MessageChannel()` constructor cares only about the incumbent, not current.)

**Example**

Consider the following more complicated example:

```html
<!DOCTYPE html>
<iframe></iframe>
<script>
    const bound = frames[0].postMessage.bind(frames[0], "some data", "+");
    window.setTimeout(bound);
</script>
```

There are two interesting environment settings objects here: that of `window`, and that of `frames[0]`. Our concern is: what is the incumbent settings object at the time that the algorithm for `postMessage()` executes?

It should be that of `window`, to capture the intuitive notion that the author script responsible for causing the algorithm to happen is executing in `window`, not `frames[0]`. Another way of capturing the intuition here is that invoking algorithms asynchronously (in this case via `setTimeout()` should not change the incumbent concept.

Let us now explain how the steps given above give us our intuitively-desired result of `window`’s relevant settings object.

When `bound` is converted to a Web IDL callback type, the incumbent settings object, is that corresponding to `window` (in the same manner as in our simple example above). Web IDL stores this as the resulting callback value’s callback context.

When the task posted by `setTimeout()` executes, the algorithm for that task uses Web IDL to invoke the stored callback value. Web IDL in turn calls the above prepare to run a callback algorithm. This pushes the stored callback context onto the backup incumbent settings object stack. At this time (inside the timer task) there is no author code on the stack, so the topmost script-having execution context is null, and nothing gets its skip-when-determining-incumbent counter incremented.

Invoking the callback then calls `bound`, which in turn calls the `postMessage()` method of `frames[0]`. When the
The `postMessage()` algorithm looks up the incumbent settings object, there is still no author code on the stack, since the bound function just directly calls the built-in method. So the topmost script-having execution context will be null: the JavaScript execution context stack only contains an execution context corresponding to `postMessage()`, with no ScriptEvaluation context or similar below it.

This is where we fall back to the backup incumbent settings object stack. As noted above, it will contain as its topmost entry the relevant settings object of `window`. So that is what is used as the incumbent settings object while executing the `postMessage()` algorithm.

Consider this final, even more convoluted example:

```
<!-- a.html -->
<!DOCTYPE html>
<button>click me</button>
<iframe></iframe>
<script>
const bound = frames[0].location.assign.bind(frames[0].location, "https://example.com/");
document.querySelector("button").addEventListener("click", bound);
</script>

<!-- b.html -->
<!DOCTYPE html>
<iframe src="a.html"></iframe>
<script>
const iframe = document.querySelector("iframe");
iframe.onload = function onLoad() {
  iframe.contentWindow.document.querySelector("button").click();
};
</script>
```

Again there are two interesting environment settings objects in play: that of `a.html`, and that of `b.html`. When the `location.assign()` method triggers the Location-object navigate algorithm, what will be the incumbent settings object? As before, it should intuitively be that of `a.html`: the click listener was originally scheduled by `a.html`, so even if something involving `b.html` causes the listener to fire, the incumbent responsible is that of `a.html`.

The callback setup is similar to the previous example: when `bound` is converted to a Web IDL callback type, the incumbent settings object is that corresponding to `a.html`, which is stored as the callback’s callback context.

When the `click()` method is called inside `b.html`, it dispatches a click event on the button that is inside `a.html`. This time, when the prepare to run a callback algorithm executes as part of event dispatch, there is author code on the stack; the topmost script-having execution context is that of the `onLoad` function, whose `skip-when-determining-incumbent counter` gets incremented. Additionally, `a.html`'s environment settings object (stored as the `EventHandler`’s callback context) is pushed onto the backup incumbent settings object stack.

Now, when the Location-object navigate algorithm looks up the incumbent settings object, the topmost script-having execution context is still that of the `onLoad` function (due to the fact we are using a bound function as the callback). Its `skip-when-determining-incumbent counter` value is one, however, so we fall back to the backup incumbent settings object stack.

This gives us the environment settings object of `a.html`, as expected.

Note that this means that even though it is the `iframe` inside `a.html` that navigates, it is `a.html` itself that is used as the source browsing context, which determines among other things the request client. This is perhaps the only justifiable use of the incumbent concept on the web platform; in all other cases the consequences of using it are simply confusing and we hope to one day switch them to use current or relevant as appropriate.
**8.1.3.5.3 Current**

The JavaScript specification defines the current Realm Record, sometimes abbreviated to the "current Realm". [JAVASCRIPT]

Then, the current settings object is the environment settings object of the current Realm Record.

Similarly, the current global object is the global object of the current Realm Record.

**8.1.3.5.4 Relevant**

The relevant settings object for a platform object is defined as follows:

↪ **If the object is a global object**

Each global object in this specification is created alongside a corresponding environment settings object, that is its relevant settings object.

↪ **Otherwise**

The relevant settings object for a non-global platform object $o$ is the environment settings object whose global object is the global object of the global environment associated with $o$.

**Note**

The "global environment associated with" concept is from the olden days, before the modern JavaScript specification and its concept of realms. We expect that as the Web IDL specification gets updated, every platform object will have a Realm associated with it, and this definition can be re-cast in those terms. [JAVASCRIPT] [WEBIDL]

Then, the relevant Realm for a platform object is the Realm of its relevant settings object.

Similarly, the relevant global object for a platform object is the global object of its relevant settings object.

**8.1.3.6 Killing scripts**

Although the JavaScript specification does not account for this possibility, it's sometimes necessary to abort a running script. This causes any ScriptEvaluation or Source Text Module Record Evaluate invocations to cease immediately, emptying the JavaScript execution context stack without triggering any of the normal mechanisms like finally blocks. [JAVASCRIPT]

User agents may impose resource limitations on scripts, for example CPU quotas, memory limits, total execution time limits, or bandwidth limitations. When a script exceeds a limit, the user agent may either throw a "QuotaExceededError" DOMException, abort the script without an exception, prompt the user, or throttle script execution.

**Example**

For example, the following script never terminates. A user agent could, after waiting for a few seconds, prompt the user to either terminate the script or let it continue.

```html
<script>
  while (true) { /* loop */ }
</script>
```

User agents are encouraged to allow users to disable scripting whenever the user is prompted either by a script (e.g. using the window.alert API) or because of a script's actions (e.g. because it has exceeded a time limit).

If scripting is disabled while a script is executing, the script should be terminated immediately.

User agents may allow users to specifically disable scripts just for the purposes of closing a browsing context.

**Example**

For example, the prompt mentioned in the example above could also offer the user with a mechanism to just close the page entirely, without running any unload event handlers.
The JavaScript specification defines the JavaScript job and job queue abstractions in order to specify certain invariants about how promise operations execute with a clean JavaScript execution context stack and in a certain order. However, as of the time of this writing the definition of `EnqueueJob` in that specification is not sufficiently flexible to integrate with HTML as a host environment. 

As such, user agents must instead use the following definition in place of that in the JavaScript specification. These ensure that the promise jobs enqueued by the JavaScript specification are properly integrated into the user agent's event loops.

The `RunJobs` abstract operation from the JavaScript specification must not be used by user agents.

### 8.1.3.7 EnqueueJob(queueName, job, arguments)

When the JavaScript specification says to call the EnqueueJob abstract operation, the following algorithm must be used in place of JavaScript's `EnqueueJob`:

1. **Assert:** `queueName` is "PromiseJobs".("ScriptJobs" must not be used by user agents.)
2. Let `job settings` be some appropriate environment settings object.
3. Let `incumbent settings` be the incumbent settings object.
4. Assert: `active script` is not null, as jobs are only enqueued by the JavaScript specification while a script is active.
5. Let `script execution context` be a new JavaScript execution context, with its Function field set to null, its Realm field set to `active script`'s Realm, and its ScriptOrModule set to `active script`'s record.
6. Queue a microtask, on `job settings`'s responsible event loop, to perform the following steps:
   1. Check if we can run script with `job settings`. If this returns "do not run" then return.
   2. Prepare to run script with `job settings`.
   3. Prepare to run a callback with `incumbent settings`.
5. Let result be the result of performing the abstract operation specified by `job`, using the elements of `arguments` as
its arguments.

6. Pop script execution context from the JavaScript execution context stack.

7. Clean up after running a callback with incumbent settings.

8. Clean up after running script with job settings.

9. If result is an abrupt completion, then report the exception given by result.[Value].

8.1.3.8 Integration with the JavaScript module system

The JavaScript specification defines a syntax for modules, as well as some host-agnostic parts of their processing model. This specification defines the rest of their processing model: how the module system is bootstrapped, via the script element with type attribute set to "module", and how modules are fetched, resolved, and executed. [JAVASCRIPT]

A module map is a map of URL records to values that are either a module script, null (used to represent failed fetches), or a placeholder value "fetching", Module maps are used to ensure that imported JavaScript modules are only fetched, parsed, and evaluated once per Document or worker.

Example

Since module maps are keyed by URL, the following code will create three separate entries in the module map, since it results in three different URLs:

```javascript
import "https://example.com/module.mjs";
import "https://example.com/module.mjs#map-buster";
import "https://example.com/module.mjs?debug=true";
```

That is, URL queries and fragments can be varied to create distinct entries in the module map; they are not ignored. Thus, three separate fetches and three separate module evaluations will be performed.

In contrast, the following code would only create a single entry in the module map, since after applying the URL parser to these inputs, the resulting URL records are equal:

```javascript
import "https://example.com/module2.mjs";
import "https://example.com/module2.mjs"
import "https://example.com/module2.mjs"
import "https://example.com/foo/../module2.mjs"
```

So in this second example, only one fetch and one module evaluation will occur.

Note that this behavior is the same as how shared workers are keyed by their parsed constructor url.

To resolve a module specifier given a URL base URL and a JavaScript string specifier, perform the following steps. It will return either a URL record or failure.

1. Apply the URL parser to specifier. If the result is not failure, return the result.

2. If specifier does not start with the character U+002F SOLIDUS (/), the two-character sequence U+002E FULL STOP, U+002F SOLIDUS (./), or the three-character sequence U+002E FULL STOP, U+002E FULL STOP, U+002F SOLIDUS (../), return failure.

Note: This restriction is in place so that in the future we can allow custom module loaders to give special meaning to "bare" import specifiers, like import "jquery" or import "web/crypto". For now any such imports will fail, instead of being treated as relative URLs.
3. Return the result of applying the URL parser to specifier with base URL as the base URL.

The following are valid module specifiers according to the above algorithm:

- https://example.com/apples.mjs
- http://example.com/pears.js
- ./strawberries.mjs.cgi
- ./lychees
- /limes.jsx
- data:text/javascript,export default 'grapes';
- blob:https://whatwg.org/d830e2f-caee-469f-9a2f-87d5b0456f6f

The following are valid module specifiers according to the above algorithm, but will invariably cause failures when they are fetched:

- javascript:export default 'artichokes';
- data:text/plain,export default 'kale';
- about:legumes
- wss://example.com/celery

The following are not valid module specifiers according to the above algorithm:

- https://eggplant:b/c
- pumpkins.js
- .tomato
- ..zucchini.mjs
- ./yam.es

8.1.3.8.1 HostResolveImportedModule(referencingScriptOrModule, specifier) §

JavaScript contains an implementation-defined HostResolveImportedModule abstract operation, very slightly updated by the import() proposal. User agents must use the following implementation: [JAVASCRIPT][1224] [JSIMPORT][1224]

1. Let referencing script be referencingScriptOrModule.[[HostDefined]].
2. Let moduleMap be referencing script's settings object's module map.
3. Let url be the result of resolving a module specifier given referencing script's base URL and specifier.
4. Assert: url is never failure, because resolving a module specifier must have been previously successful with these same two arguments.
5. Let resolved module script be moduleMap[url]. (This entry must exist for us to have gotten to this point.)
6. Assert: resolved module script is a module script (i.e., is not null or "fetching").
7. Assert: resolved module script's record is not null.
8. Return resolved module script's record.

8.1.3.8.2 HostImportModuleDynamically(referencingScriptOrModule, specifier, promiseCapability) §

The import() proposal contains an implementation-defined HostImportModuleDynamically abstract operation. User agents must use the following implementation: [JSIMPORT][1224]

1. Let referencing script be referencingScriptOrModule.[[HostDefined]].
2. Run the following steps in parallel:
   1. Let url be the result of resolving a module specifier given referencing script's base URL and specifier.
   2. If url is failure, then:
      1. Let completion be Completion { [[Type]]: throw, [[Value]]: a new TypeError, [[Target]]: empty }.
2. Perform \texttt{FinishDynamicImport}(referencingScriptOrModule, specifier, promiseCapability, completion).

3. Return.

3. Let options be the descendant script fetch options for referencing script's fetch options.

4. Fetch a module script graph given url, referencing script's settings object, "script", and options. Wait until the algorithm asynchronously completes with result.

5. If result is null, then:
   1. Let completion be Completion \{ [[Type]]: throw, [[Value]]: a new TypeError, [[Target]]: empty \}.
   2. Perform \texttt{FinishDynamicImport}(referencingScriptOrModule, specifier, promiseCapability, completion).
   3. Return.

6. Run the module script result, with the rethrow errors boolean set to true.

7. If running the module script throws an exception, then perform \texttt{FinishDynamicImport}(referencingScriptOrModule, specifier, promiseCapability, the thrown exception completion).

8. Otherwise, perform \texttt{FinishDynamicImport}(referencingScriptOrModule, specifier, promiseCapability, NormalCompletion(undefined)).

3. Return undefined.

8.1.3.8.3 \texttt{HostGetImportMetaProperties}(moduleRecord) \texttt{§88}

The import.meta proposal contains an implementation-defined \texttt{HostGetImportMetaProperties} abstract operation. User agents must use the following implementation: [JSIMPORTMETA]1224

1. Let module script be moduleRecord.\[[HostDefined]\].

2. Let urlString be module script's base URL, serialized.

3. Return « Record \{ \[[Key]\]: "url", \[[Value]\]: urlString \} ».

8.1.3.9 Integration with the JavaScript agent formalism \texttt{§88}

JavaScript defines the concept of an agent. This section gives the mapping of that language-level concept on to the web platform.

\begin{quote}
JavaScript is expected to define agents in more detail; in particular that they hold a set of realms. tc39/ecma262 issue #882.
\end{quote}

\begin{note}
Conceptually, the agent concept is an architecture-independent, idealized "thread" in which JavaScript code runs. Such code can involve multiple globals/reals that can synchronously access each other, and thus need to run in a single execution thread.
\end{note}

Until such a time that this standard has a better handle on lifetimes, it defines five types of agents that user agents must allocate at the appropriate time.

\begin{note}
In the future, this standard hopes to define exactly when agents and agent clusters are created.
\end{note}

Similar-origin window agent

An agent whose [[CanBlock]] is false and whose set of realms consists of all realms of Window objects whose relevant settings object's responsible browsing context is in the same unit of related similar-origin browsing contexts.

\begin{note}
Two Windows objects that are same origin can be in different similar-origin window agents, for instance if they are each in their own unit of related similar-origin browsing contexts.
\end{note}
Dedicated worker agent
An agent whose [[CanBlock]] is true and whose set of realms consists of a single DedicatedWorkerGlobalScope object's Realm.

Shared worker agent
An agent whose [[CanBlock]] is true and whose set of realms consists of a single SharedWorkerGlobalScope object's Realm.

Service worker agent
An agent whose [[CanBlock]] is false and whose set of realms consists of a single ServiceWorkerGlobalScope object's Realm.

Worklet agent
An agent whose [[CanBlock]] is false and whose set of realms consists of a single WorkletGlobalScope object's Realm.

JavaScript also defines the concept of an agent cluster, which this standard maps to the web platform using the can share memory with equivalence relation detailed below. On the web platform, an agent cluster consists of all agents in the same equivalence class with respect to the can share memory with equivalence relation.

The agent cluster concept is crucial for defining the JavaScript memory model, and in particular among which agents the backing data of SharedArrayBuffer objects can be shared.

8.1.3.10 Integration with the JavaScript agent cluster formalism

JavaScript also defines the concept of an agent cluster, which this standard maps to the web platform using the can share memory with equivalence relation detailed below. On the web platform, an agent cluster consists of all agents in the same equivalence class with respect to the can share memory with equivalence relation.

The agent cluster concept is crucial for defining the JavaScript memory model, and in particular among which agents the backing data of SharedArrayBuffer objects can be shared.

A similar-origin window agent, dedicated worker agent, shared worker agent, or service worker agent, agent, can share memory with any dedicated worker agent whose single realm's global object's owner set contains an item whose relevant Realm belongs to agent.

"Item" is used above as an owner set can contain Document objects.

A worklet agent... currently worklets have no clearly defined owner, see: w3c/css-houdini-drafts issue #224.

In addition, any agent A can share memory with:
- A,
- any agent B such that B can share memory with A, and
- any agent B such that there exists an agent C, where A can share memory with C and C can share memory with B.

The following pairs of global objects are each within the same agent cluster, and thus can use SharedArrayBuffer instances to share memory with each other:
- A Window object and a dedicated worker that it created.
- A worker (of any type) and a dedicated worker it created.
- A Window object A and the Window object of an iframe element that A created that could be same origin-domain with A.
- A Window object and a same origin-domain Window object that opened it.

The following pairs of global objects are not within the same agent cluster, and thus cannot share memory:
When the user agent is required to report an error for a particular script with a particular position line:col, using a particular target, it must run these steps, after which the error is either handled or not handled:

1. If target is in error reporting mode, then return; the error is not handled.
2. Let target be in error reporting mode.
3. Let message be a user-agent-defined string describing the error in a helpful manner.
4. Let errorValue be the value that represents the error: in the case of an uncaught exception, that would be the value that was thrown; in the case of a JavaScript error that would be an Error object. If there is no corresponding value, then the null value must be used instead.
5. Let urlString be the result of applying the URL serializer to the URL record that corresponds to the resource from which script was obtained.
6. If script’s muted errors is true, then set message to "Script error.", urlString to the empty string, line and col to 0, and errorValue to null.
7. Let notHandled be the result of firing an event named error named error at target, using ErrorEvent, with the cancelable attribute initialized to true, the message attribute initialized to message, the filename attribute initialized to urlString, the lineno attribute initialized to line, the colno attribute initialized to col, and the error attribute initialized to errorValue.
8. Let target no longer be in error reporting mode.
9. If notHandled is false, then the error is handled. Otherwise, the error is not handled.

Note

The resource containing the script will typically be the file from which the Document was parsed, e.g. for inline script elements or event handler content attributes, or the JavaScript file that the script was in, for external scripts. Even for dynamically-generated scripts, user agents are strongly encouraged to attempt to keep track of the original source of a script. For example, if an external script uses the document.write() API to insert an inline script element during parsing, the URL of the resource containing the script would ideally be reported as being the external script, and the line number might ideally be reported as the line with the document.write() call or where the string passed to that call was first constructed. Naturally, implementing this can be somewhat non-trivial.

Note

User agents are similarly encouraged to keep careful track of the original line numbers, even in the face of document.write() calls mutating the document as it is parsed, or event handler content attributes spanning multiple lines.

8.1.3.11 Runtime script errors

When the user agent is required to report an error for a particular script with a particular position line:col, using a particular target, it must run these steps, after which the error is either handled or not handled:

1. If target is in error reporting mode, then return; the error is not handled.
2. Let target be in error reporting mode.
3. Let message be a user-agent-defined string describing the error in a helpful manner.
4. Let errorValue be the value that represents the error: in the case of an uncaught exception, that would be the value that was thrown; in the case of a JavaScript error that would be an Error object. If there is no corresponding value, then the null value must be used instead.
5. Let urlString be the result of applying the URL serializer to the URL record that corresponds to the resource from which script was obtained.
6. If script’s muted errors is true, then set message to "Script error.", urlString to the empty string, line and col to 0, and errorValue to null.
7. Let notHandled be the result of firing an event named error named error at target, using ErrorEvent, with the cancelable attribute initialized to true, the message attribute initialized to message, the filename attribute initialized to urlString, the lineno attribute initialized to line, the colno attribute initialized to col, and the error attribute initialized to errorValue.
8. Let target no longer be in error reporting mode.
9. If notHandled is false, then the error is handled. Otherwise, the error is not handled.

Note

Returning true in an event handler cancels the event per the event handler processing algorithm.

8.1.3.11.1 Runtime script errors in documents

When the user agent is to report an exception E, the user agent must report the error for the relevant script, with the problematic position (line number and column number) in the resource containing the script, using the global object specified by
the script's settings object as the target. If the error is still not handled after this, then the error may be reported to a developer console.

### 8.1.3.11.2 The ErrorEvent Interface

IDL:

```idl
class ErrorEvent {
  attribute DOMString message;
  attribute USVString filename;
  attribute unsigned long lineno;
  attribute unsigned long colno;
  attribute any error;
};
```

```idl
dictionary ErrorEventInit : EventInit {
  DOMString message = "";
  USVString filename = "";
  unsigned long lineno = 0;
  unsigned long colno = 0;
  any error = null;
};
```

The `message` attribute must return the value it was initialized to. It represents the error message.

The `filename` attribute must return the value it was initialized to. It represents the URL of the script in which the error originally occurred.

The `lineno` attribute must return the value it was initialized to. It represents the line number where the error occurred in the script.

The `colno` attribute must return the value it was initialized to. It represents the column number where the error occurred in the script.

The `error` attribute must return the value it was initialized to. Where appropriate, it is set to the object representing the error (e.g., the exception object in the case of an uncaught DOM exception).

### 8.1.3.12 Unhandled promise rejections

In addition to synchronous runtime script errors, scripts may experience asynchronous promise rejections, tracked via the `unhandledrejection` and `rejectionhandled` events.

When the user agent is to notify about rejected promises on a given environment settings object settings object, it must run these steps:

1. Let `list` be a copy of settings object's about-to-be-notified rejected promises list.
2. If `list` is empty, return.
4. Queue a task to run the following substep:

   1. For each promise `p` in `list`:
      1. If `p`'s [[PromiseIsHandled]] internal slot is true, continue to the next iteration of the loop.
      2. Let `notHandled` be the result of firing an event named `unhandledrejection` at settings object's global object, using PromiseRejectionEvent, with the cancelable attribute initialized to true, the promise attribute initialized to `p`, and the reason attribute initialized to the value of `p`'s [[PromiseResult]] internal slot.
      3. If `notHandled` is false, then the promise rejection is handled. Otherwise, the promise rejection is not handled.
4. If p's [[PromiseIsHandled]] internal slot is false, add p to settings object's outstanding rejected promises weak set.

This algorithm results in promise rejections being marked as handled or not handled. These concepts parallel handled and not handled script errors. If a rejection is still not handled after this, then the rejection may be reported to a developer console.

### 8.1.3.12 HostPromiseRejectionTracker(promise, operation)

JavaScript contains an implementation-defined HostPromiseRejectionTracker(promise, operation) abstract operation. User agents must use the following implementation:

```javascript
1. Let script be the running script.
2. If script's muted errors is true, terminate these steps.
3. Let settings object be script's settings object.
4. If operation is "reject",
   1. Add promise to settings object's about-to-be-notified rejected promises list.
5. If operation is "handle",
   1. If settings object's about-to-be-notified rejected promises list contains promise, then remove promise from that list and return.
   2. If settings object's outstanding rejected promises weak set does not contain promise, then return.
   3. Remove promise from settings object's outstanding rejected promises weak set.
   4. Queue a task to fire an event named rejectionhandled at settings object's global object, using PromiseRejectionEvent, with the promise attribute initialized to promise, and the reason attribute initialized to the value of promise's [[PromiseResult]] internal slot.
```

### 8.1.3.13 HostEnsureCanCompileStrings(callerRealm, calleeRealm)

JavaScript contains an implementation-defined HostEnsureCanCompileStrings(callerRealm, calleeRealm) abstract operation. User agents must use the following implementation:

```javascript
```
To coordinate events, user interaction, scripts, rendering, networking, and so forth, user agents must use event loops as described in this section. There are two kinds of event loops: those for browsing contexts and those for workers.

There must be at least one browsing context per user agent, and at most one per unit of related similar-origin browsing contexts.

A browsing context always has at least one event loop. If such an event loop's browsing contexts all go away, then the event loop goes away as well. A browsing context always has an event loop coordinating its activities.

Worker event loops are simpler: each worker has one event loop, and the worker processing model manages the event loop's lifetime.

An event loop has one or more task queues. A task queue is an ordered list of tasks, which are algorithms that are responsible for such work as:

**Events**
- Dispatching an Event object at a particular EventTarget object is often done by a dedicated task.

**Note**
Not all events are dispatched using the task queue, many are dispatched during other tasks.

**Parsing**
- The HTML parser tokenizing one or more bytes, and then processing any resulting tokens, is typically a task.

**Callbacks**
- Calling a callback is often done by a dedicated task.

**Using a resource**
- When an algorithm fetches a resource, if the fetching occurs in a non-blocking fashion then the processing of the resource once some or all of the resource is available is performed by a task.

**Reacting to DOM manipulation**
- Some elements have tasks that trigger in response to DOM manipulation, e.g. when that element is inserted into the document.

Each task in a browsing context is associated with a Document; if the task was queued in the context of an element, then it is the element's node document; if the task was queued in the context of a browsing context, then it is the browsing context's active document at the time the task was queued; if the task was queued by or for a script, then the document is the responsible document specified by the script's settings object.

A task is intended for a specific event loop; the event loop that is handling tasks for the task's associated Document or worker.

When a user agent is to queue a task, it must add the given task to one of the task queues of the relevant event loop.

Each task is defined as coming from a specific task source. All the tasks from one particular task source and destined to a particular event loop (e.g. the callbacks generated by timers of a Document, the events fired for mouse movements over that Document, the tasks queued for the parser of that Document) must always be added to the same task queue, but tasks from different task sources may be placed in different task queues.

**Example**
For example, a user agent could have one task queue for mouse and key events (the user interaction task source), and another for everything else. The user agent could then give keyboard and mouse events preference over other tasks three quarters of the time, keeping the interface responsive but not starving other task queues, and never processing events from any one task.
Each event loop has a currently running task. Initially, this is null. It is used to handle reentrancy. Each event loop also has a performing a microtask checkpoint flag, which must initially be false. It is used to prevent reentrant invocation of the perform a microtask checkpoint algorithm.

8.1.4.2 Processing model

An event loop must continually run through the following steps for as long as it exists:

1. Let oldestTask be the oldest task on one of the event loop’s task queues, if any, ignoring, in the case of a browsing context event loop, tasks whose associated Documents are not fully active. The user agent may pick any task queue. If there is no task to select, then jump to the microtasks step below.

2. Set the event loop’s currently running task to oldestTask.

3. Run oldestTask.

4. Set the event loop’s currently running task back to null.

5. Remove oldestTask from its task queue.

7. Update the rendering: If this event loop is a browsing context event loop (as opposed to a worker event loop), then run the following substeps.

   1. Let now be the current high resolution time. [HRT]

   2. Let docs be the list of Document objects associated with the event loop in question, sorted arbitrarily except that the following conditions must be met:

      - Any Document B that is nested through a Document A must be listed after A in the list.

      - If there are two documents A and B whose browsing contexts are both nested browsing contexts and their browsing context containers, are both elements in the same Document C, then the order of A and B in the list must match the relative tree order of their respective browsing context containers in C.

   In the steps below that iterate over docs, each Document must be processed in the order it is found in the list.

   3. If there are top-level browsing contexts B that the user agent believes would not benefit from having their rendering updated at this time, then remove from docs all Document objects whose browsing context is top-level browsing context is in B.

   4. If there are nested browsing contexts B that the user agent believes would not benefit from having their rendering updated at this time, then remove from docs all Document objects whose browsing context is in B.

Note

Whether a top-level browsing context would benefit from having its rendering updated depends on various factors, such as the update frequency. For example, if the browser is attempting to achieve a 60Hz refresh rate, then these steps are only necessary every 60th of a second (about 16.7ms). If the browser finds that a top-level browsing context is not able to sustain this rate, it might drop to a more sustainable 30Hz for that set of Documents, rather than occasionally dropping frames. (This specification does not mandate any particular model for when to update the rendering.) Similarly, if a top-level browsing context is in the background, the user agent might decide to drop that page to a much slower 4Hz, or even less.

Another example of why a browser might skip updating the rendering is to ensure certain tasks are executed immediately after each other, with only microtask checkpoints interleaved (and without, e.g., animation frame callbacks interleaved). For example, a user agent might wish to coalesce timer callbacks together, with no intermediate rendering updates.
5. For each fully active\(^\text{6782}\) Document\(^\text{6118}\) in docs, run the resize steps for that Document\(^\text{6110}\), passing in now as the timestamp. [CSSOMVIEW]\(^\text{6122}\)

6. For each fully active\(^\text{6782}\) Document\(^\text{6118}\) in docs, run the scroll steps for that Document\(^\text{6110}\), passing in now as the timestamp. [CSSOMVIEW]\(^\text{6122}\)

7. For each fully active\(^\text{6782}\) Document\(^\text{6118}\) in docs, evaluate media queries and report changes for that Document\(^\text{6110}\), passing in now as the timestamp. [CSSOMVIEW]\(^\text{6122}\)

8. For each fully active\(^\text{6782}\) Document\(^\text{6118}\) in docs, update animations and send events for that Document\(^\text{6110}\), passing in now as the timestamp. [WEBANIMATIONS]\(^\text{6127}\)

9. For each fully active\(^\text{6782}\) Document\(^\text{6118}\) in docs, run the fullscreen steps for that Document\(^\text{6110}\), passing in now as the timestamp. [FULLSCREEN]\(^\text{6123}\)

10. For each fully active\(^\text{6782}\) Document\(^\text{6118}\) in docs, run the animation frame callbacks\(^\text{6940}\) for that Document\(^\text{6110}\), passing in now as the timestamp.

11. For each fully active\(^\text{6782}\) Document\(^\text{6118}\) in docs, run the update intersection observations steps for that Document\(^\text{6110}\), passing in now as the timestamp. [INTERSECTIONOBSERVER]\(^\text{6124}\)

12. For each fully active\(^\text{6782}\) Document\(^\text{6118}\) in docs, update the rendering or user interface of that Document\(^\text{6110}\) and its browsing context\(^\text{6780}\) to reflect the current state.

8. If this is a worker\(^\text{6972}\), event loop\(^\text{6983}\) (i.e. one running for a WorkerGlobalScope\(^\text{6988}\)), but there are no tasks\(^\text{6983}\) in the event loop\(^\text{6983}\)’s task queues\(^\text{6983}\) and the WorkerGlobalScope\(^\text{6988}\) object’s closing\(^\text{9991}\) flag is true, then destroy the event loop\(^\text{6983}\), aborting these steps, resuming the run a worker\(^\text{6992}\) steps described in the Web workers\(^\text{6972}\) section below.

Each event loop\(^\text{6983}\) has a microtask queue. A microtask is a task\(^\text{6983}\) that is originally to be queued on the microtask queue\(^\text{6995}\) rather than a task queue\(^\text{6983}\). There are two kinds of microtasks\(^\text{6985}\): solitary callback microtasks, and compound microtasks.

Note

This specification only has solitary callback microtasks\(^\text{6985}\). Specifications that use compound microtasks\(^\text{6985}\) have to take extra care to wrap callbacks\(^\text{6986}\) to handle spinning the event loop\(^\text{6986}\).

When an algorithm requires a microtask\(^\text{6985}\) to be queued, it must be appended to the relevant event loop\(^\text{6983}\)’s microtask queue\(^\text{6995}\). the task source\(^\text{6983}\) of such a microtask\(^\text{6985}\) is the microtask task source.

Note

It is possible for a microtask\(^\text{6985}\) to be moved to a regular task queue\(^\text{6983}\), if, during its initial execution, it spins the event loop\(^\text{6986}\). In that case, the microtask task source\(^\text{6995}\) is the task source\(^\text{6983}\) used. Normally, the task source\(^\text{6983}\) of a microtask\(^\text{6985}\) is irrelevant.

When a user agent is to perform a microtask checkpoint, if the performing a microtask checkpoint\(^\text{6994}\) flag is false, then the user agent must run the following steps:

1. Set the performing a microtask checkpoint\(^\text{6994}\) flag to true.

2. While the event loop\(^\text{6983}\)’s microtask queue\(^\text{6995}\) is not empty:

   1. Let oldestMicrotask be the oldest microtask\(^\text{6985}\) on the event loop\(^\text{6983}\)’s microtask queue\(^\text{6995}\).

   2. Set the event loop\(^\text{6983}\)’s currently running task\(^\text{6984}\) to oldestMicrotask.

   3. Run oldestMicrotask.

Note

This might involve invoking scripted callbacks, which eventually calls the clean up after running script\(^\text{6879}\).
4. Set the `event loop`'s currently running task back to null.

5. Remove oldestMicrotask from the `microtask queue`.

3. For each `environment settings object` whose responsible event loop is this `event loop`, notify about rejected promises on that `environment settings object`.

4. Cleanup Indexed Database transactions.

5. Set the `performing a microtask checkpoint` flag to false.

If, while a `compound microtask` is running, the user agent is required to execute a compound microtask subtask to run a series of steps, the user agent must run the following steps:

1. Let `parent` be the `event loop`'s currently running task (the currently running compound microtask).
2. Let `subtask` be a new task that consists of running the given series of steps. The `task source` of such a `microtask` is the `microtask task source`. This is a `compound microtask subtask`.
3. Set the `event loop`'s currently running task to `subtask`.
4. Run `subtask`.
5. Set the `event loop`'s currently running task back to `parent`.

When an algorithm running in parallel is to await a stable state, the user agent must queue a microtask that runs the following steps, and must then stop executing (execution of the algorithm resumes when the microtask is run, as described in the following steps):

1. Run the algorithm's synchronous section.
2. Resumes execution of the algorithm in parallel, if appropriate, as described in the algorithm's steps.

Note: Steps in synchronous sections are marked with ⌛.

When an algorithm says to spin the event loop until a condition goal is met, the user agent must run the following steps:

1. Let `task` be the `event loop`'s currently running task.

Note: This might be a `microtask`, in which case it is a solitary callback microtask. It could also be a compound microtask subtask or a regular task that is not a `microtask`. It will not be a compound microtask.

2. Let `task source` be task's `task source`.
3. Let `old stack` be a copy of the `JavaScript execution context stack`.
4. Empty the `JavaScript execution context stack`.
5. Perform a microtask checkpoint.
6. Stop `task`, allowing whatever algorithm that invoked it to resume, but continue these steps in parallel.

Note: This causes one of the following algorithms to continue: the `event loop`'s main set of steps, the `perform a microtask checkpoint` algorithm, or the `execute a compound microtask subtask` algorithm.

7. Wait until the condition goal is met.
8. Queue a task to continue running these steps, using the task source task source. Wait until this new task runs before
continuing these steps.

9. Replace the JavaScript execution context stack with the old stack.

10. Return to the caller.

Some of the algorithms in this specification, for historical reasons, require the user agent to pause while running a task until a condition goal is met. This means running the following steps:

1. If necessary, update the rendering or user interface of any Document or browsing context to reflect the current state.

2. Wait until the condition goal is met. While a user agent has a paused task, the corresponding event loop must not run further tasks, and any script in the currently running task must block. User agents should remain responsive to user input while paused, however, albeit in a reduced capacity since the event loop will not be doing anything.

⚠ Warning!

Pausing is highly detrimental to the user experience, especially in scenarios where a single event loop is shared among multiple documents. User agents are encouraged to experiment with alternatives to pausing, such as spinning the event loop or even simply proceeding without any kind of suspended execution at all, insofar as it is possible to do so while preserving compatibility with existing content. This specification will happily change if a less-drastic alternative is discovered to be web-compatible.

In the interim, implementers should be aware that the variety of alternatives that user agents might experiment with can change subtle aspects of event loop behavior, including task and microtask timing. Implementations should continue experimenting even if doing so causes them to violate the exact semantics implied by the pause operation.

8.1.4.3 Generic task sources

The following task sources are used by a number of mostly unrelated features in this and other specifications.

The DOM manipulation task source
This task source is used for features that react to DOM manipulations, such as things that happen in a non-blocking fashion when an element is inserted into the document.

The user interaction task source
This task source is used for features that react to user interaction, for example keyboard or mouse input.

Events sent in response to user input (e.g. click events) must be fired using tasks queued with the user interaction task source. [UIEVENTS]

The networking task source
This task source is used for features that trigger in response to network activity.

The history traversal task source
This task source is used to queue calls to history.back() and similar APIs.

8.1.4.4 Dealing with the event loop from other specifications

Writing specifications that correctly interact with the event loop can be tricky. This is compounded by how this specification uses concurrency-model-independent terminology, so we say things like "event loop" and "in parallel" instead of using more familiar model-specific terms like "main thread" or "on a background thread".

By default, specification text generally runs on the event loop. This falls out from the formal event loop processing model, in that you can eventually trace most algorithms back to a task queued there.

Example

The algorithm steps for any JavaScript method will be invoked by author code calling that method. And author code can only be run via queued tasks, usually originating somewhere in the script processing model.
From this starting point, the overriding guideline is that any work a specification needs to perform that would otherwise block the event loop must instead be performed in parallel with it. This includes (but is not limited to):

- performing heavy computation;
- displaying a user-facing prompt;
- performing operations which could require involving outside systems (i.e. "going out of process").

The next complication is that, in algorithm sections that are in parallel, you must not create or manipulate objects associated to a specific JavaScript realm, global, or environment settings object. (Stated in more familiar terms, you must not directly access main-thread artifacts from a background thread.) Doing so would create data races observable to JavaScript code, since after all, your algorithm steps are running in parallel to the JavaScript code.

You can, however, manipulate specification-level data structures and values from the WHATWG Infra Standard, as those are realm-agnostic. They are never directly exposed to JavaScript without a specific conversion taking place (often via Web IDL).

To affect the world of observable JavaScript objects, then, you must queue a task to perform any such manipulations. This ensures your steps are properly interleaved with respect to other things happening on the event loop. Furthermore, you must choose a task source when queuing a task; this governs the relative order of your steps versus others. If you are unsure which task source to use, pick one of the generic task sources that sounds most applicable.

Most invocations of queue a task implicitly use "the relevant event loop", i.e., the one that is obvious from context. That is because it is very rare for algorithms to be invoked in contexts involving multiple event loops. (Unlike contexts involving multiple global objects, which happen all the time!) So unless you are writing a specification which, e.g., deals with manipulating workers, you can omit this argument when queueing a task.

Putting this all together, we can provide a template for a typical algorithm that needs to do work asynchronously:

1. Do any synchronous setup work, while still on the event loop. This may include converting realm-specific JavaScript values into realm-agnostic specification-level values.
2. Perform a set of potentially-expensive steps in parallel, operating entirely on realm-agnostic values, and producing a realm-agnostic result.
3. Queue a task, on a specified task source, to convert the realm-agnostic result back into observable effects on the observable world of JavaScript objects on the event loop.

Example

The following is an algorithm that "encrypts" a passed-in list of scalar value strings input, after parsing them as URLs:

1. Let urls be an empty list.
2. For each string of input:
   1. Let parsed be the result of parsing string relative to the current settings object.
   2. If parsed is failure, return a promise rejected with a "SyntaxError" DOMException.
   3. Let serialized be the result of applying the URL serializer to parsed.
   4. Append serialized to urls.
3. Let realm be the current Realm Record.
4. Let p be a new promise.
5. Run the following steps in parallel:
   1. Let encryptedURLs be an empty list.
   2. For each url of urls:
      1. Wait 100 milliseconds, so that people think we're doing heavy-duty encryption.
      2. Let encrypted be a new JavaScript string derived from url, whose nth code unit is equal to url's nth...
code unit plus 13.

3. Append encrypted to encryptedURLs.

3. Queue a task\(^{893}\), on the networking task source\(^{897}\), to perform the following steps:
   1. Let array be the result of converting encryptedURLs to a JavaScript array, in realm.
   2. Resolve p with array.

Here are several things to notice about this algorithm:

- It does its URL parsing up front, on the event loop\(^{893}\), before going to the in parallel\(^{42}\) steps. This is necessary, since parsing depends on the current settings object\(^{884}\), which would no longer be current after going in parallel\(^{42}\).

- Alternately, it could have saved a reference to the current settings object\(^{884}\)’s API base URL\(^{869}\) and used it during the in parallel\(^{42}\) steps; that would have been equivalent. However, we recommend instead doing as much work as possible up front, as this example does. Attempting to save the correct values can be error prone; for example, if we’d saved just the current settings object\(^{884}\), instead of its API base URL\(^{869}\), there would have been a potential race.

- It implicitly passes a list of JavaScript strings from the initial steps to the in parallel\(^{42}\) steps. This is OK, as both lists and JavaScript strings are realm-agnostic.

- It performs “expensive computation” (waiting for 100 milliseconds per input URL) during the in parallel\(^{42}\) steps, thus not blocking the main event loop\(^{893}\).

- Promises, as observable JavaScript objects, are never created and manipulated during the in parallel\(^{42}\) steps. p is created before entering those steps, and then is manipulated during a task\(^{893}\) that is queued\(^{893}\) specifically for that purpose.

- The creation of a JavaScript array object also happens during the queued task, and is careful to specify which realm it creates the array in since that is no longer obvious from context.

(On these last two points, see also w3ctag/promises-guide#52, heycam/webidl#135, and heycam/webidl#371, where we are still mulling over the subtleties of the above promise-resolution pattern.)

Another thing to note is that, in the event this algorithm was called from a Web IDL-specified operation taking a sequence<USVString>, there was an automatic conversion from realm-specific JavaScript objects provided by the author as input, into the realm-agnostic sequence<USVString> Web IDL type, which we then treat as a list of scalar value strings. So depending on how your specification is structured, there may be other implicit steps happening on the main event loop\(^{893}\) that play a part in this whole process of getting you ready to go in parallel\(^{42}\).

8.1.5 Events §\(^{89}\)

8.1.5.1 Event handlers §\(^{89}\)

Many objects can have event handlers specified. These act as non-capture event listeners for the object on which they are specified. [DOM]\(^{1223}\)

An event handler\(^{899}\) is a struct with two items:

- a value, which is either null, a callback object, or an internal raw uncompiled handler\(^{905}\). The EventHandler\(^{904}\) callback function type describes how this is exposed to scripts. Initially, an event handler\(^{899}\)’s value\(^{899}\) must be set to null.

- a listener, which is either null or an event listener responsible for running the event handler processing algorithm\(^{900}\). Initially, an event handler\(^{899}\)’s listener\(^{899}\) must be set to null.

Event handlers are exposed in two ways.

The first way, common to all event handlers, is as an event handler IDL attribute\(^{900}\). 

899
The second way is as an event handler content attribute. Event handlers on HTML elements and some of the event handlers on Window objects are exposed in this way.

For both of these two ways, the event handler is exposed through a name, which is a string that always starts with "on" and is followed by the name of the event for which the handler is intended.

Most of the time, the object that exposes an event handler is the same as the object on which the corresponding event listener is added. However, the body and frameset elements expose several event handlers that act upon the element's Window object, if one exists. In either case, we call the object an event handler acts upon the target of that event handler.

To determine the target of an event handler, given an EventTarget object eventTarget on which the event handler is exposed, and an event handler name, the following steps are taken:

1. If eventTarget is not a body element or a frameset element, then return eventTarget.
2. If name is not the name of an attribute member of the WindowEventHandlers interface mixin and the Window-reflecting body element event handler set does not contain name, then return eventTarget.
3. If eventTarget's node document is not an active document, then return null.
4. Return eventTarget's node document's relevant global object.

Each EventTarget object that has one or more event handlers specified has an associated event handler map, which is a map of strings representing names of event handlers to event handlers.

When an EventTarget object that has one or more event handlers specified is created, its event handler map must be initialized such that it contains an entry for each event handler that has that object as target, with items in those event handlers set to their initial values.

An event handler IDL attribute is an IDL attribute for a specific event handler. The name of the IDL attribute is the same as the name of the event handler.

The getter of an event handler IDL attribute with name name, when called, must run these steps:

1. Let eventTarget be the result of determining the target of an event handler given this object and name.
2. If eventTarget is null, then return null.
3. Return the result of getting the current value of the event handler given eventTarget and name.

The setter of an event handler IDL attribute with name name, when called, must run these steps:

1. Let eventTarget be the result of determining the target of an event handler given this object and name.
2. If `eventTarget` is null, then return.

3. If the given value is null, then **deactivate an event handler** given `eventTarget` and `name`.

4. Otherwise:
   1. Let `handlerMap` be `eventTarget`'s **event handler map**.
   2. Let `eventHandler` be `handlerMap["name"]`.
   3. Set `eventHandler`'s **value** to the given value.
   4. **Activate an event handler** given `eventTarget` and `name`.

---

**Note**

Certain **event handler IDL attributes** have additional requirements, in particular the **onmessage** attribute of **MessagePort** objects.

---

An **event handler content attribute** is a content attribute for a specific **event handler**. The name of the content attribute is the same as the **name** of the **event handler**.

**Event handler content attributes**, when specified, must contain valid JavaScript code which, when parsed, would match the **FunctionBody** production after automatic semicolon insertion.

The following **attribute change steps** are used to synchronize between **event handler content attributes** and **event handlers**. [DOM]

1. If `namespace` is not null, or `localName` is not the name of an **event handler content attribute** on `element`, then return.
2. Let `eventTarget` be the result of **determining the target of an event handler** given `element` and `localName`.
3. If `eventTarget` is null, then return.
4. If `value` is null, then **deactivate an event handler** given `eventTarget` and `localName`.
5. Otherwise:
   1. If the **Should element's inline behavior be blocked by Content Security Policy?** algorithm returns "Blocked" when executed upon `element`, "script attribute", and `value`, then return. [CSP]
   2. Let `handlerMap` be `eventTarget`'s **event handler map**.
   3. Let `eventHandler` be `handlerMap[localName]`.
   4. Let `location` be the script location that triggered the execution of these steps.
   5. Set `eventHandler`'s **value** to the **internal raw uncompiled handler** value/*location*.
   6. **Activate an event handler** given `eventTarget` and `localName`.

---

**Note**

Per the DOM Standard, these steps are run even if `oldValue` and `value` are identical (setting an attribute to its current value), but not if `oldValue` and `value` are both null (removing an attribute that doesn't currently exist). [DOM]

---

To **deactivate an event handler** given an **EventTarget** object `eventTarget` and a string `name` that is the **name** of an **event handler**, run these steps:

1. Let `handlerMap` be `eventTarget`'s **event handler map**.
2. Let `eventHandler` be `handlerMap[name]`.
3. Set `eventHandler`'s **value** to null.
4. Let `listener` be `eventHandler`'s **listener**.
5. If `listener` is not null, then **remove an event listener** with `eventTarget` and `listener`. 

---

901
6. Set eventHandler's listener to null.

To erase all event listeners and handlers given an EventTarget object eventTarget, run these steps:

1. If eventTarget has an associated event handler map, then for each name → eventHandler of eventTarget's associated event handler map, deactivate an event handler given eventTarget and name.
2. Remove all event listeners given eventTarget.

Note

This algorithm is used to define `document.open(type, replace)`.

To activate an event handler given an EventTarget object eventTarget and a string name that is the name of an event handler, run these steps:

1. Let handlerMap be eventTarget's event handler map.
2. Let eventHandler be handlerMap[name].
3. If eventHandler's listener is not null, then return.
4. Let callback be the result of creating a Web IDL EventListener instance representing a reference to a function of one argument that executes the steps of the event handler processing algorithm, given eventTarget, name, and its argument.

The EventListener's callback context can be arbitrary; it does not impact the steps of the event handler processing algorithm. [DOM]

Note

The callback is emphatically not the event handler itself. Every event handler ends up registering the same callback, the algorithm defined below, which takes care of invoking the right code, and processing the code's return value.

5. Let listener be a new event listener whose type is the event handler event type corresponding to eventHandler and callback is callback.

Note

To be clear, an event listener is different from an EventListener.

6. Add an event listener with eventTarget and listener.
7. Set eventHandler's listener to listener.

Note

The event listener registration happens only if the event handler's value is being set to non-null, and the event handler is not already activated. Since listeners are called in the order they were registered, assuming no deactivation occurred, the order of event listeners for a particular event type will always be:

1. the event listeners registered with `addEventListener()` before the first time the event handler's value was set to non-null
2. then the callback to which it is currently set, if any
3. and finally the event listeners registered with `addEventListener()` after the first time the event handler's value was set to non-null.

Example

This example demonstrates the order in which event listeners are invoked. If the button in this example is clicked by the user, the page will show four alerts, with the text "ONE", "TWO", "THREE", and "FOUR" respectively.

```html
<button id="test">Start Demo</button>
<script>
  var button = document.getElementById('test');
  button.addEventListener('click', function () { alert('ONE') }, false);
</script>
```
However, in the following example, the event handler is deactivated after its initial activation (and its event listener is removed), before being reactivated at a later time. The page will show five alerts with “ONE”, “TWO”, “THREE”, “FOUR”, and “FIVE” respectively, in order.

```html
<button id="test">Start Demo</button>
<script>
  var button = document.getElementById('test');
  button.addEventListener('click', function () { alert('ONE') }, false);
  button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler listener is registered
  button.onclick = function () { alert('TWO') };
  button.addEventListener('click', function () { alert('THREE') }, false);
  button.onclick = null; // but deactivated here
  button.addEventListener('click', function () { alert('FOUR') }, false);
  button.onclick = function () { alert('FIVE') }, false);
</script>
```

The interfaces implemented by the event object do not influence whether an event handler is triggered or not.

The event handler processing algorithm for an EventTarget object eventTarget, a string name representing the name of an event handler, and an Event object event as follows:

1. Let `callback` be the result of getting the current value of the event handler given eventTarget and name.
2. If `callback` is null, then return.
3. Let `special error event handling` be true if event is an ErrorEvent object, event's type is error, and event's currentTarget implements the WindowOrWorkerGlobalScope mixin. Otherwise, let special error event handling be false.
4. Process the Event object event as follows:
   - If special error event handling is true
     - Invoke `callback` with five arguments, the first one having the value of event's message attribute, the second having the value of event's filename attribute, the third having the value of event's lineno attribute, the fourth having the value of event's colno attribute, the fifth having the value of event's error attribute, and with the `callback this value` set to event's currentTarget. Let return value be the callback's return value. [WEBIDL]
   - Otherwise
     - Invoke `callback` with one argument, the value of which is the Event object event, with the `callback this value` set to event's currentTarget. Let return value be the callback's return value. [WEBIDL]

If an exception gets thrown by the callback, end these steps and allow the exception to propagate. (It will propagate to the DOM event dispatch logic, which will then report the exception.)

5. Process return value as follows:
   - If event is a BeforeUnloadEvent object and event's type is beforeunload
     - In this case, the event handler IDL attribute's type will be OnBeforeUnloadEventHandler, so return value will have been coerced into either null or a DOMString.
     - If return value is not null, then:
       1. Set event's canceled flag.
2. If event's `returnValue` attribute's value is the empty string, then set event's `returnValue` attribute's value to `return value`.

→ If special error event handling is true

If `return value` is true, then set event's `canceled` flag.

→ Otherwise

If `return value` is false, then set event's `canceled` flag.

Note

If we've gotten to this "Otherwise" clause because event's `type` is `beforeunload` but event is not a `BeforeUnloadEvent` object, then return value will never be false, since in such cases return value will have been coerced into either null or a `DOMString`.

The `EventHandler` callback function type represents a callback used for event handlers. It is represented in Web IDL as follows:

```idl
[TreatNonObjectAsNull]
callback EventHandlerNonNullAny = any (Event event);
typedef EventHandlerNonNull? EventHandler;
```

Note

In JavaScript, any `Function` object implements this interface.

Example

For example, the following document fragment:

```html
<body onload="alert(this)" onclick="alert(this)"
```

...leads to an alert saying "[object Window]" when the document is loaded, and an alert saying "[object HTMLBodyElement]" whenever the user clicks something in the page.

Note

The return value of the function affects whether the event is canceled or not: as described above, if the return value is false, the event is canceled.

There are two exceptions in the platform, for historical reasons:

• The `onerror` handlers on global objects, where returning `true` cancels the event

• The `onbeforeunload` handler, where returning any non-null and non-undefined value will cancel the event.

For historical reasons, the `onerror` handler has different arguments:

```idl
[TreatNonObjectAsNull]
callback OnErrorEventHandlerNonNullAny = any ((Event or DOMString) event, optional DOMString source, optional unsigned long lineno, optional unsigned long colno, optional any error);
typedef OnErrorEventHandlerNonNull? OnErrorEventHandler;
```

Example

```javascript
window.onerror = (message, source, lineno, colno, error) => { ... };
```

Similarly, the `onbeforeunload` handler has a different return value:

```idl
[TreatNonObjectAsNull]
```
An **internal raw uncompiled handler** is a tuple with the following information:

- An uncompiled script body
- A location where the script body originated, in case an error needs to be reported

When the user agent is to **get the current value of the event handler** given an `EventTarget` object `eventTarget` and a string `name` that is the `name` of an `event handler`, it must run these steps:

1. Let `handlerMap` be `eventTarget`'s `event handler map`.
2. Let `eventHandler` be `handlerMap[name]`.
3. If `eventHandler`'s `value` is an **internal raw uncompiled handler**, then:
   1. If `eventTarget` is an element, then let `element` be `eventTarget`, and `document` be `element`'s `node document`. Otherwise, `eventTarget` is a `Window` object, let `element` be null, and `document` be `eventTarget`'s `associated Document`.
   2. If `scripting is disabled` for `document`, then return null.
   3. Let `body` be the uncompiled script body in `eventHandler`'s `value`.
   4. Let `location` be the location where the script body originated, as given by `eventHandler`'s `value`.
   5. If `element` is not null and `element` has a `form owner`, let `form owner` be that `form owner`. Otherwise, let `form owner` be null.
   6. Let `settings object` be the `relevant settings object` of `document`.
   7. If `body` is not parsable as `FunctionBody` or if parsing detects an `early error`, then follow these substeps:
      1. Set `eventHandler`'s `value` to null.
      
      **Note**
      This does not deactivate the event handler, which additionally removes the event handler's listener (if present).
      2. Report the error for the appropriate `script` and with the appropriate position (line number and column number) given by `location`, using `settings object`'s `global object`. If the error is still not handled after this, then the error may be reported to a developer console.
   3. Return null.
8. If `body` begins with a `Directive Prologue` that contains a `Use Strict Directive` then let `strict` be true, otherwise let `strict` be false.
9. Push `settings object`'s `realm execution context` onto the `JavaScript execution context stack`; it is now the `running JavaScript execution context`.

**Note**
This is necessary so the subsequent invocation of `FunctionCreate` takes place in the correct `JavaScript Realm`.

10. Let `function` be the result of calling `FunctionCreate`, with arguments:

    **kind**
    Normal

    **ParameterList**
    → If `eventHandler` is an `onerror` event handler of a `Window` object
    Let the function have five arguments, named `event`, `source`, `lineno`, `colno`, and `error`.
    → Otherwise
    Let the function have a single argument called `event`.
Body

The result of parsing body above.

Scope

1. If eventHandler is an element's event handler, then let Scope be
   NewObjectEnvironment(document, the global environment).
   Otherwise, eventHandler is a Window object's event handler:
   let Scope be the global environment.

2. If form owner is not null, let Scope be NewObjectEnvironment(form owner, Scope).

3. If element is not null, let Scope be NewObjectEnvironment(element, Scope).

Strict

The value of strict.

11. Remove settings object's realm execution context from the JavaScript execution context stack.

12. Set eventHandler's value to the result of creating a Web IDL EventHandler callback function object whose
    object reference is function and whose callback context is settings object.

4. Return eventHandler's value.

8.1.5.2 Event handlers on elements, Document objects, and Window objects

The following are the event handlers (and their corresponding event handler event types) that must be supported by all HTML
elements, as both event handler content attributes and event handler IDL attributes, and that must be supported by all
Document and Window objects, as event handler IDL attributes:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onabort</td>
<td>abort</td>
</tr>
<tr>
<td>onauxclick</td>
<td>auxclick</td>
</tr>
<tr>
<td>oncancel</td>
<td>cancel</td>
</tr>
<tr>
<td>oncanplay</td>
<td>canplay</td>
</tr>
<tr>
<td>oncanplaythrough</td>
<td>canplaythrough</td>
</tr>
<tr>
<td>onchange</td>
<td>change</td>
</tr>
<tr>
<td>onclick</td>
<td>click</td>
</tr>
<tr>
<td>onclose</td>
<td>close</td>
</tr>
<tr>
<td>oncontextmenu</td>
<td>contextmenu</td>
</tr>
<tr>
<td>oncuechange</td>
<td>cuechange</td>
</tr>
<tr>
<td>ondblclick</td>
<td>dblclick</td>
</tr>
<tr>
<td>ondrag</td>
<td>drag</td>
</tr>
<tr>
<td>ondragend</td>
<td>dragend</td>
</tr>
<tr>
<td>ondragenter</td>
<td>dragenter</td>
</tr>
<tr>
<td>ondragexit</td>
<td>dragexit</td>
</tr>
<tr>
<td>ondragleave</td>
<td>dragleave</td>
</tr>
<tr>
<td>ondragover</td>
<td>dragover</td>
</tr>
<tr>
<td>ondragstart</td>
<td>dragstart</td>
</tr>
<tr>
<td>ondrop</td>
<td>drop</td>
</tr>
<tr>
<td>ondurationchange</td>
<td>durationchange</td>
</tr>
<tr>
<td>onemptied</td>
<td>emptied</td>
</tr>
<tr>
<td>onended</td>
<td>ended</td>
</tr>
<tr>
<td>oninput</td>
<td>input</td>
</tr>
<tr>
<td>oninvalid</td>
<td>invalid</td>
</tr>
<tr>
<td>onkeydown</td>
<td>keydown</td>
</tr>
<tr>
<td>onkeypress</td>
<td>keypress</td>
</tr>
<tr>
<td>onkeyup</td>
<td>keyup</td>
</tr>
<tr>
<td>onloadeddata</td>
<td>loadeddata</td>
</tr>
</tbody>
</table>
### Event handler event type

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onblur</td>
<td>blur</td>
</tr>
<tr>
<td>onerror</td>
<td>error</td>
</tr>
<tr>
<td>onfocus</td>
<td>focus</td>
</tr>
<tr>
<td>onload</td>
<td>load</td>
</tr>
<tr>
<td>onresize</td>
<td>resize</td>
</tr>
<tr>
<td>onscroll</td>
<td>scroll</td>
</tr>
</tbody>
</table>

We call the set of the names of the event handlers listed in the first column of this table the Window-reflecting body element event handler set.

The following are the event handlers (and their corresponding event handler event types) that must be supported by all HTML elements other than body and frameset elements, as both event handler content attributes and event handler IDL attributes, that must be supported by all Document objects, as event handler IDL attributes on the Window objects themselves, and with corresponding event handler content attributes and event handler IDL attributes exposed on all body and frameset elements that are owned by that Window object's associated Document:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onafterprint</td>
<td>afterprint</td>
</tr>
</tbody>
</table>

We call the set of the names of the event handlers listed in the first column of this table the Window-reflecting body element event handler set.
Event handler types:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onbeforeprint</td>
<td>beforeprint</td>
</tr>
<tr>
<td>onbeforeunload</td>
<td>beforeunload</td>
</tr>
<tr>
<td>onhashchange</td>
<td>hashchange</td>
</tr>
<tr>
<td>onlanguagechange</td>
<td>languagechange</td>
</tr>
<tr>
<td>onmessage</td>
<td>message</td>
</tr>
<tr>
<td>onmessageerror</td>
<td>messageerror</td>
</tr>
<tr>
<td>onoffline</td>
<td>offline</td>
</tr>
<tr>
<td>ononline</td>
<td>online</td>
</tr>
<tr>
<td>onpagehide</td>
<td>pagehide</td>
</tr>
<tr>
<td>onpageshow</td>
<td>pageshow</td>
</tr>
<tr>
<td>onpopstate</td>
<td>popstate</td>
</tr>
<tr>
<td>onrejectionhandled</td>
<td>rejectionhandled</td>
</tr>
<tr>
<td>onstorage</td>
<td>storage</td>
</tr>
<tr>
<td>onunhandledrejection</td>
<td>unhandledrejection</td>
</tr>
<tr>
<td>onunload</td>
<td>unload</td>
</tr>
</tbody>
</table>

This list of event handlers is reified as event handler IDL attributes through the WindowEventHandlers interface mixin.

The following are the event handlers (and their corresponding event handler event types) that must be supported by all HTML elements, as both event handler content attributes and event handler IDL attributes, and that must be supported by all Document objects, as event handler IDL attributes:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>oncut</td>
<td>cut</td>
</tr>
<tr>
<td>oncopy</td>
<td>copy</td>
</tr>
<tr>
<td>onpaste</td>
<td>paste</td>
</tr>
</tbody>
</table>

This list of event handlers is reified as event handler IDL attributes through the DocumentAndElementEventHandlers interface mixin.

The following are the event handlers (and their corresponding event handler event types) that must be supported on Document objects as event handler IDL attributes:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onreadystatechange</td>
<td>readystatechange</td>
</tr>
</tbody>
</table>

}
8.1.5.3 Event firing

Certain operations and methods are defined as firing events on elements. For example, the `click()` method on the `HTMLElement` interface is defined as firing a `click` event on the element. [UIEVENTS]

Firing a synthetic mouse event named `e` at `target`, with an optional not trusted flag, means running these steps:

1. Let `event` be the result of creating an event using `MouseEvent`.
2. Initialize `event`'s `type` attribute to `e`.
3. Initialize `event`'s `bubbles` and `cancelable` attributes to true.
4. Set `event`'s `composed` flag.
5. If the not trusted flag is set, initialize `event`'s `isTrusted` attribute to false.
6. Initialize `event`'s `ctrlKey`, `shiftKey`, `altKey`, and `metaKey` attributes according to the current state of the key input device, if any (false for any keys that are not available).
7. Initialize `event`'s `view` attribute to `target`'s `node document`'s `Window` object, if any, and null otherwise.
8. `event`'s `getModifierState()` method is to return values appropriately describing the current state of the key input device.
9. Return the result of dispatching `event` at `target`.

Firing a `click` event at `target` means firing a synthetic mouse event named `click` at `target`.

8.2 The `WindowOrWorkerGlobalScope` mixin

The `WindowOrWorkerGlobalScope` mixin is for use of APIs that are to be exposed on `Window` and `WorkerGlobalScope` objects.

Note
Other standards are encouraged to further extend it using partial interface mixin `WindowOrWorkerGlobalScope` { ... }; along with an appropriate reference.

IDL
typedef (DOMString or Function) TimerHandler;

interface mixin WindowOrWorkerGlobalScope {
    [Replaceable] readonly attribute USVString origin;

    // base64 utility methods
    DOMString btoa(DOMString data);
    ByteString atob(DOMString data);

    // timers
long setTimeout(TimerHandler handler, optional long timeout = 0, any... arguments);
void clearTimeout(optional long handle = 0);
long setInterval(TimerHandler handler, optional long timeout = 0, any... arguments);
void clearInterval(optional long handle = 0);

// microtask queuing
void queueMicrotask(Function callback);

// ImageBitmap
Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, optional ImageBitmapOptions options);
Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, long sx, long sy, long sw, long sh, optional ImageBitmapOptions options);
}

Window includes WindowOrWorkerGlobalScope;
WorkerGlobalScope includes WindowOrWorkerGlobalScope;

For web developers (non-normative)

origin = self . origin
Returns the global object's origin, serialized as string.

Example

Developers are strongly encouraged to use self.origin over location.origin. The former returns the origin of the environment, the latter of the URL of the environment. Imagine the following script executing in a document on https://stargate.example/:

```javascript
var frame = document.createElement("iframe")
frame.onload = function() {
  var frameWin = frame.contentWindow
  console.log(frameWin.location.origin) // "null"
  console.log(frameWin.origin) // "https://stargate.example"
}
document.body.appendChild(frame)
```

self.origin is a more reliable security indicator.

The origin attribute's getter must return this object's relevant settings object's origin serialized.

8.3 Base64 utility methods

The atob() and btoa() methods allow developers to transform content to and from the base64 encoding.

Note

In these APIs, for mnemonic purposes, the "b" can be considered to stand for "binary", and the "a" for "ASCII". In practice, though, for primarily historical reasons, both the input and output of these functions are Unicode strings.

For web developers (non-normative)

result = self . btoa( data )

Takes the input data, in the form of a Unicode string containing only characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, and converts it to its base64 representation, which it returns.

Throws an "InvalidCharacterError" DOMException exception if the input string contains any out-of-range characters.
result = self. atob( data )

Takes the input data, in the form of a Unicode string containing base64-encoded binary data, decodes it, and returns a string consisting of characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, corresponding to that binary data.

Throws an "InvalidCharacterError" DOMException if the input string is not valid base64 data.

The btoa(data) method must throw an "InvalidCharacterError" DOMException if data contains any character whose code point is greater than U+00FF. Otherwise, the user agent must convert data to a byte sequence whose nth byte is the eight-bit representation of the nth code point of data, and then must apply forgiving-base64 encode to that byte sequence and return the result.

The atob(data) method, when invoked, must run the following steps:

1. Let decodedData be the result of running forgiving-base64 decode on data.
2. If decodedData is failure, then throw an "InvalidCharacterError" DOMException.
3. Return decodedData.

8.4 Dynamic markup insertion

Note

APIs for dynamically inserting markup into the document interact with the parser, and thus their behavior varies depending on whether they are used with HTML documents (and the HTML parser) or XML documents (and the XML parser).

Document objects have a throw-on-dynamic-markup-insertion counter, which is used in conjunction with the create an element for the token algorithm to prevent custom element constructors from being able to use document.open(type, replace) and document.close() and document.write() when they are invoked by the parser. Initially, the counter must be set to zero.

8.4.1 Opening the input stream

document = document.open([ type [, replace ] ])

Causes the Document to be replaced in-place, as if it was a new Document object, but reusing the previous object, which is then returned.

The resulting Document has an HTML parser associated with it, which can be given data to parse using document.write(). (The type argument is ignored.)

If the replace argument is present and has the value "replace", the existing entries in the session history for the Document object are removed.

The method has no effect if the Document is still being parsed.

Throws an "InvalidStateError" DOMException if the Document is an XML document.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor.

window = document.open( url, name, features )

Works like the window.open() method.

Document objects have an ignore-opens-during-unload counter, which is used to prevent scripts from invoking the document.open(type, replace) method (directly or indirectly) while the document is being unloaded. Initially, the counter must be set to zero.

The document open steps, given a document and replaceInput, are as follows:
1. If `document` is an XML document, then throw an "InvalidStateError" DOMException exception.

2. If `document`'s `throw-on-dynamic-markup-insertion-counter` is greater than 0, then throw an "InvalidStateError" DOMException.

3. If `document` is not an active document, then return `document`.

4. Let `window` be `document`'s relevant global object.

5. If `document`'s `origin` is not same origin to the `origin` of the responsible document specified by the entry settings object, then throw a "SecurityError" DOMException.

6. If `document` has an active parser whose script nesting level is greater than 0, then return `document`.

   **Note** This basically causes `document.open(type, replace)` to be ignored when it's called in an inline script found during parsing, while still letting it have an effect when called from a non-parser task such as a timer callback or event handler.

7. Similarly, if `document`'s ignore-opens-during-unload counter is greater than 0, then return `document`.

   **Note** This basically causes `document.open(type, replace)` to be ignored when it's called from a `beforeunload`, `pagehide`, or `unload` event handler while the `Document` is being unloaded.

8. Let `replace` be false.

9. If `replaceInput` is an ASCII case-insensitive match for "replace", then set `replace` to true.

   Otherwise, if `document`'s `browsing context` contains only one `Document` object, and that was the `about:blank` `Document` created when `document`'s `browsing context` was created and that `Document` object has never had the `unload a document` algorithm invoked on it (e.g., by a previous call to `document.open(type, replace)`), then set `replace` to true.

10. Set `document`'s `salvageable` state to false.

11. Prompt to unload, `document`. If the user refused to allow the document to be unloaded, then return `document`.

12. Unload `document`, with the `recycle` parameter set to true.

14. For each shadow-including inclusive descendant node of `document`, erase all event listeners and handlers given node.

15. Erase all event listeners and handlers given `window`.

16. Remove any tasks associated with `document` in any task source.

17. Replace all with null within `document`, without firing any mutation events.

18. Let realm execution context be the result of creating a new JavaScript realm with the following customizations:

   - For the global object, create a new `Window` object and set `window` to it.
   - For the global `this` binding, use `document`'s `browsing context`'s associated `WindowProxy`.

   **This is not universally implemented and can perhaps be removed; see issue #1698.**

19. Set up a window environment settings object with realm execution context.

20. Set the active document of `document`'s `browsing context` to `document` with `window`.

21. Replace `document`'s singleton objects with new instances of those objects, created in `window`'s Realm. (This includes in particular the `History`, `ApplicationCache`, and `Navigator` objects, the various `BarProp` objects, the two `Storage` objects, the various `HTMLCollection` objects, and objects defined by other specifications, like `Selection`. It also includes all the Web IDL prototypes in the JavaScript binding, including `document`'s prototype.)

22. If `document` is `ready for post-load tasks`, then set `document`'s `reload override flag` and set `document`'s `reload override buffer` to the empty string.
23. Set document's salvageable state back to true.

24. Change document's URL to the URL of the responsible document specified by the entry settings object.

25. If document's iframe load in progress flag is set, then set document's mute iframe load flag.

26. Create a new HTML parser and associate it with document. This is a script-created parser (meaning that it can be closed by the document.open(type, replace) and document.close() methods, and that the tokenizer will wait for an explicit call to document.close() before emitting an end-of-file token). The encoding confidence is irrelevant.

27. Set the current document readiness of document to "loading".

28. Remove any tasks queued by the history traversal task source that are associated with any Document objects in the top-level browsing context's document family.

29. Remove all the entries in the browsing context's session history after the current entry. If the current entry is the last entry in the session history, then no entries are removed.

---

This doesn't necessarily have to affect the user agent's user interface.

---

30. Remove any earlier entries whose Document object is document.

31. If replace is false, then add a new entry, just before the last entry, and associate with the new entry the text that was parsed by the previous parser associated with document, as well as the state of document at the start of these steps. This allows the user to step backwards in the session history to see the page before it was blown away by the document.open(type, replace) call. This new entry does not have a Document object, so a new one will be created if the session history is traversed to that entry.

32. Set document's fired unload flag to false. (It could have been set to true during the unload step above.)

33. Finally, set the insertion point to point at just before the end of the input stream (which at this point will be empty).

34. Return document.

The open(type, replace) method must return the result of running the document open steps with this Document object and replace.

---

The type argument is ignored. Also, the document.open(type, replace) method does not affect whether a Document is ready for post-load tasks or completely loaded.

---

The open(url, name, features) method must run these steps:

1. If this Document object is not an active document, then throw an "InvalidStateError" DOMException exception.

2. Return the result of running the window open steps with url, name, and features.

8.4.2 Closing the input stream

For web developers (non-normative)

`document.close()`

Closes the input stream that was opened by the document.open(type, replace) method.

Throws an "InvalidStateError" DOMException if the Document is an XML document.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor.

The close() method must run the following steps:

1. If the Document object is an XML document, then throw an "InvalidStateError" DOMException.

2. If the Document object's throw-on-dynamic-markup-insertion counter is greater than zero, then throw an
3. If there is no script-created parser\textsuperscript{914} associated with the document, then return.

4. Insert an explicit "EOF" character\textsuperscript{1035} at the end of the parser's input stream\textsuperscript{1034}.

5. If there is a pending parsing-blocking script\textsuperscript{963}, then return.

6. Run the tokenizer, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the explicit "EOF" character\textsuperscript{1035} or spins the event loop\textsuperscript{896}.

### 8.4.3 document\texttt{.write()}\textsuperscript{916}

For web developers (non-normative)

\texttt{document\ .write()}\textsuperscript{916}(\texttt{text}...)

In general, adds the given string(s) to the Document's input stream.

\textbf{⚠ Warning!}

This method has very idiosyncratic behavior. In some cases, this method can affect the state of the HTML parser\textsuperscript{1022} while the parser is running, resulting in a DOM that does not correspond to the source of the document (e.g. if the string written is the string "<plaintext>" or "<\---"). In other cases, the call can clear the current page first, as if \texttt{document.open(type, replace)}\textsuperscript{914} had been called. In yet more cases, the method is simply ignored, or throws an exception. Users agents are explicitly allowed to avoid executing script elements inserted via this method\textsuperscript{914}. And to make matters even worse, the exact behavior of this method can in some cases be dependent on network latency, which can lead to failures that are very hard to debug. For all these reasons, use of this method is strongly discouraged.

Throws an "InvalidStateError" DOMException when invoked on XML documents.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor\textsuperscript{681}.

\texttt{Document}\textsuperscript{110} objects have an ignore-destructive-writes counter, which is used in conjunction with the processing of script\textsuperscript{594} elements to prevent external scripts from being able to use \texttt{document.write()}\textsuperscript{916} to blow away the document by implicitly calling \texttt{document.open(type, replace)}\textsuperscript{914}. Initially, the counter must be set to zero.

The document write steps, given a \texttt{Document} object \texttt{document} and a string \texttt{input}, are as follows:

1. If \texttt{document} is an XML document, then throw an "InvalidStateError" DOMException.

2. If \texttt{document}'s throw-on-dynamic-markup-insertion counter\textsuperscript{912} is greater than 0, then throw an "InvalidStateError" DOMException.

3. If \texttt{document} is not an active document\textsuperscript{780}, then return.

4. If the insertion point\textsuperscript{1035} is undefined, then:
   1. If \texttt{document}'s ignore-opens-during-unload counter\textsuperscript{912} is greater than 0 or \texttt{document}'s ignore-destructive-writes counter\textsuperscript{915} is greater than 0, then return.
   2. Run the document open steps\textsuperscript{912} with \texttt{document} and the empty string. If the user refused to allow the document to be unloaded\textsuperscript{841}, then return. Otherwise, the insertion point\textsuperscript{1035} will point at just before the end of the (empty) input stream\textsuperscript{1034}.

5. Insert \texttt{input} into the input stream\textsuperscript{1034} just before the insertion point\textsuperscript{1035}.

6. If \texttt{document}'s reload override flag\textsuperscript{110} is set, then append \texttt{input} to \texttt{document}'s reload override buffer\textsuperscript{110}.

7. If there is no pending parsing-blocking script\textsuperscript{963}, have the HTML parser\textsuperscript{1022} process \texttt{input}, one code point at a time, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the insertion point or when the processing of the tokenizer is aborted by the tree construction stage (this can happen if a script\textsuperscript{594} end tag token is emitted by the tokenizer).

\textbf{Note}

If the \texttt{document.write()}\textsuperscript{916} method was called from script executing inline (i.e. executing because the parser parsed a
The `document.write(...)` method, when invoked, must run the *document write steps* with this `Document` object and a string that is the concatenation of all arguments passed.

8.4.4 **document.writeln()**

For web developers (non-normative)

```javascript
document.writeln(text...) // Adds the given string(s) to the Document's input stream, followed by a newline character. If necessary, calls the open(type, replace) method implicitly first.
```

Throws an "InvalidStateError" DOMException when invoked on XML documents.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor.

The `document.writeln(...)` method, when invoked, must run the *document write steps* with this `Document` object and a string that is the concatenation of all arguments passed and U+000A LINE FEED.

8.5 Timers

The `setTimeout()` and `setInterval()` methods allow authors to schedule timer-based callbacks.

For web developers (non-normative)

```javascript
handle = self.setTimeout(handler, timeout [ arguments... ])
```

Schedules a timeout to run `handler` after `timeout` milliseconds. Any arguments are passed straight through to the `handler`.

```javascript
handle = self.setTimeout(code, timeout)
```

Schedules a timeout to compile and run `code` after `timeout` milliseconds.

```javascript
self.clearTimeout(handle)
```

Cancels the timeout set with `setTimeout()` or `setInterval()` identified by `handle`.

```javascript
handle = self.setInterval(handler, timeout [ arguments... ])
```

Schedules a timeout to run `handler` every `timeout` milliseconds. Any arguments are passed straight through to the `handler`.

```javascript
handle = self.setInterval(code, timeout)
```

Schedules a timeout to compile and run `code` every `timeout` milliseconds.

```javascript
self.clearInterval(handle)
```

Cancels the timeout set with `setInterval()` or `setTimeout()` identified by `handle`.

**Note**

Timers can be nested; after five such nested timers, however, the interval is forced to be at least four milliseconds.

**Note**

This API does not guarantee that timers will run exactly on schedule. Delays due to CPU load, other tasks, etc, are to be expected.

Objects that implement the `WindowOrWorkerGlobalScope` mixin have a list of active timers. Each entry in this list is identified by a number, which must be unique within the list for the lifetime of the object that implements the `WindowOrWorkerGlobalScope` mixin.
The `setTimeout()` method must return the value returned by the timer initialization steps, passing them the method's arguments, the object on which the method for which the algorithm is running is implemented (a `Window` or `WindowGlobalScope` object) as the method context, and the repeat flag set to false.

The `setInterval()` method must return the value returned by the timer initialization steps, passing them the method's arguments, the object on which the method for which the algorithm is running is implemented (a `Window` or `WindowGlobalScope` object) as the method context, and the repeat flag set to true.

The `clearTimeout()` and `clearInterval()` methods must clear the entry identified as `handle` from the list of active timers of the `WindowOrWorkerGlobalScope` object on which the method was invoked, if any, where `handle` is the argument passed to the method. (If `handle` does not identify an entry in the list of active timers of the `WindowOrWorkerGlobalScope` object on which the method was invoked, the method does nothing.)

**Note** Because `clearTimeout()` and `clearInterval()` clear entries from the same list, either method can be used to clear timers created by `setTimeout()` or `setInterval()`.

The timer initialization steps, which are invoked with some method arguments, a method context, a repeat flag which can be true or false, and optionally (and only if the repeat flag is true) a previous handle, are as follows:

1. Let method context proxy be method context if that is a `WorkerGlobalScope` object, or else the `WindowProxy` that corresponds to method context.
2. If previous handle was provided, let handle be previous handle; otherwise, let handle be a user-agent-defined integer that is greater than zero that will identify the timeout to be set by this call in the list of active timers.
3. If previous handle was not provided, add an entry to the list of active timers for handle.
4. Let callerRealm be the current Realm Record, and calleeRealm be method context's JavaScript realm.
5. Let initiating script be the active script.
6. Assert: initiating script is not null, since this algorithm is always called from some script.
7. Let task that runs the following substeps:
   1. If the entry for handle in the list of active timers has been cleared, then abort these steps.
   2. Run the appropriate set of steps from the following list:

   **→ If the first method argument is a Function**
   
   Invoke the Function. Use the third and subsequent method arguments (if any) as the arguments for invoking the Function. Use method context proxy as the callback this value.

   **→ Otherwise**

   1. Perform `HostEnsureCanCompileStrings(callerRealm, calleeRealm)`. If this throws an exception, catch it, report the exception, and abort these steps.
   2. Let script source be the first method argument.
   3. Let settings object be method context's environment settings object.
   4. Let base URL be initiating script's base URL.
   5. Let fetch options be a script fetch options whose cryptographic nonce is initiating script's fetch options, cryptographic nonce is the empty string, integrity metadata is "not-parser-inserted", credentials mode is initiating script's fetch options' credentials mode, and referer policy is initiating script's fetch options' referer policy.

   **Note** The effect of these options ensures that the string compilation done by `setTimeout()` and `setInterval()` behaves equivalently to that done by `eval()`. That is, `module script` fetches via `import()` will behave the same in both contexts.
6. Let script be the result of creating a classic script given script source, settings object, base URL, and fetch options.

7. Run the classic script script.

3. If the repeat flag is true, then call timer initialization steps again, passing them the same method arguments, the same method context, with the repeat flag still set to true, and with the previous handle set to handler.

8. Let timeout be the second method argument.

9. If the currently running task is a task that was created by this algorithm, then let nesting level be the task's timer nesting level. Otherwise, let nesting level be zero.

10. Let timeout be the second method argument.

11. If nesting level is greater than 5, and timeout is less than 4, then set timeout to 4.

12. Increment nesting level by one.

13. Let task's timer nesting level be nesting level.

14. Return handle, and then continue running this algorithm in parallel.

15. If method context is a Window object, wait until the Document associated with method context has been fully active for a further timeout milliseconds (not necessarily consecutively).

   Otherwise, method context is a WorkerGlobalScope object; wait until timeout milliseconds have passed with the worker not suspended (not necessarily consecutively).

16. Wait until any invocations of this algorithm that had the same method context, that started before this one, and whose timeout is equal to or less than this one’s, have completed.

17. Optionally, wait a further user-agent defined length of time.

18. Queue the task task.
The task source for these tasks is the timer task source.

To run tasks of several milliseconds back to back without any delay, while still yielding back to the browser to avoid starving the user interface (and to avoid the browser killing the script for hogging the CPU), simply queue the next timer before performing work:

```javascript
function doExpensiveWork() {
    var done = false;
    // ... 
    // this part of the function takes up to five milliseconds 
    // set done to true if we're done 
    // ... 
    return done;
}

function rescheduleWork() {
    var handle = setTimeout(rescheduleWork, 0); // preschedule next iteration 
    if (doExpensiveWork())
        clearTimeout(handle); // clear the timeout if we don't need it 
}

function scheduleWork() {
    setTimeout(rescheduleWork, 0);
}

scheduleWork(); // queues a task to do lots of work
```

The `queueMicrotask()` method must queue a microtask to run the given callback.

For web developers (non-normative)

The `queueMicrotask(callback)` method allows authors to schedule a callback on the microtask queue. This allows their code to run after the currently-executing task has run to completion and the JavaScript execution context stack is empty, but without yielding control back to the browser's event loop, as would be the case when using, for example, `setTimeout(f, 0)`.

Authors ought to be aware that scheduling a lot of microtasks has the same performance downsides as running a lot of synchronous code. Both will prevent the browser from doing its own work, such as rendering or scrolling. In many cases, `requestAnimationFrame()` or `requestIdleCallback()` is a better choice. In particular, if the goal is to run code before the next rendering cycle, that is the purpose of `requestAnimationFrame()`.

As can be seen from the following examples, the best way of thinking about `queueMicrotask()` is as a mechanism for rearranging synchronous code, effectively placing the queued code immediately after the current task's worth of non-queued JavaScript.
The most common reason for using `queueMicrotask()` is to create consistent ordering, even in the cases where information is available synchronously, without introducing undue delay.

For example, consider a custom element firing a `load` event, that also maintains an internal cache of previously-loaded data. A naïve implementation might look like:

```javascript
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    this._setData(this._cache[url]);
    this.dispatchEvent(new Event("load"));
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

This naïve implementation is problematic, however, in that it causes its users to experience inconsistent behavior. For example, code such as

```javascript
element.addEventListener("load", () => console.log("loaded"));
console.log("1");
element.loadData();
console.log("2");
```

will sometimes log “1, 2, loaded” (if the data needs to be fetched), and sometimes log “1, loaded, 2” (if the data is already cached). Similarly, after the call to `loadData()`, it will be inconsistent whether or not the data is set on the element.

To get a consistent ordering, `queueMicrotask()` can be used:

```javascript
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    queueMicrotask(() => {
      this._setData(this._cache[url]);
      this.dispatchEvent(new Event("load"));
    });
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

By essentially rearranging the queued code to be after the currently-executing task, this ensures a consistent ordering and update of the element's state.

Another interesting use of `queueMicrotask()` is to allow uncoordinated “batching” of work by multiple callers. For example, consider a library function that wants to send data somewhere as soon as possible, but doesn’t want to make multiple network requests if doing so is easily avoidable. One way to balance this would be like so:

```javascript
const queuedToSend = [];
```
function sendData(data) {
    queuedToSend.push(data);

    if (queuedToSend.length === 1) {
        queueMicrotask(() => {
            const stringToSend = JSON.stringify(queuedToSend);
            queuedToSend.length = 0;

            fetch("/endpoint", stringToSend);
        });
    }
}

With this architecture, multiple subsequent calls to `sendData()` within the same turn of the event loop will be batched together into one `fetch()` call, but with no intervening event loop tasks preempting the fetch (as would have happened with similar code that instead used `setTimeout()`).

8.7 User prompts

8.7.1 Simple dialogs

For web developers (non-normative)

`window.alert(message)`

Displays a modal alert with the given message, and waits for the user to dismiss it.

`result = window.confirm(message)`

Displays a modal OK/Cancel prompt with the given message, waits for the user to dismiss it, and returns true if the user clicks OK and false if the user clicks Cancel.

`result = window.prompt(message [, default] )`

Displays a modal text control prompt with the given message, waits for the user to dismiss it, and returns the value that the user entered. If the user cancels the prompt, then returns null instead. If the second argument is present, then the given value is used as a default.

Note

Logic that depends on `tasks` or `microtasks`, such as `media elements` loading their `media data` are stalled when these methods are invoked.

To optionally truncate a simple dialog string `s`, return either `s` itself or some string derived from `s` that is shorter. User agents should not provide UI for displaying the elided portion of `s`, as this makes it too easy for abusers to create dialogs of the form "Important security alert! Click 'Show More' for full details!".

Note

For example, a user agent might want to only display the first 100 characters of a message. Or, a user agent might replace the middle of the string with "...". These types of modifications can be useful in limiting the abuse potential of unnaturally large, trustworthy-looking system dialogs.

The `alert(message)` method, when invoked, must run the following steps:

1. If the `event loop`'s `termination nesting level` is nonzero, optionally return.
2. If the `active sandboxing flag set` of this `Window` object's associated `Document` has the `sandboxed modals flag` set, then return.
3. Optionally, return. (For example, the user agent might give the user the option to ignore all alerts, and would thus abort at
this step whenever the method was invoked.)

4. If the method was invoked with no arguments, then let `message` be the empty string; otherwise, let `message` be the method’s first argument.

5. Set `message` to the result of `optionally truncating` \(^{921}\) `message`.

6. Show `message` to the user.

7. Optionally, `pause` \(^{920}\) while waiting for the user to acknowledge the message.

The `confirm(message)` method, when invoked, must run the following steps:

1. If the `event loop` \(^{983}\)’s termination nesting level \(^{986}\) is nonzero, optionally return false.

2. If the `active sandboxing flag set` \(^{989}\) of this `Window` \(^{795}\) object’s associated `Document` \(^{793}\) has the sandboxed modals flag \(^{807}\) set, then return.

3. Optionally, return false. (For example, the user agent might give the user the option to ignore all prompts, and would thus abort at this step whenever the method was invoked.)

4. Set `message` to the result of `optionally truncating` \(^{921}\) `message`.

5. Show `message` to the user, and ask the user to respond with a positive or negative response.

6. `Pause` \(^{989}\) until the user responds either positively or negatively.

7. If the user responded positively, return true; otherwise, the user responded negatively: return false.

The `prompt(message, default)` method, when invoked, must run the following steps:

1. If the `event loop` \(^{983}\)’s termination nesting level \(^{986}\) is nonzero, optionally return null.

2. If the `active sandboxing flag set` \(^{989}\) of this `Window` \(^{795}\) object’s associated `Document` \(^{793}\) has the sandboxed modals flag \(^{807}\) set, then return.

3. Optionally, return null. (For example, the user agent might give the user the option to ignore all prompts, and would thus abort at this step whenever the method was invoked.)

4. Set `message` to the result of `optionally truncating` \(^{921}\) `message`.

5. Set `default` to the result of `optionally truncating` \(^{921}\) `default`.

6. Show `message` to the user, and ask the user to either respond with a string value or abort. The response must be defaulted to the value given by `default`.

7. `Pause` \(^{989}\) while waiting for the user’s response.

8. If the user aborts, then return null; otherwise, return the string that the user responded with.

8.7.2 Printing \(^{92}\)

For web developers (non-normative)

```javascript
window . print() // Prompts the user to print the page.
```

When the `print()` method is invoked, if the `Document` \(^{116}\) is ready for post-load tasks \(^{117}\), then the user agent must run the printing steps \(^{922}\) in parallel \(^{42}\). Otherwise, the user agent must only set the print when loaded flag on the `Document` \(^{116}\).

User agents should also run the printing steps \(^{922}\) whenever the user asks for the opportunity to obtain a physical form \(^{116}\) (e.g. printed copy), or the representation of a physical form (e.g. PDF copy), of a document.

The printing steps are as follows:
1. The user agent may display a message to the user or return (or both).

Example: For instance, a kiosk browser could silently ignore any invocations of the `print()` method.

Example: For instance, a browser on a mobile device could detect that there are no printers in the vicinity and display a message saying so before continuing to offer a "save to PDF" option.

2. If the `active sandboxing flag` set\(^\text{809}\) of this `Window` object's associated `Document` has the `sandboxed modals flag`\(^\text{807}\) set, then return.

Note: If the printing dialog is blocked by a `Document`'s sandbox, then neither the `beforeprint` nor `afterprint` events will be fired.

3. The user agent must `fire an event` named `beforeprint` at the `Window` object of the `Document` that is being printed, as well as any `nested browsing contexts` in it.

Example: The `beforeprint` event can be used to annotate the printed copy, for instance adding the time at which the document was printed.

4. The user agent should offer the user the opportunity to obtain a physical form (or the representation of a physical form) of the document. The user agent may wait for the user to either accept or decline before returning; if so, the user agent must `pause` while the method is waiting. Even if the user agent doesn't wait at this point, the user agent must use the state of the relevant documents as they are at this point in the algorithm if and when it eventually creates the alternate form.

5. The user agent must `fire an event` named `afterprint` at the `Window` object of the `Document` that is being printed, as well as any `nested browsing contexts` in it.

Example: The `afterprint` event can be used to revert annotations added in the earlier event, as well as showing post-printing UI. For instance, if a page is walking the user through the steps of applying for a home loan, the script could automatically advance to the next step after having printed a form or other.

8.8 System state and capabilities

8.8.1 The `Navigator` object

The `navigator` attribute of the `Window` interface must return an instance of the `Navigator` interface, which represents the identity and state of the user agent (the client), and allows Web pages to register themselves as potential protocol handlers:

```
IDL [Exposed=Window]
interface Navigator {
    // objects implementing this interface also implement the interfaces given below
};
Navigator includes NavigatorID;
Navigator includes NavigatorLanguage;
Navigator includes NavigatorOnline;
Navigator includes NavigatorContentUtils;
Navigator includes NavigatorCookies;
Navigator includes NavigatorPlugins;
Navigator includes NavigatorConcurrentHardware;
```

These interface mixins are defined separately so that `WorkerNavigator` can re-use parts of the `Navigator` interface.
In certain cases, despite the best efforts of the entire industry, Web browsers have bugs and limitations that Web authors are forced to work around.

This section defines a collection of attributes that can be used to determine, from script, the kind of user agent in use, in order to work around these issues.

The user agent has a **navigator compatibility mode**, which is either Chrome, Gecko, or WebKit.

---

### IDL

```idl
interface mixin NavigatorID {
    readonly attribute DOMString appCodeName; // constant "Mozilla"
    readonly attribute DOMString appName; // constant "Netscape"
    readonly attribute DOMString appVersion;
    readonly attribute DOMString platform;
    readonly attribute DOMString product; // constant "Gecko"
    [Exposed=Window] readonly attribute DOMString productSub;
    [Exposed=Window] readonly attribute DOMString userAgent;
    [Exposed=Window] readonly attribute DOMString vendor;
    [Exposed=Window] readonly attribute DOMString vendorSub; // constant ""
};
```

---

**Note**

The **navigator compatibility mode** constrains the **NavigatorID** interface to the combinations of attribute values and presence of `taintEnabled()` and `oscpu` that are known to be compatible with existing Web content.

---

Client detection should always be limited to detecting known current versions; future versions and unknown versions should always be assumed to be fully compliant.

---

### For web developers (non-normative)

- **self. navigator.appCodeName**
  - Returns the string "Mozilla".

- **self. navigator.appName**
  - Returns the string "Netscape".

- **self. navigator.appVersion**
  - Returns the version of the browser.

- **self. navigator.platform**
  - Returns the name of the platform.

- **self. navigator.product**
  - Returns the string "Gecko".

- **window. navigator.productSub**
  - Returns either the string "20030107", or the string "20100101".

- **self. navigator.userAgent**
  - Returns the complete 'User-Agent' header.

- **window. navigator.vendor**
  - Returns either the empty string, the string "Apple Computer, Inc.", or the string "Google Inc.".

- **window. navigator.vendorSub**
  - Returns the empty string.

---

**appCodeName**

Must return the string "Mozilla".
appName
  Must return the string "Netscape".

appVersion
  Must return either the string "4.0" or a string representing the version of the browser in detail, e.g. "1.0 (VMS; en-US) Mellblomenator/9000".

platform
  Must return either the empty string or a string representing the platform on which the browser is executing, e.g. "MacIntel", "Win32", "FreeBSD 1386", "WebTV 05".

product
  Must return the string "Gecko".

productSub
  Must return the appropriate string from the following list:

  ↩ If the navigator compatibility mode is Chrome or WebKit
  The string "20030107".

  ↩ If the navigator compatibility mode is Gecko
  The string "20100101".

userAgent
  Must return the default "User-Agent" value.

vendor
  Must return the appropriate string from the following list:

  ↩ If the navigator compatibility mode is Chrome
  The string "Google Inc.".

  ↩ If the navigator compatibility mode is Gecko
  The empty string.

  ↩ If the navigator compatibility mode is WebKit
  The string "Apple Computer, Inc.".

vendorSub
  Must return the empty string.

If the navigator compatibility mode is Gecko, then the user agent must also support the following partial interface:

```idl
partial interface NavigatorID {
  [Exposed=Window] boolean taintEnabled(); // constant false
  [Exposed=Window] readonly attribute DOMString oscpu;
};
```

The taintEnabled() method must return false.

The oscpu attribute's getter must return either the empty string or a string representing the platform on which the browser is executing, e.g. "Windows NT 10.0; Win64; x64", "Linux x86_64".

⚠ Warning!

Any information in this API that varies from user to user can be used to profile the user. In fact, if enough such information is available, a user can actually be uniquely identified. For this reason, user agent implementers are strongly urged to include as little information in this API as possible.
8.8.1.2 Language preferences

IDL

```idl
interface mixin NavigatorLanguage {
  readonly attribute DOMString language;
  readonly attribute FrozenArray<DOMString> languages;
};
```

For web developers (non-normative)

```javascript
self.navigator.language
```

Returns a language tag representing the user's preferred language.

```javascript
self.navigator.languages
```

Returns an array of language tags representing the user's preferred languages, with the most preferred language first. The most preferred language is the one returned by `navigator.language`.

Note

A `languagechange` event is fired at the `Window` or `WorkerGlobalScope` object when the user agent's understanding of what the user's preferred languages are changes.

language

Must return a valid BCP 47 language tag representing either a plausible language, or the user's most preferred language. [BCP47]

languages

Must return a frozen array of valid BCP 47 language tags representing either one or more plausible languages, or the user's preferred languages, ordered by preference with the most preferred language first. The same object must be returned until the user agent needs to return different values, or values in a different order. [BCP47]

Whenever the user agent needs to make the `navigator.languages` attribute of a `Window` or `WorkerGlobalScope` object return a new set of language tags, the user agent must queue a task to fire an event named `languagechange`, at the `Window` or `WorkerGlobalScope` object and wait until that task begins to be executed before actually returning a new value.

The task source for this task is the DOM manipulation task source.

To determine a plausible language, the user agent should bear in mind the following:

- Any information in this API that varies from user to user can be used to profile or identify the user.
- If the user is not using a service that obfuscates the user's point of origin (e.g. the Tor anonymity network), then the value that is least likely to distinguish the user from other users with similar origins (e.g. from the same IP address block) is the language used by the majority of such users. [TOR]
- If the user is using an anonymizing service, then the value "en-US" is suggested; if all users of the service use that same value, that reduces the possibility of distinguishing the users from each other.

To avoid introducing any more fingerprinting vectors, user agents should use the same list for the APIs defined in this function as for the HTTP `Accept-Language` header.

8.8.1.3 Custom scheme handlers: the `registerProtocolHandler()` method

IDL

```idl
interface mixin NavigatorContentUtils {
  void registerProtocolHandler(DOMString scheme, USVString url, DOMString title);
  void unregisterProtocolHandler(DOMString scheme, USVString url);
};
```

The `registerProtocolHandler()` method allows Web sites to register themselves as possible handlers for particular schemes. For example, an online telephone messaging service could register itself as a handler of the `sms:` scheme, so that if the user clicks on such a link, they are given the opportunity to use that web site. [SMS]
User agents may, within the constraints described in this section, do whatever they like when the method is called. A UA could, for instance, prompt the user and offer the user the opportunity to add the site to a shortlist of handlers, or make the handlers their default, or cancel the request. UAs could provide such a UI through modal UI or through a non-modal transient notification interface. UAs could also simply silently collect the information, providing it only when relevant to the user.

User agents should keep track of which sites have registered handlers (even if the user has declined such registrations) so that the user is not repeatedly prompted with the same request.

The arguments to the method have the following meanings and corresponding implementation requirements. The requirements that involve throwing exceptions must be processed in the order given below, stopping at the first exception thrown. (So the exceptions for the first argument take precedence over the exceptions for the second argument.)

**scheme**

A scheme, such as "mailto" or "web+auth". The scheme must be compared in an ASCII case-insensitive manner by user agents for the purposes of comparing with the scheme part of URLs that they consider against the list of registered handlers.

The scheme value, if it contains a colon (as in "mailto:"), will never match anything, since schemes don't contain colons.

If the `registerProtocolHandler()` method is invoked with a scheme that is neither a safelisted scheme nor a scheme whose value starts with the substring "web+" and otherwise contains only ASCII lower alphas, and whose length is at least five characters (including the "web+" prefix), the user agent must throw a "SecurityError" DOMException.

The following schemes are the safelisted schemes:

- bitcoin
- geo
- im
- irc
- ircs
- magnet
- mailto
- mms
- news
- nntp
- openpgp4fpr
- sip
- sms
- smsto
- ssh
- tel
- urn
- webcal
- wtai
- xmpp

**url**

A string used to build the URL of the page that will handle the requests.

---

For web developers (non-normative)

```javascript
window.navigator.registerProtocolHandler(scheme, url, title)
```

Registers a handler for the given scheme, at the given URL, with the given title.

The string "%s" in the URL is used as a placeholder for where to put the URL of the content to be handled.

Throws a "SecurityError" DOMException if the user agent blocks the registration (this might happen if trying to register as a handler for "http", for instance).

Throws a "SyntaxError" DOMException if the "%s" string is missing in the URL.

---

927
User agents must throw a "SyntaxError" DOMException if the url argument passed to one of these methods does not contain the exact literal string "%s".

User agents must throw a "SyntaxError" DOMException if parsing the url argument relative to the relevant settings object of this NavigatorContentUtils object is not successful.

Note
The resulting URL string would by definition not be a valid URL string as it would include the string "%s" which is not a valid component in a URL.

User agents must throw a "SecurityError" DOMException if the resulting URL record has an origin that differs from the origin specified by the relevant settings object of this NavigatorContentUtils object.

Note
This is forcibly the case if the %s placeholder is in the scheme, host, or port parts of the URL.

The resulting URL string is the proto-URL. It identifies the handler for the purposes of the methods described below.

When the user agent uses this handler, it must replace the first occurrence of the exact literal string "%s" in the url argument with an escaped version of the absolute URL of the content in question (as defined below), then parse the resulting URL, relative to the relevant settings object of the NavigatorContentUtils object on which the registerProtocolHandler() method was invoked, and then navigate an appropriate browsing context to the resulting URL.

To get the escaped version of the absolute URL of the content in question, the user agent must replace every character in that absolute URL that is not a character in the URL default encode set with the result of UTF-8 percent encoding that character.

Example
If the user had visited a site at https://example.com/ that made the following call:

navigator.registerProtocolHandler('web+soup', 'soup?url=%s', 'SoupWeb™')

...and then, much later, while visiting https://www.example.net/, clicked on a link such as:

<a href="web+soup:chicken-kïwi">Download our Chicken Kïwi soup!</a>

...then the UA might navigate to the following URL:

https://example.com/soup?url=web+soup:chicken-k%C3%AFwi

This site could then do whatever it is that it does with soup (synthesize it and ship it to the user, or whatever).

title
A descriptive title of the handler, which the UA might use to remind the user what the site in question is.

This section does not define how the pages registered by this method are used, beyond the requirements on how to process the url value (see above). To some extent, the processing model for navigating across documents defines some cases where these methods are relevant, but in general UAs may use this information wherever they would otherwise consider handing content to native plugins or helper applications.

In addition to the registration method, there is also a method for unregistering handlers.

For web developers (non-normative)
window . navigator . unregisterProtocolHandler(scheme, url)
Unregisters the handler given by the arguments.

The unregisterProtocolHandler() method must unregister the handler described by the two arguments to the method, where the first argument gives the scheme and the second gives the string used to build the URL of the page that will handle the requests.

The first argument must be compared to the schemes for which custom protocol handlers are registered in an ASCII case-insensitive manner to find the relevant handlers.
The second argument must be preprocessed as described below, and if that is successful, must then be matched against the `proto-URLs` of the relevant handlers to find the described handler.

The second argument must be preprocessed as follows:

1. If the string does not contain the substring "%s", then return. There's no matching handler.
2. Parse the string relative to the `relevant settings object` of this `NavigatorContentUtils` object. If this fails, then throw a "SyntaxError" `DOMException`.
3. If the `resulting URL record`'s `origin` is not the `same origin` as the `origin` of the `relevant settings object` of this `NavigatorContentUtils` object, then throw a "SecurityError" `DOMException`.
4. Return the `resulting URL string` as the result of preprocessing the argument.

8.8.1.3.1 Security and privacy

These mechanisms can introduce a number of concerns, in particular privacy concerns.

Hijacking all Web usage. User agents should not allow schemes that are key to its normal operation, such as an `HTTP(S)` scheme, to be rerouted through third-party sites. This would allow a user's activities to be trivially tracked, and would allow user information, even in secure connections, to be collected.

Hijacking defaults. User agents are strongly urged to not automatically change any defaults, as this could lead the user to send data to remote hosts that the user is not expecting. New handlers registering themselves should never automatically cause those sites to be used.

Registration spamming. User agents should consider the possibility that a site will attempt to register a large number of handlers, possibly from multiple domains (e.g., by redirecting through a series of pages each on a different domain, and each registering a handler for `web+spam` — analogous practices abusing other web browser features have been used by pornography Web sites for many years). User agents should gracefully handle such hostile attempts, protecting the user.

Misleading titles. User agents should not rely wholly on the title argument to the methods when presenting the registered handlers to the user, since sites could easily lie. For example, a site `hostile.example.net` could claim that it was registering the "Cuddly Bear Happy Scheme Handler". User agents should therefore use the handler's origin in any UI along with any title.

Hostile handler metadata. User agents should protect against typical attacks against strings embedded in their interface, for example ensuring that markup or escape characters in such strings are not executed, that null bytes are properly handled, that over-long strings do not cause crashes or buffer overruns, and so forth.

Leaking Intranet URLs. The mechanism described in this section can result in secret Intranet URLs being leaked, in the following manner:

1. The user registers a third-party scheme handler as the default handler for a scheme.
2. The user then browses their corporate Intranet site and accesses a URL that uses that scheme.
3. The user agent contacts the third party and hands the third party the URL to the Intranet content.

No actual confidential file data is leaked in this manner, but the URLs themselves could contain confidential information. For example, the URL could be `https://www.corp.example.com/upcoming-aquisitions/the-sample-company.egf`, which might tell the third party that Example Corporation is intending to merge with The Sample Company. Implementors might wish to consider allowing administrators to disable this feature for certain subdomains, content types, or schemes.

Leaking credentials. User agents must never send username or password information in the URLs that are escaped and included sent to the handler sites. User agents may even avoid attempting to pass to Web-based handlers the URLs of resources that are known to require authentication to access, as such sites would be unable to access the resources in question without prompting the user for credentials themselves (a practice that would require the user to know whether to trust the third-party handler, a decision many users are unable to make or even understand).

Interface interference. User agents should be prepared to handle intentionally long arguments to the methods. For example, if the user interface exposed consists of an "accept" button and a "deny" button, with the "accept" binding containing the name of the handler, it's important that a long name not cause the "deny" button to be pushed off the screen.
8.8.1.4 Cookies

IDL interface mixin NavigatorCookies {
  readonly attribute boolean cookieEnabled;
};

For web developers (non-normative)

window.navigator.cookieEnabled

Returns false if setting a cookie will be ignored, and true otherwise.

The cookieEnabled attribute must return true if the user agent attempts to handle cookies according to the cookie specification, and false if it ignores cookie change requests.

8.8.1.5 Plugins

IDL interface mixin NavigatorPlugins {
  [SameObject] readonly attribute PluginArray plugins;
  [SameObject] readonly attribute MimeArray mimeTypes;
  boolean javaEnabled();
};

[Exposed=Window, LegacyUnenumerableNamedProperties]
interface PluginArray {
  void refresh(optional boolean reload = false);
  readonly attribute unsigned long length;
  getter Plugin? item(unsigned long index);
  getter Plugin? namedItem(DOMString name);
};

[Exposed=Window, LegacyUnenumerableNamedProperties]
interface MimeArray {
  readonly attribute unsigned long length;
  getter Mime? item(unsigned long index);
  getter Mime? namedItem(DOMString name);
};

[Exposed=Window, LegacyUnenumerableNamedProperties]
interface Plugin {
  readonly attribute DOMString name;
  readonly attribute DOMString description;
  readonly attribute DOMString filename;
  readonly attribute unsigned long length;
  getter Mime? item(unsigned long index);
  getter Mime? namedItem(DOMString name);
};

[Exposed=Window]
interface Mime {
  readonly attribute DOMString type;
  readonly attribute DOMString description;
  readonly attribute DOMString suffixes; // comma-separated
  readonly attribute Plugin enabledPlugin;
};
window.navigator.plugins.refresh([refresh])

Updates the lists of supported plugins and MIME types for this page, and reloads the page if the lists have changed.

window.navigator.plugins.length

Returns the number of plugins, represented by Plugin objects, that the user agent reports.

plugin = window.navigator.plugins.item(index)

Returns the specified Plugin object.

plugin = window.navigator.plugins.item(name)

Returns the Plugin object for the plugin with the given name.

window.navigator.mimeTypes.length

Returns the number of MIME types, represented by MimeType objects, supported by the plugins that the user agent reports.

mimeType = window.navigator.mimeTypes.item(index)

Returns the specified MimeType object.

mimeType = window.navigator.mimeTypes.item(name)

Returns the MimeType object for the given MIME type.

plugin.name

Returns the plugin's name.

plugin.description

Returns the plugin's description.

plugin.filename

Returns the plugin library's filename, if applicable on the current platform.

plugin.length

Returns the number of MIME types, represented by MimeType objects, supported by the plugin.

mimeType = plugin.item(index)

Returns the specified MimeType object.

mimeType = plugin.item(name)

Returns the MimeType object for the given MIME type.

mimeType.type

Returns the MIME type.

mimeType.description

Returns the MIME type's description.

mimeType.suffixes

Returns the MIME type's typical file extensions, in a comma-separated list.

mimeType.enabledPlugin

Returns the Plugin object that implements this MIME type.
The `navigator.plugins` attribute must return a `PluginArray` object.

The `navigator.mimeTypes` attribute must return a `MimeTypeArray` object.

A `PluginArray` object represents none, some, or all of the plugins supported by the user agent, each of which is represented by a `Plugin` object. Each of these `Plugin` objects may be hidden plugins. A hidden plugin can't be enumerated, but can still be inspected by using its name.

**Note**

The fewer plugins are represented by the `PluginArray` object, and of those, the more that are hidden, the more the user's privacy will be protected. Each exposed plugin increases the number of bits that can be derived for fingerprinting. Hiding a plugin helps, but unless it is an extremely rare plugin, it is likely that a site attempting to derive the list of plugins can still determine whether the plugin is supported or not by probing for it by name (the names of popular plugins are widely known). Therefore not exposing a plugin at all is preferred. Unfortunately, many legacy sites use this feature to determine, for example, which plugin to use to play video. Not exposing any plugins at all might therefore not be entirely plausible.

The `PluginArray` objects created by a user agent must not be live. The set of plugins represented by the objects must not change once an object is created, except when it is updated by the `refresh()` method.

Each plugin represented by a `PluginArray` can support a number of MIME types. For each such plugin, the user agent must pick one or more of these MIME types to be those that are explicitly supported.

**Note**

The explicitly supported MIME types of a plugin are those that are exposed through the `Plugin` and `MimeTypeArray` interfaces. As with plugins themselves, any variation between users regarding what is exposed allows sites to fingerprint users. User agents are therefore encouraged to expose the same MIME types for all users of a plugin, regardless of the actual types supported... at least, within the constraints imposed by compatibility with legacy content.

The supported property indices of a `PluginArray` object are the numbers from zero to the number of non-hidden plugins represented by the object, if any.

The length attribute must return the number of non-hidden plugins represented by the object.

The `item()` method of a `PluginArray` object must return null if the argument is not one of the object's supported property indices and otherwise must return the result of running the following steps, using the method's argument as index:

1. Let list be the `Plugin` objects representing the non-hidden plugins represented by the `PluginArray` object.
2. Sort list alphabetically by the name of each `Plugin`.
3. Return the indexth entry in list.

**Note**

It is important for privacy that the order of plugins not leak additional information, e.g. the order in which plugins were installed.

The supported property names of a `PluginArray` object are the values of the name attributes of all the `Plugin` objects represented by the `PluginArray` object.

The `namedItem()` method of a `PluginArray` object must return null if the argument is not one of the object's supported property names, and otherwise must return the `Plugin` object, of those represented by the `PluginArray` object, that has a name equal to the method's argument.

The `refresh()` method of the `PluginArray` object of a `Navigator` object, when invoked, must check to see if any plugins have been installed or reconfigured since the user agent created the `PluginArray` object. If so, and the method's argument is true, then the user agent must act as if the `location.reload()` method was called instead. Otherwise, the user agent must update the `PluginArray` object and `MimeTypeArray` object created for attributes of that `Navigator` object, and the `Plugin` and
MimeType objects created for those PluginArray and MimeTypeArray objects, using the same Plugin objects for cases where the name is the same, and the same MimeType objects for cases where the type is the same, and creating new objects for cases where there were no matching objects immediately prior to the refresh() call. Old Plugin and MimeType objects must continue to return the same values that they had prior to the update, though naturally now the data is stale and may appear inconsistent (for example, an old MimeType entry might list as its enabledPlugin, a Plugin object that no longer lists that MimeType as a supported MimeType).

A MimeTypeArray object represents the MIME types explicitly supported by plugins supported by the user agent, each of which is represented by a MimeType object.

The MimeTypeArray objects created by a user agent must not be live. The set of MIME types represented by the objects must not change once an object is created, except when it is updated by the PluginArray object's refresh() method.

The supported property indices of a MimeTypeArray object are the numbers from zero to the number of MIME types explicitly supported by non-hidden plugins represented by the corresponding PluginArray object, if any.

The length attribute must return the number of MIME types explicitly supported by non-hidden plugins represented by the corresponding PluginArray object, if any.

The item() method of a MimeTypeArray object must return null if the argument is not one of the object's supported property indices, and otherwise must return the result of running the following steps, using the method's argument as index:

1. Let list be the MimeType objects representing the MIME types explicitly supported by non-hidden plugins represented by the corresponding PluginArray object, if any.

2. Sort list alphabetically by the type of each MimeType.

3. Return the indexth entry in list.

Note: It is important for privacy that the order of MIME types not leak additional information, e.g. the order in which plugins were installed.

The supported property names of a MimeTypeArray object are the values of the type attributes of all the MimeType objects represented by the MimeTypeArray object.

The namedItem() method of a MimeTypeArray object must return null if the argument is not one of the object's supported property names, and otherwise must return the MimeType object that has a Type equal to the method's argument.

A Plugin object represents a plugin. It has several attributes to provide details about the plugin, and can be enumerated to obtain the list of MIME types that it explicitly supports.

The Plugin objects created by a user agent must not be live. The set of MIME types represented by the objects, and the values of the objects' attributes, must not change once an object is created, except when updated by the PluginArray object's refresh() method.

The reported MIME types for a Plugin object are the MIME types explicitly supported by the corresponding plugin, when this object was last created or updated by PluginArray.refresh(), whichever happened most recently.

The supported property indices of a Plugin object are the numbers from zero to the number of reported MIME types.

The length attribute must return the number of reported MIME types.

The item() method of a Plugin object must return null if the argument is not one of the object's supported property indices, and otherwise must return the result of running the following steps, using the method's argument as index:

1. Let list be the MimeType objects representing the reported MIME types.

2. Sort list alphabetically by the Type of each MimeType.

3. Return the indexth entry in list.
The supported property names of a Plugin object are the values of the type attributes of the MimeType objects representing the reported MIME types.

The namedItem() method of a Plugin object must return null if the argument is not one of the object's supported property names and otherwise must return the MimeType object that has a type equal to the method's argument.

The name attribute must return the plugin's name.

The description and filename attributes must return user-agent-defined (or, in all likelihood, plugin-defined) strings. In each case, the same string must be returned each time, except that the strings returned may change when the PluginArray.refresh() method updates the object.

⚠️ Warning!

If the values returned by the description or filename attributes vary between versions of a plugin, they can be used both as a fingerprinting vector and, even more importantly, as a trivial way to determine what security vulnerabilities a plugin (and thus a browser) may have. It is thus highly recommended that the description attribute just return the same value as the name attribute, and that the filename attribute return the empty string.

⚠️ Warning!

Commas in the suffixes attribute are interpreted as separating subsequent filename extensions, as in "htm,html".

Note

It is important for privacy that the order of MIME types not leak additional information, e.g. the order in which plugins were installed.

8.9 Images

IDL

[Exposed=(Window,Worker), Serializable, Transferable]

interface ImageBitmap {
  readonly attribute unsigned long width;
  readonly attribute unsigned long height;
}
void close();
};

typedef (CanvasImageSource or Blob or ImageData) ImageBitmapSource;

dictionary ImageBitmapOptions {
    ImageOrientation imageOrientation = "none";
    PremultiplyAlpha premultiplyAlpha = "default";
    ColorSpaceConversion colorSpaceConversion = "default";
    [EnforceRange] unsigned long resizeWidth;
    [EnforceRange] unsigned long resizeHeight;
    ResizeQuality resizeQuality = "low";
}

An ImageBitmap object represents a bitmap image that can be painted to a canvas without undue latency.

Note
The exact judgement of what is undue latency of this is left up to the implementer, but in general if making use of the bitmap requires network I/O, or even local disk I/O, then the latency is probably undue; whereas if it only requires a blocking read from a GPU or system RAM, the latency is probably acceptable.

For web developers (non-normative)

promise = self . createImageBitmap(image [, options ])
promise = self . createImageBitmap(image, sx, sy, sw, sh [, options ])

Takes image, which can be an img element, an SVG image element, a video element, a canvas element, a Blob object, an ImageData object, or another ImageBitmap object, and returns a promise that is resolved when a new ImageBitmap is created.

If no ImageBitmap object can be constructed, for example because the provided image data is not actually an image, then the promise is rejected instead.

If sx, sy, sw, and sh arguments are provided, the source image is cropped to the given pixels, with any pixels missing in the original replaced by transparent black. These coordinates are in the source image's pixel coordinate space, not in CSS pixels.

If options is provided, the ImageBitmap object's bitmap data is modified according to options. For example, if the premultiplyAlpha option is set to "premultiply", the bitmap data's color channels are premultiplied by its alpha channel.

Rejects the promise with an "InvalidStateError" DOMException if the source image is not in a valid state (e.g., an img element that hasn't loaded successfully, an ImageBitmap object whose [[Detached]] internal slot value is true, an ImageData object whose data attribute value's [[ViewedArrayBuffer]] internal slot is detached, or a Blob whose data cannot be interpreted as a bitmap image).

Rejects the promise with a "SecurityError" DOMException if the script is not allowed to access the image data of the source image (e.g. a video that is CORS-cross-origin, or a canvas being drawn on by a script in a worker from another origin).

imageBitmap . close()

Releases imageBitmap's underlying bitmap data.

imageBitmap . width

Returns the intrinsic width of the image, in CSS pixels.

imageBitmap . height

Returns the intrinsic height of the image, in CSS pixels.
An `ImageBitmap` object whose `[[Detached]]` internal slot value is false always has associated `bitmap data`, with a width and a height. However, it is possible for this data to be corrupted. If an `ImageBitmap` object's media data can be decoded without errors, it is said to be **fully decodable**.

An `ImageBitmap` object's bitmap has an `origin-clean` flag, which indicates whether the bitmap is tainted by content from a different `origin`. The flag is initially set to true and may be changed to false by the steps of `createImageBitmap()`.

`ImageBitmap` objects are **serializable objects** and **transferable objects**.

Their **serialization steps**, given `value` and serialized, are:

1. Set `serialized.[[BitmapData]]` to a copy of `value's bitmap data`.
2. Set `serialized.[[OriginClean]]` to true if `value's origin-clean` flag is set, and false otherwise.

Their **deserialization steps**, given serialized and `value`, are:

1. Set `value's bitmap data` to `serialized.[[BitmapData]]`.
2. If `serialized.[[OriginClean]]` is true, set `value's origin-clean` flag.

Their **transfer steps**, given `value` and `dataHolder`, are:

1. Set `dataHolder.[[BitmapData]]` to `value's bitmap data`.
2. Set `dataHolder.[[OriginClean]]` to true if `value's origin-clean` flag is set, and false otherwise.
3. Unset `value's bitmap data`.

Their **transfer-receiving steps**, given `dataHolder` and `value`, are:

1. Set `value's bitmap data` to `dataHolder.[[BitmapData]]`.
2. If `dataHolder.[[OriginClean]]` is true, set `value's origin-clean` flag.

The `createImageBitmap(image, options)` and `createImageBitmap(image sx, sy, sw, sh, options)` methods, when invoked, must run these steps:

1. Let `p` be a new promise.
2. If either `sw` or `sh` is given and is 0, then return `p` rejected with a `RangeError`.
3. If either `options's resizeWidth` or `options's resizeHeight` is present and is 0, then return `p` rejected with an "`InvalidStateError`" DOMException.
4. **Check the usability of the image argument**. If this throws an exception or returns `bad`, then return `p` rejected with an "`InvalidStateError`" DOMException.
5. Let `imageBitmap` be a new `ImageBitmap` object.
6. Switch on `image`:
   
   ```
   ➡️ img
   ➡️ SVG image
   ```

   1. If `image`'s media data has no `intrinsic dimensions` (e.g., it's a vector graphic with no specified content size) and either `options's resizeWidth` or `options's resizeHeight` is not present, then return `p` rejected with an "`InvalidStateError`" DOMException.
   
   2. If `image`'s media data has no `intrinsic dimensions` (e.g., it's a vector graphics with no specified content size), it should be rendered to a bitmap of the size specified by the `resizeWidth` and the `resizeHeight` options.
   
   3. Set `imageBitmap's bitmap data` to a copy of `image`'s media data, **cropped to the source rectangle with formatting**. If this is an animated image, `imageBitmap`'s `bitmap data` must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not
4. If the `origin` of `image`'s image is not `same origin` with `entry settings object`'s `origin`, then set the `origin-clean` flag of `imageBitmap`'s bitmap to false.

5. Run this step in parallel:

   1. Resolve `p` with `imageBitmap`.

   ↪ `video`

   1. If `image`'s `networkState` attribute is `NETWORK EMPTY`, then return `p` rejected with an "InvalidStateError" DOMException.

   2. Set `imageBitmap`'s `bitmap data` to a copy of the frame at the `current playback position`, at the media resource's `intrinsic width` and `intrinsic height` (i.e., after any aspect-ratio correction has been applied), cropped to the source rectangle with formatting.

   3. If the `origin` of `image`'s video is not `same origin` with `entry settings object`'s `origin`, then set the `origin-clean` flag of `imageBitmap`'s bitmap to false.

4. Run this step in parallel:

   1. Resolve `p` with `imageBitmap`.

   ↪ `canvas`

   1. Set `imageBitmap`'s `bitmap data` to a copy of `image`'s `bitmap data`, cropped to the source rectangle with formatting.

   2. Set the `origin-clean` flag of the `imageBitmap`'s bitmap to the same value as the `origin-clean` flag of `image`'s bitmap.

   3. Run this step in parallel:

   1. Resolve `p` with `imageBitmap`.

   ↪ `Blob`

   Run these step in parallel:

   1. Let `imageData` be the result of reading `image`'s data. If an error occurs during reading of the object, then reject `p` with an "InvalidStateError" DOMException and abort these steps.

   2. Apply the image sniffing rules to determine the file format of `imageData`, with MIME type of `image` (as given by `image`'s `type` attribute) giving the official type.

   3. If `imageData` is not in a supported image file format (e.g., it’s not an image at all), or if `imageData` is corrupted in some fatal way such that the image dimensions cannot be obtained (e.g., a vector graphic with no intrinsic size), then reject `p` with an "InvalidStateError" DOMException and abort these steps.

   4. Set `imageBitmap`'s `bitmap data` to `imageData`, cropped to the source rectangle with formatting. If this is an animated image, `imageBitmap`'s `bitmap data` must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.

5. Resolve `p` with `imageBitmap`.

   ↪ `ImageData`

   1. Let `buffer` be `image`'s `data` attribute value's `[[ViewedArrayBuffer]]` internal slot.

   2. If `IsDetachedBuffer(buffer)` is true, then return `p` rejected with an "InvalidStateError" DOMException.

   3. Set `imageBitmap`'s `bitmap data` to `image`'s image data, cropped to the source rectangle with formatting.

   4. Run this step in parallel:

   1. Resolve `p` with `imageBitmap`. 937
1. Set `imageBitmap`'s `bitmap data` to a copy of `image`'s `bitmap data`, cropped to the source rectangle with formatting.

2. Set the `origin-clean` flag of `imageBitmap`'s bitmap to the same value as the `origin-clean` flag of `image`'s bitmap.

3. Run this step in parallel:
   1. Resolve `p` with `imageBitmap`.

When the steps above require that the user agent **crop bitmap data to the source rectangle with formatting**, the user agent must run the following steps:

1. Let `input` be the `bitmap data` being transformed.

2. If `sx`, `sy`, `sw` and `sh` are specified, let `sourceRectangle` be a rectangle whose corners are the four points `(sx, sy), (sx+sw, sy), (sx+sw, sy+sh), (sx, sy+sh)`. Otherwise let `sourceRectangle` be a rectangle whose corners are the four points `(0,0), (width of `input`, 0), (width of `input`, height of `input`), (0, height of `input`).

   If either `sw` or `sh` are negative, then the top-left corner of this rectangle will be to the left or above the `(sx, sy)` point.

3. Clip `sourceRectangle` to the dimensions of `input`.

4. Let `outputWidth` be determined as follows:

   - **If the `resizeWidth` member of `options` is specified**
     - the value of the `resizeWidth` member of `options`
   - **If the `resizeWidth` member of `options` is not specified, but the `resizeHeight` member is specified**
     - the width of `sourceRectangle`, times the value of the `resizeHeight` member of `options`, divided by the height of `sourceRectangle`, rounded up to the nearest integer
   - **If neither `resizeWidth` nor `resizeHeight` are specified**
     - the width of `sourceRectangle`

5. Let `outputHeight` be determined as follows:

   - **If the `resizeHeight` member of `options` is specified**
     - the value of the `resizeHeight` member of `options`
   - **If the `resizeHeight` member of `options` is not specified, but the `resizeWidth` member is specified**
     - the height of `sourceRectangle`, times the value of the `resizeWidth` member of `options`, divided by the width of `sourceRectangle`, rounded up to the nearest integer
   - **If neither `resizeWidth` nor `resizeHeight` are specified**
     - the height of `sourceRectangle`

6. Place `input` on an infinite transparent black grid plane, positioned so that its top left corner is at the origin of the plane, with the x-coordinate increasing to the right, and the y-coordinate increasing down, and with each pixel in the `input` image data occupying a cell on the plane's grid.

7. Let `output` be the rectangle on the plane denoted by `sourceRectangle`.

8. Scale `output` to the size specified by `outputWidth` and `outputHeight`. The user agent should use the value of the `resizeQuality` option to guide the choice of scaling algorithm.

9. If the value of the `imageOrientation` member of `options` is "flipY", `output` must be flipped vertically, disregarding any image orientation metadata of the source (such as EXIF metadata), if any. [EXIF]

   If the value is "none", no extra step is required.

10. If `image` is an `img` element or a `Blob` object, let `val` be the value of the `colorSpaceConversion` member of `options`, and
then run these substeps:

1. If `val` is "default", the color space conversion behavior is implementation-specific, and should be chosen according to the color space that the implementation uses for drawing images onto the canvas.

2. If `val` is "none", `output` must be decoded without performing any color space conversions. This means that the image decoding algorithm must ignore color profile metadata embedded in the source data as well as the display device color profile.

**Note**

The native color space of canvas is currently unspecified, but this is expected to change in the future.

11. Let `val` be the value of `premultiplyAlpha` member of `options`, and then run these substeps:

   1. If `val` is "default", the alpha premultiplication behavior is implementation-specific, and should be chosen according to implementation deems optimal for drawing images onto the canvas.

   2. If `val` is "premultiply", the `output` that is not premultiplied by alpha must have its color components multiplied by alpha and that is premultiplied by alpha must be left untouched.

   3. If `val` is "none", the `output` that is not premultiplied by alpha must be left untouched and that is premultiplied by alpha must have its color components divided by alpha.

12. Return `output`.

When the `close()` method is called, the user agent must run these steps:

1. Set this `ImageBitmap` object's `[[Detached]]` internal slot value to true.

2. Unset this `ImageBitmap` object's `bitmap data`.

The `width` attribute's getter must run these steps:

1. If this `ImageBitmap` object's `[[Detached]]` internal slot's value is true, then return 0.

2. Return this `ImageBitmap` object's width, in CSS pixels.

The `height` attribute's getter must run these steps:

1. If this `ImageBitmap` object's `[[Detached]]` internal slot's value is true, then return 0.

2. Return this `ImageBitmap` object's height, in CSS pixels.

The `ResizeQuality` enumeration is used to express a preference for the interpolation quality to use when scaling images.

The "pixelated" value indicates a preference to scale the image that maximizes the appearance. Scaling algorithms that "smooth" colors are acceptable, such as bilinear interpolation.

The "low" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "medium" value indicates a preference for a medium level of image interpolation quality.

The "high" value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

**Note**

Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-scaling algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used unless the value is "pixelated".

**Example**

Using this API, a sprite sheet can be precut and prepared:

```javascript
var sprites = {};
```
function loadMySprites() {
    var image = new Image();
    image.src = 'mysprites.png';
    var resolver;
    var promise = new Promise(function (arg) { resolver = arg });
    image.onload = function () {
        resolver(Promise.all([createImageBitmap(image, 0, 0, 40, 40).then(function (image) { sprites.person = image }),
            createImageBitmap(image, 40, 0, 40, 40).then(function (image) { sprites.grass = image }),
            createImageBitmap(image, 80, 0, 40, 40).then(function (image) { sprites.tree = image }),
            createImageBitmap(image, 0, 40, 40, 40).then(function (image) { sprites.hut = image }),
            createImageBitmap(image, 40, 40, 40, 40).then(function (image) { sprites.apple = image }),
            createImageBitmap(image, 80, 40, 40, 40).then(function (image) { sprites.snake = image })
        ]));
    }
    return promise;
}

function runDemo() {
    var canvas = document.querySelector('canvas#demo');
    var context = canvas.getContext('2d');
    context.drawImage(sprites.tree, 30, 10);
    context.drawImage(sprites.snake, 70, 10);
}

loadMySprites().then(runDemo);

8.10 Animation frames

Each Document has a list of animation frame callbacks, which must be initially empty, and an animation frame callback identifier, which is a number which must initially be zero.

When the `requestAnimationFrame()` method is called, the user agent must run the following steps:

1. Let `document` be this Window object's associated Document.
2. Increment `document`'s animation frame callback identifier by one.
3. Append the method's argument to `document`'s list of animation frame callbacks, associated with `document`'s animation frame callback identifier's current value.
4. Return `document`'s animation frame callback identifier's current value.

When the `cancelAnimationFrame()` method is called, the user agent must run the following steps:

1. Let `document` be this Window object's associated Document.
2. Find the entry in `document`'s list of animation frame callbacks that is associated with the value given by the method's argument.
3. If there is such an entry, remove it from `document`'s list of animation frame callbacks.

When the user agent is to run the animation frame callbacks for a Document doc with a timestamp now, it must run the following steps:

1. Let `callbacks` be a list of the entries in `doc`'s list of animation frame callbacks, in the order in which they were added to the list.
2. Set `doc`'s list of animation frame callbacks to the empty list.
3. For each entry in *callbacks*, in order: invoke the callback, passing `now` as the only argument, and if an exception is thrown, report the exception. ¹⁶⁰⁰ [WEBIDL]²¹²⁷
9 Communication

9.1 The MessageEvent interface

Messages in server-sent events, Web sockets, cross-document messaging, channel messaging, and broadcast channels use the MessageEvent interface for their message events:

```idl
[Constructor(DOMString type, optional MessageEventInit eventInitDict),
 Exposed=(Window, Worker, AudioWorklet)]
interface MessageEvent : Event {
    readonly attribute any data;
    readonly attribute USVString origin;
    readonly attribute DOMString lastEventId;
    readonly attribute MessageEventSource? source;
    readonly attribute FrozenArray<MessagePort> ports;
    void initMessageEvent(DOMString type, optional boolean bubbles = false, optional boolean cancelable = false, optional any data = null, optional USVString origin = "", optional DOMString lastEventId = "", optional MessageEventSource? source = null, optional sequence<MessagePort> ports = []);
};
dictionary MessageEventInit : EventInit {
    any data = null;
    USVString origin = "";
    DOMString lastEventId = "";
    MessageEventSource? source = null;
    sequence<MessagePort> ports = [];
};
typedef (WindowProxy or MessagePort or ServiceWorker) MessageEventSource;
```

For web developers (non-normative)

- **event.data**
  - Returns the data of the message.

- **event.origin**
  - Returns the origin of the message, for server-sent events and cross-document messaging.

- **event.lastEventId**
  - Returns the last event ID string, for server-sent events.

- **event.source**
  - Returns the WindowProxy of the source window, for cross-document messaging, and the MessagePort being attached, in the connect event fired at SharedWorkerGlobalScope objects.

- **event.ports**
  - Returns the MessagePort array sent with the message, for cross-document messaging and channel messaging.

The `data` attribute must return the value it was initialized to. It represents the message being sent.

The `origin` attribute must return the value it was initialized to. It represents, in server-sent events and cross-document messaging, the `origin` of the document that sent the message (typically the scheme, hostname, and port of the document, but not its path or fragment).

The `lastEventId` attribute must return the value it was initialized to. It represents, in server-sent events, the `last event ID string` of the event source.
The `source` attribute must return the value it was initialized to. It represents, in cross-document messaging, the `WindowProxy` of the `Window` object from which the message came; and in the `connect` events used by shared workers, the newly connecting `MessagePort`.

The `ports` attribute must return the value it was initialized to. It represents, in cross-document messaging and channel messaging, the `MessagePort` array being sent.

The `initMessageEvent()` method must initialize the event in a manner analogous to the similarly-named `initEvent()` method.

Note: Various APIs (e.g., `WebSocket`, `EventSource`) use the `MessageEvent` interface for their `message` event without using the `MessagePort` API.

## 9.2 Server-sent events

### 9.2.1 Introduction

This section is non-normative.

To enable servers to push data to Web pages over HTTP or using dedicated server-push protocols, this specification introduces the `EventSource` interface.

Using this API consists of creating an `EventSource` object and registering an event listener.

```javascript
var source = new EventSource('updates.cgi');
source.onloadmessage = function (event) {
    alert(event.data);
};
```

On the server-side, the script ("updates.cgi" in this case) sends messages in the following form, with the `text/event-stream` MIME type:

```
data: This is the first message.

data: This is the second message, it
data: has two lines.

data: This is the third message.
```

Authors can separate events by using different event types. Here is a stream that has two event types, "add" and "remove":

```
event: add
data: 73857293

event: remove
data: 2153

event: add
data: 113411
```

The script to handle such a stream would look like this (where `addHandler` and `removeHandler` are functions that take one argument, the event):

```javascript
var source = new EventSource('updates.cgi');
source.addEventListener('add', addHandler, false);
source.addEventListener('remove', removeHandler, false);
```

The default event type is "message."
Event streams are always decoded as UTF-8. There is no way to specify another character encoding.

Event stream requests can be redirected using HTTP 301 and 307 redirects as with normal HTTP requests. Clients will reconnect if the connection is closed; a client can be told to stop reconnecting using the HTTP 204 No Content response code.

Using this API rather than emulating it using XMLHttpRequest or an iframe allows the user agent to make better use of network resources in cases where the user agent implementer and the network operator are able to coordinate in advance. Amongst other benefits, this can result in significant savings in battery life on portable devices. This is discussed further in the section below on connectionless push.

9.2.2 The EventSource interface

```
IDL
[Constructor(USVString url, optional EventSourceInit eventSourceInitDict), Exposed=(Window, Worker)]
interface EventSource : EventTarget {
    readonly attribute USVString url;
    readonly attribute boolean withCredentials;

    // ready state
    const unsigned short CONNECTING = 0;
    const unsigned short OPEN = 1;
    const unsigned short CLOSED = 2;
    readonly attribute unsigned short readyState;

    // networking
    attribute EventHandler onopen;
    attribute EventHandler onmessage;
    attribute EventHandler onerror;
    void close();
};
```

dictionary EventSourceInit {
    boolean withCredentials = false;
};

Each EventSource object has the following associated with it:

- A url (a URL record). Set during construction.
- A request. This must initially be null.
- A reconnection time, in milliseconds. This must initially be a user-agent-defined value, probably in the region of a few seconds.
- A last event ID string. This must initially be the empty string.

Apart from url, these are not currently exposed on the EventSource object.

For web developers (non-normative)

```
source = new EventSource(url [, { withCredentials: true } ])

Creates a new EventSource object.

url is a string giving the URL that will provide the event stream.

Setting withCredentials to true will set the credentials mode for connection requests to url to "include".

source.close()

Aborts any instances of the fetch algorithm started for this EventSource object, and sets the readyState attribute to CLOSED.
```
source.url

Returns the URL providing the event stream.

source.withCredentials

Returns true if the credentials mode for connection requests to the URL providing the event stream is set to "include", and false otherwise.

source.readyState

Returns the state of this EventSource object's connection. It can have the values described below.

The EventSource(url, eventSourceInitDict) constructor, when invoked, must run these steps:

1. Let ev be a new EventSource object.
2. Let settings be ev's relevant settings object.
3. Let urlRecord be the result of parsing url with settings's API base URL and settings's API URL character encoding.
4. If urlRecord is failure, then throw a "SyntaxError" DOMException.
5. Set ev's url to urlRecord.
7. If the value of eventSourceInitDict's withCredentials member is true, then set corsAttributeState to Use Credentials and set ev's withCredentials attribute to true.
8. Let request be the result of creating a potential-CORS request given urlRecord, the empty string, and corsAttributeState, and with the same-origin fallback flag set.
9. Set request's client to settings.
10. User agents may set 'Accept'/'text/event-stream' in request's header list.
11. Set request's cache mode to "no-store".
12. Set ev's request to request.
13. Run this step in parallel:
   1. Fetch request.

The url attribute's getter must return the serialization of this EventSource object's url.

The withCredentials attribute must return the value to which it was last initialized. When the object is created, it must be initialized to false.

The readyState attribute represents the state of the connection. It can have the following values:

**CONNECTING** (numeric value 0)

The connection has not yet been established, or it was closed and the user agent is reconnecting.

**OPEN** (numeric value 1)

The user agent has an open connection and is dispatching events as it receives them.

**CLOSED** (numeric value 2)

The connection is not open, and the user agent is not trying to reconnect. Either there was a fatal error or the close method was invoked.

When the object is created its readyState must be set to CONNECTING (0). The rules given below for handling the connection define when the value changes.
The close() method must abort any instances of the fetch algorithm started for this EventSource object, and must set the readyState attribute to CLOSED.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the EventSource interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onopen</td>
<td>open</td>
</tr>
<tr>
<td>onmessage</td>
<td>message</td>
</tr>
<tr>
<td>onerror</td>
<td>error</td>
</tr>
</tbody>
</table>

9.2.3 Processing model

The resource indicated in the argument to the EventSource constructor is fetched when the constructor is run.

As data is received, the tasks, queued by the networking task source to handle the data must act as follows.

HTTP 200 OK responses with a `Content-Type` header specifying the type `text/event-stream`, ignoring any MIME type parameters, must be processed line by line as described below.

When a successful response with a supported MIME type is received, such that the user agent begins parsing the contents of the stream, the user agent must announce the connection.

The task that the networking task source places on the task queue once fetching for such a resource (with the correct MIME type) has completed must cause the user agent to reestablish the connection in parallel. This applies whether the connection is closed gracefully or unexpectedly (but does not apply when fetching is canceled by the user agent, e.g., in response to window.stop(), since in those cases the final task is actually discarded). It doesn't apply for the error conditions listed below except where explicitly specified.

HTTP 200 OK responses that have a Content-Type specifying an unsupported type, or that have no Content-Type at all, must cause the user agent to fail the connection.

Network errors that prevent the connection from being established in the first place (e.g. DNS errors), should cause the user agent to reestablish the connection in parallel, unless the user agent knows that to be futile, in which case the user agent may fail the connection.

Any other HTTP response code not listed here, as well as the cancelation of the fetch algorithm by the user agent (e.g. in response to window.stop() or the user canceling the network connection manually) must cause the user agent to fail the connection.

When a user agent is to announce the connection, the user agent must queue a task which, if the readyState attribute is set to a value other than CLOSED, sets the readyState attribute to OPEN and fires an event named open at the EventSource object.

When a user agent is to reestablish the connection, the user agent must run the following steps. These steps are run in parallel, not as part of a task. (The tasks that it queues, of course, are run like normal tasks and not themselves in parallel.)

1. Queue a task to run the following steps:
   1. If the readyState attribute is set to CLOSED, abort the task.
   2. Set the readyState attribute to CONNECTING.
   3. Fire an event named error at the EventSource object.
2. Wait a delay equal to the reconnection time of the event source.
3. Optionally, wait some more. In particular, if the previous attempt failed, then user agents might introduce an exponential backoff delay to avoid overloading a potentially already overloaded server. Alternatively, if the operating system has reported that there is no network connectivity, user agents might wait for the operating system to announce that the network connection has returned before retrying.
4. Wait until the aforementioned task has run, if it has not yet run.
5. Queue a task to run the following steps:

1. If the EventSource object's readyState attribute is not set to CONNECTING, return.

2. Let request be the EventSource object's request.

3. If the EventSource object's last event ID string is not the empty string, set `Last-Event-ID`/last event ID string, encoded as UTF-8, in request's header list.

4. Fetch request and process the response obtained in this fashion, if any, as described earlier in this section.

When a user agent is to fail the connection, the user agent must queue a task which, if the readyState attribute is set to a value other than CLOSED, sets the readyState attribute to CLOSED and fires an event named error at the EventSource object. Once the user agent has failed the connection, it does not attempt to reconnect!

The task source for any tasks that are queued by EventSource objects is the remote event task source.

9.2.4 Parsing an event stream

This event stream format's MIME type is text/event-stream.

The event stream format is as described by the stream production of the following ABNF, the character set for which is Unicode.

```
stream        = [ bom ] *event
  event        = *( comment / field ) end-of-line
  comment      = colon *any-char end-of-line
  field        = 1*name-char [ colon [ space ] *any-char ] end-of-line
  end-of-line  = ( cr lf / cr / lf )

; characters
lf            = %x000A ; U+000A LINE FEED (LF)
cr            = %x000D ; U+000D CARRIAGE RETURN (CR)
space         = %x0020 ; U+0020 SPACE
colon         = %x003A ; U+003A COLON (:)
bom           = %xFEFF ; U+FEFF BYTE ORDER MARK
name-char     = %x0000-0009 / %x000B-000C / %x000E-10FFFF
  ; a scalar value other than U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR), or U+003A COLON (:)
any-char      = %x0000-0009 / %x000B-000C / %x000E-10FFFF
  ; a scalar value other than U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR)
```

Event streams in this format must always be encoded as UTF-8.

Lines must be separated by either a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character, or a single U+000D CARRIAGE RETURN (CR) character.

Since connections established to remote servers for such resources are expected to be long-lived, UAs should ensure that appropriate buffering is used. In particular, while line buffering with lines are defined to end with a single U+000A LINE FEED (LF) character is safe, block buffering or line buffering with different expected line endings can cause delays in event dispatch.

9.2.5 Interpreting an event stream

Streams must be decoded using the UTF-8 decode algorithm.

**Note**

The UTF-8 decode algorithm strips one leading UTF-8 Byte Order Mark (BOM), if any.

The stream must then be parsed by reading everything line by line, with a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF)
character pair, a single U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, and a single U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character being the ways in which a line can end.

When a stream is parsed, a data buffer, an event type buffer, and a last event ID buffer must be associated with it. They must be initialized to the empty string

Lines must be processed, in the order they are received, as follows:

→ If the line is empty (a blank line)
   Dispatch the event\(^{948}\), as defined below.

→ If the line starts with a U+003A COLON character (:)  
   Ignore the line.

→ If the line contains a U+003A COLON character (:) 
   Collect the characters on the line before the first U+003A COLON character (:) and let field be that string.  
   Collect the characters on the line after the first U+003A COLON character (:) and let value be that string. If value starts with a U+0020 SPACE character, remove it from value.  
   Process the field\(^{948}\) using the steps described below, using field as the field name and value as the field value.

→ Otherwise, the string is not empty but does not contain a U+003A COLON character (:) 
   Process the field\(^{948}\) using the steps described below, using the whole line as the field name, and the empty string as the field value.

Once the end of the file is reached, any pending data must be discarded. (If the file ends in the middle of an event, before the final empty line, the incomplete event is not dispatched.)

The steps to process the field given a field name and a field value depend on the field name, as given in the following list. Field names must be compared literally, with no case folding performed.

→ If the field name is "event"  
   Set the event type buffer to field value.

→ If the field name is "data"  
   Append the field value to the data buffer, then append a single U+000A LINE FEED (LF) character to the data buffer.

→ If the field name is "id"  
   If the field value does not contain U+0000 NULL, then set the last event ID buffer to the field value. Otherwise, ignore the field.

→ If the field name is "retry"  
   If the field value consists of only ASCII digits, then interpret the field value as an integer in base ten, and set the event stream’s reconnection time\(^{944}\) to that integer. Otherwise, ignore the field.

→ Otherwise  
   The field is ignored.

When the user agent is required to dispatch the event, the user agent must process the data buffer, the event type buffer, and the last event ID buffer using steps appropriate for the user agent.

For Web browsers, the appropriate steps to dispatch the event\(^{948}\) are as follows:

1. Set the last event ID string\(^{944}\) of the event source to the value of the last event ID buffer. The buffer does not get reset, so the last event ID string\(^{944}\) of the event source remains set to this value until the next time it is set by the server.
2. If the data buffer is an empty string, set the data buffer and the event type buffer to the empty string and return.
3. If the data buffer’s last character is a U+000A LINE FEED (LF) character, then remove the last character from the data buffer.
4. Let event be the result of creating an event using MessageEvent\(^{942}\), in the relevant Realm\(^{984}\) of the EventSource\(^{944}\) object.
5. Initialize event’s type attribute to \(^{9127}\)message\(^{942}\), its data attribute to data, its origin\(^{942}\) attribute to the serialization\(^{985}\) of the origin of the event stream’s final URL (i.e., the URL after redirects), and its lastEventId attribute to the last event ID
6. If the event type buffer has a value other than the empty string, change the type of the newly created event to equal the value of the event type buffer.

7. Set the data buffer and the event type buffer to the empty string.

8. Queue a task which, if the readyState attribute is set to a value other than CLOSED, dispatches the newly created event at the EventSource object.

**Note**

If an event doesn’t have an "id" field, but an earlier event did set the event source's last event ID string, then the event's lastEventId field will be set to the value of whatever the last seen "id" field was.

For other user agents, the appropriate steps to dispatch the event are implementation dependent, but at a minimum they must set the data and event type buffers to the empty string before returning.

**Example**

The following event stream, once followed by a blank line:

```
data: YHOO
data: +2
data: 10
```

...would cause an event message with the interface MessageEvent to be dispatched on the EventSource object. The event's data attribute would contain the string "YHOO\n+2\n10" (where "\n" represents a newline).

This could be used as follows:

```javascript
var stocks = new EventSource("https://stocks.example.com/ticker.php");
stocks.onmessage = function (event) {
  var data = event.data.split('\n');
  updateStocks(data[0], data[1], data[2]);
};
```

...where updateStocks() is a function defined as:

```javascript
function updateStocks(symbol, delta, value) { ... }
```

...or some such.

**Example**

The following stream contains four blocks. The first block has just a comment, and will fire nothing. The second block has two fields with names "data" and "id" respectively; an event will be fired for this block, with the data "first event", and will then set the last event ID to "1" so that if the connection died between this block and the next, the server would be sent a Last-Event-ID header with the value "1". The third block fires an event with data "second event", and also has an "id" field, this time with no value, which resets the last event ID to the empty string (meaning no Last-Event-ID header will now be sent in the event of a reconnection being attempted). Finally, the last block just fires an event with the data "third event" (with a single leading space character). Note that the last still has to end with a blank line, the end of the stream is not enough to trigger the dispatch of the last event.

```
: test stream

data: first event
id: 1

data: second event
id

data: third event
```
Legacy proxy servers are known to, in certain cases, drop HTTP connections after a short timeout. To protect against such proxy servers, authors can include a comment line (one starting with a `:` character) every 15 seconds or so.

Authors wishing to relate event source connections to each other or to specific documents previously served might find that relying on IP addresses doesn't work, as individual clients can have multiple IP addresses (due to having multiple proxy servers) and individual IP addresses can have multiple clients (due to sharing a proxy server). It is better to include a unique identifier in the document when it is served and then pass that identifier as part of the URL when the connection is established.

Authors are also cautioned that HTTP chunking can have unexpected negative effects on the reliability of this protocol, in particular if the chunking is done by a different layer unaware of the timing requirements. If this is a problem, chunking can be disabled for serving event streams.

Clients that support HTTP's per-server connection limitation might run into trouble when opening multiple pages from a site if each page has an `EventSource` to the same domain. Authors can avoid this using the relatively complex mechanism of using unique domain names per connection, or by allowing the user to enable or disable the `EventSource` functionality on a per-page basis, or by sharing a single `EventSource` object using a `shared worker`.

### 9.2.6 Authoring notes

Legacy proxy servers are known to, in certain cases, drop HTTP connections after a short timeout. To protect against such proxy servers, authors can include a comment line (one starting with a `:` character) every 15 seconds or so.

Authors wishing to relate event source connections to each other or to specific documents previously served might find that relying on IP addresses doesn't work, as individual clients can have multiple IP addresses (due to having multiple proxy servers) and individual IP addresses can have multiple clients (due to sharing a proxy server). It is better to include a unique identifier in the document when it is served and then pass that identifier as part of the URL when the connection is established.

Authors are also cautioned that HTTP chunking can have unexpected negative effects on the reliability of this protocol, in particular if the chunking is done by a different layer unaware of the timing requirements. If this is a problem, chunking can be disabled for serving event streams.

Clients that support HTTP's per-server connection limitation might run into trouble when opening multiple pages from a site if each page has an `EventSource` to the same domain. Authors can avoid this using the relatively complex mechanism of using unique domain names per connection, or by allowing the user to enable or disable the `EventSource` functionality on a per-page basis, or by sharing a single `EventSource` object using a `shared worker`.

### 9.2.7 Connectionless push and other features

User agents running in controlled environments, e.g. browsers on mobile handsets tied to specific carriers, may offload the management of the connection to a proxy on the network. In such a situation, the user agent for the purposes of conformance is considered to include both the handset software and the network proxy.

For example, a browser on a mobile device, after having established a connection, might detect that it is on a supporting network and request that a proxy server on the network take over the management of the connection. The timeline for such a situation might be as follows:

1. Browser connects to a remote HTTP server and requests the resource specified by the author in the `EventSource`.
constructor.

2. The server sends occasional messages.

3. In between two messages, the browser detects that it is idle except for the network activity involved in keeping the TCP connection alive, and decides to switch to sleep mode to save power.

4. The browser disconnects from the server.

5. The browser contacts a service on the network, and requests that the service, a "push proxy", maintain the connection instead.

6. The "push proxy" service contacts the remote HTTP server and requests the resource specified by the author in the EventSource constructor (possibly including a `Last-Event-ID` HTTP header, etc).

7. The browser allows the mobile device to go to sleep.

8. The server sends another message.

9. The "push proxy" service uses a technology such as OMA push to convey the event to the mobile device, which wakes only enough to process the event and then returns to sleep.

This can reduce the total data usage, and can therefore result in considerable power savings.

As well as implementing the existing API and `text/event-stream` wire format as defined by this specification and in more distributed ways as described above, formats of event framing defined by other applicable specifications may be supported. This specification does not define how they are to be parsed or processed.

### 9.2.8 Garbage collection

While an EventSource object's `readyState` is CONNECTING, and the object has one or more event listeners registered for open, message, or error events, there must be a strong reference from the Window or WorkerGlobalScope object that the EventSource object's constructor was invoked from to the EventSource object itself.

While an EventSource object's `readyState` is OPEN, and the object has one or more event listeners registered for message or error events, there must be a strong reference from the Window or WorkerGlobalScope object that the EventSource object's constructor was invoked from to the EventSource object itself.

While there is a task queued by an EventSource object on the remote event task source, there must be a strong reference from the Window or WorkerGlobalScope object that the EventSource object's constructor was invoked from to that EventSource object.

If a user agent is to forcibly close an EventSource object (this happens when a Document object goes away permanently), the user agent must abort any instances of the fetch algorithm started for this EventSource object, and must set the `readyState` attribute to CLOSED.

If an EventSource object is garbage collected while its connection is still open, the user agent must abort any instance of the fetch algorithm opened by this EventSource object.

### 9.2.9 Implementation advice

This section is non-normative.

User agents are strongly urged to provide detailed diagnostic information about EventSource objects and their related network connections in their development consoles, to aid authors in debugging code using this API.

For example, a user agent could have a panel displaying all the EventSource objects a page has created, each listing the constructor's arguments, whether there was a network error, what the CORS status of the connection is and what headers were sent by the client and received from the server to lead to that status, the messages that were received and how they were parsed, and so
Implementations are especially encouraged to report detailed information to their development consoles whenever an error event is fired, since little to no information can be made available in the events themselves.

### 9.3 Web sockets

#### 9.3.1 Introduction

This section is non-normative.

To enable Web applications to maintain bidirectional communications with server-side processes, this specification introduces the WebSocket interface.

**Note**

This interface does not allow for raw access to the underlying network. For example, this interface could not be used to implement an IRC client without proxying messages through a custom server.

#### 9.3.2 The WebSocket interface

```idl
enum BinaryType {
  "blob", "arraybuffer"
};

[Constructor(USVString url, optional (DOMString or sequence<DOMString>) protocols = []),
Exposed=(Window,Worker)]
interface WebSocket : EventTarget {
  readonly attribute USVString url;

  // ready state
  const unsigned short CONNECTING = 0;
  const unsigned short OPEN = 1;
  const unsigned short CLOSING = 2;
  const unsigned short CLOSED = 3;
  readonly attribute unsigned short readyState;
  readonly attribute unsigned long long bufferedAmount;

  // networking
  attribute EventHandler onopen;
  attribute EventHandler onerror;
  attribute EventHandler onclose;
  readonly attribute DOMString extensions;
  readonly attribute DOMString protocol;
  void close(optional [Clamp] unsigned short code, optional USVString reason);

  // messaging
  attribute EventHandler onmessage;
  attribute BinaryType binaryType;
  void send(USVString data);
  void send(Blob data);
  void send(ArrayBuffer data);
  void send(ArrayBufferView data);
};
```

Each WebSocket object has an associated url (a URL record).

**For web developers (non-normative)**
The WebSocket constructor, when invoked, must run these steps:

1. Let `urlRecord` be the result of applying the URL parser to `url`.
2. If `urlRecord` is failure, then throw a "SyntaxError" DOMException.
3. If `urlRecord`'s `scheme` is not "ws" or "wss", then throw a "SyntaxError" DOMException.
4. If `urlRecord`'s `fragment` is non-null, then throw a "SyntaxError" DOMException.
5. If `protocols` is a string, set `protocols` to a sequence consisting of just that string.
6. If any of the values in `protocols` occur more than once or otherwise fail to match the requirements for elements that
comprise the value of Sec-WebSocket-Protocol fields as defined by the WebSocket protocol specification, then throw a "SyntaxError" DOMException. [WSP]

7. Run this step in parallel:
   1. Establish a WebSocket connection given urlRecord, protocols, and the entry settings object. [FETCH]

   **Note**: If the establish a WebSocket connection algorithm fails, it triggers the fail the WebSocket connection algorithm, which then invokes the close the WebSocket connection algorithm, which then establishes that the WebSocket connection is closed, which fires the close event as described below.

8. Return a new WebSocket object whose url is urlRecord.

The `url` attribute’s getter must return this WebSocket object's serialized.

The `readyState` attribute represents the state of the connection. It can have the following values:

- **CONNECTING** (numeric value 0)
  The connection has not yet been established.

- **OPEN** (numeric value 1)
  The WebSocket connection is established and communication is possible.

- **CLOSING** (numeric value 2)
  The connection is going through the closing handshake, or the close method has been invoked.

- **CLOSED** (numeric value 3)
  The connection has been closed or could not be opened.

When the object is created its `readyState` must be set to `CONNECTING (0)`.

The `extensions` attribute must initially return the empty string. After the WebSocket connection is established, its value might change, as defined below.

The `protocol` attribute must initially return the empty string. After the WebSocket connection is established, its value might change, as defined below.

The `close(code, reason)` method, when invoked, must run these steps:

1. If `code` is present, but is neither an integer equal to 1000 nor an integer in the range 3000 to 4999, inclusive, throw an "InvalidAccessError" DOMException.
2. If `reason` is present, then run these substeps:
   1. Let `reasonBytes` be the result of encoding `reason`.
   2. If `reasonBytes` is longer than 123 bytes, then throw a "SyntaxError" DOMException.
3. Run the first matching steps from the following list:

   - If the `readyState` attribute is in the CLOSING (2) or CLOSED (3) state
     Do nothing.

   **Note**: The connection is already closing or is already closed. If it has not already, a close event will eventually fire as described below.

   - If the WebSocket connection is not yet established and set the `readyState` attribute's value to CLOSING (2). [WSP]

   **Note**: The fail the WebSocket connection algorithm invokes the close the WebSocket connection algorithm, which then establishes that the WebSocket connection is closed, which fires the close event as described below.
If the WebSocket closing handshake has not yet been started and set the readyState attribute's value to CLOSING (2).

If neither code nor reason is present, the WebSocket Close message must not have a body.

If code is present, then the status code to use in the WebSocket Close message must be the integer given by close.

If reason is also present, then reasonBytes must be provided in the Close message after the status code.

Otherwise

Set the readyState attribute's value to CLOSING (2).

The bufferedAmount attribute must return the number of bytes of application data (UTF-8 text and binary data) that have been queued using send() but that, as of the last time the event loop reached step 1, had not yet been transmitted to the network. (This thus includes any text sent during the execution of the current task, regardless of whether the user agent is able to transmit text in the background in parallel with script execution.) This does not include framing overhead incurred by the protocol, or buffering done by the operating system or network hardware.

The bufferedAmount attribute can also be used to saturate the network without sending the data at a higher rate than the network can handle, though this requires more careful monitoring of the value of the attribute over time.
The `send(data)` method transmits data using the connection. If the `readyState` attribute is `CONNECTING`, it must throw an "InvalidStateError" DOMException. Otherwise, the user agent must run the appropriate set of steps from the following list:

1. **If the argument is a string**
   - If the WebSocket connection is established and the WebSocket closing handshake has not yet started, then the user agent must send a WebSocket Message comprised of the data argument using a text frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full and then close the WebSocket connection. Any invocation of this method with a string argument that does not throw an exception must increase the `bufferedAmount` attribute by the number of bytes needed to express the argument as UTF-8. [UNICODE] [ENCODING] [WSP]

2. **If the argument is a Blob object**
   - If the WebSocket connection is established and the WebSocket closing handshake has not yet started, then the user agent must send a WebSocket Message comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full and then close the WebSocket connection. The data to be sent is the raw data represented by the Blob object. Any invocation of this method with a Blob argument that does not throw an exception must increase the `bufferedAmount` attribute by the size of the Blob object's raw data, in bytes. [WSP] [FILEAPI]

3. **If the argument is an ArrayBuffer object**
   - If the WebSocket connection is established and the WebSocket closing handshake has not yet started, then the user agent must send a WebSocket Message comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full and then close the WebSocket connection. The data to be sent is the data stored in the buffer described by the ArrayBuffer object. Any invocation of this method with an ArrayBuffer argument that does not throw an exception must increase the `bufferedAmount` attribute by the length of the ArrayBuffer in bytes. [WSP]

4. **If the argument is an object that matches the ArrayBufferView type definition**
   - If the WebSocket connection is established and the WebSocket closing handshake has not yet started, then the user agent must send a WebSocket Message comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full and then close the WebSocket connection. The data to be sent is the data stored in the section of the buffer described by the ArrayBuffer object that data references. Any invocation of this method with this kind of argument that does not throw an exception must increase the `bufferedAmount` attribute by the length of data's buffer in bytes. [WSP]

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the WebSocket interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>open</td>
<td>open</td>
</tr>
<tr>
<td>message</td>
<td>message</td>
</tr>
<tr>
<td>error</td>
<td>error</td>
</tr>
<tr>
<td>close</td>
<td>close</td>
</tr>
</tbody>
</table>

9.3.3 Feedback from the protocol

When the WebSocket connection is established, the user agent must queue a task to run these steps:

1. Change the `readyState` attribute's value to `OPEN` (1).
2. Change the `extensions` attribute's value to the `extensions in use`, if it is not the null value. [WSP]
3. Change the protocol\textsuperscript{954} attribute's value to the subprotocol in use\textsuperscript{960}, if it is not the null value. \textsuperscript{[WSP]\textsuperscript{1228}}

4. Fire an event named open\textsuperscript{1217} at the WebSocket\textsuperscript{952} object.

**Note**

Since the algorithm above is queued as a task\textsuperscript{983}, there is no race condition between the WebSocket connection being established\textsuperscript{966} and the script setting up an event listener for the open\textsuperscript{1217} event.

When a WebSocket message has been received\textsuperscript{960} with type type and data data, the user agent must queue a task\textsuperscript{983} to follow these steps: \textsuperscript{[WSP]\textsuperscript{1228}}

1. If the readyState\textsuperscript{954} attribute's value is not OPEN\textsuperscript{954} (1), then return.

2. Let dataForEvent be determined by switching on type and binaryType\textsuperscript{955}:

   ↩ type indicates that the data is Text
   a new DOMString containing data

   ↩ type indicates that the data is Binary and binaryType\textsuperscript{955} is "blob"
   a new Blob object, created in the relevant Realm\textsuperscript{984} of the WebSocket\textsuperscript{952} object, that represents data as its raw data \textsuperscript{[FILEAPI]\textsuperscript{1223}}

   ↩ type indicates that the data is Binary and binaryType\textsuperscript{955} is "arraybuffer"
   a new ArrayBuffer object, created in the relevant Realm\textsuperscript{984} of the WebSocket\textsuperscript{952} object, whose contents are data

3. Fire an event named message\textsuperscript{1217} at the WebSocket\textsuperscript{952} object, using MessageEvent\textsuperscript{942}, with the origin\textsuperscript{942} attribute initialized to the serialization\textsuperscript{985} of the WebSocket\textsuperscript{952} object's url\textsuperscript{952}'s origin, and the data\textsuperscript{942} attribute initialized to dataForEvent.

**Note**

User agents are encouraged to check if they can perform the above steps efficiently before they run the task, picking tasks from other task queues\textsuperscript{989} while they prepare the buffers if not. For example, if the binaryType\textsuperscript{955} attribute was set to "blob\textsuperscript{957}" when the data arrived, and the user agent spooled all the data to disk, but just before running the above task\textsuperscript{983} for this particular message the script switched binaryType\textsuperscript{955} to "arraybuffer\textsuperscript{957}", the user agent would want to page the data back to RAM before running this task\textsuperscript{983} so as to avoid stalling the main thread while it created the ArrayBuffer object.

**Example**

Here is an example of how to define a handler for the message\textsuperscript{1217} event in the case of text frames:

```javascript
mysocket.onmessage = function (event) {
  if (event.data == 'on') {
    turnLampOn();
  } else if (event.data == 'off') {
    turnLampOff();
  }
};
```

The protocol here is a trivial one, with the server just sending "on" or "off" messages.

When the WebSocket closing handshake is started\textsuperscript{966}, the user agent must queue a task\textsuperscript{983} to change the readyState\textsuperscript{954} attribute's value to CLOSING\textsuperscript{954} (2). (If the close()\textsuperscript{954} method was called, the readyState\textsuperscript{954} attribute's value will already be set to CLOSING\textsuperscript{954} (2) when this task runs.) \textsuperscript{[WSP]\textsuperscript{1228}}

When the WebSocket connection is closed\textsuperscript{960}, possibly cleanly, the user agent must queue a task\textsuperscript{983} to run the following substeps:

1. Change the readyState\textsuperscript{954} attribute's value to CLOSED\textsuperscript{954} (3).

2. If the user agent was required to fail the WebSocket connection\textsuperscript{960}, or if the the WebSocket connection was closed\textsuperscript{960} after
being flagged as full, fire an event named error at the WebSocket object. [WSP]

3. **Fire an event** named close at the WebSocket object, using CloseEvent, with the wasClean attribute initialized to true if the connection closed cleanly and false otherwise, the code attribute initialized to the WebSocket connection close code, and the reason attribute initialized to the result of applying UTF-8 decode without BOM to the WebSocket connection close reason. [WSP]

⚠ **Warning!**

User agents must not convey any failure information to scripts in a way that would allow a script to distinguish the following situations:

- A server whose host name could not be resolved.
- A server to which packets could not successfully be routed.
- A server that refused the connection on the specified port.
- A server that failed to correctly perform a TLS handshake (e.g., the server certificate can't be verified).
- A server that did not complete the opening handshake (e.g. because it was not a WebSocket server).
- A WebSocket server that sent a correct opening handshake, but that specified options that caused the client to drop the connection (e.g. the server specified a subprotocol that the client did not offer).
- A WebSocket server that abruptly closed the connection after successfully completing the opening handshake.

In all of these cases, the the WebSocket connection close code would be 1006, as required by the WebSocket Protocol specification. [WSP]

Allowing a script to distinguish these cases would allow a script to probe the user's local network in preparation for an attack.

⚠ **Note**

In particular, this means the code 1015 is not used by the user agent (unless the server erroneously uses it in its close frame, of course).

The task source for all tasks queued in this section is the WebSocket task source.

### 9.3.4 Ping and Pong frames

The WebSocket protocol specification defines Ping and Pong frames that can be used for keep-alive, heart-beats, network status probing, latency instrumentation, and so forth. These are not currently exposed in the API.

User agents may send ping and unsolicited pong frames as desired, for example in an attempt to maintain local network NAT mappings, to detect failed connections, or to display latency metrics to the user. User agents must not use pings or unsolicited pongs to aid the server; it is assumed that servers will solicit pongs whenever appropriate for the server’s needs.

### 9.3.5 The CloseEvent interface

WebSocket objects use the CloseEvent interface for their close events:

```idl
[Constructor(DOMString type, optional CloseEventInit eventInitDict), Exposed=(Window,Worker)]

interface CloseEvent : Event {
    readonly attribute boolean wasClean;
    readonly attribute unsigned short code;
    readonly attribute USVString reason;
};

dictionary CloseEventInit : EventInit {
    boolean wasClean = false;
}
```
unsigned short code = 0;
USVString reason = "";
};

For web developers (non-normative)

event.
wasClean
Returns true if the connection closed cleanly; false otherwise.

event.
code
Returns the WebSocket connection close code provided by the server.

event.
reason
Returns the WebSocket connection close reason provided by the server.

The wasClean attribute must return the value it was initialized to. It represents whether the connection closed cleanly or not.

The code attribute must return the value it was initialized to. It represents the WebSocket connection close code provided by the server.

The reason attribute must return the value it was initialized to. It represents the WebSocket connection close reason provided by the server.

9.3.6 Garbage collection
A WebSocket object whose readyState attribute's value was set to CONNECTING (0) as of the last time the event loop reached step 1 must not be garbage collected if there are any event listeners registered for open events, message events, error events, or close events.

A WebSocket object whose readyState attribute's value was set to OPEN (1) as of the last time the event loop reached step 1 must not be garbage collected if there are any event listeners registered for message events, error events, or close events.

A WebSocket object whose readyState attribute's value was set to CLOSING (2) as of the last time the event loop reached step 1 must not be garbage collected if there are any event listeners registered for error or close events.

A WebSocket object with an established connection that has data queued to be transmitted to the network must not be garbage collected.

If a WebSocket object is garbage collected while its connection is still open, the user agent must start the WebSocket closing handshake, with no status code for the Close message.

If a user agent is to make disappear a WebSocket object (this happens when a Document object goes away), the user agent must follow the first appropriate set of steps from the following list:

- If the WebSocket connection is not yet established
  Fail the WebSocket connection.  
- If the WebSocket closing handshake has not yet been started
  Start the WebSocket closing handshake, with the status code to use in the WebSocket Close message being 1001.
- Otherwise
  Do nothing.

For web developers (non-normative)
9.4 Cross-document messaging

Web browsers, for security and privacy reasons, prevent documents in different domains from affecting each other; that is, cross-site scripting is disallowed.

While this is an important security feature, it prevents pages from different domains from communicating even when those pages are not hostile. This section introduces a messaging system that allows documents to communicate with each other regardless of their source domain, in a way designed to not enable cross-site scripting attacks.

The task source for the tasks in cross-document messaging is the posted message task source.

9.4.1 Introduction

This section is non-normative.

For example, if document A contains an iframe element that contains document B, and script in document A calls `postMessage()` on the `Window` object of document B, then a message event will be fired on that object, marked as originating from the `Window` of document A. The script in document A might look like:

```javascript
var o = document.getElementsByTagName('iframe')[0];
o.contentWindow.postMessage('Hello world', 'https://b.example.org/');
```

To register an event handler for incoming events, the script would use `addEventListener()` (or similar mechanisms). For example, the script in document B might look like:

```javascript
window.addEventListener('message', receiver, false);
function receiver(e) {
  if (e.origin == 'https://example.com') {
    if (e.data == 'Hello world') {
      e.source.postMessage('Hello', e.origin);
    } else {
      alert(e.data);
    }
  }
}
```

This script first checks the domain is the expected domain, and then looks at the message, which it either displays to the user, or responds to by sending a message back to the document which sent the message in the first place.

9.4.2 Security

9.4.2.1 Authors

⚠Warning!

Use of this API requires extra care to protect users from hostile entities abusing a site for their own purposes.

Authors should check the `origin` attribute to ensure that messages are only accepted from domains that they expect to receive messages from. Otherwise, bugs in the author's message handling code could be exploited by hostile sites.

Furthermore, even after checking the `origin` attribute, authors should also check that the data in question is of the expected format. Otherwise, if the source of the event has been attacked using a cross-site scripting flaw, further unchecked processing of
information sent using the `postMessage()` method could result in the attack being propagated into the receiver.

Authors should not use the wildcard keyword (*) in the `targetOrigin` argument in messages that contain any confidential information, as otherwise there is no way to guarantee that the message is only delivered to the recipient to which it was intended.

Authors who accept messages from any origin are encouraged to consider the risks of a denial-of-service attack. An attacker could send a high volume of messages; if the receiving page performs expensive computation or causes network traffic to be sent for each such message, the attacker's message could be multiplied into a denial-of-service attack. Authors are encouraged to employ rate limiting (only accepting a certain number of messages per minute) to make such attacks impractical.

### 9.4.2.2 User agents

The integrity of this API is based on the inability for scripts of one origin to post arbitrary events (using `dispatchEvent()` or otherwise) to objects in other origins (those that are not the same origin).

Implementors are urged to take extra care in the implementation of this feature. It allows authors to transmit information from one domain to another domain, which is normally disallowed for security reasons. It also requires that UAs be careful to allow access to certain properties but not others.

User agents are also encouraged to consider rate-limiting message traffic between different origins, to protect naïve sites from denial-of-service attacks.

### 9.4.3 Posting messages

For web developers (non-normative)

```javascript
window.postMessage(message, targetOrigin [, transfer ] )
```

Posts a message to the given window. Messages can be structured objects, e.g. nested objects and arrays, can contain JavaScript values (strings, numbers, `Date` objects, etc), and can contain certain data objects such as `File Blob`, `FileList`, and `ArrayBuffer` objects.

Objects listed in `transfer` are transferred, not just cloned, meaning that they are no longer usable on the sending side.

If the origin of the target window doesn't match the given origin, the message is discarded, to avoid information leakage. To send the message to the target regardless of origin, set the target origin to "*". To restrict the message to same-origin targets only, without needing to explicitly state the origin, set the target origin to "/".

Throws a `DataCloneError` DOMException if `transfer` array contains duplicate objects or if message could not be cloned.

For web developers (non-normative)

- **Note**
  - When posting a message to a `Window` of a browsing `context` that has just been navigated to a new `Document` is likely to result in the message not receiving its intended recipient: the scripts in the target `browsing context` have to have had time to set up listeners for the messages. Thus, for instance, in situations where a message is to be sent to the `Window` of newly created child `iframe`, authors are advised to have the child `Document` post a message to their parent announcing their readiness to receive messages, and for the parent to wait for this message before beginning posting messages.

The `postMessage(message, targetOrigin, transfer)` method, when invoked on a `Window` object must run the following steps:

1. Let `targetWindow` be this `Window` object.
2. Let `targetRealm` be `targetWindow`'s `Realm`.
3. Let `incumbentSettings` be the `incumbent settings object`.
4. If `targetOrigin` is a single U+002F SOLIDUS character (/), then set `targetOrigin` to `incumbentSettings`'s `origin`.
5. Otherwise, if `targetOrigin` is not a single U+002A ASTERISK character (*), then:
1. Let parsedURL be the result of running the URL parser on targetOrigin.

2. If parsedURL is failure, then throw a "SyntaxError" DOMException.

3. Set targetOrigin to parsedURL's origin.

6. Let serializeWithTransferResult be StructuredSerializeWithTransfer(message, transfer). Rethrow any exceptions.

7. Queue a task on the posted message task source to run the following steps:

   1. If the targetOrigin argument is not a single literal U+002A ASTERISK character (*) and targetWindow's associated Document's origin is not same origin, with targetOrigin, then return.

   2. Let origin be the serialization of incumbentSettings's origin.

   3. Let source be the WindowProxy object's corresponding to incumbentSettings's global object (a Window object).

   4. Let deserializeRecord be StructuredDeserializeWithTransfer(serializeWithTransferResult, targetRealm).

      If this throws an exception, catch it, fire an event named messageerror at targetWindow, using MessageEvent, with the origin attribute initialized to origin and the source attribute initialized to source, and then return.

   5. Let messageClone be deserializeRecord.\[
   \text{This section is non-normative.}\n   \]

5. Channel messaging

9.5.1 Introduction

This section is non-normative.

To enable independent pieces of code (e.g. running in different browsing contexts) to communicate directly, authors can use channel messaging.

Communication channels in this mechanism are implemented as two-ways pipes, with a port at each end. Messages sent in one port are delivered at the other port, and vice-versa. Messages are delivered as DOM events, without interrupting or blocking running tasks.

To create a connection (two "entangled" ports), the MessageChannel() constructor is called:

```javascript
var channel = new MessageChannel();
```

One of the ports is kept as the local port, and the other port is sent to the remote code, e.g. using postMessage:

```javascript
otherWindow.postMessage('hello', 'https://example.com', [channel.port2]);
```

To send messages, the postMessage method on the port is used:

```javascript
channel.port1.postMessage('hello');
```

To receive messages, one listens to message events:

```javascript
channel.port1.onmessage = handleMessage;
function handleMessage(event) {
```
Data sent on a port can be structured data; for example here an array of strings is passed on a MessagePort:

```javascript
port1.postMessage(['hello', 'world']);
```

This section is non-normative.

**9.5.1.1 Examples**

In this example, two JavaScript libraries are connected to each other using MessagePorts. This allows the libraries to later be hosted in different frames, or in Worker objects, without any change to the APIs.

```html
<script src="contacts.js"></script> <!-- exposes a contacts object -->
<script src="compose-mail.js"></script> <!-- exposes a composer object -->
<script>
  var channel = new MessageChannel();
  composer.addContactsProvider(channel.port1);
  contacts.registerConsumer(channel.port2);
</script>
```

Here's what the "addContactsProvider()" function's implementation could look like:

```javascript
function addContactsProvider(port) {
  port.onmessage = function (event) {
    switch (event.data.messageType) {
      case 'search-result': handleSearchResult(event.data.results); break;
      case 'search-done': handleSearchDone(); break;
      case 'search-error': handleSearchError(event.data.message); break;
      // ...
    }
  };
}
```

Alternatively, it could be implemented as follows:

```javascript
function addContactsProvider(port) {
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-result')
      handleSearchResult(event.data.results);
  });
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-done')
      handleSearchDone();
  });
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-error')
      handleSearchError(event.data.message);
  });
  // ...
  port.start();
}
```

The key difference is that when using addEventListener(), the `start()` method must also be invoked. When using
Ports can be viewed as a way to expose limited capabilities (in the object-capability model sense) to other actors in the system. This can either be a weak capability system, where the ports are merely used as a convenient model within a particular origin, or as a strong capability model, where they are provided by one origin provider as the only mechanism by which another origin consumer can effect change in or obtain information from provider.

For example, consider a situation in which a social Web site embeds in one iframe the user's e-mail contacts provider (an address book site, from a second origin), and in a second iframe a game (from a third origin). The outer social site and the game in the second iframe cannot access anything inside the first iframe; together they can only:

- Navigate the iframe to a new URL, such as the same URL but with a different fragment, causing the Window to receive a hashchange event.
- Resize the iframe, causing the Window in the iframe to receive a resize event.
- Send a message event to the Window in the iframe using the window.postMessage API.

The contacts provider can use these methods, most particularly the third one, to provide an API that can be accessed by other origins to manipulate the user's address book. For example, it could respond to a message "add-contact Guillaume Tell <tell@pomme.example.net>" by adding the given person and e-mail address to the user's address book.

To avoid any site on the Web being able to manipulate the user's contacts, the contacts provider might only allow certain trusted sites, such as the social site, to do this.

Now suppose the game wanted to add a contact to the user's address book, and that the social site was willing to allow it to do so on its behalf, essentially "sharing" the trust that the contacts provider had with the social site. There are several ways it could do this; most simply, it could just proxy messages between the game site and the contacts site. However, this solution has a number of difficulties: it requires the social site to either completely trust the game site not to abuse the privilege, or it requires that the social site verify each request to make sure it's not a request that it doesn't want to allow (such as adding multiple contacts, reading the contacts, or deleting them); it also requires some additional complexity if there's ever the possibility of multiple games simultaneously trying to interact with the contacts provider.

Using message channels and MessagePort objects, however, all of these problems can go away. When the game tells the social site that it wants to add a contact, the social site can ask the contacts provider not for it to add a contact, but for the capability to add a single contact. The contacts provider then creates a pair of MessagePort objects, and sends one of them back to the social site, who forwards it on to the game. The game and the contacts provider then have a direct connection, and the contacts provider knows to only honor a single "add contact" request, nothing else. In other words, the game has been granted the capability to add a single contact.

9.5.1.3 Ports as the basis of abstracting out service implementations

This section is non-normative.

Continuing the example from the previous section, consider the contacts provider in particular. While an initial implementation might have simply used XMLHttpRequest objects in the service’s iframe, an evolution of the service might instead want to use a shared worker with a single WebSocket connection.

If the initial design used MessagePort objects to grant capabilities, or even just to allow multiple simultaneous independent sessions, the service implementation can switch from the XMLHttpRequests-in-each-iframe model to the shared-WebSocket model without changing the API at all: the ports on the service provider side can all be forwarded to the shared worker without it affecting the users of the API in the slightest.
9.5.2 Message channels

IDL
```
[Constructor, Exposed=(Window, Worker)]
interface MessageChannel {
  readonly attribute MessagePort port1;
  readonly attribute MessagePort port2;
};
```

For web developers (non-normative)
```
channel = new MessageChannel();
```

Returns a new MessageChannel object with two new MessagePort objects.
```
channel.port1
```

Returns the first MessagePort object.
```
channel.port2
```

Returns the second MessagePort object.

When the MessageChannel() constructor is called, it must run the following algorithm:

1. Create a new MessagePort object whose owner is the incumbent settings object, and let port1 be that object.
2. Create a new MessagePort object whose owner is the incumbent settings object, and let port2 be that object.
3. Entangle the port1 and port2 objects.
4. Instantiate a new MessageChannel object, and let channel be that object.
5. Let the port1 attribute of the channel object be port1.
6. Let the port2 attribute of the channel object be port2.
7. Return channel.

The port1 and port2 attributes must return the values they were assigned when the MessageChannel object was created.

9.5.3 Message ports

Each channel has two message ports. Data sent through one port is received by the other port, and vice versa.

IDL
```
[Exposed=(Window, Worker, AudioWorklet), Transferable]
interface MessagePort : EventTarget {
  void postMessage(any message, optional sequence<object> transfer = []);
  void start();
  void close();

  // event handlers
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};
```

For web developers (non-normative)
```
port.postMessage(message [, transfer])
```

Posts a message through the channel. Objects listed in transfer are transferred, not just cloned, meaning that they are no longer usable on the sending side.

Throws a "DataCloneError" DOMException if transfer contains duplicate objects or port, or if message could not be cloned.
Each MessagePort object can be entangled with another (a symmetric relationship). Each MessagePort object also has a task source called the port message queue, initially empty. A port message queue can be enabled or disabled, and is initially disabled. Once enabled, a port can never be disabled again (though messages in the queue can get moved to another queue or removed altogether, which has much the same effect). A MessagePort also has a has been shipped flag, which must initially be false, and an owner, which is a settings object set when the object is created, as described below.

When a port's port message queue is enabled, the event loop must use it as one of its task sources. When a port's owner specifies a responsible event loop that is a browsing context event loop, all tasks queued on its port message queue must be associated with the responsible document specified by the port's owner.

Each MessagePort's has been shipped flag is set to true when a port, its twin, or the object it was cloned from, is or has been transferred. When a MessagePort's has been shipped flag is true, its port message queue acts as a first-class task source, unaffected to any unshipped port message queue.

When the user agent is to create a new MessagePort object with a particular environment settings object as its owner, it must instantiate a new MessagePort object, and let its owner be owner.

When the user agent is to entangle two MessagePort objects, it must run the following steps:

1. If one of the ports is already entangled, then disentangle it and the port that it was entangled with.

2. Associate the two ports to be entangled, so that they form the two parts of a new channel. (There is no MessageChannel object that represents this channel.)

Two ports A and B that have gone through this step are now said to be entangled; one is entangled to the other, and vice versa.

Note: While this specification describes this process as instantaneous, implementations are more likely to implement it via message passing. As with all algorithms, the key is "merely" that the end result be indistinguishable, in a black-box sense, from the specification.

MessagePort objects are transferable objects. Their transfer steps, given value and dataHolder, are:
1. Set value's has been shipped flag to true.
2. Set dataHolder.[PortMessageQueue] to value's port message queue.
3. If value is entangled with another port remotePort, then:
   1. Set remotePort's has been shipped flag to true.
   2. Set dataHolder.[RemotePort] to remotePort.
4. Otherwise, set dataHolder.[RemotePort] to null.

Their transfer-receiving steps, given dataHolder and value, are:

1. Set value's has been shipped flag to true.
2. Set value's owner to value's relevant settings object.
3. Move all the tasks that are to fire message events in dataHolder.[PortMessageQueue] to the port message queue of value, if any, leaving value's port message queue in its initial disabled state, and, if value's owner specifies a responsible event loop that is a browsing context event loop, associating the moved tasks with the responsible document specified by value's owner.
4. If dataHolder.[RemotePort] is not null, then entangle dataHolder.[RemotePort] and value. (This will disentangle dataHolder.[RemotePort] from the original port that was transferred.)

The postMessage(message, transfer) method, when invoked on a MessagePort object, must run the following steps:

1. Let targetPort be the port with which this MessagePort is entangled, if any; otherwise let it be null.
2. If transfer contains this MessagePort, then throw a "DataCloneError" DOMException.
3. Let doomed be false.
4. If targetPort is not null and transfer contains targetPort, then set doomed to true and optionally report to a developer console that the target port was posted to itself, causing the communication channel to be lost.
5. Let serializeWithTransferResult be StructuredSerializeWithTransfer(message, transfer). Rethrow any exceptions.
6. If targetPort is null, or if doomed is true, then return.
7. Add a task that runs the following steps to the port message queue of targetPort:
   1. Let finalTargetPort be the MessagePort in whose port message queue the task now finds itself.
   2. Let targetRealm be finalTargetPort's relevant Realm.
   3. Let deserializeRecord be StructuredDeserializeWithTransfer(serializeWithTransferResult, targetRealm).
      If this throws an exception, catch it, fire an event named messageerror at finalTargetPort, using MessageEvent, and then return.
   4. Let messageClone be deserializeRecord.[Deserialized].
   5. Let newPorts be a new frozen array consisting of all MessagePort objects in deserializeRecord.[TransferredValues], if any, maintaining their relative order.
   6. Fire an event named message at finalTargetPort, using MessageEvent, with the data attribute initialized to messageClone and the ports attribute initialized to newPorts.

The start() method, when invoked, must enable this MessagePort object's port message queue, if it is not already enabled.
The `close()` method, when invoked, must run these steps:

1. Set this `MessagePort` object’s `[[Detached]]` internal slot value to true.
2. If this `MessagePort` object is entangled, disentangle it.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the `MessagePort` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>onmessage</code></td>
<td><code>message</code></td>
</tr>
<tr>
<td><code>onmessageerror</code></td>
<td><code>messageerror</code></td>
</tr>
</tbody>
</table>

The first time a `MessagePort` object’s `onmessage` IDL attribute is set, the port’s `port message queue` must be enabled, as if the `start()` method had been called.

### 9.5.4 Broadcasting to many ports

This section is non-normative.

Broadcasting to many ports is in principle relatively simple: keep an array of `MessagePort` objects to send messages to, and iterate through the array to send a message. However, this has one rather unfortunate effect: it prevents the ports from being garbage collected, even if the other side has gone away. To avoid this problem, implement a simple protocol whereby the other side acknowledges it still exists. If it doesn’t do so after a certain amount of time, assume it’s gone, close the `MessagePort` object, and let it be garbage collected.

### 9.5.5 Ports and garbage collection

When a `MessagePort` object `o` is entangled, user agents must either act as if `o`’s entangled `MessagePort` object has a strong reference to `o`, or as if the global object specified by `o`’s `owner` has a strong reference to `o`.

**Note**

Thus, a message port can be received, given an event listener, and then forgotten, and so long as that event listener could receive a message, the channel will be maintained.

Of course, if this was to occur on both sides of the channel, then both ports could be garbage collected, since they would not be reachable from live code, despite having a strong reference to each other.

Furthermore, a `MessagePort` object must not be garbage collected while there exists an event referenced by a `task` in a `task queue` that is to be dispatched on that `MessagePort` object, or while the `MessagePort` object’s `port message queue` is enabled and not empty.

**Note**

Authors are strongly encouraged to explicitly close `MessagePort` objects to disentangle them, so that their resources can be recollected. Creating many `MessagePort` objects and discarding them without closing them can lead to high transient memory usage since garbage collection is not necessarily performed promptly, especially for `MessagePort`s where garbage collection can involve cross-process coordination.

### 9.6 Broadcasting to other browsing contexts

Pages on a single `origin` opened by the same user in the same user agent but in different unrelated `browsing contexts` sometimes need to send notifications to each other, for example “hey, the user logged in over here, check your credentials again”.
For elaborate cases, e.g. to manage locking of shared state, to manage synchronization of resources between a server and multiple local clients, to share a WebSocket connection with a remote host, and so forth, shared workers are the most appropriate solution.

For simple cases, though, where a shared worker would be an unreasonable overhead, authors can use the simple channel-based broadcast mechanism described in this section.

```
IDL [Constructor(DOMString name), Exposed=(Window,Worker)]
interface BroadcastChannel : EventTarget {
  readonly attribute DOMString name;
  void postMessage(any message);
  void close();
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};
```

For web developers (non-normative)

```
broadcastChannel = new BroadcastChannel(name)
Returns a new BroadcastChannel object via which messages for the given channel name can be sent and received.

broadcastChannel . name
Returns the channel name (as passed to the constructor).

broadcastChannel . postMessage(message)
Sends the given message to other BroadcastChannel objects set up for this channel. Messages can be structured objects, e.g. nested objects and arrays.

broadcastChannel . close()
Closes the BroadcastChannel object, opening it up to garbage collection.
```

A BroadcastChannel object has a channel name, a BroadcastChannel settings object, and a closed flag.

The BroadcastChannel() constructor, when invoked, must create and return a BroadcastChannel object whose channel name is the constructor's first argument, whose BroadcastChannel settings object is the incumbent settings object, and whose closed flag is false.

The name attribute must return the channel name.

The postMessage(message) method, when invoked on a BroadcastChannel object, must run the following steps:

1. Let source be this BroadcastChannel.
2. Let sourceSettings be source's BroadcastChannel settings object.
3. If source's closed flag is true, then throw an "InvalidStateError" DOMException.
4. Let sourceChannel be source's channel name.
5. Let targetRealm be a user-agent defined Realm.
7. Let destinations be a list of BroadcastChannel objects that match the following criteria:
   - Their BroadcastChannel settings object specifies either:
     - a global object that is a Window object and a responsible document that is fully active, or
     - a global object that is a WorkerGlobalScope object whose closing flag is false and whose worker is not a suspendable worker.
   - Their BroadcastChannel settings object's origin is same origin with sourceSettings's origin.

969
- Their **channel name** is a case-sensitive match for `sourceChannel`.
- Their **closed flag** is false.

8. Remove **source** from **destinations**.

9. Sort **destinations** such that all `BroadcastChannel` objects whose `BroadcastChannel settings object` specify the same **responsible event loop** are sorted in creation order, oldest first. (This does not define a complete ordering. Within this constraint, user agents may sort the list in any user-agent defined manner.)

10. For each `BroadcastChannel` object **destination** in **destinations**, queue a task that runs the following steps:

   1. Let `targetRealm` be **destination**'s **relevant Realm**.
   2. Let `data` be `StructuredDeserialize(serialized, targetRealm)`.

      If this throws an exception, catch it, fire an event named `messageerror` at `destination`, using `MessageEvent`, with the `origin` attribute initialized to the `serialization` of `sourceSettings`'s `origin`, and then return.

   3. Fire an event named `message` at `destination`, using `MessageEvent`, with the `data` attribute initialized to `data` and the `origin` attribute initialized to the `serialization` of `sourceSettings`'s `origin`.

   The tasks must use the DOM manipulation task source, and, for those where the event loop specified by the target `BroadcastChannel` object's `BroadcastChannel settings object` is a **browsing context** event loop, must be associated with the **responsible document** specified by that target `BroadcastChannel` object's `BroadcastChannel settings object`.

While a `BroadcastChannel` object whose **closed flag** is false has an event listener registered for `message` events, there must be a strong reference from the **global object** specified by the `BroadcastChannel` object's `BroadcastChannel settings object` to the `BroadcastChannel` object itself.

The `close()` method must set the **closed flag** of the `BroadcastChannel` object on which it was invoked to true.

**Note**

Authors are strongly encouraged to explicitly close `BroadcastChannel` objects when they are no longer needed, so that they can be garbage collected. Creating many `BroadcastChannel` objects and discarding them while leaving them with an event listener and without closing them can lead to an apparent memory leak, since the objects will continue to live for as long as they have an event listener (or until their page or worker is closed).

The following are the **event handlers** (and their corresponding **event handler event types**) that must be supported, as **event handler IDL attributes**, by all objects implementing the `BroadcastChannel` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onmessage</td>
<td>message</td>
</tr>
<tr>
<td>onmessageerror</td>
<td>messageerror</td>
</tr>
</tbody>
</table>

**Example**

Suppose a page wants to know when the user logs out, even when the user does so from another tab at the same site:

```javascript
var authChannel = new BroadcastChannel('auth');
authChannel.onmessage = function (event) {
  if (event.data == 'logout')
    showLogout();
}

function logoutRequested() {
  // called when the user asks us to log them out
  doLogout();
  showLogout();
  authChannel.postMessage('logout');
}
```
function doLogout() {
    // actually log the user out (e.g. clearing cookies)
    // ...
}

function showLogout() {
    // update the UI to indicate we're logged out
    // ...
}
This section is non-normative.

This specification defines an API for running scripts in the background independently of any user interface scripts.

This allows for long-running scripts that are not interrupted by scripts that respond to clicks or other user interactions, and allows long tasks to be executed without yielding to keep the page responsive.

Workers (as these background scripts are called herein) are relatively heavy-weight, and are not intended to be used in large numbers. For example, it would be inappropriate to launch one worker for each pixel of a four megapixel image. The examples below show some appropriate uses of workers.

Generally, workers are expected to be long-lived, have a high start-up performance cost, and a high per-instance memory cost.

This section is non-normative.

There are a variety of uses that workers can be put to. The following subsections show various examples of this use.

This section is non-normative.

The simplest use of workers is for performing a computationally expensive task without interrupting the user interface.

In this example, the main document spawns a worker to (naïvely) compute prime numbers, and progressively displays the most recently found prime number.

The main page is as follows:

```html
<!DOCTYPE HTML>
<html>
<head>
<meta charset="utf-8">
<title>Worker example: One-core computation</title>
</head>
<body>
<p>The highest prime number discovered so far is: <output id="result"></output></p>
<script>
var worker = new Worker('worker.js');
worker.onmessage = function (event) {
  document.getElementById('result').textContent = event.data;
};
</script>
</body>
</html>
```

The `Worker()` constructor call creates a worker and returns a `Worker` object representing that worker, which is used to communicate with the worker. That object's `onmessage` event handler allows the code to receive messages from the worker.

The worker itself is as follows:
var n = 1;
search: while (true) {
    n += 1;
    for (var i = 2; i <= Math.sqrt(n); i += 1)
        if (n % i == 0)
            continue search;
    // found a prime!
    postMessage(n);
}

The bulk of this code is simply an unoptimized search for a prime number. The `postMessage()` method is used to send a message back to the page when a prime is found.

View this example online.

10.1.2.2 Using a JavaScript module as a worker

This section is non-normative.

All of our examples so far show workers that run classic scripts. Workers can instead be instantiated using module scripts, which have the usual benefits: the ability to use the JavaScript `import` statement to import other modules; strict mode by default; and top-level declarations not polluting the worker's global scope.

Note that such module-based workers follow different restrictions regarding cross-origin content, compared to classic workers. Unlike classic workers, module workers can be instantiated using a cross-origin script, as long as that script is exposed using the CORS protocol. Additionally, the `importScripts()` method will automatically fail inside module workers; the JavaScript `import` statement is generally a better choice.

In this example, the main document uses a worker to do off-main-thread image manipulation. It imports the filters used from another module.

The main page is as follows:

```html
<!DOCTYPE html>
<meta charset="utf-8">
<title>Worker example: image decoding</title>
<p>
    <label>Type an image URL to decode
        <input type="url" id="image-url" list="image-list">
        <datalist id="image-list">
            <option value="https://html.spec.whatwg.org/images/drawImage.png">
            <option value="https://html.spec.whatwg.org/images/robots.jpeg">
            <option value="https://html.spec.whatwg.org/images/arcTo2.png">
        </datalist>
    </label>
</p>
<p>
    <label>Choose a filter to apply
        <select id="filter">
            <option value="none">none</option>
            <option value="grayscale">grayscale</option>
            <option value="brighten">brighten by 20%</option>
        </select>
    </label>
</p>
<canvas id="output"></canvas>
```
The worker file is then:

```javascript
import * as filters from "./filters.js";

self.onmessage = e => {
  const { imageData, filter } = e.data;
  filters[filter](imageData);
  self.postMessage(imageData, [imageData.data.buffer]);
};
```

Which imports the file `filters.js`:

```javascript
export function none () {}

export function grayscale({ data: d }) {
  for (let i = 0; i < d.length; i += 4) {
    const [r, g, b] = [d[i], d[i + 1], d[i + 2]];
  }
```

974
// CIE luminance for the RGB
// The human eye is bad at seeing red and blue, so we de-emphasize them.
d[i] = d[i + 1] = d[i + 2] = 0.2126 * r + 0.7152 * g + 0.0722 * b;
);

export function brighten({ data }) {
    for (let i = 0; i < d.length; ++i) {
        d[i] *= 1.2;
    }
}

View this example online.

10.1.2.3 Shared workers introduction

This section is non-normative.

This section introduces shared workers using a Hello World example. Shared workers use slightly different APIs, since each worker can have multiple connections.

This first example shows how you connect to a worker and how a worker can send a message back to the page when it connects to it. Received messages are displayed in a log.

Here is the HTML page:

    <!DOCTYPE HTML>
    <meta charset="utf-8">
    <title>Shared workers: demo 1</title>
    <pre id="log">Log:</pre>
    <script>
        var worker = new SharedWorker('test.js');
        var log = document.getElementById('log');
        worker.port.onmessage = function(e) {
            // note: not worker.onmessage!
            log.textContent += '
' + e.data;
        }
    </script>

Here is the JavaScript worker:

    onconnect = function(e) {
        var port = e.ports[0];
        port.postMessage('Hello World!');
    }

View this example online.

This second example extends the first one by changing two things: first, messages are received using addEventListener() instead of an event handler IDL attribute,p900 and second, a message is sent to the worker, causing the worker to send another message in return. Received messages are again displayed in a log.

Here is the HTML page:

    <!DOCTYPE HTML>
    <meta charset="utf-8">
    <title>Shared workers: demo 2</title>
    <pre id="log">Log:</pre>
    <script>
        var worker = new SharedWorker('test.js');
    </script>
Here is the JavaScript worker:

```javascript
var count = 0;
onconnect = function(e) {
    var port = e.ports[0];
    port.postMessage('Hello World!');
    port.onmessage = function(e) {
        port.postMessage('pong'); // not e.ports[0].postMessage!
        // e.target.postMessage('pong'); would work also
    };
}
```

View this example online.

Finally, the example is extended to show how two pages can connect to the same worker; in this case, the second page is merely in an iframe on the first page, but the same principle would apply to an entirely separate page in a separate top-level browsing context.

Here is the outer HTML page:

```html
<!DOCTYPE HTML>
<meta charset="utf-8">
<title>Shared workers: demo 3</title>
<pre id="log">Log:</pre>
<script>
    var worker = new SharedWorker('test.js');
    var log = document.getElementById('log');
    worker.port.addEventListener('message', function(e) {
        log.textContent += '\n' + e.data;
    }, false);
    worker.port.start(); // note: need this when using addEventListener
    worker.port.postMessage('ping');
</script>
<iframe src="inner.html"></iframe>
```

Here is the inner HTML page:

```html
<!DOCTYPE HTML>
<meta charset="utf-8">
<title>Shared workers: demo 3 inner frame</title>
<pre id="log">Inner log:</pre>
<script>
    var worker = new SharedWorker('test.js');
    var log = document.getElementById('log');
    worker.port.onmessage = function(e) {
        log.textContent += '\n' + e.data;
    }
</script>
```

Here is the JavaScript worker:

```javascript
var count = 0;
onconnect = function(e) {
```
count += 1;
var port = e.ports[0];
port.postMessage('Hello World! You are connection #' + count);
port.onmessage = function(e) {
  port.postMessage('pong');
}

View this example online.

10.1.2.4 Shared state using a shared worker

This section is non-normative.

In this example, multiple windows (viewers) can be opened that are all viewing the same map. All the windows share the same map information, with a single worker coordinating all the viewers. Each viewer can move around independently, but if they set any data on the map, all the viewers are updated.

The main page isn't interesting, it merely provides a way to open the viewers:

```html
<!DOCTYPE HTML>
<html>
<head>
<meta charset="utf-8">
<title>Workers example: Multiviewer</title>
<script>
  function openViewer() {
    window.open('viewer.html');
  }
</script>
</head>
<body>
<p><button type=button onclick="openViewer()">Open a new viewer</button></p>
<p>Each viewer opens in a new window. You can have as many viewers as you like, they all view the same data.</p>
</body>
</html>
```

The viewer is more involved:

```html
<!DOCTYPE HTML>
<html>
<head>
<meta charset="utf-8">
<title>Workers example: Multiviewer viewer</title>
<script>
  var worker = new SharedWorker('worker.js', 'core');

  // CONFIGURATION
  function configure(event) {
    if (event.data.substr(0, 4) !== 'cfg ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    // update display to mention our name is name
    document.getElementsByTagName('h1')[0].textContent += ' ' + name;
    // no longer need this listener
    worker.port.removeEventListener('message', configure, false);
  }
  worker.port.addEventListener('message', configure, false);
```
// MAP
function paintMap(event) {
    if (event.data.substr(0, 4) != 'map ') return;
    var data = event.data.substr(4).split(',',);
    // display tiles data[0] .. data[8]
    var canvas = document.getElementById('map');
    var context = canvas.getContext('2d');
    for (var y = 0; y < 3; y += 1) {
        for (var x = 0; x < 3; x += 1) {
            var tile = data[y * 3 + x];
            if (tile == '0')
                context.fillStyle = 'green';
            else
                context.fillStyle = 'maroon';
            context.fillRect(x * 50, y * 50, 50, 50);
        }
    }
}
worker.port.addEventListener('message', paintMap, false);

// PUBLIC CHAT
function updatePublicChat(event) {
    if (event.data.substr(0, 4) != 'txt ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    var message = event.data.substr(4 + name.length + 1);
    // display "<name> message" in public chat
    var public = document.getElementById('public');
    var p = document.createElement('p');
    var n = document.createElement('button');
    n.textContent = '<' + name + '>';
    n.onclick = function () { worker.port.postMessage('msg ' + name); };
    p.appendChild(n);
    var m = document.createElement('span');
    m.textContent = message;
    p.appendChild(m);
    public.appendChild(p);
}
worker.port.addEventListener('message', updatePublicChat, false);

// PRIVATE CHAT
function startPrivateChat(event) {
    if (event.data.substr(0, 4) != 'msg ') return;
    var name = event.data.substr(4).substr(4, 1)[0];
    var port = event.ports[0];
    // display a private chat UI
    var ul = document.getElementById('private');
    var li = document.createElement('li');
    var h3 = document.createElement('h3');
    h3.textContent = 'Private chat with ' + name;
    li.appendChild(h3);
    var div = document.createElement('div');
    var addMessage = function (name, message) {
        var p = document.createElement('p');
        var n = document.createElement('strong');
        n.textContent = '<' + name + '>';
        p.appendChild(n);
        var t = document.createElement('span');
        t.textContent = message;
        p.appendChild(t);
        div.appendChild(p);
    };
    port.onmessage = function (event) {
There are several key things worth noting about the way the viewer is written.

**Multiple listeners.** Instead of a single message processing function, the code here attaches multiple event listeners, each one performing a quick check to see if it is relevant for the message. In this example it doesn't make much difference, but if multiple authors wanted to collaborate using a single port to communicate with a worker, it would allow for independent code instead of changes having to all be made to a single event handling function.

Registering event listeners in this way also allows you to unregister specific listeners when you are done with them, as is done with the `configure()` method in this example.

Finally, the worker:
var nextName = 0;

function getNextName() {
    // this could use more friendly names
    // but for now just return a number
    return nextName++;
}

var map = [
    [0, 0, 0, 0, 0, 0],
    [1, 1, 0, 1, 0, 1],
    [0, 1, 0, 1, 0, 0],
    [0, 1, 0, 1, 0, 1],
    [0, 0, 0, 0, 0, 0],
    [1, 0, 0, 1, 1, 1],
    [1, 1, 1, 1, 0, 1],
];

function wrapX(x) {
    if (x < 0) return wrapX(x + map[0].length);
    if (x >= map[0].length) return wrapX(x - map[0].length);
    return x;
}

function wrapY(y) {
    if (y < 0) return wrapY(y + map.length);
    if (y >= map[0].length) return wrapY(y - map.length);
    return y;
}

function wrap(val, min, max) {
    if (val < min) return val + (max-min)+1;
    if (val > max) return val - (max-min)-1;
    return val;
}

function sendMapData(viewer) {
    var data = '';
    for (var y = viewer.y-1; y <= viewer.y+1; y += 1) {
        for (var x = viewer.x-1; x <= viewer.x+1; x += 1) {
            if (data != '')
                data += ',';
            data += map[wrap(y, 0, map[0].length-1)][wrap(x, 0, map.length-1)];
        }
    }
    viewer.port.postMessage('map ' + data);
}

var viewers = {};
onconnect = function (event) {
    var name = getNextName();
    event.ports[0]_data = { port: event.ports[0], name: name, x: 0, y: 0, };
    viewers[name] = event.ports[0]_data;
    event.ports[0].postMessage('cfg ' + name);
    event.ports[0].onmessage = getMessage;
    sendMapData(event.ports[0]_data);
};

function getMessage(event) {
    switch (event.data.substr(0, 4)) {
        case 'mov':
            // code here
            break;
    }
}
```javascript
var direction = event.data.substr(4);
var dx = 0;
var dy = 0;
switch (direction) {
    case 'up': dy = -1; break;
    case 'down': dy = 1; break;
    case 'left': dx = -1; break;
    case 'right': dx = 1; break;
}
event.target._data.x = wrapX(event.target._data.x + dx);
event.target._data.y = wrapY(event.target._data.y + dy);
sendMapData(event.target._data);
break;
case 'set ':
    var value = event.data.substr(4);
    map[event.target._data.y][event.target._data.x] = value;
    for (var viewer in viewers)
        sendMapData(viewers[viewer]);
    break;
case 'txt ':
    var name = event.target._data.name;
    var message = event.data.substr(4);
    for (var viewer in viewers)
        viewers[viewer].port.postMessage('txt ' + name + '' + message);
    break;
case 'msg ':
    var party1 = event.target._data;
    var party2 = viewers[event.data.substr(4).split(' ', 1)[0]];
    if (party2) {
        var channel = new MessageChannel();
        party1.port.postMessage('msg ' + party2.name, [channel.port1]);
        party2.port.postMessage('msg ' + party1.name, [channel.port2]);
    }
    break;
}

Connecting to multiple pages. The script uses the `onconnect` event listener to listen for multiple connections.

Direct channels. When the worker receives a "msg" message from one viewer naming another viewer, it sets up a direct connection between the two, so that the two viewers can communicate directly without the worker having to proxy all the messages.

View this example online.

10.1.2.5 Delegation

This section is non-normative.

With multicore CPUs becoming prevalent, one way to obtain better performance is to split computationally expensive tasks amongst multiple workers. In this example, a computationally expensive task that is to be performed for every number from 1 to 10,000,000 is farmed out to ten subworkers.

The main page is as follows, it just reports the result:

```html
<!DOCTYPE HTML>
<html>
<head>
    <meta charset="utf-8">
    <title>Worker example: Multicore computation</title>
</head>
<body>

981
```
The worker itself is as follows:

```javascript
// settings
var num_workers = 10;
var items_per_worker = 1000000;

// start the workers
var result = 0;
var pending_workers = num_workers;
for (var i = 0; i < num_workers; i += 1) {
    var worker = new Worker('core.js');
    worker.postMessage(i * items_per_worker);
    worker.postMessage((i+1) * items_per_worker);
    worker.onmessage = storeResult;
}

// handle the results
function storeResult(event) {
    result += 1*event.data;
    pending_workers -= 1;
    if (pending_workers <= 0)
        postMessage(result); // finished!
}
```

It consists of a loop to start the subworkers, and then a handler that waits for all the subworkers to respond.

The subworkers are implemented as follows:

```javascript
var start;
onmessage = getStart;
function getStart(event) {
    start = 1*event.data;
    onmessage = getEnd;
}

var end;
function getEnd(event) {
    end = 1*event.data;
    onmessage = null;
    work();
}

function work() {
    var result = 0;
    for (var i = start; i < end; i += 1) {
        // perform some complex calculation here
        result += 1;
    }
    postMessage(result);
    close();
}
```
They receive two numbers in two events, perform the computation for the range of numbers thus specified, and then report the result back to the parent.

View this example online.

10.1.2.6 Providing libraries

This section is non-normative.

Suppose that a cryptography library is made available that provides three tasks:

**Generate a public/private key pair**
- Takes a port, on which it will send two messages, first the public key and then the private key.

**Given a plaintext and a public key, return the corresponding ciphertext**
- Takes a port, to which any number of messages can be sent, the first giving the public key, and the remainder giving the plaintext, each of which is encrypted and then sent on that same channel as the ciphertext. The user can close the port when it is done encrypting content.

**Given a ciphertext and a private key, return the corresponding plaintext**
- Takes a port, to which any number of messages can be sent, the first giving the private key, and the remainder giving the ciphertext, each of which is decrypted and then sent on that same channel as the plaintext. The user can close the port when it is done decrypting content.

The library itself is as follows:

```javascript
function handleMessage(e) {
  if (e.data == "genkeys")
    genkeys(e.ports[0]);
  else if (e.data == "encrypt")
    encrypt(e.ports[0]);
  else if (e.data == "decrypt")
    decrypt(e.ports[0]);
}

function genkeys(p) {
  var keys = _generateKeyPair();
  p.postMessage(keys[0]);
  p.postMessage(keys[1]);
}

function encrypt(p) {
  var key, state = 0;
  p.onmessage = function (e) {
    if (state == 0) {
      key = e.data;
      state = 1;
    } else {
      p.postMessage(_encrypt(key, e.data));
    }
 );
}

function decrypt(p) {
  var key, state = 0;
  p.onmessage = function (e) {
    if (state == 0) {
      key = e.data;
      state = 1;
    } else {
      p.postMessage(_decrypt(key, e.data));
    }
  };
}
```
// support being used as a shared worker as well as a dedicated worker

if ('onmessage' in this) // dedicated worker
    onmessage = handleMessage;
else // shared worker
    onconnect = function (e) { e.port.onmessage = handleMessage; }

// the "crypto" functions:

function _generateKeyPair () {
    return [Math.random(), Math.random()];
}

function _encrypt (k, s) {
    return 'encrypted-' + k + ' ' + s;
}

function _decrypt (k, s) {
    return s.substr(s.indexOf(' ') + 1);
}

Note that the crypto functions here are just stubs and don't do real cryptography.

This library could be used as follows:

<!DOCTYPE HTML>
<html>
<head>
<meta charset="utf-8">
<title>Worker example: Crypto library</title>
<script>
const cryptoLib = new Worker('libcrypto-v1.js'); // or could use 'libcrypto-v2.js'

function startConversation (source, message) {
    const messageChannel = new MessageChannel();
    source.postMessage(message, [messageChannel.port2]);
    return messageChannel.port1;
}

function getKeys () {
    let state = 0;
    startConversation(cryptoLib, "genkeys").onmessage = function (e) {
        if (state === 0)
            document.getElementById('public').value = e.data;
        else if (state === 1)
            document.getElementById('private').value = e.data;
        state += 1;
    };
}

function enc() {
    const port = startConversation(cryptoLib, "encrypt");
    port.postMessage(document.getElementById('public').value);
    port.postMessage(document.getElementById('input').value);
    port.onmessage = function (e) {
        document.getElementById('input').value = e.data;
        port.close();
    };
}

function dec() {
    const port = startConversation(cryptoLib, "decrypt");
    port.postMessage(document.getElementById('private').value);
}
A later version of the API, though, might want to offload all the crypto work onto subworkers. This could be done as follows:

```javascript
function handleMessage(e) {
  if (e.data === "genkeys")
    genkeys(e.ports[0]);
  else if (e.data === "encrypt")
    encrypt(e.ports[0]);
  else if (e.data === "decrypt")
    decrypt(e.ports[0]);
}

function genkeys(p) {
  var generator = new Worker('libcrypto-v2-generator.js');
  generator.postMessage('', [p]);
}

function encrypt(p) {
  p.onmessage = function (e) {
    var key = e.data;
    var encryptor = new Worker('libcrypto-v2-encryptor.js');
    encryptor.postMessage(key, [p]);
  };
}

function decrypt(p) {
  p.onmessage = function (e) {
    var key = e.data;
    var decryptor = new Worker('libcrypto-v2-decryptor.js');
    decryptor.postMessage(key, [p]);
  };
}

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
  onmessage = handleMessage;
else // shared worker
  onconnect = function (e) { e.ports[0].onmessage = handleMessage;};
```

The little subworkers would then be as follows.
For generating key pairs:

```
for (let e of e.ports) {
  var k = _generateKeyPair();
  e.ports[0].postMessage(k[0]);
  e.ports[0].postMessage(k[1]);
}
```

```
function _generateKeyPair() {
  return [Math.random(), Math.random()];
}
```

For encrypting:

```
for (let e of e.ports) {
  var key = e.data;
  e.ports[0].onmessage = function (e) {
    var s = e.data;
    postMessage(_encrypt(key, s));
  }
}
```

```
function _encrypt(k, s) {
  return 'encrypted-' + k + ' ' + s;
}
```

For decrypting:

```
for (let e of e.ports) {
  var key = e.data;
  e.ports[0].onmessage = function (e) {
    var s = e.data;
    postMessage(_decrypt(key, s));
  }
}
```

```
function _decrypt(k, s) {
  return s.substr(s.indexOf(' ') + 1);
}
```

Notice how the users of the API don't have to even know that this is happening — the API hasn't changed; the library can delegate to subworkers without changing its API, even though it is accepting data using message channels.

[View this example online](#).

### 10.1.3 Tutorials

#### 10.1.3.1 Creating a dedicated worker

This section is non-normative.

Creating a worker requires a URL to a JavaScript file. The `Worker()` constructor is invoked with the URL to that file as its only argument; a worker is then created and returned:

```
var worker = new Worker('helper.js');
```

If you want your worker script to be interpreted as a `module script` instead of the default `classic script`, you need to use a slightly different signature:
var worker = new Worker('helper.mjs', { type: "module" });

10.1.3.2 Communicating with a dedicated worker

This section is non-normative.

Dedicated workers use MessagePort objects behind the scenes, and thus support all the same features, such as sending structured data, transferring binary data, and transferring other ports.

To receive messages from a dedicated worker, use the onmessage event handler IDL attribute on the Worker object:

worker.onmessage = function (event) { ... };

You can also use the addEventListener() method.

Note

The implicit MessagePort used by dedicated workers has its port message queue implicitly enabled when it is created, so there is no equivalent to the MessagePort interface's start() method on the Worker interface.

To send data to a worker, use the postMessage() method. Structured data can be sent over this communication channel. To send ArrayBuffer objects efficiently (by transferring them rather than cloning them), list them in an array in the second argument.

worker.postMessage({
  operation: 'find-edges',
  input: buffer, // an ArrayBuffer object
  threshold: 0.6,
}, [buffer]);

To receive a message inside the worker, the onmessage event handler IDL attribute is used.

onmessage = function (event) { ... };

You can again also use the addEventListener() method.

In either case, the data is provided in the event object's data attribute.

To send messages back, you again use postMessage(). It supports the structured data in the same manner.

postMessage(event.data.input, [event.data.input]); // transfer the buffer back

10.1.3.3 Shared workers

This section is non-normative.

Shared workers are identified by the URL of the script used to create it, optionally with an explicit name. The name allows multiple instances of a particular shared worker to be started.

Shared workers are scoped by origin. Two different sites using the same names will not collide. However, if a page tries to use the same shared worker name as another page on the same site, but with a different script URL, it will fail.

Creating shared workers is done using the SharedWorker constructor. This constructor takes the URL to the script to use for its first argument, and the name of the worker, if any, as the second argument.

var worker = new SharedWorker('service.js');

Communicating with shared workers is done with explicit MessagePort objects. The object returned by the SharedWorker constructor holds a reference to the port on its port attribute.
Inside the shared worker, new clients of the worker are announced using the `connect` event. The port for the new client is given by the event object's `source` attribute.

```javascript
onconnect = function (event) {
    var newPort = event.source;
    // set up a listener
    newPort.onmessage = function (event) { ... };
    // send a message back to the port
    newPort.postMessage('ready!'); // can also send structured data, of course
};
```

### 10.2 Infrastructure

There are two kinds of workers; dedicated workers, and shared workers. Dedicated workers, once created, are linked to their creator; but message ports can be used to communicate from a dedicated worker to multiple other browsing contexts or workers. Shared workers, on the other hand, are named, and once created any script running in the same origin can obtain a reference to that worker and communicate with it.

#### 10.2.1 The global scope

The global scope is the "inside" of a worker.

### 10.2.1.1 The `WorkerGlobalScope` common interface

```idl
[Exposed=Worker]
interface WorkerGlobalScope : EventTarget {
    readonly attribute WorkerGlobalScope self;
    readonly attribute WorkerLocation location;
    readonly attribute WorkerNavigator navigator;
    void importScripts(USVString... urls);

    attribute OnErrorEventHandler onerror;
    attribute EventHandler onlanguagechange;
    attribute EventHandler onoffline;
    attribute EventHandler ononline;
    attribute EventHandler onrejectionhandled;
    attribute EventHandler onunhandledrejection;
};
```

`WorkerGlobalScope` serves as the base class for specific types of worker global scope objects, including `DedicatedWorkerGlobalScope`, `SharedWorkerGlobalScope`, and `ServiceWorkerGlobalScope`.

A `WorkerGlobalScope` object has an associated `owner set` (a set of `Document` and `WorkerGlobalScope` objects). It is initially empty and populated when the worker is created or obtained.

#### Note

It is a `set`, instead of a single owner, to accommodate `SharedWorkerGlobalScope` objects.

A `WorkerGlobalScope` object has an associated `worker set` (a `set` of `WorkerGlobalScope` objects). It is initially empty and populated when the worker creates or obtains further workers.
A WorkerGlobalScope object has an associated type ("classic" or "module"). It is set during creation.

A WorkerGlobalScope object has an associated url (null or a URL). It is initially null.

A WorkerGlobalScope object has an associated name (a string). It is set during creation.

A WorkerGlobalScope object has an associated HTTPS state (an HTTPS state value). It is initially "none".

A WorkerGlobalScope object has an associated referrer policy (a referrer policy). It is initially the empty string.

A WorkerGlobalScope object has an associated CSP list, which is a CSP list containing all of the Content Security Policy objects active for the worker. It is initially an empty list.

A WorkerGlobalScope object has an associated module map. It is a module map, initially empty.

The self attribute must return the WorkerGlobalScope object itself.

The location attribute must return the WorkerLocation object whose associated WorkerGlobalScope object is the WorkerGlobalScope object.

Note: While the WorkerLocation object is created after the WorkerGlobalScope object, this is not problematic as it cannot be observed from script.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by objects implementing the WorkerGlobalScope interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onerror</td>
<td>error</td>
</tr>
<tr>
<td>onlanguagechange</td>
<td>languagechange</td>
</tr>
<tr>
<td>onoffline</td>
<td>offline</td>
</tr>
<tr>
<td>ononline</td>
<td>online</td>
</tr>
<tr>
<td>onrejectionhandled</td>
<td>rejectionhandled</td>
</tr>
<tr>
<td>onunhandledrejection</td>
<td>unhandledrejection</td>
</tr>
</tbody>
</table>
10.2.1.2 Dedicated workers and the DedicatedWorkerGlobalScope interface

```
interface DedicatedWorkerGlobalScope : WorkerGlobalScope {
    [Replaceable] readonly attribute DOMString name;

    void postMessage(any message, optional sequence<object> transfer = []);

    void close();

    attribute EventHandler onmessage;
    attribute EventHandler onmessageerror;
};
```

DedicatedWorkerGlobalScope objects act as if they had an implicit MessagePort associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the DedicatedWorkerGlobalScope object.

All messages received by that port must immediately be retargeted at the DedicatedWorkerGlobalScope object.

### For web developers (non-normative)

**dedicatedWorkerGlobal**. **name**

Returns `dedicatedWorkerGlobal`.name, i.e. the value given to the `Worker` constructor. Primarily useful for debugging.

**dedicatedWorkerGlobal**. **postMessage**(message [, transfer])

Clones message and transmits it to the `Worker` object associated with `dedicatedWorkerGlobal`. transfer can be passed as a list of objects that are to be transferred rather than cloned.

**dedicatedWorkerGlobal**. **close**

Aborts dedicatedWorkerGlobal.

The `name` attribute must return the DedicatedWorkerGlobalScope object's `name`, its value represents the name given to the worker using the `Worker` constructor, used primarily for debugging purposes.

The `postMessage()` method on DedicatedWorkerGlobalScope objects must act as if, when invoked, it immediately invoked the method of the same name on the port, with the same arguments, and returned the same return value.

To close a worker, given a `workerGlobal`, run these steps:

1. Discard any tasks that have been added to `workerGlobal`'s event loop's task queues.
2. Set `workerGlobal`'s `closing` flag to true. (This prevents any further tasks from being queued.)

The `close()` method, when invoked, must close a worker with this DedicatedWorkerGlobalScope object.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by objects implementing the DedicatedWorkerGlobalScope interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onmessage</td>
<td>message</td>
</tr>
<tr>
<td>onmessageerror</td>
<td>messageerror</td>
</tr>
</tbody>
</table>

For the purposes of the application cache networking model, a dedicated worker is an extension of the cache host from which it was created.
10.2.1.3 Shared workers and the **SharedWorkerGlobalScope** \[^{991}\] interface \[^{995}\]

```idl
[Global=(Worker,SharedWorker),Exposed=SharedWorker]
interface SharedWorkerGlobalScope : WorkerGlobalScope {
    [Replaceable] readonly attribute DOMString name;
    void close();
    attribute EventHandler onconnect;
}
```

A **SharedWorkerGlobalScope** \[^{991}\] object has an associated **constructor origin**, and **constructor url**. They are initialized when the **SharedWorkerGlobalScope** \[^{991}\] object is created, in the run a worker \[^{992}\] algorithm.

Shared workers receive message ports through **connect** \[^{9121}\] events on their **SharedWorkerGlobalScope** \[^{991}\] object for each connection.

For web developers (non-normative)

```
sharedWorkerGlobal . name

Returns **sharedWorkerGlobal**'s **name**, i.e. the value given to the **SharedWorker** \[^{997}\] constructor. Multiple **SharedWorker** \[^{997}\] objects can correspond to the same shared worker (and **SharedWorkerGlobalScope** \[^{991}\]), by reusing the same name.
```

```
sharedWorkerGlobal . close

Aborts **sharedWorkerGlobal**.
```

The **name** attribute must return the **SharedWorkerGlobalScope** \[^{991}\] object's **name**. Its value represents the name that can be used to obtain a reference to the worker using the **SharedWorker** \[^{997}\] constructor.

The **close()** method, when invoked, must **close a worker** with this **SharedWorkerGlobalScope** \[^{991}\] object.

The following are the **event handlers** (and their corresponding **event handler event types**) that must be supported, as **event handler IDL attributes**, by objects implementing the **SharedWorkerGlobalScope** \[^{991}\] interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onconnect</td>
<td>connect [^{9121}]</td>
</tr>
</tbody>
</table>

10.2.2 The event loop \[^{999}\]

Each **WorkerGlobalScope** \[^{988}\] object has a distinct **event loop**, separate from those used by units of related similar-origin browsing contexts. \[^{978}\] This **event loop** has no associated **browsing context**, and its **task queues** \[^{989}\] only have events, callbacks, and networking activity as **tasks**. \[^{983}\] These **event loops** \[^{983}\] are created by the run a worker \[^{992}\] algorithm.

Each **WorkerGlobalScope** \[^{988}\] object also has a **closing** flag, which must be initially false, but which can get set to true by the algorithms in the processing model section below.

Once the **WorkerGlobalScope** \[^{988}\]’s **closing** flag is set to true, the **event loop**’s **task queues** must discard any further **tasks** that would be added to them (tasks already on the queue are unaffected except where otherwise specified). Effectively, once the **closing** flag is true, timers stop firing, notifications for all pending background operations are dropped, etc.

10.2.3 The worker’s lifetime \[^{999}\]

Workers communicate with other workers and with **browsing contexts** through **message channels** and their **MessagePort** objects.

Each **WorkerGlobalScope** object **worker global scope** has a list of **the worker’s ports**, which consists of all the **MessagePort** objects that are entangled with another port and that have one (but only one) port owned by **worker global scope**. This list includes the
implicit MessagePort in the case of dedicated workers.

Given an environment settings object o when creating or obtaining a worker, the relevant owner to add depends on the type of global object specified by o. If o specifies a global object that is a WorkerGlobalScope object (i.e., if we are creating a nested worker), then the relevant owner is that global object. Otherwise, o specifies a global object that is a Window object, and the relevant owner is the responsible document specified by o.

A worker is said to be a permissible worker if its WorkerGlobalScope's owner set is not empty or:

- its owner set has been empty for no more than a short user-agent-defined timeout value,
- its WorkerGlobalScope object is a SharedWorkerGlobalScope object (i.e., the worker is a shared worker), and
- the user agent has a browsing context whose Document object is not completely loaded.

Note
The second part of this definition allows a shared worker to survive for a short time while a page is loading, in case that page is going to contact the shared worker again. This can be used by user agents as a way to avoid the cost of restarting a shared worker used by a site when the user is navigating from page to page within that site.

A worker is said to be an active needed worker if any of its owners are either Document objects that are fully active or active needed workers.

A worker is said to be a protected worker if it is an active needed worker and either it has outstanding timers, database transactions, or network connections, or its list of the worker's ports is not empty, or its WorkerGlobalScope is actually a SharedWorkerGlobalScope object (i.e. the worker is a shared worker).

A worker is said to be a suspendable worker if it is not an active needed worker but it is a permissible worker.

10.2.4 Processing model

When a user agent is to run a worker for a script with Worker or SharedWorker object worker, URL url, environment settings object outside settings, MessagePort outside port, and a WorkerOptions dictionary options, it must run the following steps.

1. Create a separate parallel execution environment (i.e. a separate thread or process or equivalent construct), and run the rest of these steps in that context.

   For the purposes of timing APIs, this is the official moment of creation of the worker.

2. Let is shared be true if worker is a SharedWorker object, and false otherwise.

3. Let owner be the relevant owner to add given outside settings.

4. Let parent worker global scope be null.

5. If owner is a WorkerGlobalScope object (i.e., we are creating a nested worker), then set parent worker global scope to owner.

6. Let realm execution context be the result of creating a new JavaScript realm with the following customizations:

   - For the global object, if is shared is true, create a new SharedWorkerGlobalScope object. Otherwise, create a new DedicatedWorkerGlobalScope object.

7. Let worker global scope be the global object of realm execution context's Realm component.

   This is the DedicatedWorkerGlobalScope or SharedWorkerGlobalScope object created in the previous step.

8. Set up a worker environment settings object with realm execution context and outside settings, and let inside settings be the result.

9. Set worker global scope's name to the value of options's name member.

10. If is shared is true, then:

    1. Set worker global scope's constructor origin to outside settings' origin.
2. Set worker global scope's constructor url to url.

11. Let destination be "sharedworker" if is shared is true, and "worker" otherwise.

12. Obtain script by switching on the value of options's type member:

   ↪ "classic"
   Fetch a classic worker script given url, outside settings, destination, and inside settings.

   ↪ "module"
   Fetch a module worker script graph given url, outside settings, destination, the value of the credentials member of options, and inside settings.

In both cases, to perform the fetch given request, perform the following steps if the is top-level flag is set:

1. Set request's reserved client to inside settings.
2. Fetch request, and asynchronously wait to run the remaining steps as part of fetch's process response for the response.
3. Set worker global scope's url to response's url.
4. Set worker global scope's HTTPS state to response's HTTPS state.
5. Set worker global scope's referrer policy to the result of parsing the `Referrer-Policy` header of response.
6. Execute the Initialize a global object's CSP list algorithm on worker global scope and response. [CSP]
7. Asynchronously complete the perform the fetch steps with response.

If the algorithm asynchronously completes with null, then:

1. Queue a task to fire an event named error at worker.
2. Run the environment discarding steps for inside settings.
3. Return.

Otherwise, continue the rest of these steps after the algorithm's asynchronous completion, with script being the asynchronous completion value.

13. Associate worker with worker global scope.

14. Create a new MessagePort object whose owner is inside settings. Let inside port be this new object.

15. Associate inside port with worker global scope.

16. Entangle outside port and inside port.

17. Append owner to worker global scope's owner set.

18. If parent worker global scope is not null, then append worker global scope to parent worker global scope's worker set.

19. Set worker global scope's type to the value of the type member of options.

20. Create a new WorkerLocation object and associate it with worker global scope.

21. Closing orphan workers: Start monitoring the worker such that no sooner than it stops being a protected worker, and no later than it stops being a permissible worker, worker global scope's closing flag is set to true.

22. Suspending workers: Start monitoring the worker, such that whenever worker global scope's closing flag is false and the worker is a suspendable worker, the user agent suspends execution of script in that worker until such time as either the closing flag switches to true or the worker stops being a suspendable worker.

24. If script is a classic script, then run the classic script script. Otherwise, it is a module script; run the module script script.

Note

In addition to the usual possibilities of returning a value or failing due to an exception, this could be prematurely.
25. Enable outside port's port message queue.

26. If is shared is false, enable the port message queue of the worker's implicit port.

27. If is shared is true, then queue a task using the DOM manipulation task source, to fire an event named connect at worker global scope, using MessageEvent, with the data attribute initialized to the empty string, the ports attribute initialized to a new frozen array containing inside port, and the source attribute initialized to inside port.

28. Enable the client message queue of the ServiceWorkerContainer object whose associated service worker client is worker global scope's relevant settings object.

29. Event loop: Run the responsible event loop specified by inside settings until it is destroyed.

Note
The handling of events or the execution of callbacks by tasks run by the event loop might get prematurely aborted by the terminate a worker algorithm defined below.

Note
The worker processing model remains on this step until the event loop is destroyed, which happens after the closing flag is set to true, as described in the event loop processing model.

30. Empty the worker global scope's list of active timers.

31. Disentangle all the ports in the list of the worker's ports.

32. Empty worker global scope's owner set.

When a user agent is to terminate a worker it must run the following steps in parallel with the worker's main loop (the "run a worker" processing model defined above):

1. Set the worker's WorkerGlobalScope object's closing flag to true.

2. If there are any tasks queued in the WorkerGlobalScope object's event loop's task queues, discard them without processing them.

3. Abort the script currently running in the worker.

4. If the worker's WorkerGlobalScope object is actually a DedicatedWorkerGlobalScope object (i.e. the worker is a dedicated worker), then empty the port message queue of the port that the worker's implicit port is entangled with.

User agents may invoke the terminate a worker algorithm when a worker stops being an active needed worker and the worker continues executing even after its closing flag was set to true.

The task source for the tasks mentioned above is the DOM manipulation task source.

10.2.5 Runtime script errors

Whenever an uncaught runtime script error occurs in one of the worker's scripts, if the error did not occur while handling a previous script error, the user agent must report the error for that script, with the position (line number and column number) where the error occurred, using the WorkerGlobalScope object as the target.

For shared workers, if the error is still not handled afterwards, the error may be reported to a developer console.

For dedicated workers, if the error is still not handled afterwards, the user agent must queue a task to run these steps:

1. Let notHandled be the result of firing an event named error at the Worker object associated with the worker, using ErrorEvent, with the cancelable attribute initialized to true, the message, filename, lineno, and colno attributes initialized appropriately, and the error attribute initialized to null.

aborted by the terminate a worker algorithm defined below.
2. If `notHandled` is true, then the user agent must act as if the uncaught runtime script error had occurred in the global scope that the `Worker` object is in, thus repeating the entire runtime script error reporting process one level up.

If the implicit port connecting the worker to its `Worker` object has been disentangled (i.e. if the parent worker has been terminated), then the user agent must act as if the `Worker` object had no `error` event handler and as if that worker's `onerror` attribute was null, but must otherwise act as described above.

---

**Note**

Thus, error reports propagate up to the chain of dedicated workers up to the original `Document`, even if some of the workers along this chain have been terminated and garbage collected.

---

The `task source` for the task mentioned above is the `DOM manipulation task source`.

### 10.2.6 Creating workers

#### 10.2.6.1 The `AbstractWorker` mixin

```idl
interface mixin AbstractWorker {
    attribute EventHandler onerror;
};
```

The following are the `event handlers` (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by objects implementing the `AbstractWorker` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>onerror</code></td>
<td><code>error</code></td>
</tr>
</tbody>
</table>

#### 10.2.6.2 Script settings for workers

When the user agent is required to **set up a worker environment settings object**, given a `JavaScript execution context` execution context and `environment settings object` outside settings, it must run the following steps:

1. Let inherited responsible browsing context be outside settings's `responsible browsing context`.
2. Let inherited origin be outside settings's `origin`.
3. Let worker event loop be a newly created `event loop`.
4. Let realm be the value of execution context's Realm component.
5. Let worker global scope be realm's `global object`.
6. Let settings object be a new `environment settings object` whose algorithms are defined as follows:

   **The** `realm execution context`

   Return execution context.

   **The** `module map`

   Return worker global scope's `module map`.

   **The** `responsible browsing context`

   Return inherited responsible browsing context.

   **The** `responsible event loop`

   Return worker event loop.

   **The** `responsible document`

   Not applicable (the `responsible event loop` is not a `browsing context` event loop).
The **API URL character encoding**

Return **UTF-8**.

The **API base URL**

Return worker global scope's **url**.

The **origin**

Return a unique opaque origin if worker global scope's **url**'s **scheme** is "data", and inherited origin otherwise.

The **HTTPS state**

Return worker global scope's **HTTPS state**.

The **referrer policy**

Return worker global scope's **referrer policy**.

7. Set settings object's **id** to a new unique opaque string, settings object's **creation URL** to worker global scope's **url**, settings object's **target browsing context** to null, and settings object's **active service worker** to null.

8. Set realm's [[HostDefined]] field to settings object.

9. Return settings object.

### 10.2.6.3 Dedicated workers and the **Worker** interface

```idl
[Constructor(USVString scriptURL, optional WorkerOptions options), Exposed=(Window,Worker)]
interface Worker : EventTarget {
  void terminate();

  void postMessage(any message, optional sequence<object> transfer = []);
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};

dictionary WorkerOptions {
  WorkerType type = "classic";
  RequestCredentials credentials = "omit";  // credentials is only used if type is "module"
  DOMString name = "";
};

enum WorkerType { "classic", "module" };

Worker includes AbstractWorker;
```

**For web developers (non-normative)**

```javascript
worker = new Worker(scriptURL [, options ])
```

Returns a new Worker object. `scriptURL` will be fetched and executed in the background, creating a new global environment for which `worker` represents the communication channel. `options` can be used to define the `name` of that global environment via the `name` option, primarily for debugging purposes. It can also ensure this new global environment supports JavaScript modules (specify type: "module"), and if that is specified, can also be used to specify how `scriptURL` is fetched through the credentials option.

```javascript
worker.terminate()
```

Aborts `worker`'s associated global environment.

```javascript
worker.postMessage(message [, transfer ])
```

Clones `message` and transmits it to `worker`'s global environment. `transfer` can be passed as a list of objects that are to be transferred rather than cloned.
The `terminate()` method, when invoked, must cause the terminate a worker\(^994\) algorithm to be run on the worker with which the object is associated.\(^996\)

`Worker\(^996\)` objects act as if they had an implicit `MessagePort\(^965\)` associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the `Worker\(^996\)` object.

All messages received by that port must immediately be retargeted at the `Worker\(^996\)` object.

The `postMessage()` method on `Worker\(^996\)` objects must act as if, when invoked, it immediately invoked the method of the same name\(^966\) on the port, with the same arguments, and returned the same return value.

The following are the event handlers\(^993\) (and their corresponding event handler event types\(^902\)) that must be supported, as event handler IDL attributes\(^900\), by objects implementing the `Worker\(^996\)` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onmessage</td>
<td><code>message</code> (^937)</td>
</tr>
<tr>
<td>onmessageerror</td>
<td><code>messageerror</code> (^937)</td>
</tr>
</tbody>
</table>

When the `Worker(scriptURL, options)` constructor is invoked, the user agent must run the following steps:

1. The user agent may throw a "SecurityError" DOMException if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start dedicated workers).

2. Let outside settings be the current settings object\(^884\).

3. Parse\(^86\) the `scriptURL` argument relative to outside settings.

4. If this fails, throw a "SyntaxError" DOMException.

5. Let worker URL be the resulting URL record\(^86\).

6. Let worker be a new `Worker\(^996\)` object.

7. Create a new `MessagePort` object\(^966\) whose `owner\(^966\)` is outside settings. Let this be the outside port.

8. Associate the outside port with worker.

9. Run this step in parallel\(^42\):

   1. Run a `worker\(^992\)` given worker, worker URL, outside settings, outside port, and options.

10. Return worker.

### 10.2.6.4 Shared workers and the `SharedWorker\(^993\)` interface \(^999\)

```idl
[Constructor(USVString scriptURL, optional (DOMString or WorkerOptions) options), Exposed=(Window,Worker)]
interface SharedWorker : EventTarget {
    readonly attribute MessagePort port;
};
SharedWorker includes AbstractWorker;
```
The `port` attribute must return the value it was assigned by the object's constructor. It represents the `MessagePort` object for communicating with the shared worker.

A user agent has an associated shared worker manager which is the result of starting a new parallel queue.

```javascript
sharedWorker = new SharedWorker(scriptURL [, name ])
```

Returns a new `SharedWorker` object. `scriptURL` will be fetched and executed in the background, creating a new global environment for which `sharedWorker` represents the communication channel. `name` can be used to define the `name` of that global environment.

```javascript
sharedWorker = new SharedWorker(scriptURL [, options ])
```

Returns a new `SharedWorker` object. `scriptURL` will be fetched and executed in the background, creating a new global environment for which `sharedWorker` represents the communication channel. `options` can be used to define the `name` of that global environment via the `name` option. It can also ensure this new global environment supports JavaScript modules (specify type: "module"), and if that is specified, can also be used to specify how `scriptURL` is fetched through the credentials option.

```javascript
sharedWorker.port
```

Returns `sharedWorker`'s `MessagePort` object which can be used to communicate with the global environment.

The `port` attribute must return the value it was assigned by the object's constructor. It represents the `MessagePort` for communicating with the shared worker.

A user agent has an associated shared worker manager which is the result of starting a new parallel queue.

```javascript
sharedWorker = new SharedWorker(scriptURL [, name ])
```

Returns a new `SharedWorker` object. `scriptURL` will be fetched and executed in the background, creating a new global environment for which `sharedWorker` represents the communication channel. `name` can be used to define the `name` of that global environment.

```
sharedWorker = new SharedWorker(scriptURL [, options ])
```

Returns a new `SharedWorker` object. `scriptURL` will be fetched and executed in the background, creating a new global environment for which `sharedWorker` represents the communication channel. `options` can be used to define the `name` of that global environment via the `name` option. It can also ensure this new global environment supports JavaScript modules (specify type: "module"), and if that is specified, can also be used to specify how `scriptURL` is fetched through the credentials option.

```javascript
sharedWorker.port
```

Returns `sharedWorker`'s `MessagePort` object which can be used to communicate with the global environment.

For web developers (non-normative)

When the `SharedWorker(scriptURL, options)` constructor is invoked:

1. Optionally, throw a "SecurityError" `DOMException` if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start shared workers).
2. If `options` is a `DOMString`, set `options` to a new `WorkerOptions` dictionary whose `name` member is set to the value of `options` and whose other members are set to their default values.
3. Let `outside settings` be the `current settings object`.
4. `Parse` `scriptURL` relative to `outside settings`.
5. If this fails, throw a "SyntaxError" `DOMException`.
6. Otherwise, let `urlRecord` be the `resulting URL record`.

```
Note
Any same-origin URL (including blob: URLs) can be used. data: URLs can also be used, but they create a worker with an opaque origin.
```

7. Let `worker` be a new `SharedWorker` object.
8. Create a new `MessagePort object` whose `owner` is `outside settings`. Let this be the `outside port`.
9. Assign `outside port` to the `port` attribute of `worker`.
10. Let `callerIsSecureContext` be the result of executing `Is environment settings object a secure context?` on `outside settings`.
11. Enqueue the following steps to the `shared worker manager`.

```
Note
data: URLs create a worker with an opaque origin. Both the constructor origin and creator url
```

For web developers (non-normative)
3. If worker global scope is not null, but the user agent has been configured to disallow communication between the worker represented by the worker global scope and the scripts whose settings object is outside settings, then set worker global scope to null.

**Note**
For example, a user agent could have a development mode that isolates a particular top-level browsing context from all other pages, and scripts in that development mode could be blocked from connecting to shared workers running in the normal browser mode.

4. If worker global scope is not null, then run these subsubsteps:
   1. Let settings object be the relevant settings object for worker global scope.
   2. Let workerIsSecureContext be the result of executing Is environment settings object a secure context? on settings object.
   3. If workerIsSecureContext is not callerIsSecureContext, then queue a task to fire an event named error at worker and abort these subsubsteps. [SECURE-CONTEXTS]
   4. Associate worker with worker global scope.
   5. Create a new MessagePort whose owner is settings object. Let this be the inside port.
   6. Entangle outside port and inside port.
   7. Queue a task, using the DOM manipulation task source, to fire an event named connect at worker global scope, using MessageEvent, with the data attribute initialized to the empty string, the ports attribute initialized to a new frozen array containing only inside port, and the source attribute initialized to inside port.
   8. Append the relevant owner to add given outside settings to worker global scope’s owner set.
   9. If outside settings’s global object is a WorkerGlobalScope object, then append worker global scope to outside settings’s global object’s worker set.

5. Otherwise, in parallel, run a worker given worker, urlRecord, outside settings, outside port, and options.

12. Return worker.

### 10.2.7 Concurrent hardware capabilities

**IDL**

```idl
interface mixin NavigatorConcurrentHardware {
    readonly attribute unsigned long long hardwareConcurrency;
};
```

For web developers (non-normative)

```javascript
self.navigator.hardwareConcurrency
```

Returns the number of logical processors potentially available to the user agent.

The `navigator.hardwareConcurrency` attribute’s getter must return a number between 1 and the number of logical processors potentially available to the user agent. If this cannot be determined, the getter must return 1.

User agents should err toward exposing the number of logical processors available, using lower values only in cases where there are user-agent specific limits in place (such as a limitation on the number of workers that can be created) or when the user agent desires to limit fingerprinting possibilities.
10.3 APIs available to workers

10.3.1 Importing scripts and libraries

When a script invokes the `importScripts(urls)` method on a `WorkerGlobalScope` object, the user agent must import scripts into worker global scope given this `WorkerGlobalScope` object and `urls`.

To import scripts into worker global scope, given a `WorkerGlobalScope` object `worker global scope` and a sequence `<DOMString>` `urls`, run these steps. The algorithm may optionally be customized by supplying custom `perform the fetch` hooks, which if provided will be used when invoking `fetch a classic worker-imported script`.

1. If `worker global scope`'s `type` is "module", throw a `TypeError` exception.
2. Let `settings object` be the `current settings object`.
3. If `urls` is empty, return.
4. Parse each value in `urls` relative to `settings object`. If any fail, throw a "`SyntaxError`" `DOMException`.
5. For each `url` in the resulting URL records, run these substeps:
   1. `Fetch a classic worker-imported script` given `url` and `settings object`, passing along any custom `perform the fetch` steps provided. If this succeeds, let `script` be the result. Otherwise, rethrow the exception.
   2. Run the classic script, with the rethrow errors argument set to true.

   **Note**
   
   The script will run until it either returns, fails to parse, fails to catch an exception, or gets prematurely aborted by the terminate a worker algorithm defined above.

If an exception was thrown or if the script was prematurely aborted, then abort all these steps, letting the exception or aborting continue to be processed by the calling script.

**Note**

Service Workers is an example of a specification that runs this algorithm with its own options for the `perform the fetch` hook. [SW]

10.3.2 The `WorkerNavigator` interface

The `navigator` attribute of the `WorkerGlobalScope` interface must return an instance of the `WorkerNavigator` interface, which represents the identity and state of the user agent (the client):

```
[Exposed=Worker]
interface WorkerNavigator {}

WorkerNavigator includes NavigatorID;
WorkerNavigator includes NavigatorLanguage;
WorkerNavigator includes NavigatorOnLine;
WorkerNavigator includes NavigatorConcurrentHardware;
```

10.3.3 The `WorkerLocation` interface

```
[Exposed=Worker]
interface WorkerLocation {
    stringifier readonly attribute USVString href;
    readonly attribute USVString origin;
    readonly attribute USVString protocol;
    readonly attribute USVString host;
    readonly attribute USVString hostname;
    readonly attribute USVString port;
}
```
A **WorkerLocation** object has an associated **WorkerGlobalScope object** (a **WorkerGlobalScope** object).

The **href** attribute's getter must return the associated **WorkerGlobalScope object**'s **url**, serialized.

The **origin** attribute's getter must return the **serialization** of the associated **WorkerGlobalScope object**'s **origin**.

The **protocol** attribute's getter must return the associated **WorkerGlobalScope object**'s **scheme**, followed by ": ".

The **host** attribute's getter must run these steps:

1. Let **url** be the associated **WorkerGlobalScope object**'s **url**.
2. If **url**'s **host** is null, return the empty string.
3. If **url**'s **port** is null, return **url**'s **host**, serialized.
4. Return **url**'s **host**, serialized, followed by ": " and **url**'s **port**, serialized.

The **hostname** attribute's getter must run these steps:

1. Let **host** be the associated **WorkerGlobalScope object**'s **url**'s **host**.
2. If **host** is null, return the empty string.

The **port** attribute's getter must run these steps:

1. Let **port** be the associated **WorkerGlobalScope object**'s **url**'s **port**.
2. If **port** is null, return the empty string.

The **pathname** attribute's getter must run these steps:

1. Let **url** be the associated **WorkerGlobalScope object**'s **url**.
2. If **url**'s **cannot-be-a-base-URL flag** is set, return the first string in **url**'s **path**.
3. Return "/", followed by the strings in **url**'s **path** (including empty strings), separated from each other by "/ ".

The **search** attribute's getter must run these steps:

1. Let **query** be the associated **WorkerGlobalScope object**'s **url**'s **query**.
2. If **query** is either null or the empty string, return the empty string.
3. Return "?", followed by **query**.

The **hash** attribute's getter must run these steps:

1. Let **fragment** be the associated **WorkerGlobalScope object**'s **url**'s **fragment**.
2. If **fragment** is either null or the empty string, return the empty string.
3. Return ": ", followed by **fragment**.
This section is non-normative.

This specification introduces two related mechanisms, similar to HTTP session cookies, for storing name-value pairs on the client side. [COOKIES][p121]

The first is designed for scenarios where the user is carrying out a single transaction, but could be carrying out multiple transactions in different windows at the same time.

Cookies don’t really handle this case well. For example, a user could be buying plane tickets in two different windows, using the same site. If the site used cookies to keep track of which ticket the user was buying, then as the user clicked from page to page in both windows, the ticket currently being purchased would “leak” from one window to the other, potentially causing the user to buy two tickets for the same flight without really noticing.

To address this, this specification introduces the sessionStorage IDL attribute. Sites can add data to the session storage, and it will be accessible to any page from the same site opened in that window.

For example, a page could have a checkbox that the user ticks to indicate that they want insurance:

```html
<label>
  <input type="checkbox" onchange="sessionStorage.insurance = checked ? 'true' : ''">
  I want insurance on this trip.
</label>
```

A later page could then check, from script, whether the user had checked the checkbox or not:

```javascript
if (sessionStorage.insurance) {
  ...
}
```

If the user had multiple windows opened on the site, each one would have its own individual copy of the session storage object.

The second storage mechanism is designed for storage that spans multiple windows, and lasts beyond the current session. In particular, Web applications might wish to store megabytes of user data, such as entire user-authored documents or a user’s mailbox, on the client side for performance reasons.

Again, cookies do not handle this case well, because they are transmitted with every request.

The localStorage IDL attribute is used to access a page’s local storage area.

The site at example.com can display a count of how many times the user has loaded its page by putting the following at the bottom of its page:

```html
<p>
  You have viewed this page
  <span id="count">an untold number of</span>
  time(s).
</p>
<script>
  if (!localStorage.pageLoadCount)
    localStorage.pageLoadCount = 0;
  localStorage.pageLoadCount = parseInt(localStorage.pageLoadCount) + 1;
  document.getElementById('count').textContent = localStorage.pageLoadCount;
</script>
```
Each site has its own separate storage area.

### 11.2 The API

#### 11.2.1 The Storage interface

```idl
[Exposed=Window]
interface Storage {
    readonly attribute unsigned long length;
    DOMString? key(unsigned long index);
    getter DOMString? get(key(DOMString key));
    setter void set(DOMString key, DOMString value);
    deleter void remove(DOMString key);
    void clear();
};
```

Each Storage object provides access to a list of key/value pairs, which are sometimes called items. Keys are strings. Any string (including the empty string) is a valid key. Values are similarly strings.

Each Storage object is associated with a list of key/value pairs when it is created, as defined in the sections on the sessionStorage and localStorage attributes. Multiple separate objects implementing the Storage interface can all be associated with the same list of key/value pairs simultaneously.

**For web developers (non-normative)**

- **storage.length**

  Returns the number of key/value pairs currently present in the list associated with the object.

- **storage.key(n)**

  Returns the name of the nth key in the list, or null if n is greater than or equal to the number of key/value pairs in the object.

- **value = storage.getItem(key)**

- **value = storage[key]**

  Returns the current value associated with the given key, or null if the given key does not exist in the list associated with the object.

- **storage.setItem(key, value)**

- **storage[key] = value**

  Sets the value of the pair identified by key to value, creating a new key/value pair if none existed for key previously.

  Throws a "QuotaExceededError" DOMException exception if the new value couldn’t be set. (Setting could fail if, e.g., the user has disabled storage for the site, or if the quota has been exceeded.)

- **storage.removeItem(key)**

- **delete storage[key]**

  Removes the key/value pair with the given key from the list associated with the object, if a key/value pair with the given key exists.

- **storage.clear()**

  Empties the list associated with the object of all key/value pairs, if there are any.

The `length` attribute must return the number of key/value pairs currently present in the list associated with the object.

The `key(n)` method must return the name of the nth key in the list. The order of keys is user-agent defined, but must be consistent
within an object so long as the number of keys doesn’t change. (Thus, adding or removing a key may change the order of the keys, but merely changing the value of an existing key must not.) If \( n \) is greater than or equal to the number of key/value pairs in the object, then this method must return null.

The supported property names on a Storage object are the keys of each key/value pair currently present in the list associated with the object, in the order that the keys were last added to the storage area.

The \( \text{setItem}(key) \) method must return the current value associated with the given key. If the given key does not exist in the list associated with the object then this method must return null.

The \( \text{setItem}(key, \text{value}) \) method must first check if a key/value pair with the given key already exists in the list associated with the object.

If it does not, then a new key/value pair must be added to the list, with the given key and with its value set to \( \text{value} \).

If the given key does exist in the list, and its value is not equal to \( \text{value} \), then it must have its value updated to \( \text{value} \). If its previous value is equal to \( \text{value} \), then the method must do nothing.

If it couldn’t set the new value, the method must throw a \"QuotaExceededError\" DOMException exception.

The \( \text{removeItem}(key) \) method must cause the key/value pair with the given key to be removed from the list associated with the object, if it exists. If no item with that key exists, the method must do nothing.

The \( \text{setItem()} \) and \( \text{removeItem()} \) methods must be atomic with respect to failure. In the case of failure, the method does nothing. That is, changes to the data storage area must either be successful, or the data storage area must not be changed at all.

The \( \text{clear()} \) method must atomically cause the list associated with the object to be emptied of all key/value pairs, if there are any. If there are none, then the method must do nothing.

Note

When the \( \text{setItem()}, \text{removeItem()}, \text{clear()} \) methods are invoked, events are fired on the Window objects of other Document\(\)s that can access the newly stored or removed data, as defined in the sections on the \( \text{sessionStorage} \) and \( \text{localStorage} \) attributes.

Note

This specification does not require that the above methods wait until the data has been physically written to disk. Only consistency in what different scripts accessing the same underlying list of key/value pairs see is required.

11.2.2 The \( \text{sessionStorage} \) attribute

IDL

\[
\text{interface mixin WindowSessionStorage} \{
\text{readonly attribute Storage sessionStorage;}
\};
\]

\[
\text{Window includes WindowSessionStorage;}
\]

The \( \text{sessionStorage} \) attribute represents the set of storage areas specific to the current top-level browsing context.

For web developers (non-normative)

\[
\text{window} . \text{sessionStorage}
\]

Returns the Storage object associated with that origin’s session storage area.

Each top-level browsing context has a unique set of session storage areas, one for each origin.

User agents should not expire data from a browsing context’s session storage areas, but may do so when the user requests that such data be deleted, or when the UA detects that it has limited storage space, or for security reasons. User agents should always avoid deleting data while a script that could access that data is running. When a top-level browsing context is destroyed (and therefore permanently inaccessible to the user) the data stored in its session storage areas can be discarded with it, as the API described in this specification provides no way for that data to ever be subsequently retrieved.
When a new Document is created in a browsing context which has a top-level browsing context, the user agent must check to see if that top-level browsing context has a session storage area for that document's origin. If it does, then that is the Document's assigned session storage area. If it does not, a new storage area for that document's origin must be created, and then that is the Document's assigned session storage area. A Document's assigned storage area does not change during the lifetime of a Document.

The sessionStorage attribute must return a Storage object associated with the Document's assigned session storage area. Each Document object must have a separate object for its Window's sessionStorage attribute.

While creating a new browsing context, the session storage area is sometimes copied over.

When the setItem(), removeItem(), and clear() methods are called on a Storage object x that is associated with a session storage area, if the methods did not throw an exception or "do nothing" as defined above, then for every Document object whose Window object's sessionStorage attribute's Storage object is associated with the same storage area, other than x, send a storage notification.

### 11.2.3 The localStorage attribute

IDL
define mixin WindowLocalStorage {  
readonly attribute Storage localStorage;
};
Window includes WindowLocalStorage;

The localStorage object provides a Storage object for an origin.

For web developers (non-normative)

window.localStorage

- Returns the Storage object associated with that origin's local storage area.
- Throws a "SecurityError" DOMException if the Document's origin is an opaque origin or if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to persist data).

User agents must have a set of local storage areas, one for each origin.

User agents should expire data from the local storage areas only for security reasons or when requested to do so by the user. User agents should always avoid deleting data while a script that could access that data is running.

When the localStorage attribute is accessed, the user agent must run the following steps, which are known as the Storage object initialization steps:

1. If the request violates a policy decision (e.g. if the user agent is configured to not allow the page to persist data), the user agent may throw a "SecurityError" DOMException instead of returning a Storage object.
2. If the Document's origin is an opaque origin, then throw a "SecurityError" DOMException.
3. Check to see if the user agent has allocated a local storage area for the origin of the Document of the Window object on which the attribute was accessed. If it has not, create a new storage area for that origin.
4. Return the Storage object associated with that origin's local storage area. Each Document object must have a separate object for its Window's localStorage attribute.
When the `setItem()` and `removeItem()` methods are called on a `Storage` object \(x\) that is associated with a local storage area, if the methods did not throw an exception or "do nothing" as defined above, then for every `Document` object whose `localStorage` attribute's `Storage` object is associated with the same storage area, other than \(x\), send a storage notification.

⚠ Warning! The `localStorage` attribute provides access to shared state. This specification does not define the interaction with other browsing contexts in a multiprocess user agent, and authors are encouraged to assume that there is no locking mechanism. A site could, for instance, try to read the value of a key, increment its value, then write it back out, using the new value as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same "unique" identifier for both sessions, with potentially disastrous effects.

11.2.4 The `storage` event

The `storage` event is fired on a `Document`'s `Window` object when a storage area changes, as described in the previous two sections (for session `storage`, for local `storage`).

When a user agent is to send a storage notification for a `Document`, the user agent must queue a task to fire an event named `storage` at the `Document` object's `Window` object, using `StorageEvent`.

The task source for these tasks is the DOM manipulation task source.

If the event is being fired due to an invocation of the `setItem()` or `removeItem()` methods, the event must have its `key` attribute initialized to the name of the key in question, its `oldValue` attribute initialized to the old value of the key in question, or null if the key is newly added, and its `newValue` attribute initialized to the new value of the key in question, or null if the key was removed.

Otherwise, if the event is being fired due to an invocation of the `clear()` method, the event must have its `key`, `oldValue`, and `newValue` attributes initialized to null.

In addition, the event must have its `url` attribute initialized to the URL of the document whose `Storage` object was affected; and its `storageArea` attribute initialized to the `Storage` object from the `Window` object of the target `Document` that represents the same kind of `Storage` area as was affected (i.e. session or local).

11.2.4.1 The `StorageEvent` interface

```idl
[Exposed=Window,
 Constructor(DOMString type, optional StorageEventInit eventInitDict)]
interface StorageEvent : Event {
    readonly attribute DOMString? key;
    readonly attribute DOMString? oldValue;
    readonly attribute DOMString? newValue;
    readonly attribute USVString url;
    readonly attribute Storage? storageArea;
};
```

```dictionary
StorageEventInit : EventInit {
    DOMString? key = null;
    DOMString? oldValue = null;
    DOMString? newValue = null;
    USVString url = "";
    Storage? storageArea = null;
};
```
The `key`, `oldValue`, `newValue`, `url`, and `storageArea` attributes must return the values they were initialized to.

### 11.3 Disk space

User agents should limit the total amount of space allowed for storage areas, because hostile authors could otherwise use this feature to exhaust the user's available disk space.

User agents should guard against sites storing data under their origin's other affiliated sites, e.g. storing up to the limit in `a1.example.com`, `a2.example.com`, `a3.example.com`, etc, circumventing the main `example.com` storage limit.

User agents may prompt the user when quotas are reached, allowing the user to grant a site more space. This enables sites to store many user-created documents on the user's computer, for instance.

User agents should allow users to see how much space each domain is using.

A mostly arbitrary limit of five megabytes per `origin` is suggested. Implementation feedback is welcome and will be used to update this suggestion in the future.

For predictability, quotas should be based on the uncompressed size of data stored.

### 11.4 Privacy

#### 11.4.1 User tracking

A third-party advertiser (or any entity capable of getting content distributed to multiple sites) could use a unique identifier stored in its local storage area to track a user across multiple sessions, building a profile of the user's interests to allow for highly targeted advertising. In conjunction with a site that is aware of the user's real identity (for example an e-commerce site that requires authenticated credentials), this could allow oppressive groups to target individuals with greater accuracy than in a world with purely anonymous Web usage.

There are a number of techniques that can be used to mitigate the risk of user tracking:

**Blocking third-party storage**

User agents may restrict access to the `LocalStorage` objects to scripts originating at the domain of the `active document` of the `top-level browsing context`, for instance denying access to the API for pages from other domains running in `iframe`s.

**Expiring stored data**

User agents may, possibly in a manner configured by the user, automatically delete stored data after a period of time.

For example, a user agent could be configured to treat third-party local storage areas as session-only storage, deleting the data...
once the user had closed all the browsing contexts that could access it. This can restrict the ability of a site to track a user, as the site would then only be able to track the user across multiple sessions when they authenticate with the site itself (e.g. by making a purchase or logging in to a service).

However, this also reduces the usefulness of the API as a long-term storage mechanism. It can also put the user's data at risk, if the user does not fully understand the implications of data expiration.

**Treating persistent storage as cookies**

If users attempt to protect their privacy by clearing cookies without also clearing data stored in the local storage area, sites can defeat those attempts by using the two features as redundant backup for each other. User agents should present the interfaces for clearing these in a way that helps users to understand this possibility and enables them to delete data in all persistent storage features simultaneously. [COOKIES]

**Site-specific safelisting of access to local storage areas**

User agents may allow sites to access session storage areas in an unrestricted manner, but require the user to authorize access to local storage areas.

**Origin-tracking of stored data**

User agents may record the origins of sites that contained content from third-party origins that caused data to be stored. If this information is then used to present the view of data currently in persistent storage, it would allow the user to make informed decisions about which parts of the persistent storage to prune. Combined with a blocklist ("delete this data and prevent this domain from ever storing data again"), the user can restrict the use of persistent storage to sites that they trust.

**Shared blocklists**

User agents may allow users to share their persistent storage domain blocklists. This would allow communities to act together to protect their privacy.

While these suggestions prevent trivial use of this API for user tracking, they do not block it altogether. Within a single domain, a site can continue to track the user during a session, and can then pass all this information to the third party along with any identifying information (names, credit card numbers, addresses) obtained by the site. If a third party cooperates with multiple sites to obtain such information, a profile can still be created.

However, user tracking is to some extent possible even with no cooperation from the user agent whatsoever, for instance by using session identifiers in URLs, a technique already commonly used for innocuous purposes but easily repurposed for user tracking (even retroactively). This information can then be shared with other sites, using visitors’ IP addresses and other user-specific data (e.g. user-agent headers and configuration settings) to combine separate sessions into coherent user profiles.

**11.4.2 Sensitivity of data**

User agents should treat persistently stored data as potentially sensitive; it’s quite possible for e-mails, calendar appointments, health records, or other confidential documents to be stored in this mechanism.

To this end, user agents should ensure that when deleting data, it is promptly deleted from the underlying storage.

**11.5 Security**

**11.5.1 DNS spoofing attacks**

Because of the potential for DNS spoofing attacks, one cannot guarantee that a host claiming to be in a certain domain really is from that domain. To mitigate this, pages can use TLS. Pages using TLS can be sure that only the user, software working on behalf of the user, and other pages using TLS that have certificates identifying them as being from the same domain, can access their storage areas.
11.5.2 Cross-directory attacks

Different authors sharing one host name, for example users hosting content on the now defunct geocities.com, all share one local storage object. There is no feature to restrict the access by pathname. Authors on shared hosts are therefore urged to avoid using these features, as it would be trivial for other authors to read the data and overwrite it.

**Note**

Even if a path-restriction feature was made available, the usual DOM scripting security model would make it trivial to bypass this protection and access the data from any path.

11.5.3 Implementation risks

The two primary risks when implementing these persistent storage features are letting hostile sites read information from other domains, and letting hostile sites write information that is then read from other domains.

Letting third-party sites read data that is not supposed to be read from their domain causes *information leakage*. For example, a user's shopping wishlist on one domain could be used by another domain for targeted advertising; or a user's work-in-progress confidential documents stored by a word-processing site could be examined by the site of a competing company.

Letting third-party sites write data to the persistent storage of other domains can result in *information spoofing*, which is equally dangerous. For example, a hostile site could add items to a user's wishlist; or a hostile site could set a user's session identifier to a known ID that the hostile site can then use to track the user's actions on the victim site.

Thus, strictly following the *origin* model described in this specification is important for user security.
12 The HTML syntax

This section only describes the rules for resources labeled with an HTML MIME type. Rules for XML resources are discussed in the section below entitled "The XML syntax".

12.1 Writing HTML documents

This section only applies to documents, authoring tools, and markup generators. In particular, it does not apply to conformance checkers; conformance checkers must use the requirements given in the next section ("parsing HTML documents").

Documents must consist of the following parts, in the given order:

1. Optionally, a single U+FEFF BYTE ORDER MARK (BOM) character.
2. Any number of comments and ASCII whitespace.
3. A DOCTYPE.
4. Any number of comments and ASCII whitespace.
5. The document element, in the form of an html element.
6. Any number of comments and ASCII whitespace.

The various types of content mentioned above are described in the next few sections.

In addition, there are some restrictions on how character encoding declarations are to be serialized, as discussed in the section on that topic.

**Note**

ASCII whitespace before the html element, at the start of the html element and before the head element, will be dropped when the document is parsed; ASCII whitespace after the html element will be parsed as if it were at the end of the body element. Thus, ASCII whitespace around the document element does not round-trip.

It is suggested that newlines be inserted after the DOCTYPE, after any comments that are before the document element, after the html element's start tag (if it is not omitted), and after any comments that are inside the html element but before the head element.

Many strings in the HTML syntax (e.g. the names of elements and their attributes) are case-insensitive, but only for ASCII upper alphas and ASCII lower alphas. For convenience, in this section this is just referred to as "case-insensitive".

12.1.1 The DOCTYPE

A DOCTYPE is a required preamble.

**Note**

DOCTYPEs are required for legacy reasons. When omitted, browsers tend to use a different rendering mode that is incompatible with some specifications. Including the DOCTYPE in a document ensures that the browser makes a best-effort attempt at following the relevant specifications.

A DOCTYPE must consist of the following components, in this order:

1. A string that is an ASCII case-insensitive match for the string "<!DOCTYPE".
2. One or more ASCII whitespace.
3. A string that is an ASCII case-insensitive match for the string "html".
4. Optionally, a DOCTYPE legacy string.
5. Zero or more ASCII whitespace.
6. A U+003E GREATER-THAN SIGN character (>).

Note
In other words, `<!DOCTYPE html>, case-insensitively.`

For the purposes of HTML generators that cannot output HTML markup with the short DOCTYPE "<!DOCTYPE html>", a DOCTYPE legacy string may be inserted into the DOCTYPE (in the position defined above). This string must consist of:

1. One or more ASCII whitespace.
2. A string that is an ASCII case-insensitive match for the string "SYSTEM".
3. One or more ASCII whitespace.
4. A U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (the quote mark).
5. The literal string "about:legacy-compat" (case-insensitively except for the part in single or double quotes).
6. A matching U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (i.e. the same character as in the earlier step labeled quote mark).

Note
In other words, `<!DOCTYPE html SYSTEM "about:legacy-compat" or <!DOCTYPE html SYSTEM 'about:legacy-compat'>, case-insensitively except for the part in single or double quotes.

The DOCTYPE legacy string should not be used unless the document is generated from a system that cannot output the shorter string.

12.1.2 Elements

There are six different kinds of elements: void elements, the template element, raw text elements, escapable raw text elements, foreign elements, and normal elements.

Void elements
area, base, br, col, embed, img, input, link, meta, param, source, track, wbr

The template element
template

Raw text elements
script, style

escapable raw text elements
textarea, title

Foreign elements
Elements from the MathML namespace and the SVG namespace.

Normal elements
All other allowed HTML elements are normal elements.

Tags are used to delimit the start and end of elements in the markup. Raw text, escapable raw text, and normal elements have a start tag to indicate where they begin, and an end tag to indicate where they end. The start and end tags of certain normal elements can be omitted, as described below in the section on optional tags. Those that cannot be omitted must not be omitted. Void elements only have a start tag; end tags must not be specified for void elements. Foreign elements must either have a start tag and an end tag, or a start tag that is marked as self-closing, in which case they must not have an end tag.

The contents of the element must be placed between just after the start tag (which might be implied, in certain cases) and just before the end tag (which again, might be implied in certain cases). The exact allowed contents of each individual element depend on the content model, of that element, as described earlier in this specification. Elements must not contain content that their content model disallows. In addition to the restrictions placed on the contents by those content models, however, the five types of elements have additional syntactic requirements.

Void elements can't have any contents (since there's no end tag, no content can be put between the start tag and the end tag).

The template element can have template contents, but such template contents are not children of the template.
element itself. Instead, they are stored in a DocumentFragment associated with a different Document — without a browsing context — so as to avoid the template contents interfering with the main Document. The markup for the template element is placed just after the template element's start tag and just before template element's end tag (as with other elements), and may consist of any text, character references, elements, and comments, but but the text must not contain the character U+003C LESS-THAN SIGN (<) or an ambiguous ampersand.

Raw text elements can have text, though it has restrictions described below.

Escapable raw text elements can have text and character references, but the text must not contain an ambiguous ampersand. There are also further restrictions described below.

Foreign elements whose start tag is marked as self-closing can't have any contents (since, again, as there’s no end tag, no content can be put between the start tag and the end tag). Foreign elements whose start tag is not marked as self-closing can have text, character references, CDATA sections, other elements, and comments, but the text must not contain the character U+003C LESS-THERN SIGN (<) or an ambiguous ampersand.

The HTML syntax does not support namespace declarations, even in foreign elements. For instance, consider the following HTML fragment:

```html
<p>
<svg>
<metadata>
<!-- this is invalid -->
<cdr:license xmlns:cdr="https://www.example.com/cdr/metadata" name="MIT"/>
</metadata>
</svg>
</p>
```

The innermost element, cdr:license, is actually in the SVG namespace, as the "xmlns:cdr" attribute has no effect (unlike in XML). In fact, as the comment in the fragment above says, the fragment is actually non-conforming. This is because the SVG specification does not define any elements called "cdr:license" in the SVG namespace.

Normal elements can have text, character references, other elements, and comments, but the text must not contain the character U+003C LESS-THERN SIGN (<) or an ambiguous ampersand. Some normal elements also have yet more restrictions on what content they are allowed to hold, beyond the restrictions imposed by the content model and those described in this paragraph. Those restrictions are described below.

Tags contain a tag name, giving the element's name. HTML elements all have names that only use ASCII alphanumerics. In the HTML syntax, tag names, even those for foreign elements, may be written with any mix of lower- and uppercase letters that, when converted to all-lowercase, matches the element's tag name; tag names are case-insensitive.

### 12.1.2.1 Start tags

Start tags must have the following format:

1. The first character of a start tag must be a U+003C LESS-THERN SIGN character (<).
2. The next few characters of a start tag must be the element's tag name.
3. If there are to be any attributes in the next step, there must first be one or more ASCII whitespace.
4. Then, the start tag may have a number of attributes, the syntax for which is described below. Attributes must be separated from each other by one or more ASCII whitespace.
5. After the attributes, or after the tag name if there are no attributes, there may be one or more ASCII whitespace. (Some attributes are required to be followed by a space. See the attributes section below.)
6. Then, if the element is one of the void elements, or if the element is a foreign element, then there may be a single U+002F SOLIDUS character (/). This character has no effect on void elements, but on foreign elements it marks the
start tag as self-closing.

7. Finally, start tags must be closed by a U+003E GREATER-THAN SIGN character (>).

12.1.2.2 End tags

End tags must have the following format:

1. The first character of an end tag must be a U+003C LESS-THAN SIGN character (<).
2. The second character of an end tag must be a U+002F SOLIDUS character (/).
3. The next few characters of an end tag must be the element's tag name.
4. After the tag name, there may be one or more ASCII whitespace.
5. Finally, end tags must be closed by a U+003E GREATER-THAN SIGN character (>).

12.1.2.3 Attributes

Attributes for an element are expressed inside the element's start tag.

Attributes have a name and a value. Attribute names must consist of one or more characters other than controls, U+0020 SPACE, U+0022 ("), U+0027 ('), U+003D (=), U+003C (<), U+003E (>), and noncharacters. In the HTML syntax, attribute names, even those for foreign elements, may be written with any mix of ASCII lower and ASCII upper alphas.

Attribute values are a mixture of text and character references, except with the additional restriction that the text cannot contain an ambiguous ampersand.

Attributes can be specified in four different ways:

Empty attribute syntax

Just the attribute name. The value is implicitly the empty string.

Example

In the following example, the disabled attribute is given with the empty attribute syntax:

<input disabled>

If an attribute using the empty attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

Unquoted attribute value syntax

The attribute name, followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by the attribute value, which, in addition to the requirements given above for attribute values, must not contain any literal ASCII whitespace, any U+0022 QUOTATION MARK characters ("), U+0027 APOSTROPHE characters ('), U+003D EQUALS SIGN characters (=), U+003C LESS-THERE SIGN characters (<), U+003E GREATER THAN SIGN characters (>), or U+0060 GRAVE ACCENT characters (`), and must not be the empty string.

Example

In the following example, the value attribute is given with the unquoted attribute value syntax:

<input value=yes>

If an attribute using the unquoted attribute value syntax is to be followed by another attribute or by the optional U+002F SOLIDUS character (/) allowed in step 6 of the start tag syntax above, then there must be ASCII whitespace separating the two.

Single-quoted attribute value syntax

The attribute name, followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by a single U+0027 APOSTROPHE character ('), followed by the attribute value, which, in addition to the requirements given above for attribute values, must not contain any literal U+0027 APOSTROPHE

1013
characters ("'), and finally followed by a second single U+0027 APOSTROPHE character (').

**Example**

In the following example, the **type** attribute is given with the single-quoted attribute value syntax:

```html
<input type='checkbox'>
```

If an attribute using the single-quoted attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

**Double-quoted attribute value syntax**

The attribute name, followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by a single U+0022 QUOTATION MARK character ("), followed by the attribute value, which, in addition to the requirements given above for attribute values, must not contain any literal U+0022 QUOTATION MARK characters ("), and finally followed by a second single U+0022 QUOTATION MARK character (").

**Example**

In the following example, the **name** attribute is given with the double-quoted attribute value syntax:

```html
<input name="be evil">
```

If an attribute using the double-quoted attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

There must never be two or more attributes on the same start tag whose names are an ASCII case-insensitive match for each other.

When a foreign element has one of the namespaced attributes given by the local name and namespace of the first and second cells of a row from the following table, it must be written using the name given by the third cell from the same row.

<table>
<thead>
<tr>
<th>Local name</th>
<th>Namespace</th>
<th>Attribute name</th>
</tr>
</thead>
<tbody>
<tr>
<td>actuate</td>
<td>XLink namespace</td>
<td>xlink:actuate</td>
</tr>
<tr>
<td>arcrole</td>
<td>XLink namespace</td>
<td>xlink:arcrole</td>
</tr>
<tr>
<td>href</td>
<td>XLink namespace</td>
<td>xlink:href</td>
</tr>
<tr>
<td>role</td>
<td>XLink namespace</td>
<td>xlink:role</td>
</tr>
<tr>
<td>show</td>
<td>XLink namespace</td>
<td>xlink:show</td>
</tr>
<tr>
<td>title</td>
<td>XLink namespace</td>
<td>xlink:title</td>
</tr>
<tr>
<td>type</td>
<td>XLink namespace</td>
<td>xlink:type</td>
</tr>
<tr>
<td>lang</td>
<td>XML namespace</td>
<td>xml:lang</td>
</tr>
<tr>
<td>space</td>
<td>XML namespace</td>
<td>xml:space</td>
</tr>
<tr>
<td>xmlns</td>
<td>XMLNS namespace</td>
<td>xmlns</td>
</tr>
<tr>
<td>xlink</td>
<td>XMLNS namespace</td>
<td>xmlns:xlink</td>
</tr>
</tbody>
</table>

No other namespaced attribute can be expressed in the HTML syntax.

**Note**

Whether the attributes in the table above are conforming or not is defined by other specifications (e.g. the SVG and MathML specifications); this section only describes the syntax rules if the attributes are serialized using the HTML syntax.

12.1.2.4 Optional tags

Certain tags can be omitted.

**Note**

Omitting an element’s start tag in the situations described below does not mean the element is not present; it is implied, but it is still there. For example, an HTML document always has a root `html` element, even if the string `<html>` doesn’t appear anywhere in the markup.

An `html` element’s start tag may be omitted if the first thing inside the `html` element is not a comment.
For example, in the following case it's ok to remove the "<html>" tag:

```html
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

Doing so would make the document look like this:

```html
<!DOCTYPE HTML>

  <head>
    <title>Hello</title>
  
  
  <body>
    <p>Welcome to this example.</p>
  
  </body>

</html>
```

This has the exact same DOM. In particular, note that whitespace around the document element is ignored by the parser. The following example would also have the exact same DOM:

```html
<!DOCTYPE HTML>

  <head>
    <title>Hello</title>
  
  
  <body>
    <p>Welcome to this example.</p>
  
  </body>

</html>
```

However, in the following example, removing the start tag moves the comment to before the html element:

```html
<!DOCTYPE HTML>

  <html>
    <!-- where is this comment in the DOM? -->
    <head>
      <title>Hello</title>
    
    
    <body>
      <p>Welcome to this example.</p>
    
    </body>

  </html>
```

With the tag removed, the document actually turns into the same as this:

```html
<!DOCTYPE HTML>

  <!-- where is this comment in the DOM? -->
  <html>
    <head>
      <title>Hello</title>
    
    
    <body>
      <p>Welcome to this example.</p>
    
    </body>

  </html>
```
An `html` element's end tag may be omitted if the `html` element is not immediately followed by a `comment`.

A `head` element's start tag may be omitted if the element is empty, or if the first thing inside the `head` element is an element.

A `head` element's end tag may be omitted if the `head` element is not immediately followed by `ASCII whitespace` or a `comment`.

A `body` element's start tag may be omitted if the element is empty, or if the first thing inside the `body` element is `ASCII whitespace` or a `comment`, except if the first thing inside the `body` element is a `meta`, `link`, `script`, `style`, or `template` element.

A `body` element's end tag may be omitted if the `body` element is not immediately followed by a `comment`.

Example

Note that in the example above, the `head` element start and end tags, and the `body` element start tag, can't be omitted, because they are surrounded by whitespace:

```html
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

(The `body` and `html` element end tags could be omitted without trouble; any spaces after those get parsed into the `body` element anyway.)

Usually, however, whitespace isn't an issue. If we first remove the whitespace we don't care about:

```html
<!DOCTYPE HTML>
<html><head><title>Hello</title></head><body><p>Welcome to this example.</p></body></html>
```

Then we can omit a number of tags without affecting the DOM:

```html
<title>Hello</title><p>Welcome to this example.</p>
```

At that point, we can also add some whitespace back:

```html
<title>Hello</title>
<p>Welcome to this example.</p>
```

This would be equivalent to this document, with the omitted tags shown in their parser-implied positions; the only whitespace text node that results from this is the newline at the end of the `head` element:

```html
<!DOCTYPE HTML>
```
An `li` element's `end tag` may be omitted if the `li` element is immediately followed by another `li` element or if there is no more content in the parent element.

A `dt` element's `end tag` may be omitted if the `dt` element is immediately followed by another `dt` element or a `dd` element.

A `dd` element's `end tag` may be omitted if the `dd` element is immediately followed by another `dd` element or a `dt` element, or if there is no more content in the parent element.

A `p` element's `end tag` may be omitted if the `p` element is immediately followed by an `address`, `article`, `aside`, `blockquote`, `details`, `div`, `dl`, `fieldset`, `figcaption`, `figure`, `footer`, `form`, `h1`, `h2`, `h3`, `h4`, `h5`, `header`, `hgroup`, `hr`, `main`, `menu`, `nav`, `ol`, `p`, `pre`, `section`, `table`, or `ul` element, or if there is no more content in the parent element and the parent element is an HTML element that is not an `a`, `audio`, `del`, `del`, `ins`, `map`, `noscript`, or `video` element, or an autonomous custom element.

**Example**

We can thus simplify the earlier example further:

```html
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.</p>
```

An `rt` element's `end tag` may be omitted if the `rt` element is immediately followed by an `rt` or `rp` element, or if there is no more content in the parent element.

An `rp` element's `end tag` may be omitted if the `rp` element is immediately followed by an `rt` or `rp` element, or if there is no more content in the parent element.

An `optgroup` element's `end tag` may be omitted if the `optgroup` element is immediately followed by another `optgroup` element, or if there is no more content in the parent element.

An `option` element's `end tag` may be omitted if the `option` element is immediately followed by another `option` element, or if it is immediately followed by an `optgroup` element, or if there is no more content in the parent element.

A `colgroup` element's `start tag` may be omitted if the first thing inside the `colgroup` element is a `col` element, and if the element is not immediately preceded by another `colgroup` element whose `end tag` has been omitted. (It can't be omitted if the element is empty.)

A `colgroup` element's `end tag` may be omitted if the `colgroup` element is not immediately followed by an `ASCII whitespace` or a `comment`.

A `caption` element's `end tag` may be omitted if the `caption` element is not immediately followed by an `ASCII whitespace` or a `comment`.

A `thead` element's `end tag` may be omitted if the `thead` element is immediately followed by a `tbody` or `tfoot` element.

A `tbody` element's `start tag` may be omitted if the first thing inside the `tbody` element is a `tr` element, and if the element is not immediately preceded by a `tbody`, `thead`, or `tfoot` element whose `end tag` has been omitted. (It can't be omitted if the element is empty.)

A `tbody` element's `end tag` may be omitted if the `tbody` element is immediately followed by a `tbody` or `tfoot` element, or if there is no more content in the parent element.

A `tfoot` element's `end tag` may be omitted if there is no more content in the parent element.

A `tr` element's `end tag` may be omitted if the `tr` element is immediately followed by another `tr` element, or if there is no more content in the parent element.
A `<td>` element's end tag may be omitted if the `<td>` element is immediately followed by a `<td>` or `<th>` element, or if there is no more content in the parent element.

A `<th>` element's end tag may be omitted if the `<th>` element is immediately followed by a `<td>` or `<th>` element, or if there is no more content in the parent element.

*Example*

The ability to omit all these table-related tags makes table markup much terser.

Take this example:

```xml
<table>
  <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
  <colgroup><col><col><col></colgroup>
  <thead>
    <tr>
      <th>Function</th>
      <th>Control Unit</th>
      <th>Central Station</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>Headlights</td>
      <td>✔</td>
      <td>✔</td>
    </tr>
    <tr>
      <td>Interior Lights</td>
      <td>✔</td>
      <td>✔</td>
    </tr>
    <tr>
      <td>Electric locomotive operating sounds</td>
      <td>✔</td>
      <td>✔</td>
    </tr>
    <tr>
      <td>Engineer's cab lighting</td>
      <td>✔</td>
    </tr>
    <tr>
      <td>Station Announcements - Swiss</td>
      <td>✔</td>
    </tr>
  </tbody>
</table>
```

The exact same table, modulo some whitespace differences, could be marked up as follows:

```xml
<table>
  <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)
  <colgroup><col><col><col>
  <thead>
    <tr>
      <th>Function</th>
      <th>Control Unit</th>
      <th>Central Station</th>
    </tr>
  </tbody>
</table>
```
However, a [start tag[^1012]] must never be omitted if it has any attributes.

### Example

Returning to the earlier example with all the whitespace removed and then all the optional tags removed:

```html
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.

If the [body][p171] element in this example had to have a [class][p133] attribute and the [html][p148] element had to have a [lang][p136] attribute, the markup would have to become:

```html
<!DOCTYPE HTML><html lang="en"><title>Hello</title><body class="demo"><p>Welcome to this example.

[^1012]: This section assumes that the document is conforming, in particular, that there are no content model[^125] violations. Omitting tags in the fashion described in this section in a document that does not conform to the content models[^125] described in this specification is likely to result in unexpected DOM differences (this is, in part, what the content models are designed to avoid).
12.1.2.5 Restrictions on content models

For historical reasons, certain elements have extra restrictions beyond even the restrictions given by their content model.

A `table` element must not contain `tr` elements, even though these elements are technically allowed inside `table` elements according to the content models described in this specification. (If a `tr` element is put inside a `table` in the markup, it will in fact imply a `tbody` start tag before it.)

A single `newline` may be placed immediately after the start tag of `pre` and `textarea` elements. This does not affect the processing of the element. The otherwise optional `newline` must be included if the element's contents themselves start with a `newline` (because otherwise the leading newline in the contents would be treated like the optional newline, and ignored).

Example

The following two `pre` blocks are equivalent:

```html
<pre>Hello</pre>
<pre>Hello</pre>
```

12.1.2.6 Restrictions on the contents of raw text and escapable raw text elements

The text in `raw text` and `escapable raw text elements` must not contain any occurrences of the string "\</" (U+003C LESS-THAN SIGN, U+002F SOLIDUS) followed by characters that case-insensitively match the tag name of the element followed by one of U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), U+0020 SPACE, U+003E GREATER-THAN SIGN (>,) or U+002F SOLIDUS (/).

12.1.3 Text

Text is allowed inside elements, attribute values, and comments. Extra constraints are placed on what is and what is not allowed in text based on where the text is to be put, as described in the other sections.

12.1.3.1 Newlines

Newlines in HTML may be represented either as U+000D CARRIAGE RETURN (CR) characters, U+000A LINE FEED (LF) characters, or pairs of U+000D CARRIAGE RETURN (CR), U+000A LINE FEED (LF) characters in that order.

Where `character references` are allowed, a character reference of a U+000A LINE FEED (LF) character (but not a U+000D CARRIAGE RETURN (CR) character) also represents a `newline`.

12.1.4 Character references

In certain cases described in other sections, `text` may be mixed with `character references`. These can be used to escape characters that couldn't otherwise legally be included in `text`.

Character references must start with a U+0026 AMPERSAND character (&). Following this, there are three possible kinds of character references:

Named character references

The ampersand must be followed by one of the names given in the `named character references` section, using the same case. The name must be one that is terminated by a U+003B SEMICOLON character (;).

Decimal numeric character reference

The ampersand must be followed by a U+0023 NUMBER SIGN character (#), followed by one or more `ASCII digits`, representing a
base-ten integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

Hexadecimal numeric character reference

The ampersand must be followed by a U+0023 NUMBER SIGN character (#), which must be followed by either a U+0078 LATIN SMALL LETTER X character (x) or a U+0058 LATIN CAPITAL LETTER X character (X), which must then be followed by one or more ASCII hex digits, representing a hexadecimal integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

The numeric character reference forms described above are allowed to reference any code point excluding U+000D CR, noncharacters, and controls other than ASCII whitespace.

An ambiguous ampersand is a U+0026 AMPERSAND character (&) that is followed by one or more ASCII alphanumerics, followed by a U+003B SEMICOLON character (;), where these characters do not match any of the names given in the named character references\textsuperscript{p1120} section.

### 12.1.5 CDATA sections\textsuperscript{p10}

**CDATA sections** must consist of the following components, in this order:

1. The string "<! [CDATA[".
2. Optionally, text\textsuperscript{p1020}, with the additional restriction that the text must not contain the string " ]]>".
3. The string " ]]>".

**Example**

CDATA sections can only be used in foreign content (MathML or SVG). In this example, a CDATA section is used to escape the contents of a MathML ms element:

```xml
<p>You can add a string to a number, but this stringifies the number:</p>
<math>
  <ms>\langle [CDATA[x>y]]\rangle</ms>
  <mo>+</mo>
  <mn>3</mn>
  <mo>\rangle</mo>
  <ms>\langle [CDATA[x>y\rangle]</ms>
</math>
```

### 12.1.6 Comments\textsuperscript{p10}

**Comments** must have the following format:

1. The string "<! - - ".
2. Optionally, text\textsuperscript{p1020}, with the additional restriction that the text must not start with the string " >", nor start with the string "--">, nor contain the strings "<! "-, "- >", or "-- >", nor end with the string "<! - ".
3. The string " - >".

**Note**

The text\textsuperscript{p1020} is allowed to end with the string "<!", as in <!-- My favorite operators are > and <!-- >.

### 12.2 Parsing HTML documents\textsuperscript{p10}

This section only applies to user agents, data mining tools, and conformance checkers.
User agents must use the parsing rules described in this section to generate the DOM trees from \text{text/html} resources. Together, these rules define what is referred to as the \text{HTML parser}.

\textbf{Note}

The rules for parsing XML documents into DOM trees are covered by the next section, entitled \text{"The XML syntax"}.

For the purposes of conformance checkers, if a resource is determined to be in the \text{HTML syntax}, then it is an \text{HTML document}.

\textbf{Note}

While the HTML syntax described in this specification bears a close resemblance to SGML and XML, it is a separate language with its own parsing rules.

Some earlier versions of HTML (in particular from HTML2 to HTML4) were based on SGML and used SGML parsing rules. However, few (if any) web browsers ever implemented true SGML parsing for HTML documents; the only user agents to strictly handle HTML as an SGML application have historically been validators. The resulting confusion — with validators claiming documents to have one representation while widely deployed Web browsers interoperably implemented a different representation — has wasted decades of productivity. This version of HTML thus returns to a non-SGML basis.

Authors interested in using SGML tools in their authoring pipeline are encouraged to use XML tools and the XML serialization of HTML.

\textbf{Note}

As stated in the terminology section, references to element types that do not explicitly specify a namespace always refer to elements in the HTML namespace. For example, if the spec talks about “a \text{menu} element”, then that is an element with the local name “menu”, the namespace “http://www.w3.org/1999/xhtml”, and the interface \text{HTMLMenuElement}. Where possible, references to such elements are hyperlinked to their definition.
The input to the HTML parsing process consists of a stream of code points, which is passed through a tokenization stage followed by a tree construction stage. The output is a Document object.

In the common case, the data handled by the tokenization stage comes from the network, but it can also come from script running in the user agent, e.g. using the `document.write()` API.

There is only one set of states for the tokenizer stage and the tree construction stage, but the tree construction stage is reentrant, meaning that while the tree construction stage is handling one token, the tokenizer might be resumed, causing further tokens to be emitted and processed before the first token’s processing is complete.

In the following example, the tree construction stage will be called upon to handle a "p" start tag token while handling the "script" end tag token:

```html
...<script>
  document.write("<p>");
</script>
...```
To handle these cases, parsers have a script nesting level, which must be initially set to zero, and a parser pause flag, which must be initially set to false.

### 12.2.2 Parse errors

This specification defines the parsing rules for HTML documents, whether they are syntactically correct or not. Certain points in the parsing algorithm are said to be parse errors. The error handling for parse errors is well-defined (that’s the processing rules described throughout this specification), but user agents, while parsing an HTML document, may abort the parser at the first parse error that they encounter for which they do not wish to apply the rules described in this specification.

Conformance checkers must report at least one parse error condition to the user if one or more parse error conditions exist in the document and must not report parse error conditions if none exist in the document. Conformance checkers may report more than one parse error condition if more than one parse error condition exists in the document.

**Note:** Parse errors are only errors with the syntax of HTML. In addition to checking for parse errors, conformance checkers will also verify that the document obeys all the other conformance requirements described in this specification.

Some parse errors have dedicated codes outlined in the table below that should be used by conformance checkers in reports.

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abrupt-closing-of-empty-comment</td>
<td>This error occurs if the parser encounters an empty <code>comment</code> that is abruptly closed by a U+003E (&gt;) <code>code point</code> (i.e., <code>&lt;!-</code> or <code>&lt;!</code> &gt;). The parser behaves as if the comment is closed correctly.</td>
</tr>
<tr>
<td>abrupt-doctype-public-identifier</td>
<td>This error occurs if the parser encounters a U+003E (&gt;) <code>code point</code> in the <code>DOCTYPE</code> public identifier (e.g., <code>&lt;!DOCTYPE html PUBLIC &quot;foo&quot;&gt;</code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the <code>Document</code> to quirks mode.</td>
</tr>
<tr>
<td>abrupt-doctype-system-identifier</td>
<td>This error occurs if the parser encounters a U+003E (&gt;) <code>code point</code> in the <code>DOCTYPE</code> system identifier (e.g., <code>&lt;!DOCTYPE html PUBLIC &quot;-//W3C//DTD HTML 4.01//EN&quot; &quot;foo&quot;&gt;</code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the <code>Document</code> to quirks mode.</td>
</tr>
<tr>
<td>absence-of-digits-in-numeric-character-reference</td>
<td>This error occurs if the parser encounters a numeric <code>character reference</code> that doesn’t contain any digits (e.g., <code>&amp;qux;</code>). In this case the parser doesn’t resolve the character reference.</td>
</tr>
<tr>
<td>cdata-in-html-content</td>
<td>This error occurs if the parser encounters a <code>CDATA section</code> outside of foreign content (SVG or MathML). The parser treats such CDATA sections (including leading <code>*[CDATA[*</code> and trailing <code>]*]</code> strings) as comments.</td>
</tr>
<tr>
<td>character-reference-outside-unicode-range</td>
<td>This error occurs if the parser encounters a numeric <code>character reference</code> that references a <code>code point</code> that is greater than the valid Unicode range. The parser resolves such a character reference to a U+FFFD REPLACEMENT CHARACTER.</td>
</tr>
<tr>
<td>control-character-in-input-stream</td>
<td>This error occurs if the <code>input stream</code> contains a <code>control code point</code> that is not ASCII whitespace or U+0000 NULL. Such code points are parsed as-is and usually, where parsing rules don’t apply any additional restrictions, make their way into the DOM.</td>
</tr>
<tr>
<td>control-character-reference</td>
<td>This error occurs if the parser encounters a numeric <code>character reference</code> that references a <code>control code point</code> that is not ASCII whitespace, a U+000D CARRIAGE RETURN, or U+0000 NULL. The parser resolves such character references as-is except C1 control references that are replaced according to the <code>numeric character reference end state</code>.</td>
</tr>
<tr>
<td>end-tag-with-attributes</td>
<td>This error occurs if the parser encounters an <code>end tag</code> with <code>attributes</code>. Attributes in end tags are completely ignored and do not make their way into the DOM.</td>
</tr>
<tr>
<td>duplicate-attribute</td>
<td>This error occurs if the parser encounters an <code>attribute</code> in a tag that already has an attribute with the same name. The parser ignores all such duplicate occurrences of the attribute.</td>
</tr>
<tr>
<td>end-tag-with-trailing-solidus</td>
<td>This error occurs if the parser encounters an <code>end tag</code> that has a U+002F (/) <code>code point</code> right before the closing U+003E (&gt;) <code>code point</code> (e.g., <code>&lt;/div/&gt;</code>). Such a tag is treated as a regular end tag.</td>
</tr>
<tr>
<td>eof-before-tag-name</td>
<td>This error occurs if the parser encounters the end of the <code>input stream</code> where a tag name is expected. In this case the parser treats the beginning of a <code>start tag</code> (i.e., <code>&lt;</code>) or an <code>end tag</code> (i.e., <code>&lt;/</code>) as text content.</td>
</tr>
<tr>
<td>eof-in-cdata</td>
<td>This error occurs if the parser encounters the end of the <code>input stream</code> in a <code>CDATA section</code>. The parser treats such CDATA sections as...</td>
</tr>
<tr>
<td>Code</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>eof-in-comment</code></td>
<td>This error occurs if the parser encounters the end of the input stream in a comment. The parser treats such comments as if they are closed immediately before the end of the input stream.</td>
</tr>
<tr>
<td><code>eof-in-doctype</code></td>
<td>This error occurs if the parser encounters the end of the input stream in a DOCTYPE. In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the document to quirks mode.</td>
</tr>
</tbody>
</table>
| `eof-in-script-html-comment-like-text` | This error occurs if the parser encounters the end of the input stream in text that resembles an HTML comment inside script elements (e.g., `<script>`). The parser treats such comments as if they are correctly closed by the `-->` code point sequence.  

Note: Syntactic structures that resemble HTML comments in script elements are parsed as text content. They can be a part of a scripting language-specific syntactic structure or be treated as an HTML-like comment, if the scripting language supports them (e.g., parsing rules for HTML-like comments can be found in Annex B of the JavaScript specification). The common reason for this error is a violation of the restrictions for contents of script elements. |
| `eof-in-tag` | This error occurs if the parser encounters the end of the input stream in a start tag or an end tag (e.g., `<div id=`). Such a tag is completely ignored. |
| `incorrectly-closed-comment` | This error occurs if the parser encounters a comment that is closed by the `-->` code point sequence. The parser treats such comments as if they are correctly closed by the `-->` code point sequence. |
| `incorrectly-opened-comment` | This error occurs if the parser encounters a code point sequence that is not immediately followed by two U+002D (-) code points and that is not the start of a DOCTYPE or a CDATA section. All content that follows the code point sequence up to a U+003E (>) code point (if present) or to the end of the input stream is treated as a comment.  

Note: One possible cause of this error is using an XML markup declaration (e.g., `<!ELEMENT br EMPTY>`) in HTML. |
| `invalid-character-sequence-after-doctype-name` | This error occurs if the parser encounters any code point sequence other than "PUBLIC" and "SYSTEM" keywords after a DOCTYPE name. In such a case, the parser ignores any following public or system identifiers, and if the DOCTYPE is correctly placed as a document preamble, sets the document to quirks mode. |
| `invalid-first-character-of-tag-name` | This error occurs if the parser encounters a code point that is not an ASCII alpha where first code point of a start tag name or an end tag name is expected. If a start tag was expected such code point and a preceding U+003E (<) is treated as text content, and all content that follows is treated as markup. Whereas, if an end tag was expected, such code point and all content that follows up to a U+003E (>) code point (if present) or to the end of the input stream is treated as a comment.  

Example:  
For example, consider the following markup:  

```
<42></42>
```

This will be parsed into:  

```
L
  html
      head
      body
  #text: <42>
  #comment: 42
```

Note: While the first code point of a tag name is limited to an ASCII alpha, a wide range of code points (including ASCII digits) is allowed in subsequent positions. |
<p>| <code>missing-attribute-value</code> | This error occurs if the parser encounters a U+003E (&gt;) code point where an attribute value is expected (e.g., <code>&lt;div id=</code>). The parser treats the attribute as having an empty value. |
| <code>missing-doctype-name</code> | This error occurs if the parser encounters a DOCTYPE that is missing a name (e.g., <code>&lt;!DOCTYPE</code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the document to quirks mode. |
| <code>missing-doctype-public-identifier</code> | This error occurs if the parser encounters a U+003E (&gt;) code point where start of the DOCTYPE public identifier is expected (e.g., <code>&lt;!DOCTYPE html PUBLIC</code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the document to quirks mode. |
| <code>missing-doctype-system-identifier</code> | This error occurs if the parser encounters a U+003E (&gt;) code point where start of the DOCTYPE system identifier is expected (e.g., <code>&lt;!DOCTYPE html SYSTEM&gt;</code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the document to quirks mode. |</p>
<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>missing-end-tag-name</td>
<td>This error occurs if the parser encounters a U+003E (&gt;) code point where an end tag name is expected, i.e., &lt;/&gt;. The parser completely ignores whole &quot;&lt;/&quot; code point sequence.</td>
</tr>
<tr>
<td>missing-quote-before-doctype-public-identifer</td>
<td>This error occurs if the parser encounters the DOCTYPE public identifier that is not preceded by a quote (e.g., &lt;!DOCTYPE html PUBLIC -//W3C//DTD HTML 4.01//EN&gt;). In such a case, the parser ignores the public identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the Document to quirks mode.</td>
</tr>
<tr>
<td>missing-quote-before-doctype-system-identifer</td>
<td>This error occurs if the parser encounters the DOCTYPE system identifier that is not preceded by a quote (e.g., &lt;!DOCTYPE html SYSTEM http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd&gt;). In such a case, the parser ignores the system identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the Document to quirks mode.</td>
</tr>
<tr>
<td>missing-semicolon-after-character-reference</td>
<td>This error occurs if the parser encounters a character reference that is not terminated by a U+003B (;) code point. Usually the parser behaves as if character reference is terminated by the U+003B (;) code point; however, there are some ambiguous cases in which the parser includes subsequent code points in the character reference.</td>
</tr>
<tr>
<td>Example</td>
<td>For example, ¬in will be parsed as &quot;¬in&quot; whereas &amp;notin will be parsed as &quot;∉&quot;.</td>
</tr>
<tr>
<td>missing-whitespace-after-doctype-public-keyword</td>
<td>This error occurs if the parser encounters a DOCTYPE whose &quot;PUBLIC&quot; keyword and public identifier are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.</td>
</tr>
<tr>
<td>missing-whitespace-after-doctype-system-keyword</td>
<td>This error occurs if the parser encounters a DOCTYPE whose &quot;SYSTEM&quot; keyword and system identifier are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.</td>
</tr>
<tr>
<td>missing-whitespace-before-doctype-name</td>
<td>This error occurs if the parser encounters attributes that are not separated by ASCII whitespace (e.g., &lt;div id=&quot;foo&quot; class=&quot;bar&quot;&gt;). In this case the parser behaves as if ASCII whitespace is present.</td>
</tr>
<tr>
<td>missing-whitespace-between-attributes</td>
<td>This error occurs if the parser encounters a DOCTYPE whose public and system identifiers are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.</td>
</tr>
<tr>
<td>nested-comment</td>
<td>This error occurs if the parser encounters a nested comment (e.g., &lt;!-- &lt;!-- nested --&gt; --&gt;). Such a comment will be closed by the first occurring &quot;--&quot; code point sequence and everything that follows will be treated as markup.</td>
</tr>
<tr>
<td>noncharacter-character-reference</td>
<td>This error occurs if the parser encounters a numeric character reference that references a noncharacter. The parser resolves such character references as-is.</td>
</tr>
<tr>
<td>noncharacter-in-input-stream</td>
<td>This error occurs if the input stream contains a noncharacter. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.</td>
</tr>
<tr>
<td>non-void-html-element-start-tag-with-trailing-solidus</td>
<td>This error occurs if the parser encounters a start tag for an element that is not in the list of void elements or is not a part of foreign content (i.e., not an SVG or MathML element) that has a U+002F (/) code point right before the closing U+003E (&gt;) code point. The parser behaves as if the U+002F (/) is not present.</td>
</tr>
<tr>
<td>Example</td>
<td>For example, consider the following markup:</td>
</tr>
<tr>
<td></td>
<td>&lt;div/&gt; &lt;span/&gt; &lt;span/&gt; &lt;span/&gt;</td>
</tr>
<tr>
<td></td>
<td>This will be parsed into:</td>
</tr>
<tr>
<td></td>
<td>html head body div span span span</td>
</tr>
<tr>
<td><strong>Code</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>null-character-reference</td>
<td>This error occurs if the parser encounters a numeric character reference that references a U+0000 NULL code point. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.</td>
</tr>
<tr>
<td>surrogate-character-reference</td>
<td>This error occurs if the parser encounters a numeric character reference that references a surrogate. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.</td>
</tr>
<tr>
<td>surrogate-in-input-stream</td>
<td>This error occurs if the input stream contains a surrogate. Such code points are parsed as-is and usually, where parsing rules don’t apply any additional restrictions, make their way into the DOM.</td>
</tr>
<tr>
<td>unexpected-character-after-doctype-system-identifier</td>
<td>This error occurs if the parser encounters any code points other than ASCII whitespace or closing U+003E (&gt; ) after the <code>DOCTYPE</code> system identifier. The parser ignores these code points.</td>
</tr>
<tr>
<td>unexpected-character-in-attribute-name</td>
<td>This error occurs if the parser encounters a U+0022 (&quot;), U+0027 (’), or U+003C (&lt;) code point in an attribute name. The parser includes such code points in the attribute name.</td>
</tr>
<tr>
<td>unexpected-equals-sign-before-attribute-name</td>
<td>This error occurs if the parser encounters a U+0022 (&quot;), U+0027 (’), U+003C (&lt;), U+003D (=), or U+0060 (`) code point in an attribute name. The parser includes such code points in the attribute value.</td>
</tr>
<tr>
<td>unexpected-equals-sign-unquoted-attribute-value</td>
<td>This error occurs if the parser encounters a U+0022 (&quot;), U+0027 (’), U+003C (&lt;), U+003D (=), or U+0060 (`) code point in an unquoted attribute value. The parser includes such code points in the attribute value.</td>
</tr>
</tbody>
</table>

**Example**

For example, consider the following markup:

```html
<div foo="bar"></div>
```

Due to a misplaced U+0027 (’) code point the parser sets the value of the "foo" attribute to "b’ar".

**Note**

Surrogates can only find their way into the input stream via script APIs such as `document.write()`.

**Note**

Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute name.

For example, consider the following markup:

```html
<div foo="b'ar"></div>
```

Due to a misplaced U+0027 (’) code point the parser sets the value of the "foo" attribute to "b’ar".

**Note**

U+0060 (`) is in the list of code points that trigger this error because certain legacy user agents treat it as a quote.

**Example**

For example, consider the following markup:

```html
<div foo='bar'>
```

Due to a forgotten U+003D (=) code point after `foo` the parser treats this markup as a single `div` element with a "foo=bar" attribute.

As another example of this error, consider the following markup:

```html
<div id='bar'>
```

Due to a forgotten U+003D (=) code point between an attribute name and value the parser treats this markup as a `div` `div` element with the attribute "id='bar'" that has an empty value.

**Note**

The common reason for this error is a forgotten attribute name.
<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unexpected-null-character</td>
<td>This error occurs if the parser encounters a U+0000 NULL code point in the input stream in certain positions. In general, such code points are either completely ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER.</td>
</tr>
<tr>
<td>unexpected-question-mark-instead-of-tag-name</td>
<td>This error occurs if the parser encounters a U+003F (?) code point where first code point of a start tag name is expected. The U+003F (?) and all content that follows up to a U+003E (&gt;) code point (if present) or to the end of the input stream is treated as a comment.</td>
</tr>
<tr>
<td>unexpected-solidus-in-tag</td>
<td>This error occurs if the parser encounters a U+002F (/) code point that is not a part of a quoted attribute value and not immediately followed by a U+003E (&gt;) code point in a tag (e.g., &lt;div / id=&quot;foo&quot;&gt;). In this case the parser behaves as if it encountered ASCII whitespace.</td>
</tr>
<tr>
<td>unknown-named-character-reference</td>
<td>This error occurs if the parser encounters an ambiguous ampersand. In this case the parser doesn't resolve the character reference.</td>
</tr>
</tbody>
</table>

For example, consider the following markup:

```xml
<div foo="bar" ="baz">
</div>
```

Due to a forgotten attribute name the parser treats this markup as a `div` element with two attributes: a `foo` attribute with a "bar" value and a "=" attribute with an empty value.

### 12.2.3 The input byte stream

The stream of code points that comprises the input to the tokenization stage will be initially seen by the user agent as a stream of bytes (typically coming over the network or from the local file system). The bytes encode the actual characters according to a particular character encoding, which the user agent uses to decode the bytes into characters.

#### Note

For XML documents, the algorithm user agents are required to use to determine the character encoding is given by the XML specification. This section does not apply to XML documents. [XML]

Usually, the encoding sniffing algorithm defined below is used to determine the character encoding.

Given a character encoding, the bytes in the input byte stream must be converted to characters for the tokenizer’s input stream, by passing the input byte stream and character encoding to decode.

#### Note

A leading Byte Order Mark (BOM) causes the character encoding argument to be ignored and will itself be skipped.

#### Note

Bytes or sequences of bytes in the original byte stream that did not conform to the Encoding standard (e.g. invalid UTF-8 byte sequences in a UTF-8 input byte stream) are errors that conformance checkers are expected to report. [ENCODING]
When the HTML parser is decoding an input byte stream, it uses a character encoding and a confidence. The confidence is either tentative, certain, or irrelevant. The encoding used, and whether the confidence in that encoding is tentative or certain, is used during the parsing to determine whether to change the encoding. If no encoding is necessary, e.g. because the parser is operating on a Unicode stream and doesn't have to use a character encoding at all, then the confidence is irrelevant.

When the HTML parser is to operate on an input byte stream that has a known definite encoding, then the character encoding is that encoding and the confidence is certain.

In some cases, it might be impractical to unambiguously determine the encoding before parsing the document. Because of this, this specification provides for a two-pass mechanism with an optional pre-scan. Implementations are allowed, as described below, to apply a simplified parsing algorithm to whatever bytes they have available before beginning to parse the document. Then, the real parser is started, using a tentative encoding derived from this pre-parse and other out-of-band metadata. If, while the document is being loaded, the user agent discovers a character encoding declaration that conflicts with this information, then the parser can get reinvoked to perform a parse of the document with the real encoding.

User agents must use the following algorithm, called the encoding sniffing algorithm, to determine the character encoding to use when decoding a document in the first pass. This algorithm takes as input any out-of-band metadata available to the user agent (e.g. the Content-Type metadata of the document) and all the bytes available so far, and returns a character encoding and a confidence that is either tentative or certain.

1. If the user has explicitly instructed the user agent to override the document's character encoding with a specific encoding, optionally return that encoding with the confidence certain.

2. The user agent may wait for more bytes of the resource to be available, either in this step or at any later step in this algorithm. For instance, a user agent might wait 500ms or 1024 bytes, whichever came first. In general preparing the source to find the encoding improves performance, as it reduces the need to throw away the data structures used when parsing upon finding the encoding information. However, if the user agent delays too long to obtain data to determine the encoding, then the cost of the delay could outweigh any performance improvements from the preparse.

3. If the transport layer specifies a character encoding, and it is supported, return that encoding with the confidence certain.

4. Optionally prescan the byte stream to determine its encoding. The end condition is that the user agent decides that scanning further bytes would not be efficient. User agents are therefore encouraged to use the prescan algorithm below (as invoked by these steps) on the first 1024 bytes, but not to stall beyond that.

The aforementioned algorithm either aborts unsuccessfully or returns a character encoding. If it returns a character encoding, it is used during the parsing to determine whether to change the encoding.

Note

Some algorithms feed the parser by directly adding characters to the input stream rather than adding bytes to the input byte stream.

⚠Warning!

The decoder algorithms describe how to handle invalid input; for security reasons, it is imperative that those rules be followed precisely. Differences in how invalid byte sequences are handled can result in, amongst other problems, script injection vulnerabilities ("XSS").

Typically, user agents remember such user requests across sessions, and in some cases apply them to documents in iframes as well.

The authoring conformance requirements for character encoding declarations limit them to only appearing in the first 1024 bytes. User agents are therefore encouraged to use the prescan algorithm below (as invoked by these steps) on the first 1024 bytes, but not to stall beyond that.

The aforementioned algorithm either aborts unsuccessfully or returns a character encoding. If it returns a character encoding, it is used during the parsing to determine whether to change the encoding.
encoding, then return the same encoding, with confidence\textsuperscript{\textit{tentative}}.

5. If the HTML parser\textsuperscript{\textit{nest}} for which this algorithm is being run is associated with a Document\textsuperscript{\textit{nest}} that is itself in a nested browsing context\textsuperscript{\textit{nest}}, run these substeps:

   1. Let new document be the Document\textsuperscript{\textit{nest}} with which the HTML parser\textsuperscript{\textit{nest}} is associated.
   2. Let parent document be the Document\textsuperscript{\textit{nest}} through which new document is nested\textsuperscript{\textit{nest}} (the active document\textsuperscript{\textit{nest}} of the parent browsing context\textsuperscript{\textit{nest}} of new document).
   3. If parent document's origin\textsuperscript{\textit{nest}} is same origin\textsuperscript{\textit{nest}} with new document's origin\textsuperscript{\textit{nest}}, and parent document's character encoding is an ASCII-compatible encoding\textsuperscript{\textit{nest}}, then return parent document's character encoding, with the confidence\textsuperscript{\textit{nest}}\textsuperscript{\textit{tentative}}.

6. Otherwise, if the user agent has information on the likely encoding for this page, e.g. based on the encoding of the page when it was last visited, then return that encoding, with the confidence\textsuperscript{\textit{nest}}\textsuperscript{\textit{tentative}}.

7. The user agent may attempt to autodetect the character encoding from applying frequency analysis or other algorithms to the data stream. Such algorithms may use information about the resource other than the resource's contents, including the address of the resource. If autodetection succeeds in determining a character encoding, and that encoding is a supported encoding, then return that encoding, with the confidence\textsuperscript{\textit{nest}}\textsuperscript{\textit{tentative}}.

8. Otherwise, return an implementation-defined or user-specified default character encoding, with the confidence\textsuperscript{\textit{nest}}\textsuperscript{\textit{tentative}}.

In controlled environments or in environments where the encoding of documents can be prescribed (for example, for user agents intended for dedicated use in new networks), the comprehensive UTF-8 encoding is suggested.

In other environments, the default encoding is typically dependent on the user's locale (an approximation of the languages, and thus often encodings, of the pages that the user is likely to frequent). The following table gives suggested defaults based on the user's locale, for compatibility with legacy content. Locales are identified by BCP 47 language tags. [BCP47]\textsuperscript{\textit{nest}} [ENCODING]\textsuperscript{\textit{nest}}

The document's character encoding must immediately be set to the value returned from this algorithm, at the same time as the user agent uses the returned value to select the decoder to use for the input byte stream.

When an algorithm requires a user agent to prescan a byte stream to determine its encoding, given some defined end condition, then it must run the following steps. These steps either abort unsuccessfully or return a character encoding. If at any point during these steps (including during instances of the get an attribute algorithm invoked by this one) the user agent either runs out of bytes (meaning the position pointer created in the first step below goes beyond the end of the byte stream obtained so far) or reaches its end condition, then abort the prescan a byte stream to determine its encoding algorithm unsuccessfully.

1. Let position be a pointer to a byte in the input byte stream, initially pointing at the first byte.
2. Loop: If position points to:
   - A sequence of bytes starting with: 0x3C 0x21 0x2D 0x2D (`<!--`)  
     Advance the position pointer so that it points at the first 0x3E byte which is preceded by two 0x2D bytes (i.e. at the end of an ASCII '<-->' sequence) and comes after the 0x3C byte that was found. (The two 0x2D bytes can be the same as those in the '<-->' sequence.)
   - A sequence of bytes starting with: 0x3C, 0x4D or 0x6D, 0x45 or 0x65, 0x54 or 0x74, 0x41 or 0x61, and one of 0x09, 0x0A, 0x0C, 0x0D, 0x20, 0x2F (case-insensitive ASCII '<meta' followed by a space or slash)
     1. Advance the position pointer so that it points at the next 0x09, 0x0A, 0x0C, 0x0D, 0x20, or 0x2F byte (the one in sequence of characters matched above).
     2. Let attribute list be an empty list of strings.
     3. Let got pragma be false.
     4. Let need pragma be null.
     5. Let charset be the null value (which, for the purposes of this algorithm, is distinct from an unrecognized encoding or the empty string).
     6. Attributes: Get an attribute and its value. If no attribute was sniffed, then jump to the processing step below.
     7. If the attribute's name is already in attribute list, then return to the step labeled attributes.
     8. Add the attribute's name to attribute list.
     9. Run the appropriate step from the following list, if one applies:
        - If the attribute's name is "http-equiv"  
          If the attribute's value is "content-type", then set got pragma to true.
If the attribute's name is "content"
Apply the algorithm for extracting a character encoding from a meta element, giving the attribute's value as the string to parse. If a character encoding is returned, and if charset is still set to null, let charset be the encoding returned, and set need pragma to true.

If the attribute's name is "charset"
Let charset be the result of getting an encoding from the attribute's value, and set need pragma to false.

10. Return to the step labeled attributes.
11. Processing: If need pragma is null, then jump to the step below labeled next byte.
12. If need pragma is true but got pragma is false, then jump to the step below labeled next byte.
13. If charset is failure, then jump to the step below labeled next byte.
14. If charset is a UTF-16 encoding, then set charset to UTF-8.
15. If charset is x-user-defined, then set charset to windows-1252.
16. Abort the prescan a byte stream to determine its encoding algorithm, returning the encoding given by charset.

A sequence of bytes starting with a 0x3C byte (<), optionally a 0x2F byte (/), and finally a byte in the range 0x41-0x5A or 0x61-0x7A (A-Z or a-z)
1. Advance the position pointer so that it points at the next 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (> ) byte.
2. Repeatedly get an attribute until no further attributes can be found, then jump to the step below labeled next byte.

A sequence of bytes starting with: 0x3C 0x21 (`!`)
A sequence of bytes starting with: 0x3C 0x2F (`/`)
A sequence of bytes starting with: 0x3C 0x3F (`?`)
Advance the position pointer so that it points at the first 0x3E byte (>) that comes after the 0x3C byte that was found.

A sequence of bytes starting with: 0x3C 0x21 (`!`)
A sequence of bytes starting with: 0x3C 0x2F (`/`)
A sequence of bytes starting with: 0x3C 0x3F (`?`)

Any other byte
Do nothing with that byte.

3. Next byte: Move position so it points at the next byte in the input byte stream, and return to the step above labeled loop.

When the prescan a byte stream to determine its encoding algorithm says to get an attribute, it means doing this:

1. If the byte at position is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x2F (/) then advance position to the next byte and redo this step.
2. If the byte at position is 0x3E (> ), then abort the get an attribute algorithm. There isn't one.
3. Otherwise, the byte at position is the start of the attribute name. Let attribute name and attribute value be the empty string.
4. Process the byte at position as follows:

If it is 0x3D (=), and the attribute name is longer than the empty string
Advance position to the next byte and jump to the step below labeled value.

If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP)
Jump to the step below labeled spaces.

If it is 0x2F (/) or 0x3E (>)
Abort the get an attribute algorithm. The attribute's name is the value of attribute name, its value is the empty string.

If it is in the range 0x41 (A) to 0x5A (Z)
Append the code point b+0x20 to attribute name (where b is the value of the byte at position). (This converts the input to lowercase.)
5. Advance position to the next byte and return to the previous step.

6. Spaces: If the byte at position is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance position to the next byte, then, repeat this step.

7. If the byte at position is not 0x3D (=), abort the get an attribute algorithm. The attribute's name is the value of attribute name, its value is the empty string.

8. Advance position past the 0x3D (=) byte.

9. Value: If the byte at position is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance position to the next byte, then, repeat this step.

10. Process the byte at position as follows:

   → If it is 0x22 (") or 0x27 (')

     1. Let b be the value of the byte at position.

     2. Quote loop: Advance position to the next byte.

     3. If the value of the byte at position is the value of b, then advance position to the next byte and abort the "get an attribute" algorithm. The attribute's name is the value of attribute name, and its value is the value of attribute value.

     4. Otherwise, if the value of the byte at position is in the range 0x41 (A) to 0x5A (Z), then append a code point to attribute value whose value is 0x20 more than the value of the byte at position.

     5. Otherwise, append a code point to attribute value whose value is the same as the value of the byte at position.

     6. Return to the step above labeled quote loop.

   → If it is 0x3E (>)

     Abort the get an attribute algorithm. The attribute's name is the value of attribute name, its value is the empty string.

   → If it is in the range 0x41 (A) to 0x5A (Z)

     Append a code point b+0x20 to attribute value (where b is the value of the byte at position). Advance position to the next byte.

   → Anything else

     Append a code point with the same value as the byte at position to attribute value. Advance position to the next byte.

11. Process the byte at position as follows:

   → If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (>)

     Abort the get an attribute algorithm. The attribute's name is the value of attribute name and its value is the value of attribute value.

   → If it is in the range 0x41 (A) to 0x5A (Z)

     Append a code point b+0x20 to attribute value (where b is the value of the byte at position).

   → Anything else

     Append a code point with the same value as the byte at position to attribute value.

12. Advance position to the next byte and return to the previous step.

For the sake of interoperability, user agents should not use a pre-scan algorithm that returns different results than the one described above. (But, if you do, please at least let us know, so that we can improve this algorithm and benefit everyone...)

1033
12.2.3.3 Character encodings

Note
The above prohibits supporting, for example, CESU-8, UTF-7, BOCU-1, SCSU, EBCDIC, and UTF-32. This specification does not make any attempt to support prohibited encodings in its algorithms; support and use of prohibited encodings would thus lead to unexpected behavior. [CESU8][1222] [UTF7][1227] [BOCU1][1222] [SCSU][1126]

12.2.3.4 Changing the encoding while parsing

When the parser requires the user agent to change the encoding, it must run the following steps. This might happen if the encoding sniffing algorithm described above failed to find a character encoding, or if it found a character encoding that was not the actual encoding of the file.

1. If the encoding that is already being used to interpret the input stream is a UTF-16 encoding, then set the confidence to certain and return. The new encoding is ignored; if it was anything but the same encoding, then it would be clearly incorrect.
2. If the new encoding is a UTF-16 encoding, then change it to UTF-8.
3. If the new encoding is x-user-defined, then change it to windows-1252.
4. If the new encoding is identical or equivalent to the encoding that is already being used to interpret the input stream, then set the confidence to certain and return. This happens when the encoding information found in the file matches what the encoding sniffing algorithm determined to be the encoding, and in the second pass through the parser if the first pass found that the encoding sniffing algorithm described in the earlier section failed to find the right encoding.
5. If all the bytes up to the last byte converted by the current decoder have the same Unicode interpretations in both the current encoding and the new encoding, and if the user agent supports changing the converter on the fly, then the user agent may change to the new converter for the encoding on the fly. Set the document's character encoding and the encoding used to convert the input stream to the new encoding, set the confidence to certain, and return.
6. Otherwise, navigate to the document again, with replacement enabled, and using the same source browsing context, but this time skip the encoding sniffing algorithm and instead just set the encoding to the new encoding and the confidence to certain. Whenever possible, this should be done without actually contacting the network layer (the bytes should be re-parsed from memory), even if, e.g., the document is marked as not being cacheable. If this is not possible and contacting the network layer would involve repeating a request that uses a method other than `GET`, then instead set the confidence to certain and ignore the new encoding. The resource will be misinterpreted. User agents may notify the user of the situation, to aid in application development.

Note
This algorithm is only invoked when a new encoding is found declared on a meta element.

12.2.3.5 Preprocessing the input stream

The input stream consists of the characters pushed into it as the input byte stream is decoded or from the various APIs that directly manipulate the input stream.

Any occurrences of surrogates are surrogate-in-input-stream parse errors. Any occurrences of noncharacters are noncharacter-in-input-stream parse errors and any occurrences of controls other than ASCII whitespace and U+0000 NULL characters are control-character-in-input-stream parse errors.

Note
The handling of U+0000 NULL characters varies based on where the characters are found and happens at the later stages of the parsing. They are either ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER. This handling is, by necessity, spread across both the tokenization stage and the tree construction stage.
The next input character is the first character in the input stream that has not yet been consumed or explicitly ignored by the requirements in this section. Initially, the next input character is the first character in the input. The current input character is the last character to have been consumed.

The insertion point is the position (just before a character or just before the end of the input stream) where content inserted using document.write() is actually inserted. The insertion point is relative to the position of the character immediately after it, it is not an absolute offset into the input stream. Initially, the insertion point is undefined.

The "EOF" character in the tables below is a conceptual character representing the end of the input stream. If the parser is a script-created parser, then the end of the input stream is reached when an explicit "EOF" character (inserted by the document.close() method) is consumed. Otherwise, the "EOF" character is not a real character in the stream, but rather the lack of any further characters.

12.2.4 Parse state

12.2.4.1 The insertion mode

The insertion mode is a state variable that controls the primary operation of the tree construction stage.

Initially, the insertion mode is "initial". It can change to "before html", "before head", "in head", "in noscript", "after head", "in body", "text", "in table", "in caption", "in column group", "in table body", "in row", "in cell", "in select", "in select in table", "in template", "after body", "in frameset", "after frameset", "after after body", and "after after frameset" during the course of the parsing, as described in the tree construction stage. The insertion mode affects how tokens are processed and whether CDATA sections are supported.

Several of these modes, namely "in head", "in body", "in table", and "in select", are special, in that the other modes defer to them at various times. When the algorithm below says that the user agent is to do something "using the rules for the m insertion mode", where m is one of these modes, the user agent must use the rules described under the m insertion mode's section, but must leave the insertion mode unchanged unless the rules in m themselves switch the insertion mode to a new value.

When the insertion mode is switched to "text" or "in table text", the original insertion mode is also set. This is the insertion mode to which the tree construction stage will return.

Similarly, to parse nested template elements, a stack of template insertion modes is used. It is initially empty. The current template insertion mode is the insertion mode that was most recently added to the stack of template insertion modes. The algorithms in the sections below will push insertion modes onto this stack, meaning that the specified insertion mode is to be added to the stack, and pop insertion modes from the stack, which means that the most recently added insertion mode must be removed from the stack.

When the steps below require the UA to reset the insertion mode appropriately, it means the UA must follow these steps:

1. Let last be false.
2. Let node be the last node in the stack of open elements.
3. Loop: If node is the first node in the stack of open elements, then set last to true, and, if the parser was originally created as part of the HTML fragment parsing algorithm (fragment case), set node to the element passed to that algorithm.
4. If node is a select element, run these substeps:
   1. If last is true, jump to the step below labeled done.
   2. Let ancestor be node.
   3. Loop: If ancestor is the first node in the stack of open elements, jump to the step below labeled done.
Let \( \text{ancestor} \) be the node before \( \text{ancestor} \) in the stack of open elements\(^{1036} \).

If \( \text{ancestor} \) is a template\(^{631} \) node, jump to the step below labeled done.

If \( \text{ancestor} \) is a table\(^{643} \) node, switch the insertion mode\(^{6135} \) to "in select in table\(^{6110} \)" and return.

Jump back to the step labeled loop.

8. Done: Switch the insertion mode\(^{6135} \) to "in select\(^{6198} \)" and return.

5. If node is a td\(^{449} \) or th\(^{443} \) element and last is false, then switch the insertion mode\(^{6135} \) to "in cell\(^{6197} \)" and return.

6. If node is a tr\(^{448} \) element, then switch the insertion mode\(^{6135} \) to "in row\(^{6106} \)" and return.

7. If node is a tbody\(^{445} \), thead\(^{446} \), or tfoot\(^{447} \) element, then switch the insertion mode\(^{6135} \) to "in table body\(^{6106} \)" and return.

8. If node is a caption\(^{442} \) element, then switch the insertion mode\(^{6135} \) to "in caption\(^{6104} \)" and return.

9. If node is a colgroup\(^{444} \) element, then switch the insertion mode\(^{6135} \) to "in column group\(^{6105} \)" and return.

10. If node is a table\(^{643} \) element, then switch the insertion mode\(^{6135} \) to "in table\(^{6102} \)" and return.

11. If node is a template\(^{6130} \) element, then switch the insertion mode\(^{6135} \) to the current template insertion mode\(^{6105} \) and return.

12. If node is a head\(^{149} \) element and last is false, then switch the insertion mode\(^{6135} \) to "in head\(^{6107} \)" and return.

13. If node is a body\(^{171} \) element, then switch the insertion mode\(^{6135} \) to "in body\(^{6108} \)" and return.

14. If node is a frameset\(^{177} \) element, then switch the insertion mode\(^{6135} \) to "in frameset\(^{6102} \)" and return. (fragment case\(^{6119} \))

15. If node is an html\(^{148} \) element, run these substeps:

   1. If the head element pointer\(^{6109} \) is null, switch the insertion mode\(^{6135} \) to "before head\(^{6107} \)" and return. (fragment case\(^{6119} \))

   2. Otherwise, the head element pointer\(^{6109} \) is not null, switch the insertion mode\(^{6135} \) to "after head\(^{6108} \)" and return.

16. If last is true, then switch the insertion mode\(^{6135} \) to "in body\(^{6101} \)" and return. (fragment case\(^{6119} \))

17. Let node now be the node before node in the stack of open elements\(^{6106} \).

18. Return to the step labeled loop.

### 12.2.4.2 The stack of open elements

Initially, the stack of open elements is empty. The stack grows downwards; the topmost node on the stack is the first one added to the stack, and the bottommost node of the stack is the most recently added node in the stack (notwithstanding when the stack is manipulated in a random access fashion as part of the handling for misnested tags\(^{6109} \)).

**Note**

The "before html\(^{6107} \)" insertion mode\(^{6135} \) creates the html\(^{148} \) document element, which is then added to the stack.

**Note**

In the fragment case\(^{6119} \), the stack of open elements\(^{6108} \) is initialized to contain an html\(^{148} \) element that is created as part of that algorithm\(^{6118} \). (The fragment case\(^{6118} \) skips the "before html\(^{6107} \)" insertion mode\(^{6135} \).)

The html\(^{148} \) node, however it is created, is the topmost node of the stack. It only gets popped off the stack when the parser finishes\(^{6118} \).

The current node is the bottommost node in this stack of open elements\(^{6106} \).

The adjusted current node is the context\(^{6118} \) element if the parser was created by the HTML fragment parsing algorithm\(^{6118} \) and the stack of open elements\(^{6106} \) has only one element in it (fragment case\(^{6119} \)); otherwise, the adjusted current node\(^{6136} \) is the current node\(^{6136} \).

Elements in the stack of open elements\(^{6106} \) fall into the following categories:
Special
The following elements have varying levels of special parsing rules: HTML's address, apple, area, article, aside, base, basefont, bgsound, blockquote, body, br, button, caption, center, col, colgroup, dd, details, dir, div, dl, dt, embed, fieldset, figcaption, figure, footer, form, frame, frameset, h1, h2, h3, h4, h5, h6, head, header, hr, iframe, img, input, keygen, li, link, listing, main, marquee, menu, meta, nav, noembed, noframes, noscript, object, ol, p, param, pre, script, section, select, source, style, summary, table, tbody, td, template, textarea, tfoot, th, thead, title, tr, track, u, video, wbr, xmp.

Note
An image start tag token is handled by the tree builder, but it is not in this list because it is not an element; it gets turned into an img element.

Formatting
The following HTML elements are those that end up in the list of active formatting elements: a, abbr, address, article, aside, base, basefont, bgsound, blockquote, body, br, button, caption, center, col, colgroup, dd, details, dir, div, dl, dt, embed, fieldset, figcaption, figure, footer, form, frame, frameset, h1, h2, h3, h4, h5, h6, head, header, hr, iframe, img, input, keygen, li, link, listing, main, marquee, menu, meta, nav, noembed, noframes, noscript, object, ol, p, param, pre, script, section, select, source, style, summary, table, tbody, td, template, textarea, tfoot, th, thead, title, tr, track, u, video, wbr, xmp.

Ordinary
All other elements found while parsing an HTML document.

Note
Typically, the special elements have the start and end tag tokens handled specifically, while ordinary elements' tokens fall into "any other start tag" and "any other end tag" clauses, and some parts of the tree builder check if a particular element in the stack of open elements is in the special category. However, some elements (e.g., the option element) have their start or end tag tokens handled specifically, but are still not in the special category, so that they get the ordinary handling elsewhere.

The stack of open elements is said to have an element target node in a specific scope consisting of a list of element types list when the following algorithm terminates in a match state:

1. Initialize node to be the current node (the bottommost node of the stack).
2. If node is the target node, terminate in a match state.
3. Otherwise, if node is one of the element types in list, terminate in a failure state.
4. Otherwise, set node to the previous entry in the stack of open elements and return to step 2. (This will never fail, since the loop will always terminate in the previous step if the top of the stack — an html element — is reached.)

The stack of open elements is said to have a particular element in scope when it has that element in the specific scope consisting of the following element types:

1. article
2. aside
3. base
4. basefont
5. bgsound
6. blockquote
7. body
8. br
9. button
10. caption
11. center
12. col
13. colgroup
14. dd
15. details
16. dir
17. div
18. dl
19. dt
20. embed
21. fieldset
22. figcaption
23. figure
24. footer
25. form
26. frame
27. frameset
28. h1
29. h2
30. h3
31. h4
32. h5
33. h6
34. head
35. header
36. hr
37. iframe
38. img
39. input
40. keygen
41. li
42. link
43. listing
44. main
45. marquee
46. menu
47. meta
48. nav
49. noembed
50. noframes
51. noscript
52. object
53. ol
54. p
55. param
56. pre
57. script
58. section
59. select
60. source
61. style
62. summary
63. table
64. tbody
65. td
66. template
67. textarea
68. tfoot
69. th
70. thead
71. title
72. tr
73. track
74. u
75. video
76. wbr
77. xmp
78. MathML mi
79. MathML mo
80. MathML mn
81. MathML ms
82. MathML mtext
83. SVG foreignObject
84. SVG desc
85. SVG title

The stack of open elements is said to have a particular element in list item scope when it has that element in the specific scope consisting of the following element types:

1. All the element types listed above for the has an element in scope algorithm.
The **stack of open elements** is said to have a particular element in **button scope** when it has that element in the specific scope consisting of the following element types:

- All the element types listed above for the **has an element in scope** algorithm.
- `button` in the HTML namespace

The **stack of open elements** is said to have a particular element in **table scope** when it has that element in the specific scope consisting of the following element types:

- `html` in the HTML namespace
- `table` in the HTML namespace
- `template` in the HTML namespace

The **stack of open elements** is said to have a particular element in **select scope** when it has that element in the specific scope consisting of all element types except:

- `optgroup` in the HTML namespace
- `option` in the HTML namespace

Nothing happens if at any time any of the elements in the **stack of open elements** are moved to a new location in, or removed from, the Document tree. In particular, the stack is not changed in this situation. This can cause, amongst other strange effects, content to be appended to nodes that are no longer in the DOM.

**Note**

In some cases (namely, when closing misnested formatting elements), the stack is manipulated in a random-access fashion.

12.2.4.3 The list of active formatting elements

Initially, the list of active formatting elements is empty. It is used to handle mis-nested formatting element tags.

The list contains elements in the formatting category, and markers. The markers are inserted when entering `applet`, `object`, `marquee`, `template`, `td`, `th`, and `caption` elements, and are used to prevent formatting from “leaking” into `applet`, `object`, `marquee`, `template`, `td`, `th`, and `caption` elements.

In addition, each element in the list of active formatting elements is associated with the token for which it was created, so that further elements can be created for that token if necessary.

When the steps below require the UA to push onto the list of active formatting elements an element, the UA must perform the following steps:

1. If there are already three elements in the list of active formatting elements after the last marker, if any, or anywhere in the list if there are no markers, that have the same tag name, namespace, and attributes as `element`, then remove the earliest such element from the list of active formatting elements. For these purposes, the attributes must be compared as they were when the elements were created by the parser; two elements have the same attributes if all their parsed attributes can be paired such that the two attributes in each pair have identical names, namespaces, and values (the order of the attributes does not matter).

**Note**

This is the Noah’s Ark clause. But with three per family instead of two.

2. Add element to the list of active formatting elements.

When the steps below require the UA to reconstruct the active formatting elements, the UA must perform the following steps:

1. If there are no entries in the list of active formatting elements, then there is nothing to reconstruct; stop this algorithm.

2. If the last (most recently added) entry in the list of active formatting elements is a marker, or if it is an element that is in the stack of open elements, then there is nothing to reconstruct; stop this algorithm.

3. Let entry be the last (most recently added) element in the list of active formatting elements.

4. **Rewind**: If there are no entries before entry in the list of active formatting elements, then jump to the step labeled...
5. Let entry be the entry one earlier than entry in the list of active formatting elements.

6. If entry is neither a marker nor an element that is also in the stack of open elements, go to the step labeled rewind.

7. Advance: Let entry be the element one later than entry in the list of active formatting elements.

8. Create: Insert an HTML element for the token for which the element entry was created, to obtain new element.

9. Replace the entry for entry in the list with an entry for new element.

10. If the entry for new element in the list of active formatting elements is not the last entry in the list, return to the step labeled advance.

This has the effect of reopening all the formatting elements that were opened in the current body, cell, or caption (whichever is youngest) that haven't been explicitly closed.

---

**Note**

The way this specification is written, the list of active formatting elements always consists of elements in chronological order with the least recently added element first and the most recently added element last (except for while steps 7 to 10 of the above algorithm are being executed, of course).

---

When the steps below require the UA to clear the list of active formatting elements up to the last marker, the UA must perform the following steps:

1. Let entry be the last (most recently added) entry in the list of active formatting elements.

2. Remove entry from the list of active formatting elements.

3. If entry was a marker, then stop the algorithm at this point. The list has been cleared up to the last marker.

4. Go to step 1.

---

### 12.2.4.4 The element pointers

Initially, the head element pointer and the form element pointer are both null.

Once a head element has been parsed (whether implicitly or explicitly) the head element pointer gets set to point to this node.

The form element pointer points to the last form element that was opened and whose end tag has not yet been seen. It is used to make form controls associate with forms in the face of dramatically bad markup, for historical reasons. It is ignored inside template elements.

---

### 12.2.4.5 Other parsing state flags

The scripting flag is set to "enabled" if scripting was enabled for the Document with which the parser is associated when the parser was created, and "disabled" otherwise.

**Note**

The scripting flag can be enabled even when the parser was originally created for the HTML fragment parsing algorithm, even though script elements don't execute in that case.

The frameset-ok flag is set to "ok" when the parser is created. It is set to "not ok" after certain tokens are seen.

---

### 12.2.5 Tokenization

Implementations must act as if they used the following state machine to tokenize HTML. The state machine must start in the data state. Most states consume a single character, which may have various side-effects, and either switches the state machine to a new state to reconsume the current input character, or switches it to a new state to consume the next character, or stays
in the same state to consume the next character. Some states have more complicated behavior and can consume several characters before switching to another state. In some cases, the tokenizer state is also changed by the tree construction stage.

When a state says to **reconsume** a matched character in a specified state, that means to switch to that state, but when it attempts to consume the *next input character*, provide it with the *current input character* instead.

The exact behavior of certain states depends on the **insertion mode** and the **stack of open elements**. Certain states also use a **temporary buffer** to track progress, and the **character reference state** uses a **return state** to return to the state it was invoked from.

The output of the tokenization step is a series of zero or more of the following tokens: DOCTYPE, start tag, end tag, comment, character, end-of-file. DOCTYPE tokens have a name, a public identifier, a system identifier, and a **force-quirks flag**. When a DOCTYPE token is created, its name, public identifier, and system identifier must be marked as missing (which is a distinct state from the empty string), and the **force-quirks flag** must be set to off (its other state is on). Start and end tag tokens have a tag name, a **self-closing flag**, and a list of attributes, each of which has a name and a value. When a start or end tag token is created, its **self-closing flag** must be unset (its other state is that it be set), and its attributes list must be empty. Comment and character tokens have data.

When a token is emitted, it must immediately be handled by the **tree construction** stage. The tree construction stage can affect the state of the tokenization stage, and can insert additional characters into the stream. (For example, the **script** element can result in scripts executing and using the **dynamic markup insertion** APIs to insert characters into the stream being tokenized.)

When a start tag token is emitted with its **self-closing flag** set, if the flag is not acknowledged when it is processed by the tree construction stage, that is a **non-void-html-element-start-tag-with-trailing-solidus** parse error.

When an end tag token is emitted with attributes, that is an **end-tag-with-attributes** parse error.

When an end tag token is emitted with its **self-closing flag** set, that is an **end-tag-with-trailing-solidus** parse error.

An **appropriate end tag token** is an end tag token whose tag name matches the tag name of the last start tag to have been emitted from this tokenizer, if any. If no start tag has been emitted from this tokenizer, then no end tag token is appropriate.

A **character reference** is said to be **consumed as part of an attribute** if the **return state** is either **attribute value (double-quoted) state**, **attribute value (single-quoted) state** or **attribute value (unquoted) state**.

When a state says to **flush code points consumed as a character reference**, it means that for each **code point** in the **temporary buffer** (in the order they were added to the buffer) user agent must append the code point from the buffer to the current attribute's value if the character reference was **consumed as part of an attribute**, or emit the code point as a character token otherwise.

Before each step of the tokenizer, the user agent must first check the **parser pause flag**. If it is true, then the tokenizer must abort the processing of any nested invocations of the tokenizer, yielding control back to the caller.

The tokenizer state machine consists of the states defined in the following subsections.

### 12.2.5.1 Data state

**Consumes the next input character**:

- **U+0026 AMPERSAND (&)**
  
  Set the **return state** to the **data state**, Switch to the **character reference state**.

- **U+003C LESS-THAN SIGN (<)**
  
  Switch to the **tag open state**.

- **U+0000 NULL**
  
  This is a **unexpected-null-character** parse error. Emit the **current input character** as a character token.
→ EOF
   Emit an end-of-file token.

→ Anything else
   Emit the current input character as a character token.

12.2.5.2 RCDATA state

Consume the next input character:

→ U+0026 AMPERSAND (&)
   Set the return state to the RCDATA state. Switch to the character reference state.

→ U+003C LESS-THAN SIGN (<)
   Switch to the RCDATA less-than sign state.

→ U+0000 NULL
   This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

→ EOF
   Emit an end-of-file token.

→ Anything else
   Emit the current input character as a character token.

12.2.5.3 RAWTEXT state

Consume the next input character:

→ U+003C LESS-THAN SIGN (<)
   Switch to the RAWTEXT less-than sign state.

→ U+0000 NULL
   This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

→ EOF
   Emit an end-of-file token.

→ Anything else
   Emit the current input character as a character token.

12.2.5.4 Script data state

Consume the next input character:

→ U+003C LESS-THAN SIGN (<)
   Switch to the script data less-than sign state.

→ U+0000 NULL
   This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

→ EOF
   Emit an end-of-file token.

→ Anything else
   Emit the current input character as a character token.
12.2.5.5 PLAINTEXT state

Consume the next input character.

↪ U+0000 NULL
This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ EOF
Emit an end-of-file token.

↪ Anything else
Emit the current input character as a character token.

12.2.5.6 Tag open state

Consume the next input character:

↪ U+0021 EXCLAMATION MARK (!)
Switch to the markup declaration open state.

↪ U+002F SOLIDUS (/)
Switch to the end tag open state.

↪ ASCII alpha
Create a new start tag token, set its tag name to the empty string. Recompose in the tag name state.

↪ U+003F QUESTION MARK (?)
This is an unexpected-question-mark-instead-of-tag-name parse error. Create a comment token whose data is the empty string. Recompose in the bogus comment state.

↪ EOF
This is an eof-before-tag-name parse error. Emit a U+003C LESS-THAN SIGN character token and an end-of-file token.

↪ Anything else
This is an invalid-first-character-of-tag-name parse error. Emit a U+003C LESS-THAN SIGN character token.

12.2.5.7 End tag open state

Consume the next input character:

↪ ASCII alpha
Create a new end tag token, set its tag name to the empty string. Recompose in the tag name state.

↪ U+003E GREATER-THAN SIGN (>)
This is a missing-end-tag-name parse error. Switch to the data state.

↪ EOF
This is an eof-before-tag-name parse error. Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token and an end-of-file token.

↪ Anything else
This is an invalid-first-character-of-tag-name parse error. Create a comment token whose data is the empty string. Recompose in the bogus comment state.

12.2.5.8 Tag name state

Consume the next input character:
12.2.5.9 RCDATA less-than sign state

Consume the next input character:

- U+002F SOLIDUS (/)
  - Set the temporary buffer to the empty string. Switch to the RCDATA end tag open state.
- Anything else
  - Emit a U+003C LESS-THEAN SIGN character token. Reconsume in the RCDATA state.

12.2.5.10 RCDATA end tag open state

Consume the next input character:

- ASCII alpha
  - Create a new end tag token, set its tag name to the empty string. Reconsume in the RCDATA end tag name state.
- Anything else
  - Emit a U+003C LESS-THEAN SIGN character token and a U+002F SOLIDUS character token. Reconsume in the RCDATA state.

12.2.5.11 RCDATA end tag name state

Consume the next input character:

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE
  - If the current end tag token is an appropriate end tag token, then switch to the before attribute name state. Otherwise, treat it as per the "anything else" entry below.
If the current end tag token is an `appropriate end tag token`\[^{1040}\] and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

If the current end tag token is an `appropriate end tag token`\[^{1040}\], then switch to the `data state`\[^{1040}\] and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

`ASCII upper alpha`

Append the lowercase version of the `current input character`\[^{1035}\] (add 0x0020 to the character's code point) to the current tag token's tag name. Append the `current input character`\[^{1035}\] to the `temporary buffer`\[^{1040}\].

`ASCII lower alpha`

Append the `current input character`\[^{1035}\] to the current tag token's tag name. Append the `current input character`\[^{1035}\] to the `temporary buffer`\[^{1040}\].

`Anything else`

Emit a U+003C LESS-THEL SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the `temporary buffer`\[^{1040}\] (in the order they were added to the buffer). `Reconsume`\[^{1040}\] in the `RCDATA state`\[^{1041}\].

12.2.5.12 RAWTEXT less-than sign state \[^{10}\]

Consume the `next input character`\[^{1035}\].

- `U+002F SOLIDUS (/)`
  
  Set the `temporary buffer`\[^{1040}\] to the empty string. Switch to the `RAWTEXT end tag open state`\[^{1044}\].

- `Anything else`
  
  Emit a U+003C LESS-THAN SIGN character token. `Reconsume`\[^{1040}\] in the `RAWTEXT state`\[^{1041}\].

12.2.5.13 RAWTEXT end tag open state \[^{10}\]

Consume the `next input character`\[^{1035}\].

- `ASCII alpha`
  
  Create a new end tag token, set its tag name to the empty string. `Reconsume`\[^{1040}\] in the `RAWTEXT end tag name state`\[^{1044}\].

- `Anything else`
  
  Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. `Reconsume`\[^{1040}\] in the `RAWTEXT state`\[^{1041}\].

12.2.5.14 RAWTEXT end tag name state \[^{10}\]

Consume the `next input character`\[^{1035}\].

- `U+0009 CHARACTER TABULATION (tab)`
- `U+000A LINE FEED (LF)`
- `U+000C FORM FEED (FF)`
- `U+0020 SPACE`
  
  If the current end tag token is an `appropriate end tag token`\[^{1040}\], then switch to the `before attribute name state`\[^{1050}\]. Otherwise, treat it as per the "anything else" entry below.

- `U+002F SOLIDUS (/)`
  
  If the current end tag token is an `appropriate end tag token`\[^{1040}\], then switch to the `self-closing start tag state`\[^{1053}\]. Otherwise, treat it as per the "anything else" entry below.

- `U+003E GREATER-THEHAN SIGN (>)`
  
  If the current end tag token is an `appropriate end tag token`\[^{1040}\], then switch to the `data state`\[^{1040}\] and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.
Append the lowercase version of the current input character (add 0x0020 to the character's code point) to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.
Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

Anything else
Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the temporary buffer (in the order they were added to the buffer). Reconsume in the script data state.

12.2.5.18 Script data escape start state

Consume the next input character:

Anything else
Switch to the script data escape start dash state. Emit a U+002D HYPHEN-MINUS character token.

Anything else
Reconsume in the script data state.

12.2.5.19 Script data escape start dash state

Consume the next input character:

Anything else
Switch to the script data escaped dash dash state. Emit a U+002D HYPHEN-MINUS character token.

Anything else
Reconsume in the script data state.

12.2.5.20 Script data escaped state

Consume the next input character:

Anything else
Switch to the script data escaped dash dash state. Emit a U+002D HYPHEN-MINUS character token.

Anything else
Switch to the script data escaped less-than sign state.

Anything else
Switch to the script data escaped less-than sign state.

Anything else
Switch to the script data escaped less-than sign state.

Anything else
Switch to the script data escaped less-than sign state.

EOF
This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

Anything else
Emit the current input character as a character token.

12.2.5.21 Script data escaped dash state

Consume the next input character:

Anything else
Switch to the script data escaped dash dash state. Emit a U+002D HYPHEN-MINUS character token.

Anything else
Switch to the script data escaped less-than sign state.
This is an unexpected-null-character parse error. Switch to the script data escaped state. Emit a U+FFFD replacement character token.

This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

Switch to the script data escaped state. Emit the current input character as a character token.

### 12.2.5.22 Script data escaped dash dash state

Consume the next input character.

- **U+002D HYPHEN-MINUS (-)**
  Emit a U+002D HYPHEN-MINUS character token.

- **U+003C LESS-THAN SIGN (<)**
  Switch to the script data escaped less-than-sign state.

- **U+003E GREATER-THAN SIGN (>)**
  Switch to the script data state. Emit a U+003E GREATER-THAN SIGN character token.

- **U+0000 NULL**
  This is an unexpected-null-character parse error. Switch to the script data escaped state. Emit a U+FFFD replacement character token.

This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

Switch to the script data escaped state. Emit the current input character as a character token.

### 12.2.5.23 Script data escaped less-than-sign state

Consume the next input character.

- **U+002F SOLIDUS (/)**
  Set the temporary buffer to the empty string. Switch to the script data escaped end tag open state.

- **ASCII alpha**
  Set the temporary buffer to the empty string. Emit a U+003C LESS-THAN SIGN character token. Recomsume in the script data double escape start state.

- **Anything else**
  Emit a U+003C LESS-THAN SIGN character token. Recomsume in the script data escaped state.

### 12.2.5.24 Script data escaped end tag open state

Consume the next input character.

- **ASCII alpha**
  Create a new end tag token. Recomsume in the script data escaped end tag name state. (Don't emit the token yet; further details will be filled in before it is emitted.)

- **Anything else**
  Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Recomsume in the script data escaped state.
12.2.5.25 Script data escaped end tag name state

Consume the next input character.

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE

If the current end tag token is an appropriate end tag token, then switch to the before attribute name state. Otherwise, treat it as per the "anything else" entry below.

- U+002F SOLIDUS (/)

If the current end tag token is an appropriate end tag token, then switch to the self-closing start tag state. Otherwise, treat it as per the "anything else" entry below.

- U+003E GREATER-THERE SIGN (>)

If the current end tag token is an appropriate end tag token, then switch to the data state and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

- ASCII upper alpha

Append the lowercase version of the current input character (add 0x0020 to the character's code point) to the current tag token's tag name. Append the current input character to the temporary buffer.

- ASCII lower alpha

Append the current input character to the current tag token's tag name. Append the current input character to the temporary buffer.

- Anything else

Emit a U+003C LESS-THEEN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the temporary buffer (in the order they were added to the buffer). Recomsume in the script data escaped state.

12.2.5.26 Script data double escape start state

Consume the next input character:

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE
- U+002F SOLIDUS (/)
- U+003E GREATER-THERE SIGN (>)

If the temporary buffer is the string "script", then switch to the script data double escaped state. Otherwise, switch to the script data escaped state. Emit the current input character as a character token.

- ASCII upper alpha

Append the lowercase version of the current input character (add 0x0020 to the character's code point) to the temporary buffer. Emit the current input character as a character token.

- ASCII lower alpha

Append the current input character to the temporary buffer. Emit the current input character as a character token.

- Anything else

Reconsume in the script data escaped state.

12.2.5.27 Script data double escaped state

Consume the next input character:
12.2.5.28 Script data double escaped dash dash state

Consume the next input character:

- **U+002D HYPHEN-MINUS (-)**
  - Switch to the script data double escaped dash dash state. Emit a U+002D HYPHEN-MINUS character token.

- **U+003C LESS-THAN SIGN (<)**
  - Switch to the script data double escaped less-than sign state. Emit a U+003C LESS-THAN SIGN character token.

- **U+0000 NULL**
  - This is an unexpected-null-character parse error. Switch to the script data double escaped state. Emit a U+FFFD REPLACEMENT CHARACTER character token.

- **EOF**
  - This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

- **Anything else**
  - Switch to the script data double escaped state. Emit the current input character as a character token.

12.2.5.29 Script data double escaped dash dash state

Consume the next input character:

- **U+002D HYPHEN-MINUS (-)**
  - Switch to the script data double escaped dash dash state. Emit a U+002D HYPHEN-MINUS character token.

- **U+003C LESS-THAN SIGN (<)**
  - Switch to the script data double escaped less-than sign state. Emit a U+003C LESS-THAN SIGN character token.

- **U+0000 NULL**
  - This is an unexpected-null-character parse error. Switch to the script data double escaped state. Emit a U+FFFD REPLACEMENT CHARACTER character token.

- **EOF**
  - This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

- **Anything else**
  - Switch to the script data double escaped state. Emit the current input character as a character token.

12.2.5.30 Script data double escaped less-than sign state

Consume the next input character:

- **U+0000 NULL**
  - This is an unexpected-null-character parse error. Switch to the script data double escaped state. Emit a U+FFFD REPLACEMENT CHARACTER character token.

- **EOF**
  - This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

- **Anything else**
  - Switch to the script data double escaped state. Emit the current input character as a character token.
Set the temporary buffer to the empty string. Switch to the script data double escape end state. Emit a U+002F SOLIDUS character token.

Anything else
Reconsume in the script data double escaped state.

12.2.5.31 Script data double escape end state

Consume the next input character.

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE
- U+002F SOLIDUS (/)
- U+003E GREATER-THAN SIGN (>)
  If the temporary buffer is the string "script", then switch to the script data escaped state. Otherwise, switch to the script data double escaped state. Emit the current input character as a character token.

- ASCII upper alpha
  Append the lowercase version of the current input character (add 0x0020 to the character's code point) to the temporary buffer. Emit the current input character as a character token.

- ASCII lower alpha
  Append the current input character to the temporary buffer. Emit the current input character as a character token.

- Anything else
  Reconsume in the script data double escaped state.

12.2.5.32 Before attribute name state

Consume the next input character.

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE
  Ignore the character.
- U+002F SOLIDUS (/)
- U+003E GREATER-THAN SIGN (>)
- EOF
  Reconsume in the after attribute name state.

- U+003D EQUALS SIGN (=)
  This is an unexpected-equals-sign-before-attribute-name parse error. Start a new attribute in the current tag token. Set that attribute's name to the current input character, and its value to the empty string. Switch to the attribute name state.

- Anything else
  Start a new attribute in the current tag token. Set that attribute name and value to the empty string. Reconsume in the attribute name state.

12.2.5.33 Attribute name state

Consume the next input character.
When the user agent leaves the attribute name state (and before emitting the tag token, if appropriate), the complete attribute's name must be compared to the other attributes on the same token; if there is already an attribute on the token with the exact same name, then this is a duplicate-attribute parse error and the new attribute must be removed from the token.

### Note

If an attribute is so removed from a token, it, and the value that gets associated with it, if any, are never subsequently used by the parser, and are therefore effectively discarded. Removing the attribute in this way does not change its status as the "current attribute" for the purposes of the tokenizer, however.

---

### 12.2.5.34 After attribute name state

Consume the next input character.

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE
- U+002F SOLIDUS (/)
- U+003E GREATER-THAN SIGN (>)
- EOF
  
  Recomsume in the after attribute name state.

- U+003D EQUALS SIGN (=)
  
  Switch to the before attribute value state.

- ASCII upper alpha
  
  Append the lowercase version of the current input character (add 0x0020 to the character's code point) to the current attribute's name.

- U+0000 NULL
  
  This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's name.

- U+0022 QUOTATION MARK ("")
- U+0027 APOSTROPHE (’)
- U+003C LESS-THAN SIGN (<)
  
  This is an unexpected-character-in-attribute-name parse error. Treat it as per the "anything else" entry below.

- Anything else
  
  Append the current input character to the current attribute's name.
12.2.5.35 Before attribute value state

Consume the next input character.

- \(\rightarrow\) \text{U+0009 CHARACTER TABULATION (tab)}
- \(\rightarrow\) \text{U+000A LINE FEED (LF)}
- \(\rightarrow\) \text{U+000C FORM FEED (FF)}
- \(\rightarrow\) \text{U+0020 SPACE}

Ignore the character.

- \(\rightarrow\) \text{U+0022 QUOTATION MARK (")}
  Switch to the attribute value (double-quoted) state.

- \(\rightarrow\) \text{U+0027 APOSTROPHE (')}
  Switch to the attribute value (single-quoted) state.

- \(\rightarrow\) \text{U+003E GREATER-THAN SIGN (>)}
  This is a missing-attribute-value parse error. Switch to the data state. Emit the current tag token.

- \(\rightarrow\) Anything else
  Reconsume in the attribute value (unquoted) state.

12.2.5.36 Attribute value (double-quoted) state

Consume the next input character:

- \(\rightarrow\) \text{U+0022 QUOTATION MARK (")}
  Switch to the after attribute value (quoted) state.

- \(\rightarrow\) \text{U+0026 AMPERSAND (&)}
  Set the return state to the attribute value (double-quoted) state. Switch to the character reference state.

- \(\rightarrow\) \text{U+0000 NULL}
  This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.

- \(\rightarrow\) EOF
  This is an eof-in-tag, parse error. Emit an end-of-file token.

- \(\rightarrow\) Anything else
  Append the current input character to the current attribute's value.

12.2.5.37 Attribute value (single-quoted) state

Consume the next input character:

- \(\rightarrow\) \text{U+0027 APOSTROPHE (')}
  Switch to the after attribute value (quoted) state.

- \(\rightarrow\) \text{U+0026 AMPERSAND (&)}
  Set the return state to the attribute value (single-quoted) state. Switch to the character reference state.

- \(\rightarrow\) \text{U+0000 NULL}
  This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.

- \(\rightarrow\) EOF
  This is an eof-in-tag, parse error. Emit an end-of-file token.

- \(\rightarrow\) Anything else
  Append the current input character to the current attribute's value.
12.2.5.38 Attribute value (unquoted) state

Consume the next input character:

- U+0009 CHARACTER TABULATION (tab)
- U+00A LINE FEED (LF)
- U+00C FORM FEED (FF)
- U+020 SPACE
  Switch to the before attribute name state.
- U+026 AMPERSAND (&)
  Set the return state to the attribute value (unquoted) state. Switch to the character reference state.
- U+03E GREATER-THAN SIGN (>)
  Switch to the data state. Emit the current tag token.
- U+000 NULL
  This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.
- U+0022 QUOTATION MARK ("
- U+0027 APOSTROPHE (')
- U+003C LESS-THAN SIGN (<)
- U+003D EQUALS SIGN (=)
- U+006 GRAVE ACCENT (’)
  This is an unexpected-character-in-unquoted-attribute-value parse error. Treat it as per the "anything else" entry below.
- EOF
  This is an eof-in-tag parse error. Emit an end-of-file token.
- Anything else
  Append the current input character to the current attribute's value.

12.2.5.39 After attribute value (quoted) state

Consume the next input character:

- U+0009 CHARACTER TABULATION (tab)
- U+00A LINE FEED (LF)
- U+00C FORM FEED (FF)
- U+020 SPACE
  Switch to the before attribute name state.
- U+02F SOLIDUS (/)
  Switch to the self-closing start tag state.
- U+03E GREATER-THAN SIGN (>)
  Switch to the data state. Emit the current tag token.
- EOF
  This is an eof-in-tag parse error. Emit an end-of-file token.
- Anything else
  This is a missing-whitespace-between-attributes parse error. Reconsume in the before attribute name state.

12.2.5.40 Self-closing start tag state

Consume the next input character:
Set the `self-closing flag` of the current tag token. Switch to the `data state`. Emit the current tag token.

- EOF
  This is an `eof-in-tag`, `parse error`. Emit an end-of-file token.

- Anything else
  This is an `unexpected-solidus-in-tag`, `parse error`. Reconsume in the `before attribute name state`.

12.2.5.41 Bogus comment state

Consume the `next input character`.

- U+003E GREATER-TAN SIGN (>)
  Switch to the `data state`. Emit the comment token.

- EOF
  Emit the comment. Emit an end-of-file token.

- U+0000 NULL
  This is an `unexpected-null-character`, `parse error`. Append a U+FFFD REPLACEMENT CHARACTER character to the comment token's data.

- Anything else
  Append the `current input character` to the comment token's data.

12.2.5.42 Markup declaration open state

If the next few characters are:

- Two U+002D HYPHEN-MINUS characters (-)
  Consume those two characters, create a comment token whose data is the empty string, and switch to the `comment start state`.

- ASCII case-insensitive match for the word "DOCTYPE"
  Consume those characters and switch to the `DOCTYPE state`.

- Case-sensitive match for the string "[CDATA[" (the five uppercase letters "CDATA" with a U+005B LEFT SQUARE BRACKET character before and after)
  Consume those characters. If there is an adjusted current node and it is not an element in the HTML namespace, then switch to the `CDATA section state`. Otherwise, this is a `data-in-html-content`, `parse error`. Create a comment token whose data is the "$[CDATA[" string. Switch to the `bogus comment state` (don't consume anything in the current state).

- Anything else
  This is an `incorrectly-opened-comment`, `parse error`. Create a comment token whose data is the empty string. Switch to the `bogus comment state` (don't consume anything in the current state).

12.2.5.43 Comment start state

Consume the `next input character`.

- U+002D HYPHEN-MINUS (-)
  Switch to the `comment start dash state`.

- U+003E GREATER-TAN SIGN (>)
  This is an `abrupt-closing-of-empty-comment`, `parse error`. Switch to the `data state`. Emit the comment token.

- Anything else
  Reconsume in the `comment state`.
12.2.5.44 Comment start dash state

Consume the next input character:

- U+002D HYPHEN-MINUS (-)
  Switch to the comment end state.
- U+003E GREATER-THAN SIGN (>)
  This is an abrupt-closing-of-empty-comment parse error. Switch to the data state. Emit the comment token.
- EOF
  This is an eof-in-comment parse error. Emit the comment token. Emit an end-of-file token.
- Anything else
  Append a U+002D HYPHEN-MINUS character (-) to the comment token's data. Reconsume in the comment state.

12.2.5.45 Comment state

Consume the next input character:

- U+003C LESS-THAN SIGN (<)
  Append the current input character to the comment token's data. Switch to the comment less-than sign state.
- U+002D HYPHEN-MINUS (-)
  Switch to the comment end dash state.
- U+0000 NULL
  This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the comment token's data.
- EOF
  This is an eof-in-comment parse error. Emit the comment token. Emit an end-of-file token.
- Anything else
  Append the current input character to the comment token's data.

12.2.5.46 Comment less-than sign state

Consume the next input character:

- U+0021 EXCLAMATION MARK (!)
  Append the current input character to the comment token's data. Switch to the comment less-than sign bang state.
- U+003C LESS-THAN SIGN (<)
  Append the current input character to the comment token's data.
- Anything else
  Reconsume in the comment state.

12.2.5.47 Comment less-than sign bang state

Consume the next input character:

- U+002D HYPHEN-MINUS (-)
  Switch to the comment less-than sign bang dash state.
- Anything else
  Reconsume in the comment state.
12.2.5.48 Comment less-than sign bang dash state \( \text{§p}1056 \)

Consume the \textit{next input character}\( ^{\text{p}1035} \).

→ U+002D HYPHEN-MINUS (-)
  
  Switch to the \textit{comment less-than sign bang dash dash state}\( ^{\text{p}1056} \).

→ Anything else
  
  \textit{Reconsume}\( ^{\text{p}1040} \) in the \textit{comment end dash state}\( ^{\text{p}1056} \).

12.2.5.49 Comment less-than sign bang dash dash state \( \text{§p}1056 \)

Consume the \textit{next input character}\( ^{\text{p}1035} \):

→ U+003E GREATER-T HAN SIGN (>)
  
  \textit{EOF}

  \textit{Reconsume}\( ^{\text{p}1040} \) in the \textit{comment end state}\( ^{\text{p}1056} \).

→ Anything else
  
  This is a \textit{nested-comment}\( ^{\text{p}1026} \) \textit{parse error}\( ^{\text{p}1024} \). \textit{Reconsume}\( ^{\text{p}1040} \) in the \textit{comment end state}\( ^{\text{p}1056} \).

12.2.5.50 Comment end dash state \( \text{§p}1056 \)

Consume the \textit{next input character}\( ^{\text{p}1035} \):

→ U+002D HYPHEN-MINUS (-)
  
  Switch to the \textit{comment end state}\( ^{\text{p}1056} \).

→ EOF
  
  This is an \textit{eof-in-comment}\( ^{\text{p}1025} \) \textit{parse error}\( ^{\text{p}1024} \). Emit the comment token. Emit an end-of-file token.

→ Anything else
  
  Append a U+002D HYPHEN-MINUS character (-) to the comment token's data. \textit{Reconsume}\( ^{\text{p}1040} \) in the \textit{comment state}\( ^{\text{p}1055} \).

12.2.5.51 Comment end state \( \text{§p}1056 \)

Consume the \textit{next input character}\( ^{\text{p}1035} \):

→ U+003E GREATER-T HAN SIGN (>)
  
  Switch to the \textit{data state}\( ^{\text{p}1050} \). Emit the comment token.

→ U+0021 EXCLAMATION MARK (!)
  
  Switch to the \textit{comment end bang state}\( ^{\text{p}1056} \).

→ U+002D HYPHEN-MINUS (-)
  
  Append a U+002D HYPHEN-MINUS character (-) to the comment token's data.

→ EOF
  
  This is an \textit{eof-in-comment}\( ^{\text{p}1025} \) \textit{parse error}\( ^{\text{p}1024} \). Emit the comment token. Emit an end-of-file token.

→ Anything else
  
  Append two U+002D HYPHEN-MINUS characters (-) to the comment token's data. \textit{Reconsume}\( ^{\text{p}1040} \) in the \textit{comment state}\( ^{\text{p}1055} \).

12.2.5.52 Comment end bang state \( \text{§p}1056 \)

Consume the \textit{next input character}\( ^{\text{p}1035} \):
Append two U+002D HYPHEN-MINUS characters (-) and a U+0021 EXCLAMATION MARK character (!) to the comment token's data. Switch to the comment end dash state.

This is an incorrectly-closed-comment parse error. Switch to the data state. Emit the comment token.

This is an eof-in-comment parse error. Emit the comment token. Emit an end-of-file token.

This is an incorrectly-closed-comment parse error. Switch to the data state. Emit the comment token.

This is an eof-in-doctype parse error. Create a new DOCTYPE token. Set its force-quirks flag to on. Emit the token. Emit an end-of-file token.

This is a missing-whitespace-before-doctype-name parse error. Recompute in the before DOCTYPE name state.

Consume the next input character.

Switch to the before DOCTYPE name state.

Reconsume in the before DOCTYPE name state.

This is a missing-doctype-name parse error. Create a new DOCTYPE token. Set its force-quirks flag to on. Switch to the data state. Emit the token.

This is an eof-in-doctype parse error. Create a new DOCTYPE token. Set its force-quirks flag to on. Emit the token. Emit an end-of-file token.

Consume the next input character.

Ignore the character.

Create a new DOCTYPE token. Set the token's name to the lowercase version of the current input character (add 0x0020 to the character's code point). Switch to the DOCTYPE name state.

This is an unexpected-null-character parse error. Create a new DOCTYPE token. Set the token's name to a U+FFFD replacement character. Switch to the DOCTYPE name state.

This is a missing-doctype-name parse error. Create a new DOCTYPE token. Set its force-quirks flag to on. Switch to the data state. Emit the token.

This is an eof-in-doctype parse error. Create a new DOCTYPE token. Set its force-quirks flag to on. Emit the token. Emit an end-of-file token.

12.2.5.53 DOCTYPE state

Consume the next input character.

Switch to the before DOCTYPE name state.

Reconsume in the before DOCTYPE name state.

This is a missing-doctype-name parse error. Create a new DOCTYPE token. Set its force-quirks flag to on. Switch to the data state. Emit the token.

Emit an end-of-file token.

12.2.5.54 Before DOCTYPE name state

Consume the next input character.

Ignore the character.

Create a new DOCTYPE token. Set the token's name to the lowercase version of the current input character (add 0x0020 to the character's code point). Switch to the DOCTYPE name state.

This is an unexpected-null-character parse error. Create a new DOCTYPE token. Set the token's name to a U+FFFD replacement character. Switch to the DOCTYPE name state.

This is a missing-doctype-name parse error. Create a new DOCTYPE token. Set its force-quirks flag to on. Switch to the data state. Emit the token.

This is an eof-in-doctype parse error. Create a new DOCTYPE token. Set its force-quirks flag to on. Emit the token. Emit an end-of-file token.
Anything else
Create a new DOCTYPE token. Set the token's name to the current input character. Switch to the DOCTYPE name state.

12.2.5.55 DOCTYPE name state

Consume the next input character:

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE
  Switch to the after DOCTYPE name state.

- U+003E GREATER-THAN SIGN (>)
  Switch to the data state. Emit the current DOCTYPE token.

- ASCII upper alpha
  Append the lowercase version of the current input character (add 0x0020 to the character's code point) to the current DOCTYPE token's name.

- U+0000 NULL
  This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's name.

- EOF
  This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token.

- Anything else
  Append the current input character to the current DOCTYPE token's name.

12.2.5.56 After DOCTYPE name state

Consume the next input character:

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE
  Ignore the character.

- U+003E GREATER-THAN SIGN (>)
  Switch to the data state. Emit the current DOCTYPE token.

- EOF
  This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token.

- Anything else
  If the six characters starting from the current input character are an ASCII case-insensitive match for the word "PUBLIC", then consume those characters and switch to the after DOCTYPE public keyword state.

  Otherwise, if the six characters starting from the current input character are an ASCII case-insensitive match for the word "SYSTEM", then consume those characters and switch to the after DOCTYPE system keyword state.

  Otherwise, this is an invalid-character-sequence-after-doctype-name parse error. Set the DOCTYPE token's force-quirks flag to on. Reconsume in the bogus DOCTYPE state.
12.2.5.57 After DOCTYPE public keyword state

Consume the next input character.

↪ U+0009 CHARACTER TABULATION (tab)
↪ U+000A LINE FEED (LF)
↪ U+000C FORM FEED (FF)
↪ U+0020 SPACE

Switch to the before DOCTYPE public identifier state.

↪ U+0022 QUOTATION MARK (" )
This is a missing-whitespace-after-doctype-public-keyword parse error. Set the DOCTYPE token's public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (double-quoted) state.

↪ U+0027 APOSTROPHE (’)
This is a missing-whitespace-after-doctype-public-keyword parse error. Set the DOCTYPE token's public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (single-quoted) state.

↪ U+003E GREATER-THAN SIGN (>)
This is a missing-doctype-public-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Switch to the data state. Emit that DOCTYPE token.

↪ EOF
This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token. Emit an end-of-file token.

↪ Anything else
This is a missing-quote-before-doctype-public-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Reconsume in the bogus DOCTYPE state.

12.2.5.58 Before DOCTYPE public identifier state

Consume the next input character:

↪ U+0009 CHARACTER TABULATION (tab)
↪ U+000A LINE FEED (LF)
↪ U+000C FORM FEED (FF)
↪ U+0020 SPACE

Ignore the character.

↪ U+0022 QUOTATION MARK (" )
Set the DOCTYPE token's public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (double-quoted) state.

↪ U+0027 APOSTROPHE (’)
Set the DOCTYPE token's public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (single-quoted) state.

↪ U+003E GREATER-THAN SIGN (>)
This is a missing-doctype-public-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Switch to the data state. Emit that DOCTYPE token.

↪ EOF
This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token. Emit an end-of-file token.

↪ Anything else
This is a missing-quote-before-doctype-public-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Reconsume in the bogus DOCTYPE state.
12.2.5.59 **DOCTYPE public identifier (double-quoted) state**

Consume the next input character\(^{1035}\).

- ↪ **U+0022 QUOTATION MARK (")**
  Switch to the *after DOCTYPE public identifier state*\(^{1069}\).

- ↪ **U+0000 NULL**
  This is an *unexpected-null-character parse error*. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's public identifier.

- ↪ **U+003E GREATER-THAN SIGN (>)**
  This is an *abrupt-doctype-public-identifier parse error*. Set the DOCTYPE token's *force-quirks flag*\(^{1040}\) to on. Switch to the *data state*. Emit that DOCTYPE token.

- ↪ **EOF**
  This is an *eof-in-doctype parse error*. Set the DOCTYPE token's *force-quirks flag*\(^{1040}\) to on. Emit that DOCTYPE token.

- ↪ **Anything else**
  Append the *current input character*\(^{1035}\) to the current DOCTYPE token's public identifier.

12.2.5.60 **DOCTYPE public identifier (single-quoted) state**

Consume the next input character\(^{1035}\):

- ↪ **U+0027 APOSTROPHE (’)**
  Switch to the *after DOCTYPE public identifier state*\(^{1069}\).

- ↪ **U+0000 NULL**
  This is an *unexpected-null-character parse error*. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's public identifier.

- ↪ **U+003E GREATER-THAN SIGN (>)**
  This is an *abrupt-doctype-public-identifier parse error*. Set the DOCTYPE token's *force-quirks flag*\(^{1040}\) to on. Switch to the *data state*. Emit that DOCTYPE token.

- ↪ **EOF**
  This is an *eof-in-doctype parse error*. Set the DOCTYPE token's *force-quirks flag*\(^{1040}\) to on. Emit that DOCTYPE token.

- ↪ **Anything else**
  Append the *current input character*\(^{1035}\) to the current DOCTYPE token's public identifier.

12.2.5.61 **After DOCTYPE public identifier state**

Consume the next input character\(^{1035}\):

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+00A0 LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**
  Switch to the *between DOCTYPE public and system identifiers state*\(^{1061}\).

- ↪ **U+003E GREATER-THAN SIGN (>)**
  Switch to the *data state*. Emit the current DOCTYPE token.

- ↪ **U+0022 QUOTATION MARK (")**
  This is a *missing-whitespace-between-doctype-public-and-system-identifiers parse error*. Set the DOCTYPE token's system identifier to the empty string (not missing), then switch to the *DOCTYPE system identifier (double-quoted) state*\(^{1062}\).
12.2.5.62 Between DOCTYPE public and system identifiers state  

Consume the next input character.  

- U+0009 CHARACTER TABULATION (tab)  
- U+000A LINE FEED (LF)  
- U+000C FORM FEED (FF)  
- U+0020 SPACE  
  Ignore the character.  
- U+003E GREATER-THEAN SIGN (>)  
  Switch to the data state. Emit the current DOCTYPE token.  
- U+0022 QUOTATION MARK (")  
  Set the DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state.  
- U+0027 APOSTROPHE ('')  
  Set the DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state.  
- EOF  
  This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token. Emit an end-of-file token.  
- Anything else  
  This is a missing-quote-before-doctype-system-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Recomsume in the bogus DOCTYPE state.  

12.2.5.63 After DOCTYPE system keyword state  

Consume the next input character:  

- U+0009 CHARACTER TABULATION (tab)  
- U+000A LINE FEED (LF)  
- U+000C FORM FEED (FF)  
- U+0020 SPACE  
  Switch to the before DOCTYPE system identifier state.  
- U+0022 QUOTATION MARK (")  
  This is a missing-whitespace-after-doctype-system-keyword parse error. Set the DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state.  
- U+0027 APOSTROPHE ('')  
  This is a missing-whitespace-after-doctype-system-keyword parse error. Set the DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state.  
- EOF  
  This is a missing-doctype-system-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Switch to
the data state. Emit that DOCTYPE token.

↪ EOF
This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token. Emit an end-of-file token.

↪ Anything else
This is a missing-quote-before-doctype-system-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Reconsume in the bogus DOCTYPE state.

12.2.5.64 Before DOCTYPE system identifier state

Consume the next input character:

↪ U+0009 CHARACTER TABULATION (tab)
↪ U+000A LINE FEED (LF)
↪ U+000C FORM FEED (FF)
↪ U+0020 SPACE
Ignore the character.

↪ U+0022 QUOTATION MARK ("")
Set the DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state.

↪ U+0027 APOSTROPE (’)
Set the DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state.

↪ U+003E GREATER-THAN SIGN (>)
This is a missing-doctype-system-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Switch to the data state. Emit that DOCTYPE token.

↪ EOF
This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token. Emit an end-of-file token.

↪ Anything else
This is a missing-quote-before-doctype-system-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Reconsume in the bogus DOCTYPE state.

12.2.5.65 DOCTYPE system identifier (double-quoted) state

Consume the next input character:

↪ U+0022 QUOTATION MARK ("")
Switch to the after DOCTYPE system identifier state.

↪ U+0000 NULL
This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's system identifier.

↪ U+003E GREATER-THAN SIGN (>)
This is an abrupt-doctype-system-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Switch to the data state. Emit that DOCTYPE token.

↪ EOF
This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token. Emit an end-of-file token.

↪ Anything else
Append the current input character to the current DOCTYPE token's system identifier.
12.2.5.66 **DOCTYPE system identifier (single-quoted) state**

Consume the next input character.

↪ U+0027 APOSTROPHE (’)
Switch to the after DOCTYPE system identifier state.

↪ U+0000 NULL
This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's system identifier.

↪ U+003E GREATER-THAN SIGN (>)
This is an abrupt-doctype-system-identifier parse error. Set the DOCTYPE token's force-quirks flag to on. Switch to the data state. Emit that DOCTYPE token.

↪ EOF
This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token.

↪ Anything else
Append the current input character to the current DOCTYPE token's system identifier.

12.2.5.67 **After DOCTYPE system identifier state**

Consume the next input character:

↪ U+0009 CHARACTER TABULATION (tab)
↪ U+000A LINE FEED (LF)
↪ U+000C FORM FEED (FF)
↪ U+0020 SPACE
Ignore the character.

↪ U+003E GREATER-THAN SIGN (>)
Switch to the data state. Emit the current DOCTYPE token.

↪ EOF
This is an eof-in-doctype parse error. Set the DOCTYPE token's force-quirks flag to on. Emit that DOCTYPE token. Emit an end-of-file token.

↪ Anything else
This is an unexpected-character-after-doctype-system-identifier parse error. Reconsume in the bogus DOCTYPE state. (This does not set the DOCTYPE token's force-quirks flag to on.)

12.2.5.68 **Bogus DOCTYPE state**

Consume the next input character:

↪ U+003E GREATER-THAN SIGN (>)
Switch to the data state. Emit the DOCTYPE token.

↪ U+0000 NULL
This is an unexpected-null-character parse error. Ignore the character.

↪ EOF
Emit the DOCTYPE token. Emit an end-of-file token.

↪ Anything else
Ignore the character.
12.2.5.69 CDATA section state

Consume the next input character\(^{p1035}\).

\(\leftarrow U+005D\) RIGHT SQUARE BRACKET (]
  Switch to the CDATA section bracket state\(^{p1064}\).

\(\leftarrow\) EOF
  This is an eof-in-cdata\(^{p1024}\) parse error\(^{p1024}\). Emit an end-of-file token.

\(\leftarrow\) Anything else
  Emit the current input character\(^{p1035}\) as a character token.

*Note*

\(U+0000\) NULL characters are handled in the tree construction stage, as part of the in foreign content\(^{p1014}\) insertion mode, which is the only place where CDATA sections can appear.

12.2.5.70 CDATA section bracket state

Consume the next input character\(^{p1035}\).

\(\leftarrow U+005D\) RIGHT SQUARE BRACKET (]
  Switch to the CDATA section end state\(^{p1064}\).

\(\leftarrow\) Anything else
  Emit a U+005D RIGHT SQUARE BRACKET character token. Reconsume\(^{p1040}\) in the CDATA section state\(^{p1064}\).

12.2.5.71 CDATA section end state

Consume the next input character\(^{p1035}\).

\(\leftarrow U+005D\) RIGHT SQUARE BRACKET (]
  Emit a U+005D RIGHT SQUARE BRACKET character token.

\(\leftarrow U+003E\) GREATER-THAN SIGN character
  Switch to the data state\(^{p1040}\).

\(\leftarrow\) Anything else
  Emit two U+005D RIGHT SQUARE BRACKET character tokens. Reconsume\(^{p1040}\) in the CDATA section state\(^{p1064}\).

12.2.5.72 Character reference state

Set the temporary buffer\(^{p1040}\) to the empty string. Append a U+0026 AMPERSAND (&) character to the temporary buffer\(^{p1040}\). Consume the next input character\(^{p1035}\).

\(\leftarrow\) ASCII alphanumeric
  Reconsume\(^{p1040}\) in the named character reference state\(^{p1064}\).

\(\leftarrow U+0023\) NUMBER SIGN (#)
  Append the current input character\(^{p1035}\) to the temporary buffer\(^{p1040}\). Switch to the numeric character reference state\(^{p1065}\).

\(\leftarrow\) Anything else
  Flush code points consumed as a character reference\(^{p1040}\). Reconsume\(^{p1040}\) in the return state\(^{p1040}\).

12.2.5.73 Named character reference state

Consume the maximum number of characters possible, with the consumed characters matching one of the identifiers in the first
column of the named character references table (in a case-sensitive manner). Append each character to the temporary buffer when it's consumed.

If there is a match
If the character reference was consumed as part of an attribute, and the last character matched is not a U+003B SEMICOLON character (;), and the next input character is either a U+003D EQUALS SIGN character (=) or an ASCII alphanumeric, then, for historical reasons, flush code points consumed as a character reference and switch to the return state.

Otherwise:
1. If the last character matched is not a U+003B SEMICOLON character (;), then this is a missing-semicolon-after-character-reference parse error.
2. Set the temporary buffer to the empty string. Append one or two characters corresponding to the character reference name (as given by the second column of the named character references table) to the temporary buffer.
3. Flush code points consumed as a character reference. Switch to the return state.

Otherwise
Flush code points consumed as a character reference. Switch to the ambiguous ampersand state.

Example

If the markup contains (not in an attribute) the string I'm &notit; I tell you, the character reference is parsed as "not", as in, I'm ¬it; I tell you (and this is a parse error). But if the markup was I'm &notin; I tell you, the character reference would be parsed as "notin;", resulting in I'm ∉ I tell you (and no parse error).

However, if the markup contains the string I'm &notit; I tell you in an attribute, no character reference is parsed and string remains intact (and there is no parse error).

12.2.5.74 Ambiguous ampersand state

Consume the next input character:

ASCII alphanumeric
If the character reference was consumed as part of an attribute, then append the current input character to the current attribute's value. Otherwise, emit the current input character as a character token.

U+003B SEMICOLON (;)
This is an unknown-named-character-reference parse error. Reconsume in the return state.

Anything else
Reconsume in the return state.

12.2.5.75 Numeric character reference state

Set the character reference code to zero (0).

Consume the next input character:

U+0078 LATIN SMALL LETTER X
U+0058 LATIN CAPITAL LETTER X
Append the current input character to the temporary buffer. Switch to the hexadecimal character reference start state.

Anything else
Reconsume in the decimal character reference start state.
12.2.5.76 Hexademical character reference start state

Consume the next input character.

↪ **ASCII hex digit**
   Reconsume in the hexademical character reference state.

↪ **Anything else**
   This is an absence-of-digits-in-numeric-character-reference parse error. Flush code points consumed as a character reference. Reconsume in the return state.

12.2.5.77 Decimal character reference start state

Consume the next input character:

↪ **ASCII digit**
   Reconsume in the decimal character reference state.

↪ **Anything else**
   This is an absence-of-digits-in-numeric-character-reference parse error. Flush code points consumed as a character reference. Reconsume in the return state.

12.2.5.78 Hexademical character reference state

Consume the next input character:

↪ **ASCII digit**
   Multiply the character reference code by 16. Add a numeric version of the current input character (subtract 0x0030 from the character's code point) to the character reference code.

↪ **ASCII upper hex digit**
   Multiply the character reference code by 16. Add a numeric version of the current input character as a hexademical digit (subtract 0x0037 from the character's code point) to the character reference code.

↪ **ASCII lower hex digit**
   Multiply the character reference code by 16. Add a numeric version of the current input character as a hexademical digit (subtract 0x0057 from the character's code point) to the character reference code.

↪ **U+003B SEMICOLON**
   Switch to the numeric character reference end state.

↪ **Anything else**
   This is a missing-semicolon-after-character-reference parse error. Reconsume in the numeric character reference end state.

12.2.5.79 Decimal character reference state

Consume the next input character:

↪ **ASCII digit**
   Multiply the character reference code by 10. Add a numeric version of the current input character (subtract 0x0030 from the character's code point) to the character reference code.

↪ **U+003B SEMICOLON**
   Switch to the numeric character reference end state.

↪ **Anything else**
   This is a missing-semicolon-after-character-reference parse error. Reconsume in the numeric character reference end state.
Check the character reference code:

- If the number is 0x00, then this is a null-character-reference parse error. Set the character reference code to 0xFFFD.
- If the number is greater than 0x10FFFF, then this is a character-reference-outside-unicode-range parse error. Set the character reference code to 0xFFFD.
- If the number is a surrogate, then this is a surrogate-character-reference parse error. Set the character reference code to 0xFFFD.
- If the number is a noncharacter, then this is a noncharacter-character-reference parse error.
- If the number is 0x0D, or a control that's not ASCII whitespace, then this is a control-character-reference parse error.

If the number is one of the numbers in the first column of the following table, then find the row with that number in the first column, and set the character reference code to the number in the second column of that row.

<table>

</tbody>
</table>

Set the temporary buffer to the empty string. Append a code point equal to the character reference code to the temporary buffer. Flush code points consumed as a character reference. Switch to the return state.

### 12.2.6 Tree construction

The input to the tree construction stage is a sequence of tokens from the tokenization stage. The tree construction stage is associated with a DOM Document object when a parser is created. The "output" of this stage consists of dynamically modifying or extending that document's DOM tree.

This specification does not define when an interactive user agent has to render the Document so that it is available to the user, or when it has to begin accepting user input.
As each token is emitted from the tokenizer, the user agent must follow the appropriate steps from the following list, known as the tree construction dispatcher:

↪ If the stack of open elements is empty
↪ If the adjusted current node is an element in the HTML namespace
↪ If the adjusted current node is a MathML text integration point and the token is a start tag whose tag name is neither "mglyph" nor "malignmark"
↪ If the adjusted current node is a MathML text integration point and the token is a character token
↪ If the adjusted current node is a MathML annotation-xml element and the token is a start tag whose tag name is "svg"
↪ If the adjusted current node is an HTML integration point and the token is a start tag
↪ If the adjusted current node is an HTML integration point and the token is a character token
↪ If the token is an end-of-file token
  Process the token according to the rules given in the section corresponding to the current insertion mode in HTML content.
↪ Otherwise
  Process the token according to the rules given in the section for parsing tokens in foreign content.

The next token is the token that is about to be processed by the tree construction dispatcher (even if the token is subsequently just ignored).

A node is a MathML text integration point if it is one of the following elements:

- A MathML mi element
- A MathML mo element
- A MathML mn element
- A MathML ms element
- A MathML mtext element

A node is an HTML integration point if it is one of the following elements:

- A MathML annotation-xml element whose start tag token had an attribute with the name "encoding" whose value was an ASCII case-insensitive match for the string "text/html"
- A MathML annotation-xml element whose start tag token had an attribute with the name "encoding" whose value was an ASCII case-insensitive match for the string "application/xhtml+xml"
- An SVG foreignObject element
- An SVG desc element
- An SVG title element

If the node in question is the context element passed to the HTML fragment parsing algorithm, then the start tag token for that element is the "fake" token created during by that HTML fragment parsing algorithm.

Not all of the tag names mentioned below are conformant tag names in this specification; many are included to handle legacy content. They still form part of the algorithm that implementations are required to implement to claim conformance.

The algorithm described below places no limit on the depth of the DOM tree generated, or on the length of tag names, attribute names, attribute values, Text nodes, etc. While implementers are encouraged to avoid arbitrary limits, it is recognized that practical concerns will likely force user agents to impose nesting depth constraints.

### 12.2.6.1 Creating and inserting nodes

While the parser is processing a token, it can enable or disable foster parenting. This affects the following algorithm.

The appropriate place for inserting a node, optionally using a particular override target, is the position in an element returned by running the following steps:

1. If there was an override target specified, then let target be the override target.

Otherwise, let target be the current node.
2. Determine the **adjusted insertion location** using the first matching steps from the following list:

→ **If foster parenting** is enabled and **target** is a **table**, **tbody**, **tfoot**, **thead**, or **tr** element

**Note**

*Foster parenting happens when content is misnested in tables.*

Run these substeps:

1. Let *last template* be the last **template** element in the **stack of open elements**, if any.
2. Let *last table* be the last **table** element in the **stack of open elements**, if any.
3. If there is a *last template* and either there is no *last table*, or there is one, but *last template* is lower (more recently added) than *last table* in the **stack of open elements**, then: let *adjusted insertion location* be inside *last template*'s **template contents**, after its last child (if any), and abort these substeps.
4. If there is no *last table*, then let *adjusted insertion location* be inside the first element in the **stack of open elements** (the **html** element), after its last child (if any), and abort these substeps. (fragment case)
5. If *last table* has a parent node, then let *adjusted insertion location* be inside *last table*'s parent node, immediately before *last table*, and abort these substeps.
6. Let *previous element* be the element immediately above *last table* in the **stack of open elements**.
7. Let *adjusted insertion location* be inside *previous element*, after its last child (if any).

**Note**

*These steps are involved in part because it's possible for elements, the **table** element in this case in particular, to have been moved by a script around in the DOM, or indeed removed from the DOM entirely, after the element was inserted by the parser.*

→ **Otherwise**

Let *adjusted insertion location* be inside *target*, after its last child (if any).

3. If the *adjusted insertion location* is inside a **template** element, let it instead be inside the **template** element's **template contents**, after its last child (if any).
4. Return the *adjusted insertion location*.

When the steps below require the UA to **create an element for a token** in a particular **given namespace** and with a particular **intended parent**, the UA must run the following steps:

1. Let *document* be *intended parent*'s **node document**.
2. Let *local name* be the tag name of the token.
3. Let *is* be the value of the "**is**" attribute in the given token, if such an attribute exists, or null otherwise.
4. Let *definition* be the result of **looking up a custom element definition** given *document*, **given namespace**, *local name*, and *is*.
5. If *definition* is non-null and the parser was not originally created for the **HTML fragment parsing algorithm**, then let will execute script be true. Otherwise, let it be false.
6. If will execute script is true, then:
   1. Increment *document*'s **throw-on-dynamic-markup-insertion counter**.
   2. If the **JavaScript execution context stack** is empty, then **perform a microtask checkpoint**.
   3. Push a new **element queue** onto the **custom element reactions stack**.
7. Let *element* be the result of **creating an element** given *document*, *localName*, **given namespace**, null, and *is*. If will execute script is true, set the synchronous custom elements flag; otherwise, leave it unset.
8. Append each attribute in the given token to element.

9. If will execute script is true, then:
   1. Let queue be the result of popping the current element queue from the custom element reactions stack. (This will be the same element queue as was pushed above.)
   2. Invoke custom element reactions in queue.
   3. Decrement document's throw-on-dynamic-markup-insertion counter.

10. If element has an xmlns attribute in the XMLNS namespace whose value is not exactly the same as the element's namespace, that is a parse error. Similarly, if element has an xmlns:xlink attribute in the XMLNS namespace whose value is not the XLink Namespace, that is a parse error.

11. If element is a resettable element, invoke its reset algorithm. (This initializes the element's value and checkedness based on the element's attributes.)

12. If element is a form-associated element, the form element pointer is not null, there is no template element on the stack of open elements, element is either not listed or doesn't have a form attribute, and the intended parent is in the same tree as the element pointed to by the form element pointer, then associate element with the form element pointed to by the form element pointer and set element's parser inserted flag.

13. Return element.

When the steps below require the user agent to insert a foreign element for a token in a given namespace, the user agent must run these steps:

1. Let the adjusted insertion location be the appropriate place for inserting a node.

2. Let element be the result of creating an element for the token in the given namespace, with the intended parent being the element in which the adjusted insertion location finds itself.

3. If it is possible to insert element at the adjusted insertion location, then:
   1. Push a new element queue onto the custom element reactions stack.
   2. Insert element at the adjusted insertion location.
   3. Pop the element queue from the custom element reactions stack, and invoke custom element reactions in that queue.

   *Note* If the adjusted insertion location cannot accept more elements, e.g. because it's a Document that already has an element child, then element is dropped on the floor.

4. Push element onto the stack of open elements so that it is the new current node.

5. Return element.

When the steps below require the user agent to insert an HTML element for a token, the user agent must insert a foreign element for the token, in the HTML namespace.
When the steps below require the user agent to **adjust MathML attributes** for a token, then, if the token has an attribute named `definitionurl`, change its name to `definitionURL` (note the case difference).

When the steps below require the user agent to **adjust SVG attributes** for a token, then, for each attribute on the token whose attribute name is one of the ones in the first column of the following table, change the attribute's name to the name given in the corresponding cell in the second column. (This fixes the case of SVG attributes that are not all lowercase.)

When the steps below require the user agent to **adjust foreign attributes** for a token, then, if any of the attributes on the token match the strings given in the first column of the following table, let the attribute be a namespaced attribute, with the prefix being the string given in the corresponding cell in the second column, the local name being the string given in the corresponding cell in the third column, and the namespace being the namespace given in the corresponding cell in the fourth column. (This fixes the use of namespaced attributes, in particular [lang attributes in the XML namespace](#).)

</tbody>
</table>

When the steps below require the user agent to **insert a character** while processing a token, the user agent must run the following steps:

1. Let `data` be the characters passed to the algorithm, or, if no characters were explicitly specified, the character of the character token being processed.

2. Let the **adjusted insertion location** be the appropriate place for inserting a node.

3. If the **adjusted insertion location** is in a `Document` node, then return.

4. If there is a `Text` node immediately before the **adjusted insertion location**, then append `data` to that `Text` node's data.

   Otherwise, create a new `Text` node whose data is `data` and whose `node document` is the same as that of the element in which the **adjusted insertion location** finds itself, and insert the newly created node at the **adjusted insertion location**.

   **Example**

Here are some sample inputs to the parser and the corresponding number of `Text` nodes that they result in, assuming a user agent that executes scripts.

<table>
<thead>
<tr>
<th>Input</th>
<th>Number of <code>Text</code> nodes</th>
</tr>
</thead>
</table>
| \(<\!\-\-\)
\<script>
 var script = document.getElementsByTagName('script')[0];
 document.body.removeChild(script);
\</script>\> | One `Text` node in the document, containing "AB". |
When the steps below require the user agent to **insert a comment** while processing a comment token, optionally with an explicitly insertion position, the user agent must run the following steps:

1. Let data be the data given in the comment token being processed.
2. If position was specified, then let the adjusted insertion location be position. Otherwise, let adjusted insertion location be the appropriate place for inserting a node.
3. Create a Comment node whose data attribute is set to data and whose node document is the same as that of the node in which the adjusted insertion location finds itself.
4. Insert the newly created node at the adjusted insertion location.

DOM mutation events must not fire for changes caused by the UA parsing the document. This includes the parsing of any content inserted using `document.write()` and `document.writeln()` calls. However, mutation observers do fire, as required by the WHATWG DOM Standard.

### 12.2.6.2 Parsing elements that contain only text

The **generic raw text element parsing algorithm** and the **generic RCDATA element parsing algorithm** consist of the following steps. These algorithms are always invoked in response to a start tag token.

1. **Insert an HTML element** for the token.
2. If the algorithm that was invoked is the **generic raw text element parsing algorithm**, switch the tokenizer to the RAWTEXT state; otherwise the algorithm invoked was the **generic RCDATA element parsing algorithm**, switch the tokenizer to the RCDATA state.
3. Let the original insertion mode be the current insertion mode.
4. Then, switch the insertion mode to "text".
12.2.6.3 Closing elements that have implied end tags

When the steps below require the UA to generate implied end tags, then, while the current node is a dd, dt, li, optgroup, option, p, rb, rt, rtc, th, tbody, table, tr, th, td, li, caption, the UA must pop the current node off the stack of open elements.

If a step requires the UA to generate implied end tags but lists an element to exclude from the process, then the UA must perform the above steps as if that element was not in the above list.

When the steps below require the UA to generate all implied end tags thoroughly, then, while the current node is a caption, colorgroup, dd, dt, li, optgroup, option, p, rb, rt, rtc, th, tbody, table, tr, th, td, li, caption, the UA must pop the current node off the stack of open elements.

12.2.6.4 The rules for parsing tokens in HTML content

12.2.6.4.1 The "initial" insertion mode

When the user agent is to apply the rules for the "initial" insertion mode, the user agent must handle the token as follows:

→ A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+0020 SPACE

  Ignore the token.

→ A comment token

  Insert a comment as the last child of the Document object.

→ A DOCTYPE token

  If the DOCTYPE token's name is not a case-sensitive match for the string "html", or the token's public identifier is not missing, or the token's system identifier is neither missing nor a case-sensitive match for the string "about:legacy-compat", then there is a parse error.

  Append a Document node to the Document node, with the name attribute set to the name given in the DOCTYPE token, or the empty string if the name was missing; the publicId attribute set to the public identifier given in the DOCTYPE token, or the empty string if the public identifier was missing; the systemId attribute set to the system identifier given in the DOCTYPE token, or the empty string if the system identifier was missing; and the other attributes specific to Document objects set to null and empty lists as appropriate. Associate the Document node with the Document object so that it is returned as the value of the doctype attribute of the Document object.

  Then, if the document is not an iframe srcdoc document, and the DOCTYPE token matches one of the conditions in the following list, then set the Document to quirks mode:

  • The force-quirks flag is set to on.
  • The name is set to anything other than "html" (compared case-sensitively).
  • The public identifier is set to: "://W3C//DTD W3 HTML Strict 3.0//EN/"
  • The public identifier is set to: "://W3C/DTD HTML 4.0 Transitional/EN"
  • The public identifier is set to: "HTML"
  • The system identifier is set to: "http://www.iana.org/assignments/dtd-namespaces.html" (compared case-sensitively).
  • The public identifier starts with: "://Silmaril/dtd/html Pro v8r11 19970101/"
  • The public identifier starts with: "//AS/DTD HTML 3.0 asWedit + extensions/"
  • The public identifier starts with: "//AdvaSoft Ltd/DTD HTML 3.0 asWedit + extensions/"
  • The public identifier starts with: "//IETF/DTD HTML 2.0 Level 1/"
  • The public identifier starts with: "//IETF/DTD HTML 2.0 Level 2/"
  • The public identifier starts with: "//IETF/DTD HTML 2.0 Strict Level 1/"
  • The public identifier starts with: "//IETF/DTD HTML 2.0 Strict Level 2/"
  • The public identifier starts with: "//IETF/DTD HTML 2.0 Strict/"
  • The public identifier starts with: "//IETF/DTD HTML 2.0/"
  • The public identifier starts with: "//IETF/DTD HTML 2.1E/"
  • The public identifier starts with: "//IETF/DTD HTML 3.0/"
  • The public identifier starts with: "//IETF/DTD HTML 3.2 Final/"
  • The public identifier starts with: "//IETF/DTD HTML 3.2/"
  • The public identifier starts with: "//IETF/DTD HTML 3/"
  • The public identifier starts with: "//IETF/DTD HTML Level 0/"
  • The public identifier starts with: "//IETF/DTD HTML Level 1/"
  • The public identifier starts with: "//IETF/DTD HTML Level 2/"
  • The public identifier starts with: "//IETF/DTD HTML Level 3/"
• The public identifier starts with: "-//IETF/DTD HTML Strict Level 1/"
• The public identifier starts with: "-//IETF/DTD HTML Strict Level 2/"
• The public identifier starts with: "-//IETF/DTD HTML Strict Level 3/"
• The public identifier starts with: "-//IETF/DTD HTML Strict/"
• The public identifier starts with: "-//IETF/DTD HTML/"
• The public identifier starts with: "-//Metrius/DTD Metrius Presentational/"
• The public identifier starts with: "-//Microsoft/DTD Internet Explorer 2.0 HTML Strict/"
• The public identifier starts with: "-//Microsoft/DTD Internet Explorer 2.0 HTML/"
• The public identifier starts with: "-//Microsoft/DTD Internet Explorer 2.0 Tables/"
• The public identifier starts with: "-//Microsoft/DTD Internet Explorer 3.0 HTML Strict/"
• The public identifier starts with: "-//Microsoft/DTD Internet Explorer 3.0 HTML/"
• The public identifier starts with: "-//Microsoft/DTD Internet Explorer 3.0 Tables/"
• The public identifier starts with: "-//Netscape Comm. Corp./DTD HTML Strict/"
• The public identifier starts with: "-//Netscape Comm. Corp./DTD HTML/"
• The public identifier starts with: "-//O'Reilly and Associates/DTD HTML 2.0/"
• The public identifier starts with: "-//O'Reilly and Associates/DTD HTML Extended 1.0/"
• The public identifier starts with: "-//O'Reilly and Associates/DTD HTML Extended Relaxed 1.0/"
• The public identifier starts with: "-//SQ/DTD HTML 2.0 HoTMetaL + extensions/"
• The public identifier starts with: "-//SoftQuad Software/DTD HoTMetaL PRO 6.0::19990601::extensions to HTML 4.0/"
• The public identifier starts with: "-//SoftQuad/DTD HoTMetaL PRO 4.0::19971010::extensions to HTML 4.0/"
• The public identifier starts with: "-//Spyglass/DTD HTML 2.0 Extended/"
• The public identifier starts with: "-//Sun Microsystems Corp./DTD HotJava HTML/"
• The public identifier starts with: "-//Sun Microsystems Corp./DTD HotJava Strict HTML/"
• The public identifier starts with: "-//W3C/DTD HTML 3 1995-03-24/"
• The public identifier starts with: "-//W3C/DTD HTML 3.2 Draft/"
• The public identifier starts with: "-//W3C/DTD HTML 3.2 Final/"
• The public identifier starts with: "-//W3C/DTD HTML 3.2/"
• The public identifier starts with: "-//W3C/DTD HTML 3.2S Draft/"
• The public identifier starts with: "-//W3C/DTD HTML 4.0 Draft/"
• The public identifier starts with: "-//W3C/DTD HTML 4.0 Transitional/"
• The public identifier starts with: "-//W3C/DTD HTML Experimental 19960712/"
• The public identifier starts with: "-//W3C/DTD HTML Experimental 970421/"
• The public identifier starts with: "-//W3C/DTD HTML 3 W3 HTML/"
• The public identifier starts with: "-//W3C/DTD HTML 3.0/"
• The public identifier starts with: "-//WebTechs/DTD Mozilla HTML 2.0/"
• The public identifier starts with: "-//WebTechs/DTD Mozilla HTML/"
• The system identifier is missing and the public identifier starts with: "-//W3C/DTD HTML 4.01 Frameset/"
• The system identifier is missing and the public identifier starts with: "-//W3C/DTD HTML 4.01 Transitional/"

Otherwise, if the document is not an iframe srcdoc document\(^{348}\), and the DOCTYPE token matches one of the conditions in the following list, then set the Document\(^{110}\) to limited-quirks mode:

• The public identifier starts with: "-//W3C/DTD XHTML 1.0 Frameset/"
• The public identifier starts with: "-//W3C/DTD XHTML 1.0 Transitional/"
• The system identifier is not missing and the public identifier starts with: "-//W3C/DTD HTML 4.01 Frameset/"
• The system identifier is not missing and the public identifier starts with: "-//W3C/DTD HTML 4.01 Transitional/"

The system identifier and public identifier strings must be compared to the values given in the lists above in an ASCII case-insensitive manner. A system identifier whose value is the empty string is not considered missing for the purposes of the conditions above.

Then, switch the insertion mode\(^{1035}\) to "before html\(^{1075}\)."

Anything else

If the document is not an iframe srcdoc document\(^{348}\), then this is a parse error\(^{1024}\), set the Document\(^{118}\) to quirks mode.

In any case, switch the insertion mode\(^{1035}\) to "before html\(^{1075}\), then reprocess the token.

12.2.6.4 The "before html" insertion mode\(^{529}\)

When the user agent is to apply the rules for the "before html\(^{1075}\)", the user agent must handle the token as follows:

A DOCTYPE token

Parse error\(^{1024}\). Ignore the token.

A comment token

Insert a comment\(^{1073}\) as the last child of the Document\(^{110}\) object.
A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Ignore the token.

A start tag whose tag name is "html"

Create an element for the token in the HTML namespace, with the Document object as the intended parent. Append it to the Document object. Put this element in the stack of open elements.

If the Document is being loaded as part of navigation of a browsing context, run these steps:

1. If the result of running match service worker registration for the document's URL is non-null, run the application cache selection algorithm passing the Document object with no manifest.
2. Otherwise, run these substeps:
   1. If the newly created element has a manifest attribute whose value is not the empty string, then parse the value of that attribute, relative to the newly created element's node document, and if that is successful, run the application cache selection algorithm passing the Document object with the result of applying the URL serializer algorithm to the resulting URL record with the exclude fragment flag set.
   2. Otherwise, run the application cache selection algorithm passing the Document object with no manifest.

Switch the insertion mode to "before head".

An end tag whose tag name is one of: "head", "body", "html", "br"

Act as described in the "anything else" entry below.

Any other end tag

Parse error. Ignore the token.

Anything else

If the Document is being loaded as part of navigation of a browsing context, then: run the application cache selection algorithm with no manifest, passing it the Document object.

Switch the insertion mode to "before head", then reprocess the token.

The document element can end up being removed from the Document object, e.g. by scripts; nothing in particular happens in such cases, content continues being appended to the nodes as described in the next section.

12.2.6.4.3 The "before head" insertion mode

When the user agent is to apply the rules for the "before head" insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Ignore the token.

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" insertion mode.
A start tag whose tag name is "head"

Insert an HTML element\(^{p1070}\) for the token.

Set the head element pointer\(^{p1039}\) to the newly created head\(^{p149}\) element.

Switch the insertion mode\(^{p1035}\) to "in head\(^{p1077}\)".

An end tag whose tag name is one of: "head", "body", "html", "br"

Act as described in the "anything else" entry below.

Any other end tag

Parse error\(^{p1024}\). Ignore the token.

Anything else

Insert an HTML element\(^{p1070}\) for a "head" start tag token with no attributes.

Set the head element pointer\(^{p1039}\) to the newly created head\(^{p149}\) element.

Switch the insertion mode\(^{p1035}\) to "in head\(^{p1077}\)".

Reprocess the current token.

12.2.6.4.4 The "in head" insertion mode \(^{p1077}\)

When the user agent is to apply the rules for the "in head\(^{p1077}\)" insertion mode\(^{p1035}\), the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character\(^{p1072}\).

A comment token

Insert a comment\(^{p1073}\).

A DOCTYPE token

Parse error\(^{p1024}\). Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for\(^{p1035}\) the "in body\(^{p1081}\)" insertion mode\(^{p1035}\).

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link"

Insert an HTML element\(^{p1070}\) for the token. Immediately pop the current node\(^{p1036}\) off the stack of open elements\(^{p1036}\).

Acknowledge the token's self-closing flag\(^{p1040}\), if it is set.

A start tag whose tag name is "meta"

Insert an HTML element\(^{p1070}\) for the token. Immediately pop the current node\(^{p1036}\) off the stack of open elements\(^{p1036}\).

Acknowledge the token's self-closing flag\(^{p1040}\), if it is set.

If the element has a charset\(^{p159}\) attribute, and getting an encoding from its value results in an encoding, and the confidence\(^{p1029}\) is currently tentative, then change the encoding\(^{p1034}\) to the resulting encoding.

Otherwise, if the element has an http-equiv\(^{p163}\) attribute whose value is an ASCII case-insensitive match for the string "Content-Type", and the element has a content\(^{p159}\) attribute, and applying the algorithm for extracting a character encoding from a meta element\(^{p88}\) to that attribute's value returns an encoding, and the confidence\(^{p1029}\) is currently tentative, then change the encoding\(^{p1034}\) to the extracted encoding.

A start tag whose tag name is "title"

Follow the generic RCDATA element parsing algorithm\(^{p1073}\).
A start tag whose tag name is "noscript", if the scripting flag is enabled
Follow the generic raw text element parsing algorithm.

A start tag whose tag name is "noscript", if the scripting flag is disabled
Insert an HTML element for the token.

Switch the insertion mode to "in head noscript".

A start tag whose tag name is "script"
Run these steps:

1. Let the adjusted insertion location be the appropriate place for inserting a node.
2. Create an element for the token in the HTML namespace, with the intended parent being the element in which the adjusted insertion location finds itself.
3. Mark the element as being "parser-inserted" and unset the element's "non-blocking" flag.

Note
This ensures that, if the script is external, any document.write() calls in the script will execute in-line, instead of blowing the document away, as would happen in most other cases. It also prevents the script from executing until the end tag is seen.

4. If the parser was originally created for the HTML fragment parsing algorithm, then mark the script element as "already started". (fragment case)
5. If the parser was invoked via the document.write() or document.writeln() methods, then optionally mark the script element as "already started". (For example, the user agent might use this clause to prevent execution of cross-origin scripts inserted via document.write() under slow network conditions, or when the page has already taken a long time to load.)
6. Insert the newly created element at the adjusted insertion location.
7. Push the element onto the stack of open elements so that it is the new current node.
8. Switch the tokenizer to the script data state.
9. Let the original insertion mode be the current insertion mode.
10. Switch the insertion mode to "text".

An end tag whose tag name is "head"
Pop the current node (which will be the head element) off the stack of open elements.
Switch the insertion mode to "after head".

An end tag whose tag name is one of: "body", "html", "br"
Act as described in the "anything else" entry below.

A start tag whose tag name is "template"
Insert an HTML element for the token.
Insert a marker at the end of the list of active formatting elements.
Set the frameset-ok flag to "not ok".
Switch the insertion mode to "in template".
Push "in template" onto the stack of template insertion modes so that it is the new current template insertion mode.

An end tag whose tag name is "template"
If there is no template element on the stack of open elements, then this is a parse error; ignore the token.
Otherwise, run these steps:
1. Generate all implied end tags thoroughly\(^\text{p1074}\).
2. If the current node\(^\text{p1036}\) is not a template\(^\text{p610}\) element, then this is a parse error\(^\text{p1024}\).
3. Pop elements from the stack of open elements\(^\text{p1036}\) until a template\(^\text{p610}\) element has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker\(^\text{p1039}\).
5. Pop the current template insertion mode\(^\text{p1035}\) off the stack of template insertion modes\(^\text{p1035}\).
6. Reset the insertion mode appropriately\(^\text{p1035}\).

↩ A start tag whose tag name is “head”

↩ Any other end tag
   \(\text{Parse error}^\text{p1024}\). Ignore the token.

↩ Anything else
   Pop the current node\(^\text{p1036}\) (which will be the head\(^\text{p149}\) element) off the stack of open elements\(^\text{p1036}\).
   Switch the insertion mode\(^\text{p1035}\) to “after head\(^\text{p180}\)”.
   Reprocess the token.

12.2.6.4.5 The “in head noscript” insertion mode\(^\text{p1079}\)

When the user agent is to apply the rules for the “in head noscript\(^\text{p1079}\)” insertion mode\(^\text{p1035}\), the user agent must handle the token as follows:

↩ A DOCTYPE token
   \(\text{Parse error}^\text{p1024}\). Ignore the token.

↩ A start tag whose tag name is “html”
   Process the token using the rules for\(^\text{p1035}\) the “in body\(^\text{p1081}\)” insertion mode\(^\text{p1035}\).

↩ An end tag whose tag name is “noscript”
   Pop the current node\(^\text{p1036}\) (which will be a noscript\(^\text{p608}\) element) from the stack of open elements\(^\text{p1036}\); the new current node\(^\text{p1036}\) will be a head\(^\text{p149}\) element.
   Switch the insertion mode\(^\text{p1035}\) to “in head\(^\text{p1077}\)”.

↩ A character token that is one of U+0009 CHARACTER TABULATION, U+00A LINE FEED (LF), U+00C FORM FEED (FF), U+00D CARRIAGE RETURN (CR), or U+0020 SPACE

↩ A comment token

↩ A start tag whose tag name is one of: "basefont", "bgsound", "link", "meta", "noframes", "style"
   Process the token using the rules for\(^\text{p1035}\) the “in head\(^\text{p1077}\)” insertion mode\(^\text{p1035}\).

↩ An end tag whose tag name is "br"
   Act as described in the “anything else” entry below.

↩ A start tag whose tag name is one of: "head", "noscript"

↩ Any other end tag
   \(\text{Parse error}^\text{p1024}\). Ignore the token.

↩ Anything else
   \(\text{Parse error}^\text{p1024}\).

   Pop the current node\(^\text{p1036}\) (which will be a noscript\(^\text{p608}\) element) from the stack of open elements\(^\text{p1036}\); the new current node\(^\text{p1036}\) will be a head\(^\text{p149}\) element.
   Switch the insertion mode\(^\text{p1035}\) to “in head\(^\text{p1077}\)”.
   Reprocess the token.
12.2.6.4.6 The "after head" insertion mode

When the user agent is to apply the rules for the "after head" insertion mode, the user agent must handle the token as follows:

↪ A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE
  Insert the character.

↪ A comment token
  Insert a comment.

↪ A DOCTYPE token
  Parse error. Ignore the token.

↪ A start tag whose tag name is "html"
  Process the token using the rules for the "in body" insertion mode.

↪ A start tag whose tag name is "body"
  Insert an HTML element for the token.
  Set the frameset-ok flag to "not ok".
  Switch the insertion mode to "in body".

↪ A start tag whose tag name is "frameset"
  Insert an HTML element for the token.
  Switch the insertion mode to "in frameset".

↪ A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"
  Parse error.
  Push the node pointed to by the head element pointer onto the stack of open elements.
  Process the token using the rules for the "in head" insertion mode.
  Remove the node pointed to by the head element pointer from the stack of open elements. (It might not be the current node at this point.)

Note: The head element pointer cannot be null at this point.

↪ An end tag whose tag name is "template"
  Process the token using the rules for the "in head" insertion mode.

↪ An end tag whose tag name is one of: "body", "html", "br"
  Act as described in the "anything else" entry below.

↪ A start tag whose tag name is "head"

↪ Any other end tag
  Parse error. Ignore the token.

↪ Anything else
  Insert an HTML element for a "body" start tag token with no attributes.
  Switch the insertion mode to "in body".

Reprocess the current token.
When the user agent is to apply the rules for the "in body" insertion mode, the user agent must handle the token as follows:

- A character token that is U+0000 NULL
  Parse error. Ignore the token.

- A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE
  Reconstruct the active formatting elements, if any.
  Insert the token's character.

- Any other character token
  Reconstruct the active formatting elements, if any.
  Insert the token's character.
  Set the frameset-ok flag to "not ok".

- A comment token
  Insert a comment.

- A DOCTYPE token
  Parse error. Ignore the token.

- A start tag whose tag name is "html"
  Parse error.
  If there is a template element on the stack of open elements, then ignore the token.
  Otherwise, for each attribute on the token, check to see if the attribute is already present on the top element of the stack of open elements. If it is not, add the attribute and its corresponding value to that element.

- A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"
  An end tag whose tag name is "template"
  Process the token using the rules for the "in head" insertion mode.

- A start tag whose tag name is "body"
  Parse error.
  If the second element on the stack of open elements is not a body element, if the stack of open elements has only one node on it, or if there is a template element on the stack of open elements, then ignore the token. (fragment case)
  Otherwise, set the frameset-ok flag to "not ok"; then, for each attribute on the token, check to see if the attribute is already present on the body element (the second element) on the stack of open elements, and if it is not, add the attribute and its corresponding value to that element.

- A start tag whose tag name is "frameset"
  Parse error.
  If the stack of open elements has only one node on it, or if the second element on the stack of open elements is not a body element, then ignore the token. (fragment case)
  If the frameset-ok flag is set to "not ok", ignore the token.
  Otherwise, run the following steps:
  1. Remove the second element on the stack of open elements from its parent node, if it has one.
  2. Pop all the nodes from the bottom of the stack of open elements, from the current node up to, but not including, the root html element.
3. Insert an HTML element \textsuperscript{1070} for the token.

4. Switch the insertion mode \textsuperscript{1035} to "in frameset\textsuperscript{1102}".

\rightarrow \textbf{An end-of-file token}

If the \textit{stack of template insertion modes} \textsuperscript{1035} is not empty, then process the token \textit{using the rules for} \textsuperscript{1035} the "in template\textsuperscript{1100}" insertion mode \textsuperscript{1029}.

Otherwise, follow these steps:

1. If there is a node in the \textit{stack of open elements} \textsuperscript{1036} that is not either a \texttt{dd} element, a \texttt{dt} element, an \texttt{li} element, an \texttt{optgroup} element, a \texttt{option} element, a \texttt{p} element, an \texttt{rb} element, an \texttt{rt} element, an \texttt{rtc} element, a \texttt{tbody} element, a \texttt{td} element, an \texttt{tfoot} element, a \texttt{th} element, a \texttt{thead} element, a \texttt{tr} element, the \texttt{body} element, or the \texttt{html} element, then this is a \textit{parse error} \textsuperscript{1024}.

2. Stop parsing \textsuperscript{1016}.

\rightarrow \textbf{An end tag whose tag name is "body"}

If the \textit{stack of open elements} \textsuperscript{1036} does not have a \texttt{body} element in scope \textsuperscript{1037}, this is a \textit{parse error} \textsuperscript{1024}; ignore the token.

Otherwise, if there is a node in the \textit{stack of open elements} \textsuperscript{1036} that is not either a \texttt{dd} element, a \texttt{dt} element, an \texttt{li} element, an \texttt{optgroup} element, an \texttt{option} element, a \texttt{p} element, an \texttt{rb} element, an \texttt{rt} element, an \texttt{rtc} element, a \texttt{tbody} element, a \texttt{td} element, an \texttt{tfoot} element, a \texttt{th} element, a \texttt{thead} element, a \texttt{tr} element, the \texttt{body} element, or the \texttt{html} element, then this is a \textit{parse error} \textsuperscript{1024}.

Switch the insertion mode \textsuperscript{1035} to "after body\textsuperscript{1101}".

\rightarrow \textbf{An end tag whose tag name is "html"}

If the \textit{stack of open elements} \textsuperscript{1036} does not have a \texttt{body} element in scope \textsuperscript{1037}, this is a \textit{parse error} \textsuperscript{1024}; ignore the token.

Otherwise, if there is a node in the \textit{stack of open elements} \textsuperscript{1036} that is not either a \texttt{dd} element, a \texttt{dt} element, an \texttt{li} element, an \texttt{optgroup} element, an \texttt{option} element, a \texttt{p} element, an \texttt{rb} element, an \texttt{rt} element, an \texttt{rtc} element, a \texttt{tbody} element, a \texttt{td} element, an \texttt{tfoot} element, a \texttt{th} element, a \texttt{thead} element, a \texttt{tr} element, the \texttt{body} element, or the \texttt{html} element, then this is a \textit{parse error} \textsuperscript{1024}.

Switch the insertion mode \textsuperscript{1035} to "after body\textsuperscript{1101}".

Reprocess the token.

\rightarrow \textbf{A start tag whose tag name is one of: "address", "article", "aside", "blockquote", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "main", "menu", "nav", "ol", "p", "section", "summary", "ul"}

If the \textit{stack of open elements} \textsuperscript{1036} has a \texttt{p} element in button scope \textsuperscript{1038}, then close a \texttt{p} element \textsuperscript{1089}.

Insert an HTML element \textsuperscript{1070} for the token.

\rightarrow \textbf{A start tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"}

If the \textit{stack of open elements} \textsuperscript{1036} has a \texttt{p} element in button scope \textsuperscript{1038}, then close a \texttt{p} element \textsuperscript{1089}.

If the \textit{current node} \textsuperscript{1036} is an HTML element \textsuperscript{144} whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a \textit{parse error} \textsuperscript{1024}; pop the \textit{current node} \textsuperscript{1036} off the \textit{stack of open elements} \textsuperscript{1036}.

Insert an HTML element \textsuperscript{1070} for the token.

\rightarrow \textbf{A start tag whose tag name is one of: "pre", "listing"}

If the \textit{stack of open elements} \textsuperscript{1036} has a \texttt{p} element in button scope \textsuperscript{1038}, then close a \texttt{p} element \textsuperscript{1089}.

Insert an HTML element \textsuperscript{1070} for the token.

If the \textit{next token} \textsuperscript{1066} is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of \texttt{pre} blocks are ignored as an authoring convenience.)

Set the frameset-ok flag \textsuperscript{1039} to "not ok".
A start tag whose tag name is "form"

If the form element pointer is not null, and there is no template element on the stack of open elements, then this is a parse error; ignore the token.

Otherwise:

If the stack of open elements has a p element in button scope, then close a p element.

Insert an HTML element for the token, and, if there is no template element on the stack of open elements, set the form element pointer to point to the element created.

A start tag whose tag name is "li"

Run these steps:

1. Set the frameset-ok flag to "not ok".
2. Initialize node to be the current node (the bottommost node of the stack).
3. Loop: If node is an li element, then run these substeps:
   1. Generate implied end tags, except for li elements.
   2. If the current node is not an li element, then this is a parse error.
   3. Pop elements from the stack of open elements until an li element has been popped from the stack.
   4. Jump to the step labeled done below.
4. If node is in the special category, but is not an address, div, or p element, then jump to the step labeled done below.
5. Otherwise, set node to the previous entry in the stack of open elements and return to the step labeled loop.
6. Done: If the stack of open elements has a p element in button scope, then close a p element.
7. Finally, insert an HTML element for the token.

A start tag whose tag name is one of: "dd", "dt"

Run these steps:

1. Set the frameset-ok flag to "not ok".
2. Initialize node to be the current node (the bottommost node of the stack).
3. Loop: If node is a dd element, then run these substeps:
   1. Generate implied end tags, except for dd elements.
   2. If the current node is not a dd element, then this is a parse error.
   3. Pop elements from the stack of open elements until a dd element has been popped from the stack.
   4. Jump to the step labeled done below.
4. If node is a dt element, then run these substeps:
   1. Generate implied end tags, except for dt elements.
   2. If the current node is not a dt element, then this is a parse error.
   3. Pop elements from the stack of open elements until a dt element has been popped from the stack.
   4. Jump to the step labeled done below.
5. If node is in the special category, but is not an address, div, or p element, then jump to the step labeled done below.
6. Otherwise, set node to the previous entry in the stack of open elements and return to the step labeled loop.
7. Done: If the stack of open elements has a p element in button scope, then close a p element.
8. Finally, insert an HTML element for the token.

↪ A start tag whose tag name is "plaintext"

If the stack of open elements has a p element in button scope, then close a p element.

Insert an HTML element for the token.

Switch the tokenizer to the PLAINTEXT state.

Note: Once a start tag with the tag name "plaintext" has been seen, that will be the last token ever seen other than character tokens (and the end-of-file token), because there is no way to switch out of the PLAINTEXT state.

↪ A start tag whose tag name is "button"

1. If the stack of open elements has a button element in scope, then run these substeps:
   1. Parse error.
   2. Generate implied end tags.
   3. Pop elements from the stack of open elements until a button element has been popped from the stack.
   2. Reconstruct the active formatting elements, if any.
   3. Insert an HTML element for the token.
   4. Set the frameset-ok flag to "not ok".

↪ An end tag whose tag name is one of: "address", "article", "aside", "blockquote", "button", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "listing", "main", "menu", "nav", "ol", "pre", "section", "summary", "ul"

If the stack of open elements does not have an element in scope that is an HTML element with the same tag name as that of the token, then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags.
2. If the current node is not an HTML element with the same tag name as that of the token, then this is a parse error.
3. Pop elements from the stack of open elements until an HTML element with the same tag name as the token has been popped from the stack.

↪ An end tag whose tag name is "form"

If there is no template element on the stack of open elements, then run these substeps:

1. Let node be the element that the form element pointer is set to, or null if it is not set to an element.
2. Set the form element pointer to null.
3. If node is null or if the stack of open elements does not have node in scope, then this is a parse error; return and ignore the token.
4. Generate implied end tags.
5. If the current node is not node, then this is a parse error.
6. Remove node from the stack of open elements.

If there is a template element on the stack of open elements, then run these substeps instead:

1. If the stack of open elements does not have a form element in scope, then this is a parse error; return and ignore the token.
2. Generate implied end tags.
3. If the current node is not a `form` element, then this is a `parse error`.

4. Pop elements from the `stack of open elements` until a `form` element has been popped from the stack.

↪ **An end tag whose tag name is "p"**

If the `stack of open elements` does not have a `p` element in button scope, then this is a `parse error`; insert an HTML element for a "p" start tag token with no attributes.

Close a `p` element.

↪ **An end tag whose tag name is "li"**

If the `stack of open elements` does not have an `li` element in list item scope, then this is a `parse error`; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags, except for `li` elements.

2. If the current node is not an `li` element, then this is a `parse error`.

3. Pop elements from the `stack of open elements` until an `li` element has been popped from the stack.

↪ **An end tag whose tag name is one of: "dd", "dt"**

If the `stack of open elements` does not have an element in scope that is an HTML element with the same tag name as that of the token, then this is a `parse error`; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags, except for HTML elements with the same tag name as the token.

2. If the current node is not an HTML element with the same tag name as that of the token, then this is a `parse error`.

3. Pop elements from the `stack of open elements` until an HTML element with the same tag name as the token has been popped from the stack.

↪ **An end tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"**

If the `stack of open elements` does not have an element in scope that is an HTML element and whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a `parse error`; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags.

2. If the current node is not an HTML element with the same tag name as that of the token, then this is a `parse error`.

3. Pop elements from the `stack of open elements` until an HTML element whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6" has been popped from the stack.

↪ **An end tag whose tag name is "sarcasm"**

Take a deep breath, then act as described in the "any other end tag" entry below.

↪ **A start tag whose tag name is "a"**

If the `list of active formatting elements` contains an `a` element between the end of the list and the last marker on the list (or the start of the list if there is no marker on the list), then this is a `parse error`; run the adoption agency algorithm for the token, then remove that element from the `list of active formatting elements` and the `stack of open elements` if the adoption agency algorithm didn't already remove it (it might not have if the element is not in table scope).

**Example**

In the non-conforming stream `<a href="a">a</a><table><a href="b">b</a></table>x`, the first `a` element would be closed upon seeing the second one, and the "x" character would be inside a link to "b", not to "a". This is despite the fact that the outer `a` element is not in table scope (meaning that a regular `</a>` end tag at the start of the table wouldn't close the outer `a` element). The result is that the two `a` elements are indirectly nested inside each other — non-conforming markup will often result in non-conforming DOMs when parsed.
Reconstruct the active formatting elements if any.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

A start tag whose tag name is one of: "b", "big", "code", "em", "font", "i", "s", "small", "strike", "strong", "tt", "u"
Reconstruct the active formatting elements if any.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

A start tag whose tag name is "nobr"

Reconstruct the active formatting elements if any.

If the stack of open elements has a nobr element in scope, then this is a parse error; run the adoption agency algorithm for the token, then once again reconstruct the active formatting elements if any.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

An end tag whose tag name is one of: "a", "b", "big", "code", "em", "font", "i", "nobr", "s", "small", "strike", "strong", "tt", "u"

Run the adoption agency algorithm for the token.

A start tag whose tag name is one of: "applet", "marquee", "object"

Reconstruct the active formatting elements if any.

Insert an HTML element for the token.

Insert a marker at the end of the list of active formatting elements.

Set the frameset-ok flag to "not ok".

An end tag token whose tag name is one of: "applet", "marquee", "object"

If the stack of open elements does not have an element in scope that is an HTML element with the same tag name as that of the token, then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags.
2. If the current node is not an HTML element with the same tag name as that of the token, then this is a parse error.
3. Pop elements from the stack of open elements until an HTML element with the same tag name as the token has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker.

A start tag whose tag name is "table"

If the Document is not set to quirks mode, and the stack of open elements has a p element in button scope, then close a p element.

Insert an HTML element for the token.

Set the frameset-ok flag to "not ok".

Switch the insertion mode to "in table".

An end tag whose tag name is "br"

Parse error. Drop the attributes from the token, and act as described in the next entry; i.e. act as if this was a "br" start tag token with no attributes, rather than the end tag token that it actually is.

A start tag whose tag name is one of: "area", "br", "embed", "img", "keygen", "wbr"

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.
Acknowledge the token's `self-closing flag`\textsuperscript{1040}, if it is set.

Set the `frameset-ok flag`\textsuperscript{1039} to "not ok".

.closest-tag{tag_name} {input}

Reconstruct the active formatting elements\textsuperscript{1038}, if any.

Insert an HTML element\textsuperscript{1070} for the token. Immediately pop the current node\textsuperscript{1036} off the stack of open elements\textsuperscript{1036}.

Acknowledge the token's `self-closing flag`\textsuperscript{1040}, if it is set.

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an ASCII case-insensitive match for the string "hidden", then: set the `frameset-ok flag`\textsuperscript{1039} to "not ok".

.closest-tag{tag_name} {param, source, track}

Insert an HTML element\textsuperscript{1070} for the token. Immediately pop the current node\textsuperscript{1036} off the stack of open elements\textsuperscript{1036}.

Acknowledge the token's `self-closing flag`\textsuperscript{1040}, if it is set.

.closest-tag{tag_name} {hr}

If the stack of open elements\textsuperscript{1036} has a p element in button scope\textsuperscript{1038}, then close a p element\textsuperscript{1039}.

Insert an HTML element\textsuperscript{1070} for the token. Immediately pop the current node\textsuperscript{1036} off the stack of open elements\textsuperscript{1036}.

Acknowledge the token's `self-closing flag`\textsuperscript{1040}, if it is set.

Set the `frameset-ok flag`\textsuperscript{1039} to "not ok".

.closest-tag{tag_name} {textarea}

Run these steps:

1. Insert an HTML element\textsuperscript{1070} for the token.
2. If the next token\textsuperscript{1068} is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of textarea\textsuperscript{530} elements are ignored as an authoring convenience.)
3. Switch the tokenizer to the RCDATA state\textsuperscript{1041}.
4. Let the original insertion mode\textsuperscript{1035} be the current insertion mode\textsuperscript{1035}.
5. Set the `frameset-ok flag`\textsuperscript{1039} to "not ok".
6. Switch the insertion mode\textsuperscript{1035} to "text\textsuperscript{1090}".

.closest-tag{tag_name} {xmp}

If the stack of open elements\textsuperscript{1036} has a p element in button scope\textsuperscript{1038}, then close a p element\textsuperscript{1039}.

Reconstruct the active formatting elements\textsuperscript{1038}, if any.

Set the `frameset-ok flag`\textsuperscript{1039} to "not ok".

Follow the generic raw text element parsing algorithm\textsuperscript{1073}.

.closest-tag{tag_name} {iframe}

Set the `frameset-ok flag`\textsuperscript{1039} to "not ok".

Follow the generic raw text element parsing algorithm\textsuperscript{1073}.

.closest-tag{tag_name} {noembed}

closest-tag{tag_name} {noscript}, if the scripting flag\textsuperscript{1039} is enabled

Follow the generic raw text element parsing algorithm\textsuperscript{1073}.
A start tag whose tag name is "select"

Reconstruct the active formatting elements if any.

Insert an HTML element for the token.

Set the frameset-ok flag to "not ok".

If the insertion mode is one of "in table", "in caption", "in table body", "in row", or "in cell", then switch the insertion mode to "in select in table". Otherwise, switch the insertion mode to "in select".

A start tag whose tag name is one of: "optgroup", "option"

If the current node is an option element, then pop the current node off the stack of open elements.

Reconstruct the active formatting elements, if any.

A start tag whose tag name is one of: "rb", "rtc"

If the stack of open elements has a ruby element in scope, then generate implied end tags. If the current node is not now a ruby element, this is a parse error.

Insert an HTML element for the token.

A start tag whose tag name is one of: "rp", "rt"

If the stack of open elements has a ruby element in scope, then generate implied end tags, except for rtc elements. If the current node is not now a rtc element or a ruby element, this is a parse error.

Insert an HTML element for the token.

A start tag whose tag name is "math"

Reconstruct the active formatting elements, if any.

Adjust MathML attributes for the token. (This fixes the case of MathML attributes that are not all lowercase.)

Adjust foreign attributes for the token. (This fixes the use of namespaced attributes, in particular XLink.)

Insert a foreign element for the token, in the MathML namespace.

If the token has its self-closing flag set, pop the current node off the stack of open elements and acknowledge the token's self-closing flag.

A start tag whose tag name is "svg"

Reconstruct the active formatting elements, if any.

Adjust SVG attributes for the token. (This fixes the case of SVG attributes that are not all lowercase.)

Adjust foreign attributes for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)

Insert a foreign element for the token, in the SVG namespace.

If the token has its self-closing flag set, pop the current node off the stack of open elements and acknowledge the token's self-closing flag.

A start tag whose tag name is one of: "caption", "col", "colgroup", "frame", "head", "tbody", "td", "tfoot", "th", "thead", "tr"

Parse error. Ignore the token.

Any other start tag

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token.

Note

This element will be an ordinary element.
Any other end tag

Run these steps:

1. Initialize node to be the current node (the bottommost node of the stack).
2. Loop: If node is an HTML element with the same tag name as the token, then:
   1. Generate implied end tags except for HTML elements with the same tag name as the token.
   2. If node is not the current node, then this is a parse error; ignore the token, and return.
   3. Pop all the nodes from the current node up to node, including node, then stop these steps.
3. Otherwise, if node is in the special category, then this is a parse error; ignore the token, and return.
4. Set node to the previous entry in the stack of open elements.
5. Return to the step labeled loop.

When the steps above say the user agent is to close a p element, it means that the user agent must run the following steps:

1. Generate implied end tags, except for p elements.
2. If the current node is not a p element, then this is a parse error.
3. Pop elements from the stack of open elements until a p element has been popped from the stack.

The adoption agency algorithm, which takes as its only argument a token token for which the algorithm is being run, consists of the following steps:

1. Let subject be token's tag name.
2. If the current node is an HTML element whose tag name is subject, and the current node is not in the list of active formatting elements, then pop the current node off the stack of open elements, and return.
3. Let outer loop counter be zero.
4. Outer loop: If outer loop counter is greater than or equal to eight, then return.
5. Increment outer loop counter by one.
6. Let formatting element be the last element in the list of active formatting elements that:
   ○ is between the end of the list and the last marker in the list, if any, or the start of the list otherwise, and
   ○ has the tag name subject.
   If there is no such element, then return and instead act as described in the "any other end tag" entry above.
7. If formatting element is not in the stack of open elements, then this is a parse error; remove the element from the list, and return.
8. If formatting element is in the stack of open elements, but the element is not in scope, then this is a parse error; return.
9. If formatting element is not the current node, this is a parse error. (But do not return.)
10. Let furthest block be the topmost node in the stack of open elements that is lower in the stack than formatting element, and is an element in the special category. There might not be one.
11. If there is no furthest block, then the UA must first pop all the nodes from the bottom of the stack than formatting element, and finally return.
12. Let common ancestor be the element immediately above formatting element in the stack of open elements.
13. Let a bookmark note the position of formatting element in the list of active formatting elements relative to the elements on either side of it in the list.
14. Let node and last node be furthest block. Follow these steps:
1. Let inner loop counter be zero.

2. Inner loop: Increment inner loop counter by one.

3. Let node be the element immediately above node in the stack of open elements, or if node is no longer in the stack of open elements (e.g. because it got removed by this algorithm), the element that was immediately above node in the stack of open elements before node was removed.

4. If node is formatting element, then go to the next step in the overall algorithm.

5. If inner loop counter is greater than three and node is in the list of active formatting elements, then remove node from the list of active formatting elements and then go back to the step labeled inner loop.

6. If node is not in the list of active formatting elements, then remove node from the stack of open elements and then go back to the step labeled inner loop.

7. Create an element for the token for which the element node was created, in the HTML namespace, with common ancestor as the intended parent; replace the entry for node in the list of active formatting elements with an entry for the new element, and let node be the new element.

8. If last node is furthest block, then move the aforementioned bookmark to be immediately after the new node in the list of active formatting elements.

9. Insert last node into node, first removing it from its previous parent node if any.

10. Let last node be node.

11. Return to the step labeled inner loop.

15. Insert whatever last node ended up being in the previous step at the appropriate place for inserting a node, but using common ancestor as the override target.

16. Create an element for the token for which formatting element was created, in the HTML namespace, with furthest block as the intended parent.

17. Take all of the child nodes of furthest block and append them to the element created in the last step.

18. Append that new element to furthest block.

19. Remove formatting element from the list of active formatting elements, and insert the new element into the list of active formatting elements at the position of the aforementioned bookmark.

20. Remove formatting element from the stack of open elements, and insert the new element into the stack of open elements immediately below the position of furthest block in that stack.

Note: This algorithm's name, the "adoption agency algorithm", comes from the way it causes elements to change parents, and is in contrast with other possible algorithms for dealing with misnested content.

12.2.6.4.8 The "text" insertion mode

When the user agent is to apply the rules for the "text insertion mode", the user agent must handle the token as follows:

↪ A character token
Insert the token's character.

Note: This can never be a U+0000 NULL character; the tokenizer converts those to U+FFFD REPLACEMENT CHARACTER characters.

↪ An end-of-file token
Parse error.
If the current node is a `script` element, mark the `script` element as "already started".

Pop the current node off the stack of open elements.

Switch the insertion mode to the original insertion mode and reprocess the token.

→ An end tag whose tag name is "script"

If the JavaScript execution context stack is empty, perform a microtask checkpoint.

Let `script` be the current node (which will be a `script` element).

Pop the current node off the stack of open elements.

Switch the insertion mode to the original insertion mode.

Let the old insertion point have the same value as the current insertion point. Let the insertion point be just before the next input character.

Increment the parser's script nesting level by one.

Prepare the script. This might cause some script to execute, which might cause new characters to be inserted into the tokenizer, and might cause the tokenizer to output more tokens, resulting in a reentrant invocation of the parser.

Decrement the parser's script nesting level by one. If the parser's script nesting level is zero, then set the parser pause flag to false.

Let the insertion point have the value of the old insertion point. (In other words, restore the insertion point to its previous value. This value might be the "undefined" value.)

At this stage, if there is a pending parsing-blocking script, then:

→ If the script nesting level is not zero:

  Set the parser pause flag to true, and abort the processing of any nested invocations of the tokenizer, yielding control back to the caller. (Tokenization will resume when the caller returns to the "outer" tree construction stage.)

  Note

  The tree construction stage of this particular parser is being called reentrantly, say from a call to `document.write()`.

→ Otherwise:

  Run these steps:

  1. Let the script be the pending parsing-blocking script. There is no longer a pending parsing-blocking script.

  2. Block the tokenizer for this instance of the HTML parser, such that the event loop will not run tasks that invoke the tokenizer.

  3. If the parser's Document has a style sheet that is blocking scripts or the script's "ready to be parser-executed" flag is not set: spin the event loop until the parser's Document has no style sheet that is blocking scripts and the script's "ready to be parser-executed" flag is set.

  4. If this parser has been aborted in the meantime, return.

     Note

     This could happen if, e.g., while the spin the event loop algorithm is running, the browsing context gets closed, or the `document.open(type, replace)` method gets invoked on the Document.

  5. Unblock the tokenizer for this instance of the HTML parser, such that tasks that invoke the tokenizer can again be run.

  6. Let the insertion point be just before the next input character.

  7. Increment the parser's script nesting level by one (it should be zero before this step, so this sets it to one).

  8. Execute the script.
9. Decrement the parser's script nesting level by one. If the parser's script nesting level is zero (which it always should be at this point), then set the parser pause flag to false.

10. Let the insertion point be undefined again.

11. If there is once again a pending parsing-blocking script, then repeat these steps from step 1.

Any other end tag

Pop the current node off the stack of open elements.

Switch the insertion mode to the original insertion mode.

12.2.6.4.9 The "in table" insertion mode

When the user agent is to apply the rules for the "in table" insertion mode, the user agent must handle the token as follows:

 → A character token, if the current node is table, tbody, tfoot, thead, or tr element

Let the pending table character tokens be an empty list of tokens.

Let the original insertion mode be the current insertion mode.

Switch the insertion mode to "in table text" and reprocess the token.

 → A comment token

Insert a comment.

 → A DOCTYPE token

Parse error. Ignore the token.

 → A start tag whose tag name is "caption"

Clear the stack back to a table context. (See below.)

Insert a marker at the end of the list of active formatting elements.

Insert an HTML element for the token, then switch the insertion mode to "in caption".

 → A start tag whose tag name is "colgroup"

Clear the stack back to a table context. (See below.)

Insert an HTML element for the token, then switch the insertion mode to "in column group".

 → A start tag whose tag name is "col"

Clear the stack back to a table context. (See below.)

Insert an HTML element for a "colgroup" start tag token with no attributes, then switch the insertion mode to "in column group".

Reprocess the current token.

 → A start tag whose tag name is one of: "tbody", "tfoot", "thead"

Clear the stack back to a table context. (See below.)

Insert an HTML element for the token, then switch the insertion mode to "in table body".

 → A start tag whose tag name is one of: "td", "th", "tr"

Clear the stack back to a table context. (See below.)

Insert an HTML element for a "tbody" start tag token with no attributes, then switch the insertion mode to "in table body".

Reprocess the current token.
A start tag whose tag name is "table"

Parse error. If the stack of open elements does not have a table element in table scope, ignore the token. Otherwise:

Pop elements from this stack until a table element has been popped from the stack. Reset the insertion mode appropriately. Reprocess the token.

An end tag whose tag name is "table"

If the stack of open elements does not have a table element in table scope, this is a parse error; ignore the token. Otherwise:

Pop elements from this stack until a table element has been popped from the stack. Reset the insertion mode appropriately.

An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"

Parse error. Ignore the token.

A start tag whose tag name is one of: "style", "script", "template"

An end tag whose tag name is "template"

Process the token using the rules for the "in head" insertion mode.

A start tag whose tag name is "input"

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an ASCII case-insensitive match for the string "hidden", then: act as described in the "anything else" entry below. Otherwise:

Parse error. Insert an HTML element for the token. Pop that input element off the stack of open elements. Acknowledge the token's self-closing flag, if it is set.

A start tag whose tag name is "form"

Parse error. If there is a template element on the stack of open elements, or if the form element pointer is not null, ignore the token. Otherwise: Insert an HTML element for the token, and set the form element pointer to point to the element created. Pop that form element off the stack of open elements.

An end-of-file token

Process the token using the rules for the "in body" insertion mode.

Anything else

Parse error. Enable foster parenting, process the token using the rules for the "in body" insertion mode, and then disable foster parenting.

When the steps above require the UA to clear the stack back to a table context, it means that the UA must, while the current.
The current node being an html element after this process is a fragment case.

12.2.6.4.10 The "in table text" insertion mode

When the user agent is to apply the rules for the "in table text" insertion mode, the user agent must handle the token as follows:

↪ A character token that is U+0000 NULL
  Parse error. Ignore the token.

↪ Any other character token
  Append the character token to the pending table character tokens list.

↪ Anything else
  If any of the tokens in the pending table character tokens list are character tokens that are not ASCII whitespace, then this is a parse error; reprocess the character tokens in the pending table character tokens list using the rules given in the "anything else" entry in the "in table" insertion mode.
  Otherwise, insert the characters given by the pending table character tokens list.
  Switch the insertion mode to the original insertion mode and reprocess the token.

12.2.6.4.11 The "in caption" insertion mode

When the user agent is to apply the rules for the "in caption" insertion mode, the user agent must handle the token as follows:

↪ An end tag whose tag name is "caption"
  If the stack of open elements does not have a caption element in table scope, this is a parse error; ignore the token. (fragment case)
  Otherwise:
  Generate implied end tags.
  Now, if the current node is not a caption element, then this is a parse error.
  Pop elements from this stack until a caption element has been popped from the stack.
  Clear the list of active formatting elements up to the last marker.
  Switch the insertion mode to "in table".

↪ A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"

↪ An end tag whose tag name is "table"
  If the stack of open elements does not have a caption element in table scope, this is a parse error; ignore the token. (fragment case)
  Otherwise:
  Generate implied end tags.
  Now, if the current node is not a caption element, then this is a parse error.
  Pop elements from this stack until a caption element has been popped from the stack.
Clear the list of active formatting elements up to the last marker.

Switch the insertion mode to “in table”.

Reprocess the token.

An end tag whose tag name is one of: "body", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"

Parse error. Ignore the token.

Anything else

Process the token using the rules for the “in body” insertion mode.

12.2.6.4.12 The “in column group” insertion mode

When the user agent is to apply the rules for the “in column group” insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character.

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is “html”

Process the token using the rules for the “in body” insertion mode.

A start tag whose tag name is “col”

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token's self-closing flag if it is set.

An end tag whose tag name is “colgroup”

If the current node is not a colgroup element, then this is a parse error; ignore the token.

Otherwise, pop the current node from the stack of open elements. Switch the insertion mode to “in table”.

An end tag whose tag name is “col”

Parse error. Ignore the token.

A start tag whose tag name is “template”

An end tag whose tag name is “template”

Process the token using the rules for the “in head” insertion mode.

An end-of-file token

Process the token using the rules for the “in body” insertion mode.

Anything else

If the current node is not a colgroup element, then this is a parse error; ignore the token.

Otherwise, pop the current node from the stack of open elements.

Switch the insertion mode to “in table”.

Reprocess the token.
12.2.6.4.13 The "in table body" insertion mode

When the user agent is to apply the rules for the "in table body" insertion mode, the user agent must handle the token as follows:

↪ A start tag whose tag name is "tr"

Clear the stack back to a table body context. (See below.)

Insert an HTML element for the token, then switch the insertion mode to "in row".

↪ A start tag whose tag name is one of: "th", "td"

Parse error.

Clear the stack back to a table body context. (See below.)

Insert an HTML element for a "tr" start tag token with no attributes, then switch the insertion mode to "in row".

Reprocess the current token.

↪ An end tag whose tag name is one of: "tbody", "tfoot", "thead"

If the stack of open elements does not have an element in table scope that is an HTML element with the same tag name as the token, this is a parse error; ignore the token.

Otherwise:

Clear the stack back to a table body context. (See below.)

Pop the current node from the stack of open elements. Switch the insertion mode to "in table".

↪ A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead"

↪ An end tag whose tag name is "table"

If the stack of open elements does not have a tbody, thead, or tfoot element in table scope, this is a parse error; ignore the token.

Otherwise:

Clear the stack back to a table body context. (See below.)

Pop the current node from the stack of open elements. Switch the insertion mode to "in table".

Reprocess the token.

↪ An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th", "tr"

Parse error. Ignore the token.

↪ Anything else

Process the token using the rules for the "in table" insertion mode.

When the steps above require the UA to clear the stack back to a table body context, it means that the UA must, while the current node is not a tbody, tfoot, thead, template, or html element, pop elements from the stack of open elements.

The current node being an html element after this process is a fragment case.

12.2.6.4.14 The "in row" insertion mode

When the user agent is to apply the rules for the "in row" insertion mode, the user agent must handle the token as follows:

↪ A start tag whose tag name is one of: "th", "td"

Clear the stack back to a table row context. (See below.)
Insert an HTML element for the token, then switch the insertion mode to "in cell".

Insert a marker at the end of the list of active formatting elements.

An end tag whose tag name is "tr"

If the stack of open elements does not have a tr element in table scope, this is a parse error; ignore the token.

Otherwise:

Clear the stack back to a table row context. (See below.)

Pop the current node (which will be a tr element) from the stack of open elements. Switch the insertion mode to "in table body".

A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead", "tr"

An end tag whose tag name is "table"

If the stack of open elements does not have a tr element in table scope, this is a parse error; ignore the token.

Otherwise:

Clear the stack back to a table row context. (See below.)

Pop the current node (which will be a tr element) from the stack of open elements. Switch the insertion mode to "in table body".

Reprocess the token.

An end tag whose tag name is one of: "tbody", "tfoot", "thead"

If the stack of open elements does not have an element in table scope that is an HTML element with the same tag name as the token, this is a parse error; ignore the token.

If the stack of open elements does not have a tr element in table scope, ignore the token.

Otherwise:

Clear the stack back to a table row context. (See below.)

Pop the current node (which will be a tr element) from the stack of open elements. Switch the insertion mode to "in table body".

Reprocess the token.

An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th"

Parse error. Ignore the token.

Anything else

Process the token using the rules for the "in table" insertion mode.

When the steps above require the UA to clear the stack back to a table row context, it means that the UA must, while the current node is not a tr, template, or html element, pop elements from the stack of open elements.

The current node being an html element after this process is a fragment case.

12.2.6.4.15 The "in cell" insertion mode

When the user agent is to apply the rules for the "in cell" insertion mode, the user agent must handle the token as follows:

An end tag whose tag name is one of: "td", "th"

If the stack of open elements does not have an element in table scope that is an HTML element with the same tag name as that of the token, then this is a parse error; ignore the token.
Otherwise:

Generate implied end tags\textsuperscript{p1074}.

Now, if the current node\textsuperscript{p1036} is not an HTML element\textsuperscript{p44} with the same tag name as the token, then this is a parse error\textsuperscript{p1024}.

Pop elements from the stack of open elements\textsuperscript{p1036} stack until an HTML element\textsuperscript{p44} with the same tag name as the token has been popped from the stack.

Clear the list of active formatting elements up to the last marker\textsuperscript{p1039}.

Switch the insertion mode\textsuperscript{p1035} to “in row\textsuperscript{p1096}”.

\textbf{↪} A start tag whose tag name is one of: “caption”, “col”, “colgroup”, “tbody”, “td”, “tfoot”, “th”, “thead”, “tr”

If the stack of open elements\textsuperscript{p1036} does not have a td or th element in table scope\textsuperscript{p1038}, then this is a parse error\textsuperscript{p1024}; ignore the token. (fragment case\textsuperscript{p1112})

Otherwise, close the cell\textsuperscript{p1098} (see below) and reprocess the token.

\textbf{↪} An end tag whose tag name is one of: “body”, “caption”, “col”, “colgroup”, “html”

Parse error\textsuperscript{p1024}. Ignore the token.

\textbf{↪} An end tag whose tag name is one of: “table”, “tbody”, “tfoot”, “thead”, “tr”

If the stack of open elements\textsuperscript{p1036} does not have an element in table scope\textsuperscript{p1038} that is an HTML element\textsuperscript{p44} with the same tag name as that of the token, then this is a parse error\textsuperscript{p1024}; ignore the token.

Otherwise, close the cell\textsuperscript{p1098} (see below) and reprocess the token.

\textbf{↪} Anything else

Process the token using the rules for the “in body\textsuperscript{p1081}” insertion mode\textsuperscript{p1035}.

Where the steps above say to close the cell, they mean to run the following algorithm:

1. Generate implied end tags\textsuperscript{p1074}.

2. If the current node\textsuperscript{p1036} is not now a td\textsuperscript{p449} element or a th\textsuperscript{p451} element, then this is a parse error\textsuperscript{p1024}.

3. Pop elements from the stack of open elements\textsuperscript{p1036} stack until a td\textsuperscript{p449} element or a th\textsuperscript{p451} element has been popped from the stack.

4. Clear the list of active formatting elements up to the last marker\textsuperscript{p1039}.

5. Switch the insertion mode\textsuperscript{p1035} to “in row\textsuperscript{p1096}”.

\textbf{Note}

The stack of open elements\textsuperscript{p1036} cannot have both a td\textsuperscript{p449} and a th\textsuperscript{p451} element in table scope\textsuperscript{p1038} at the same time, nor can it have neither when the close the cell\textsuperscript{p1098} algorithm is invoked.

\sectionp{12.6.4.16 The “in select” insertion mode}

When the user agent is to apply the rules for the “in select\textsuperscript{p1098}” insertion mode\textsuperscript{p1035}, the user agent must handle the token as follows:

\textbf{↪} A character token that is U+0000 NULL

Parse error\textsuperscript{p1024}. Ignore the token.

\textbf{↪} Any other character token

Insert the token’s character\textsuperscript{p1072}.

\textbf{↪} A comment token

Insert a comment\textsuperscript{p1073}.
A DOCTYPE token
Parse error. Ignore the token.

A start tag whose tag name is "html"
Process the token using the rules for the "in body" insertion mode.

A start tag whose tag name is "option"
If the current node is an option element, pop that node from the stack of open elements.
Insert an HTML element for the token.

A start tag whose tag name is "optgroup"
If the current node is an option element, pop that node from the stack of open elements.
If the current node is an optgroup element, pop that node from the stack of open elements.
Insert an HTML element for the token.

An end tag whose tag name is "optgroup"
First, if the current node is an option element, and the node immediately before it in the stack of open elements is an optgroup element, then pop the current node from the stack of open elements.
If the current node is an optgroup element, then pop that node from the stack of open elements. Otherwise, this is a parse error; ignore the token.

An end tag whose tag name is "option"
If the current node is an option element, then pop that node from the stack of open elements. Otherwise, this is a parse error; ignore the token.

An end tag whose tag name is "select"
If the stack of open elements does not have a select element in select scope, this is a parse error; ignore the token. (fragment case)
Otherwise:
Pop elements from the stack of open elements until a select element has been popped from the stack.
Reset the insertion mode appropriately.

A start tag whose tag name is "select"
Parse error.
If the stack of open elements does not have a select element in select scope, ignore the token. (fragment case)
Otherwise:
Pop elements from the stack of open elements until a select element has been popped from the stack.
Reset the insertion mode appropriately.

A start tag whose tag name is one of: "input", "keygen", "textarea"
Parse error.
If the stack of open elements does not have a select element in select scope, ignore the token. (fragment case)
Otherwise:
Pop elements from the stack of open elements until a select element has been popped from the stack.
Reset the insertion mode appropriately.

Note
It just gets treated like an end tag.
Reprocess the token.

- A start tag whose tag name is one of: "script", "template"
- An end tag whose tag name is "template"
  Process the token using the rules for the "in head" insertion mode.
- An end-of-file token
  Process the token using the rules for the "in body" insertion mode.
- Anything else
  Parse error. Ignore the token.

12.2.6.4.17 The "in select in table" insertion mode

When the user agent is to apply the rules for the "in select in table" insertion mode, the user agent must handle the token as follows:

- A start tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"
  Parse error.
  Pop elements from the stack of open elements until a select element has been popped from the stack.
  Reset the insertion mode appropriately.
  Reprocess the token.

- An end tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"
  Parse error.
  If the stack of open elements does not have an element in table scope that is an HTML element with the same tag name as that of the token, then ignore the token.
  Otherwise:
  Pop elements from the stack of open elements until a select element has been popped from the stack.
  Reset the insertion mode appropriately.
  Reprocess the token.

- Anything else
  Process the token using the rules for the "in select" insertion mode.

12.2.6.4.18 The "in template" insertion mode

When the user agent is to apply the rules for the "in template" insertion mode, the user agent must handle the token as follows:

- A character token
- A comment token
- A DOCTYPE token
  Process the token using the rules for the "in body" insertion mode.
- A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"
- An end tag whose tag name is "template"
  Process the token using the rules for the "in head" insertion mode.
A start tag whose tag name is one of: "caption", "colgroup", "tbody", "tfoot", "thead"

Pop the current template insertion mode off the stack of template insertion modes.

Push "in table" onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to "in table", and reprocess the token.

A start tag whose tag name is "col"

Pop the current template insertion mode off the stack of template insertion modes.

Push "in column group" onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to "in column group", and reprocess the token.

A start tag whose tag name is "tr"

Pop the current template insertion mode off the stack of template insertion modes.

Push "in table body" onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to "in table body", and reprocess the token.

A start tag whose tag name is one of: "td", "th"

Pop the current template insertion mode off the stack of template insertion modes.

Push "in row" onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to "in row", and reprocess the token.

Any other start tag

Pop the current template insertion mode off the stack of template insertion modes.

Push "in body" onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to "in body", and reprocess the token.

Any other end tag

Parse error. Ignore the token.

An end-of-file token

If there is no template element on the stack of open elements, then stop parsing. (fragment case)

Otherwise, this is a parse error.

Pop elements from the stack of open elements until a template element has been popped from the stack.

Clear the list of active formatting elements up to the last marker.

Pop the current template insertion mode off the stack of template insertion modes.

Reset the insertion mode appropriately.

Reprocess the token.

12.2.6.4.19 The "after body" insertion mode

When the user agent is to apply the rules for the "after body" insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Process the token using the rules for the "in body" insertion mode.
A comment token

Insert a comment as the last child of the first element in the stack of open elements (the html element).

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" insertion mode.

An end tag whose tag name is "html"

If the parser was originally created as part of the HTML fragment parsing algorithm, this is a parse error; ignore the token. (fragment case)

Otherwise, switch the insertion mode to "after after body".

An end-of-file token

Stop parsing.

Anything else

Parse error. Switch the insertion mode to "in body" and reprocess the token.

12.2.6.4.20 The "in frameset" insertion mode

When the user agent is to apply the rules for the "in frameset" insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character.

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" insertion mode.

A start tag whose tag name is "frameset"

Insert an HTML element for the token.

An end tag whose tag name is "frameset"

If the current node is the root html element, then this is a parse error; ignore the token. (fragment case)

Otherwise, pop the current node from the stack of open elements.

If the parser was not originally created as part of the HTML fragment parsing algorithm, and the current node is no longer a frameset element, then switch the insertion mode to "after frameset".

A start tag whose tag name is "frame"

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token's self-closing flag, if it is set.

A start tag whose tag name is "noframes"

Process the token using the rules for the "in head" insertion mode.

An end-of-file token

If the current node is not the root html element, then this is a parse error.
Note: The current node can only be the root html element in the fragment case.

Stop parsing.

Anything else
Parse error. Ignore the token.

12.2.6.4.21 The "after frameset" insertion mode

When the user agent is to apply the rules for the "after frameset" insertion mode, the user agent must handle the token as follows:

- A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE
  Insert the character.

- A comment token
  Insert a comment.

- A DOCTYPE token
  Parse error. Ignore the token.

- A start tag whose tag name is "html"
  Process the token using the rules for the "in body" insertion mode.

- An end tag whose tag name is "html"
  Switch the insertion mode to "after after frameset".

- A start tag whose tag name is "noframes"
  Process the token using the rules for the "in head" insertion mode.

- An end-of-file token
  Stop parsing.

- Anything else
  Parse error. Ignore the token.

12.2.6.4.22 The "after after body" insertion mode

When the user agent is to apply the rules for the "after after body" insertion mode, the user agent must handle the token as follows:

- A comment token
  Insert a comment as the last child of the Document object.

- A DOCTYPE token
  A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

- A start tag whose tag name is "html"
  Process the token using the rules for the "in body" insertion mode.

- An end-of-file token
  Stop parsing.

- Anything else
  Parse error. Switch the insertion mode to "in body" and reprocess the token.

Stop parsing.
12.2.6.4.23 The "after after frameset" insertion mode

When the user agent is to apply the rules for the "after after frameset" insertion mode, the user agent must handle the token as follows:

↪ A comment token
   Insert a comment as the last child of the Document object.

↪ A DOCTYPE token
↪ A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE
↪ A start tag whose tag name is "html"
   Process the token using the rules for the "in body" insertion mode.
↪ An end-of-file token
   Stop parsing.
↪ A start tag whose tag name is "noframes"
   Process the token using the rules for the "in head" insertion mode.
↪ Anything else
   Parse error. Ignore the token.

12.2.6.5 The rules for parsing tokens in foreign content

When the user agent is to apply the rules for parsing tokens in foreign content, the user agent must handle the token as follows:

↪ A character token that is U+0000 NULL
   Parse error. Insert a U+FFFD REPLACEMENT CHARACTER character.
↪ A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE
   Insert the token's character.
↪ Any other character token
   Insert the token's character.
↪ A comment token
   Insert a comment.
↪ A DOCTYPE token
   Parse error. Ignore the token.
↪ A start tag whose tag name is "font", if the token has any attributes named "color", "face", or "size"
   Parse error.

If the parser was originally created for the HTML fragment parsing algorithm, then act as described in the "any other start tag" entry below. (fragment case)

Otherwise:

Pop an element from the stack of open elements, and then keep popping more elements from the stack of open elements until the current node is a MathML text integration point, an HTML integration point, or an element in the HTML namespace.

Then, reprocess the token.
Any other start tag

If the adjusted current node \(^{1036}\) is an element in the MathML namespace, adjust MathML attributes \(^{1071}\) for the token. (This fixes the case of MathML attributes that are not all lowercase.)

If the adjusted current node \(^{1036}\) is an element in the SVG namespace, and the token's tag name is one of the ones in the first column of the following table, change the tag name to the name given in the corresponding cell in the second column. (This fixes the case of SVG elements that are not all lowercase.)

<table>

</table>

If the adjusted current node \(^{1036}\) is an element in the SVG namespace, adjust SVG attributes \(^{1071}\) for the token. (This fixes the case of SVG attributes that are not all lowercase.)

Adjust foreign attributes \(^{1072}\) for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)

Insert a foreign element \(^{1070}\) for the token, in the same namespace as the adjusted current node \(^{1036}\).

If the token has its self-closing flag \(^{1040}\) set, then run the appropriate steps from the following list:

- If the token's tag name is "script", and the new current node \(^{1036}\) is in the SVG namespace, Acknowledge the token's self-closing flag \(^{1040}\), and then act as described in the steps for a "script" end tag below.
Otherwise
Pop the current node off the stack of open elements and acknowledge the token's self-closing flag.

An end tag whose tag name is "script", if the current node is an SVG script element
Pop the current node off the stack of open elements.
Let the old insertion point have the same value as the current insertion point. Let the insertion point be just before the next input character.
Increment the parser's script nesting level by one. Set the parser pause flag to true.
Process the SVG script element according to the SVG rules, if the user agent supports SVG. [SVG]

Note
Even if this causes new characters to be inserted into the tokenizer, the parser will not be executed reentrantly, since the parser pause flag is true.

Decrement the parser's script nesting level by one. If the parser's script nesting level is zero, then set the parser pause flag to false.
Let the insertion point have the value of the old insertion point. (In other words, restore the insertion point to its previous value. This value might be the "undefined" value.)

Any other end tag
Run these steps:

1. Initialize node to be the current node (the bottommost node of the stack).
2. If node's tag name, converted to ASCII lowercase, is not the same as the tag name of the token, then this is a parse error.
3. Loop: If node is the topmost element in the stack of open elements, then return. (fragment case)
4. If node's tag name, converted to ASCII lowercase, is the same as the tag name of the token, pop elements from the stack of open elements until node has been popped from the stack, and then return.
5. Set node to the previous entry in the stack of open elements.
6. If node is not an element in the HTML namespace, return to the step labeled loop.
7. Otherwise, process the token according to the rules given in the section corresponding to the current insertion mode in HTML content.

12.2.7 The end
Once the user agent stops parsing the document, the user agent must run the following steps:

1. Set the current document readiness to "interactive" and the insertion point to undefined.
2. Pop all the nodes off the stack of open elements.
3. If the list of scripts that will execute when the document has finished parsing is not empty, run these substeps:
   1. Spin the event loop until the first script in the list of scripts that will execute when the document has finished parsing has its ready to be parser-executed flag set and the parser's Document has no style sheet that is blocking scripts.
   2. Execute the first script in the list of scripts that will execute when the document has finished parsing.
   3. Remove the first script element from the list of scripts that will execute when the document has finished parsing (i.e. shift out the first entry in the list).
   4. If the list of scripts that will execute when the document has finished parsing is still not empty, repeat these substeps again from step 1.
4. Queue a task\textsuperscript{893} to run the following substeps:
   1. Fire an event named DOMContentLoaded\textsuperscript{1216} at the Document\textsuperscript{110} object, with its bubbles attribute initialized to true.
   2. Enable the client message queue of the ServiceWorkerContainer object whose associated service worker client is the Document\textsuperscript{110} object's relevant settings object\textsuperscript{884}.

5. Spin the event loop\textsuperscript{896} until the set of scripts that will execute as soon as possible\textsuperscript{603} and the list of scripts that will execute in order as soon as possible\textsuperscript{603} are empty.

6. Spin the event loop\textsuperscript{896} until there is nothing that delays the load event in the Document\textsuperscript{110}.

7. Queue a task\textsuperscript{893} to run the following substeps:
   1. Set the current document readiness\textsuperscript{113} to "complete".
   2. Load event: If the Document\textsuperscript{110} has a browsing context\textsuperscript{870}, then fire an event named load\textsuperscript{1217} at the Document\textsuperscript{110} object's Window\textsuperscript{791} object, with legacy target override flag set.

8. If the Document\textsuperscript{110} has a browsing context\textsuperscript{870}, then queue a task\textsuperscript{893} to run the following substeps:
   1. If the Document\textsuperscript{110}'s page showing\textsuperscript{840} flag is true, then return (i.e. don't fire the event below).
   2. Set the Document\textsuperscript{110}'s page showing\textsuperscript{840} flag to true.
   3. Fire an event named pageshow\textsuperscript{1217} at the Document\textsuperscript{110} object's Window\textsuperscript{791} object, using PageTransitionEvent\textsuperscript{840}, with the persisted\textsuperscript{840} attribute initialized to false, and legacy target override flag set.

9. If the Document\textsuperscript{110} has any pending application cache download process tasks\textsuperscript{860}, then queue\textsuperscript{893} each such task\textsuperscript{893} in the order they were added to the list of pending application cache download process tasks\textsuperscript{860}, and then empty the list of pending application cache download process tasks\textsuperscript{860}. The task source\textsuperscript{893} for these tasks\textsuperscript{893} is the networking task source\textsuperscript{897}.

10. If the Document\textsuperscript{110}'s print when loaded\textsuperscript{922} flag is set, then run the printing steps\textsuperscript{922}.

11. The Document\textsuperscript{110} is now ready for post-load tasks.

12. Queue a task\textsuperscript{893} to mark the Document\textsuperscript{110} as completely loaded.

When the user agent is to abort a parser, it must run the following steps:

1. Throw away any pending content in the input stream\textsuperscript{1034}, and discard any future content that would have been added to it.
2. Set the current document readiness\textsuperscript{113} to "interactive".
3. Pop all the nodes off the stack of open elements\textsuperscript{1036}.
4. Set the current document readiness\textsuperscript{113} to "complete".

Except where otherwise specified, the task source\textsuperscript{893} for the tasks\textsuperscript{893} mentioned in this section is the DOM manipulation task source\textsuperscript{897}.

### 12.2.8 Coercing an HTML DOM into an infoset \textsuperscript{5811}\textsuperscript{5807}

When an application uses an HTML parser\textsuperscript{1022} in conjunction with an XML pipeline, it is possible that the constructed DOM is not compatible with the XML tool chain in certain subtle ways. For example, an XML toolchain might not be able to represent attributes with the name xmlns, since they conflict with the Namespaces in XML syntax. There is also some data that the HTML parser\textsuperscript{1022} generates that isn't included in the DOM itself. This section specifies some rules for handling these issues.

If the XML API being used doesn't support DOCTYPEs, the tool may drop DOCTYPEs altogether.

If the XML API doesn't support attributes in no namespace that are named "xmlns", attributes whose names start with "xmlns:", or attributes in the XMLNS namespace, then the tool may drop such attributes.

The tool may annotate the output with any namespace declarations required for proper operation.
If the XML API being used restricts the allowable characters in the local names of elements and attributes, then the tool may map all element and attribute local names that the API wouldn't support to a set of names that are allowed, by replacing any character that isn't supported with the uppercase letter U and the six digits of the character's code point when expressed in hexadecimal, using digits 0-9 and capital letters A-F as the symbols, in increasing numeric order.

Example
For example, the element name foo<bar, which can be output by the HTML parser, though it is neither a legal HTML element name nor a well-formed XML element name, would be converted into fooU00003Cbar, which is a well-formed XML element name (though it's still not legal in HTML by any means).

Example
As another example, consider the attribute xlink:href. Used on a MathML element, it becomes, after being adjusted, an attribute with a prefix "xlink" and a local name "href". However, used on an HTML element, it becomes an attribute with no prefix and the local name "xlink:href", which is not a valid NCName, and thus might not be accepted by an XML API. It could thus get converted, becoming "xlinkU00003Ahref".

Note
The resulting names from this conversion conveniently can't clash with any attribute generated by the HTML parser, since those are all either lowercase or those listed in the adjust foreign attributes algorithm's table.

If the XML API restricts comments from having two consecutive U+002D HYPHEN-MINUS characters (--), the tool may insert a single U+0020 SPACE character between any such offending characters.

If the XML API restricts comments from ending in a U+002D HYPHEN-MINUS character (-), the tool may insert a single U+0020 SPACE character at the end of such comments.

If the XML API restricts allowed characters in character data, attribute values, or comments, the tool may replace any U+000C FORM FEED (FF) character with a U+0020 SPACE character, and any other literal non-XML character with a U+FFFD REPLACEMENT CHARACTER.

If the tool has no way to convey out-of-band information, then the tool may drop the following information:

- Whether the document is set to no-quirks mode, limited-quirks mode, or quirks mode
- The association between form controls and forms that aren't their nearest form element ancestor (use of the form element pointer in the parser)
- The template contents of any template elements.

Note
The mutations allowed by this section apply after the HTML parser's rules have been applied. For example, a <a::> start tag will be closed by a </a::> end tag, and never by a </aU00003AU00003A> end tag, even if the user agent is using the rules above to then generate an actual element in the DOM with the name aU00003AU00003A for that start tag.

12.2.9 An introduction to error handling and strange cases in the parser

This section is non-normative.

This section examines some erroneous markup and discusses how the HTML parser handles these cases.

12.2.9.1 Misnested tags: <b><i></b></i>

This section is non-normative.

The most-often discussed example of erroneous markup is as follows:

<p>1<b>2<i>3</i></b>4</p>

The parsing of this markup is straightforward up to the "3". At this point, the DOM looks like this:
Here, the stack of open elements has five elements on it: html, body, p, b, and i. The list of active formatting elements just has two: b and i. The insertion mode is "in body".

Upon receiving the end tag token with the tag name "b", the adoption agency algorithm is invoked. This is a simple case, in that the formatting element is the b element, and there is no furthest block. Thus, the stack of open elements ends up with just three elements: html, body, and p, while the list of active formatting elements has just one: i. The DOM tree is unmodified at this point.

The next token is a character ("4"), triggers the reconstruction of the active formatting elements, in this case just the i element. A new i element is thus created for the "4" Text node. After the end tag token for the "i" is also received, and the "5" Text node is inserted, the DOM looks as follows:

12.2.9.2 Misnested tags: &lt;b&gt;&lt;p&gt;&lt;/b&gt;&lt;/p&gt;  
This section is non-normative.

A case similar to the previous one is the following:

&lt;b&gt;1&lt;p&gt;2&lt;/b&gt;&lt;/p&gt;

Up to the "2" the parsing here is straightforward:

The interesting part is when the end tag token with the tag name "b" is parsed.

Before that token is seen, the stack of open elements has four elements on it: html, body, b, and p. The list of active formatting elements just has the one: b. The insertion mode is "in body".

Upon receiving the end tag token with the tag name "b", the adoption agency algorithm is invoked, as in the previous example. However, in this case, there is a furthest block, namely the p element. Thus, this time the adoption agency algorithm isn't skipped over.
The common ancestor is the body element. A conceptual "bookmark" marks the position of the b in the list of active formatting elements, but since that list has only one element in it, the bookmark won't have much effect.

As the algorithm progresses, node ends up set to the formatting element (b), and last node ends up set to the furthest block (p).

The last node gets appended (moved) to the common ancestor, so that the DOM looks like:

```
html
  head
    body
      b
        #text: I
      p
        #text: 2
```

A new b element is created, and the children of the p element are moved to it:

```
html
  head
    body
      b
        #text: I
      p
        b
          #text: 2
```

Finally, the new b element is appended to the p element, so that the DOM looks like:

```
html
  head
    body
      b
        #text: I
      p
        b
          #text: 2
```

The b element is removed from the list of active formatting elements and the stack of open elements, so that when the "3" is parsed, it is appended to the p element:

```
html
  head
    body
      p
        b
          #text: 2
        #text: 3
```

12.2.9.3 Unexpected markup in tables

This section is non-normative.

Error handling in tables is, for historical reasons, especially strange. For example, consider the following markup:

```
<table><b><tr><td>aaa</td></tr><b>bbb</table>ccc
```

The highlighted b element start tag is not allowed directly inside a table like that, and the parser handles this case by placing the element before the table. (This is called foster parenting.) This can be seen by examining the DOM tree as it stands just after the table element's start tag has been seen:
...and then immediately after the `b` element start tag has been seen:

```html
<head>
  <title>Page Title</title>
</head>
<body>
  <table>
    <tr>
      <td>aaa</td>
    </tr>
  </table>
</body>
```

At this point, the stack of open elements has on it the elements `html`, `body`, `table`, and `b` (in that order, despite the resulting DOM tree); the list of active formatting elements just has the `b` element in it; and the insertion mode is "in table".

The `tr` start tag causes the `b` element to be popped off the stack and a `tbody` start tag to be implied; the `tbody` and `tr` elements are then handled in a rather straight-forward manner, taking the parser through the "in table body" and "in row" insertion modes, after which the DOM looks as follows:

```html
<head>
  <title>Page Title</title>
</head>
<body>
  <table>
    <tbody>
      <tr>
        <td>aaa</td>
      </tr>
    </tbody>
  </table>
</body>
```

Here, the stack of open elements has on it the elements `html`, `body`, `table`, `tbody`, and `tr`; the list of active formatting elements still has the `b` element in it; and the insertion mode is "in row".

The `td` element start tag token, after putting a `td` element on the tree, puts a marker on the list of active formatting elements (it also switches to the "in cell", insertion mode).

The marker means that when the "aaa" character tokens are seen, no `b` element is created to hold the resulting Text node:

```html
<head>
  <title>Page Title</title>
</head>
<body>
  <table>
    <tbody>
      <tr>
        <td>aaa</td>
      </tr>
    </tbody>
  </table>
</body>
```

The end tags are handled in a straight-forward manner; after handling them, the stack of open elements has on it the elements `html`, `body`, `table`, and `tbody`; the list of active formatting elements still has the `b` element in it (the marker having been removed by the "td" end tag token); and the insertion mode is "in table body".

Thus it is that the "bbb" character tokens are found. These trigger the "in table text" insertion mode to be used (with the original insertion mode set to "in table body"). The character tokens are collected, and when the next token (the `table` element end tag) is seen, they are processed as a group. Since they are not all spaces, they are handled as per the "anything else" rules in the "in
table insertion mode, which defer to the "in body" insertion mode but with foster parenting.

When the active formatting elements are reconstructed, a b element is created and foster parented, and then the "bbb" Text node is appended to it:

```
  html
  head
  body
  b
  b
  #text: bbb
table
tbody
  tr
  td
  #text: aaa
```

The stack of open elements has on it the elements html, body, table, tbody, and the new b (again, note that this doesn't match the resulting tree!); the list of active formatting elements has the new b element in it; and the insertion mode is still "in table body".

Had the character tokens been only ASCII whitespace instead of "bbb", then that ASCII whitespace would just be appended to the tbody element.

Finally, the table is closed by a "table" end tag. This pops all the nodes from the stack of open elements up to and including the table element, but it doesn't affect the list of active formatting elements, so the "ccc" character tokens after the table result in yet another b element being created, this time after the table:

```
  html
  head
  body
  b
  b
  #text: bbb
table
tbody
  tr
  td
  #text: aaa
  b
  #text: ccc
```

12.2.9.4 Scripts that modify the page as it is being parsed

This section is non-normative.

Consider the following markup, which for this example we will assume is the document with URL https://example.com/inner, being rendered as the content of an iframe in another document with the URL https://example.com/outer:

```html
<div id="a">
  <script>
    var div = document.getElementById('a');
    parent.document.body.appendChild(div);
  </script>
  alert(document.URL);
</div>
<script>
  alert(document.URL);
</script>
```

1112
Up to the first "script" end tag, before the script is parsed, the result is relatively straightforward:

```
<html>
  <head>
    <b class="x"></b><b class="x"></b><b><b class="x"></b><b class="x"></b>
  </head>
  <body>
    <div id="a">
      <script>
        var div = document.getElementById('a');
        parent.document.body.appendChild(div);
      </script>
    </div>
  </body>
</html>
```

After the script is parsed, though, the `div` element and its child `script` element are gone:

```
<html>
  <head>
    <b class="x"></b><b class="x"></b><b>
  </head>
  <body>
  </body>
</html>
```

They are, at this point, in the `Document` of the aforementioned outer `browsing context`. However, the `stack of open elements` still contains the `div` element.

Thus, when the second `script` element is parsed, it is inserted into the outer `Document` object.

Those parsed into different `Document`s than the one the parser was created for do not execute, so the first alert does not show.

Once the `div` element's end tag is parsed, the `div` element is popped off the stack, and so the next `script` element is in the inner `Document`:

```
<html>
  <head>
    <script>
      alert(document.URL);
    </script>
  </head>
  <body>
  </body>
</html>
```

This script does execute, resulting in an alert that says "https://example.com/inner".

12.2.9.5 The execution of scripts that are moving across multiple documents

This section is non-normative.

Elaborating on the example in the previous section, consider the case where the second `script` element is an external script (i.e. one with a `src` attribute). Since the element was not in the parser's `Document` when it was created, that external script is not even downloaded.

In a case where a `script` element with a `src` attribute is parsed normally into its parser's `Document`, but while the external script is being downloaded, the element is moved to another document, the script continues to download, but does not execute.

```
<!DOCTYPE html>
<p><b class="x"><b class="x"></b><b class="x"></b><b class="x"><b class="x"></b><b class="x"></b><b class="x"><b class="x"><b class="x"></b></b></b></p>
```

12.2.9.6 Unclosed formatting elements

This section is non-normative.

The following markup shows how nested formatting elements (such as `<b class="x">`) get collected and continue to be applied even as the elements they are contained in are closed, but that excessive duplicates are thrown away.

```
<!DOCTYPE html>
<p><b class="x"><b class="x"><b class="x"><b class="x"><b class="x"><b class="x"><b class="x"><b class="x"></b></b></b></b></b></p>
```

1113
The resulting DOM tree is as follows:

```
<!DOCTYPE html>
<html>
<head>
<body>
<p class="x" class="x" class="x"
    class="x" class="x" class="x"
        class="x"
            #text: X
        
    
</p>
<p class="x" class="x" class="x"
    class="x" class="x" class="x"
        class="x"
            #text: X
        
    
</p>
<p class="x" class="x" class="x"
    class="x" class="x" class="x"
        class="x"
            #text: X
        
    
</p>
<p class="x" class="x" class="x"
    class="x" class="x" class="x"
        class="x"
            #text: X
        
    
</p>
</body>
</html>
```

Note how the second element in the markup has no explicit elements, but in the resulting DOM, up to three of each kind of formatting element (in this case three elements with the class attribute, and two unadorned elements) get reconstructed before the element's "X".

Also note how this means that in the final paragraph only six end tags are needed to completely clear the list of active formatting elements, even though nine start tags have been seen up to this point.

### 12.3 Serializing HTML fragments

The following steps form the HTML fragment serialization algorithm. The algorithm takes as input a DOM Element, Document, or DocumentFragment referred to as the node, and returns a string.

**Note**

This algorithm serializes the children of the node being serialized, not the node itself.

1. Let s be a string, and initialize it to the empty string.

2. If the node is a template element, then let the node instead be the template's template contents (a DocumentFragment node).

3. For each child node of the node, in tree order, run the following steps:

   1. Let current node be the child node being processed.
2. Append the appropriate string from the following list to s:

- If current node is an Element
  
  If current node is an element in the HTML namespace, the MathML namespace, or the SVG namespace, then let tagname be current node's local name. Otherwise, let tagname be current node's qualified name.

  Append a U+003C LESS-THAN SIGN character (<), followed by tagname.

  Note: For HTML elements created by the HTML parser or createElement(), tagname will be lowercase.

  If current node's is value is not null, and the element does not have an is attribute in its attribute list, then append the string " is=" standalone="false" in attribute mode, followed by a U+0022 QUOTATION MARK character (").

  For each attribute that the element has, append a U+0020 SPACE character, the attribute's serialized name as described below, a U+003D EQUALS SIGN character (=), a U+0022 QUOTATION MARK character ("), the attribute's value, escaped as described below in attribute mode, and a second U+0022 QUOTATION MARK character (").

  An attribute's serialized name for the purposes of the previous paragraph must be determined as follows:

  - If the attribute has no namespace
    The attribute's serialized name is the attribute's local name.

  Note: For attributes on HTML elements set by the HTML parser or by Element.setAttribute(), the local name will be lowercase.

  - If the attribute is in the XML namespace
    The attribute's serialized name is the string "xml:" followed by the attribute's local name.

  - If the attribute is in the XMLNS namespace and the attribute's local name is xmlns
    The attribute's serialized name is the string "xmlns".

  - If the attribute is in the XMLNS namespace and the attribute's local name is not xmlns
    The attribute's serialized name is the string "xmlns:" followed by the attribute's local name.

  - If the attribute is in the XLink namespace
    The attribute's serialized name is the string "xlink:" followed by the attribute's local name.

  - If the attribute is in some other namespace
    The attribute's serialized name is the attribute's qualified name.

  While the exact order of attributes is UA-defined, and may depend on factors such as the order that the attributes were given in the original markup, the sort order must be stable, such that consecutive invocations of this algorithm serialize an element's attributes in the same order.

  Append a U+003E GREATER-THAN SIGN character (>).

  If current node is an area, base, basefont, bgsound, br, col, embed, frame, hr, img, input, keygen, link, meta, param, source, track or wbr element, then continue on to the next child node at this point.

  Append the value of running the HTML fragment serialization algorithm on the current node element (thus recursing into this algorithm for that element), followed by a U+003C LESS-THAN SIGN character (<), a U+002F SOLIDUS character (/), tagname again, and finally a U+003E GREATER-THAN SIGN character (>).

- If current node is a Text node

  If the parent of current node is a style, script, xmp, iframe, noembed, noframes, or plaintext element, or if the parent of current node is a noscript element and scripting is enabled for the node, then append the value of current node's data IDL attribute literally.
Otherwise, append the value of current node’s data IDL attribute, escaped as described below.

→ If current node is a Comment
   Append the literal string "--" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS), followed by the value of current node’s data IDL attribute, followed by the literal string "-->" (U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS, U+003E GREATER-THAN SIGN).

→ If current node is a ProcessingInstruction
   Append the literal string "<?" (U+003C LESS-THAN SIGN, U+003F QUESTION MARK), followed by the value of current node’s target IDL attribute, followed by a single U+0020 SPACE character, followed by the value of current node’s data IDL attribute, followed by a single U+003E GREATER-THAN SIGN character (>).

→ If current node is a DocumentType
   Append the literal string "<!DOCTYPE" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+0044 LATIN CAPITAL LETTER D, U+004F LATIN CAPITAL LETTER O, U+0043 LATIN CAPITAL LETTER C, U+0054 LATIN CAPITAL LETTER T, U+0059 LATIN CAPITAL LETTER Y, U+0050 LATIN CAPITAL LETTER P, U+0045 LATIN CAPITAL LETTER E), followed by a space (U+0020 SPACE), followed by the value of current node’s name IDL attribute, followed by the literal string ">" (U+003E GREATER-THAN SIGN).

4. The result of the algorithm is the string s.

⚠ Warning!

It is possible that the output of this algorithm, if parsed with an HTML parser, will not return the original tree structure. Tree structures that do not roundtrip a serialize and reparse step can also be produced by the HTML parser itself, although such cases are typically non-conforming.

Example

For instance, if a textarea element to which a Comment node has been appended is serialized and the output is then reparsed, the comment will end up being displayed in the text control. Similarly, if, as a result of DOM manipulation, an element contains a comment that contains the literal string "-->", then when the result of serializing the element is parsed, the comment will be truncated at that point and the rest of the comment will be interpreted as markup. More examples would be making a script element contain a Text node with the text string "</script>", or having a p element that contains a ul element (as the ul element’s start tag would imply the end tag for the p).

This can enable cross-site scripting attacks. An example of this would be a page that lets the user enter some font family names that are then inserted into a CSS style block via the DOM and which then uses the innerHTML IDL attribute to get the HTML serialization of that style element: if the user enters "</style><script>alert()</script>" as a font family name, innerHTML will return markup that, if parsed in a different context, would contain a script node, even though no script node existed in the original DOM.

Example

For example, consider the following markup:

```html
<form id="outer"><div></form><form id="inner"><input>
```

This will be parsed into:

```
<body>
<form id="outer"
  <div/>
</form>
<form id="inner"
  <input/>
```

The input element will be associated with the inner form element. Now, if this tree structure is serialized and reparsed, the <form id="inner"> start tag will be ignored, and so the input element will be associated with the outer form element instead.
For historical reasons, this algorithm does not round-trip an initial U+000A LINE FEED (LF) character in pre, textarea, or listing elements, even though (in the first two cases) the markup being round-tripped can be conforming. The HTML parser will drop such a character during parsing, but this algorithm does not serialize an extra U+000A LINE FEED (LF) character.

As another example, consider the following markup:

```html
<pre>Hello.</pre>
```

When this document is first parsed, the `pre` element's `child text content` starts with a single newline character. After a serialize-reparse roundtrip, the `pre` element's `child text content` is simply "Hello."

Because of the special role of the `is` attribute in signaling the creation of customized built-in elements, in that it provides a mechanism for parsed HTML to set the element's `is value`, we special-case its handling during serialization. This ensures that an element's `is value` is preserved through serialize-parse roundtrips.
When creating a customized built-in element via the parser, a developer uses the `is` attribute directly; in such cases serialize-parse roundtrips work fine.

```html
<script>
  window.SuperP = class extends HTMLParagraphElement {};
customElements.define("super-p", SuperP, { extends: "p" });
</script>

<div id="container"><p is="super-p">Superb!</p></div>

<script>
  console.log(container.innerHTML); // <p is="super-p">
  container.innerHTML = container.innerHTML;
  console.log(container.innerHTML); // <p is="super-p">
  console.assert(container.firstChild instanceof SuperP);
</script>

But when creating a customized built-in element via its constructor or via `createElement()`, the `is` attribute is not added. Instead, the `is value` (which is what the custom elements machinery uses) is set without intermediating through an attribute.

```html
<script>
  container.innerHTML = "";
  const p = document.createElement("p", { is: "super-p" });
  container.appendChild(p);

  // The is attribute is not present in the DOM:
  console.assert(!p.hasAttribute("is"));

  // But the element is still a super-p:
  console.assert(p instanceof SuperP);
</script>

To ensure that serialize-parse roundtrips still work, the serialization process explicitly writes out the element's `is value` as an `is` attribute:

```html
<script>
  console.log(container.innerHTML); // <p is="super-p">
  container.innerHTML = container.innerHTML;
  console.log(container.innerHTML); // <p is="super-p">
  console.assert(container.firstChild instanceof SuperP);
</script>
```

### Escaping a string

(for the purposes of the algorithm above) consists of running the following steps:

1. Replace any occurrence of the "&" character by the string "&amp;".
2. Replace any occurrences of the U+00A0 NO-BREAK SPACE character by the string "&nbsp;".
3. If the algorithm was invoked in the `attribute mode`, replace any occurrences of the "" character by the string "&quot;".
4. If the algorithm was not invoked in the `attribute mode`, replace any occurrences of the "<" character by the string "&lt;", and any occurrences of the ">" character by the string "&gt;".

### 12.4 Parsing HTML fragments

The following steps form the HTML fragment parsing algorithm. The algorithm takes as input an `Element` node, referred to as the `context` element, which gives the context for the parser, as well as `input`, a string to parse, and returns a list of zero or more nodes.
1. Create a new Document node, and mark it as being an HTML document.

2. If the node document of the context element is in quirks mode, then let the Document be in quirks mode. Otherwise, the node document of the context element is in limited-quirks mode, then let the Document be in limited-quirks mode. Otherwise, leave the Document in no-quirks mode.

3. Create a new HTML parser, and associate it with the just created Document node.

4. Set the state of the HTML parser's tokenization stage as follows, switching on the context element:
   - `title`
   - `textarea`
     Switch the tokenizer to the RCDATA state.
   - `style`
   - `xmp`
   - `iframe`
   - `noembed`
   - `noframes`
     Switch the tokenizer to the RAWTEXT state.
   - `script`
     Switch the tokenizer to the script data state.
   - `noscript`
     If the scripting flag is enabled, switch the tokenizer to the RAWTEXT state. Otherwise, leave the tokenizer in the data state.
   - `plaintext`
     Switch the tokenizer to the PLAINTEXT state.
   - Any other element
     Leave the tokenizer in the data state.

5. Let root be a new html element with no attributes.

6. Append the element root to the Document node created above.

7. Set up the parser's stack of open elements so that it contains just the single element root.

8. If the context element is a template element, push "in template" onto the stack of template insertion modes so that it is the new current template insertion mode.

9. Create a start tag token whose name is the local name of context and whose attributes are the attributes of context.

10. Reset the parser's insertion mode appropriately.

11. Set the parser's form element pointer to the nearest node to the context element that is a form element (going...
straight up the ancestor chain, and including the element itself, if it is a form element, the form element pointer keeps its initial value, null.)

12. Place the input into the input stream just created. The encoding confidence is irrelevant.

13. Start the parser and let it run until it has consumed all the characters just inserted into the input stream.

14. Return the child nodes of root, in tree order.

12.5 Named character references

This table lists the character reference names that are supported by HTML, and the code points to which they refer. It is referenced by the previous sections.

</tbody>
</table>

1120
This data is also available as a JSON file.

The glyphs displayed above are non-normative. Refer to the Unicode specifications for formal definitions of the characters listed above.

Note: The character reference names originate from the XML Entity Definitions for Characters specification, though only the above is considered normative.
13 The XML syntax

Note
This section only describes the rules for XML resources. Rules for text/html resources are discussed in the section above entitled "The HTML syntax".

13.1 Writing documents in the XML syntax

Note
The XML syntax for HTML was formerly referred to as "XHTML", but this specification does not use that term (among other reasons, because no such term is used for the HTML syntaxes of MathML and SVG).

The syntax for XML is defined in the XML and Namespaces in XML specifications. [XML] [XMLNS]

This specification does not define any syntax-level requirements beyond those defined for XML proper.

XML documents may contain a DOCTYPE if desired, but this is not required to conform to this specification. This specification does not define a public or system identifier, nor provide a formal DTD.

Note
According to the XML specification, XML processors are not guaranteed to process the external DTD subset referenced in the DOCTYPE. This means, for example, that using entity references for characters in XML documents is unsafe if they are defined in an external file (except for &lt;, &gt;, &amp;, &quot; and &apos;).

13.2 Parsing XML documents

This section describes the relationship between XML and the DOM, with a particular emphasis on how this interacts with HTML.

An XML parser, for the purposes of this specification, is a construct that follows the rules given in the XML specification to map a string of bytes or characters into a Document object.

Note
At the time of writing, no such rules actually exist.

An XML parser is either associated with a Document object when it is created, or creates one implicitly.

This Document must then be populated with DOM nodes that represent the tree structure of the input passed to the parser, as defined by the XML specification, the Namespaces in XML specification, and the WHATWG DOM standard. When creating DOM nodes representing elements, the create an element for a token algorithm or some equivalent that operates on appropriate XML datastructures must be used, to ensure the proper element interfaces are created and that custom elements are set up correctly.

DOM mutation events must not fire for the operations that the XML parser performs on the Document's tree, but the user agent must act as if elements and attributes were individually appended and set respectively so as to trigger rules in this specification regarding what happens when an element is inserted into a document or has its attributes set, and the WHATWG DOM standard's requirements regarding mutation observers mean that mutation observers are fired (unlike mutation events). [XML] [XMLNS] [DOM] [UIEVENTS]

Between the time an element's start tag is parsed and the time either the element's end tag is parsed or the parser detects a well-formedness error, the user agent must act as if the element was in a stack of open elements.

Note
This is used, e.g. by the object element to avoid instantiating plugins before the param element children have been parsed.
This specification provides the following additional information that user agents should use when retrieving an external entity: the public identifiers given in the following list all correspond to the URL given by this link. (This URL is a DTD containing the entity declarations for the names listed in the [named character references](#) section.)

- //W3C//DTD XHTML 1.0 Transitional//EN
- //W3C//DTD XHTML 1.1//EN
- //W3C//DTD XHTML 1.0 Strict//EN
- //W3C//DTD XHTML 1.0 Frameset//EN
- //W3C//DTD XHTML Basic 1.0//EN
- //W3C//DTD XHTML 1.1 plus MathML 2.0//EN
- //W3C//DTD MathML 2.0 plus SVG 1.1//EN
- //WAPFORUM/DTD XHTML Mobile 1.0//EN

Furthermore, user agents should attempt to retrieve the above external entity's content when one of the above public identifiers is used, and should not attempt to retrieve any other external entity's content.

**Note**

This is not strictly a violation of the XML specification, but it does contradict the spirit of the XML specification's requirements. This is motivated by a desire for user agents to all handle entities in an interoperable fashion without requiring any network access for handling external subsets.

XML parsers can be invoked with [XML scripting support enabled](#) or [XML scripting support disabled](#). Except where otherwise specified, XML parsers are invoked with [XML scripting support enabled](#).

When an [XML parser](#) with [XML scripting support enabled](#) creates a [script](#) element, it must be marked as being "parser-inserted" and its "non-blocking" flag must be unset. If the parser was originally created for the [XML fragment parsing algorithm](#), then the element must be marked as "already started" also. When the element's end tag is subsequently parsed, the user agent must [perform a microtask checkpoint](#), and then [prepare](#) the [script](#) element. If this causes there to be a [pending parsing-blocking script](#), then the user agent must run the following steps:

1. Block this instance of the [XML parser](#), such that the [event loop](#) will not run [tasks](#) that invoke it.
2. Spin the event loop until the parser's [Document](#) has no style sheet that is blocking scripts and the pending parsing-blocking script's "ready to be parser-executed" flag is set.
3. Unblock this instance of the [XML parser](#), such that [tasks](#) that invoke it can again be run.
4. Execute the pending parsing-blocking script.
5. There is no longer a pending parsing-blocking script.

**Note**

Since the [document.write()](#) API is not available for [XML documents](#), much of the complexity in the [HTML parser](#) is not needed in the [XML parser](#).

When an [XML parser](#) has [XML scripting support disabled](#), none of this happens.

When an [XML parser](#) would append a node to a [template](#) element, it must instead append it to the [template](#) element's template contents (a [DocumentFragment](#) node).

**Note**

This is a willful violation of the XML specification; unfortunately, XML is not formally extensible in the manner that is needed for [template](#) processing.

When an [XML parser](#) creates a [Node](#) object, its [node document](#) must be set to the [node document](#) of the node into which the newly created node is to be inserted.

Certain algorithms in this specification spoon-feed the parser characters one string at a time. In such cases, the [XML parser](#) must act as it would have if faced with a single string consisting of the concatenation of all those characters.

When an [XML parser](#) reaches the end of its input, it must [stop parsing](#), following the same rules as the [HTML parser](#). An [XML parser](#) can also be [aborted](#), which must again be done in the same way as for an [HTML parser](#).

For the purposes of conformance checkers, if a resource is determined to be in the XML syntax, then it is an [XML document](#).
### 13.3 Serializing XML fragments

The **XML fragment serialization algorithm** for a `Document` or `Element` node either returns a fragment of XML that represents that node or throws an exception.

For `Document`s, the algorithm must return a string in the form of a `document entity`, if none of the error cases below apply.

For `Element`s, the algorithm must return a string in the form of an `internal general parsed entity`, if none of the error cases below apply.

In both cases, the string returned must be XML namespace-well-formed and must be an isomorphic serialization of all of that node’s relevant child nodes, in tree order. User agents may adjust prefixes and namespace declarations in the serialization (and indeed might be forced to do so in some cases to obtain namespace-well-formed XML). User agents may use a combination of regular text and character references to represent `Text` nodes in the DOM.

A node’s relevant child nodes are those that apply given the following rules:

**For template elements**

- The relevant child nodes are the child nodes of the template element’s template contents, if any.

**For all other nodes**

- The relevant child nodes are the child nodes of node itself, if any.

For `Element`s, if any of the elements in the serialization are in no namespace, the default namespace in scope for those elements must be explicitly declared as the empty string. (This doesn't apply in the `Document` case.)

For the purposes of this section, an internal general parsed entity is considered XML namespace-well-formed if a document consisting of an element with no namespace declarations whose contents are the internal general parsed entity would itself be XML namespace-well-formed.

If any of the following error cases are found in the DOM subtree being serialized, then the algorithm must throw an "InvalidStateError" `DOMException` instead of returning a string:

- A `Document` node with no child element nodes.
- A `DocumentType` node that has an external subset public identifier that contains characters that are not matched by the XML PubidChar production.
- A `DocumentType` node that has an external subset system identifier that contains both a U+0022 QUOTATION MARK (”) and a U+0027 APOSTROPHE (‘) or that contains characters that are not matched by the XML Char production.
- A node with a local name containing a U+003A COLON (:).
- A node with a local name that does not match the XML Name production.
- An `Attr` node with no namespace whose local name is the lowercase string "xmlns".
- An `Element` node with two or more attributes with the same local name and namespace.
- An `Attr` node, `Text` node, `Comment` node, or `ProcessingInstruction` node whose data contains characters that are not matched by the XML Char production.
- A `Comment` node whose data contains two adjacent U+002D HYPHEN-MINUS characters (-) or ends with such a character.
- A `ProcessingInstruction` node whose target name is an ASCII case-insensitive match for the string "xml".
- A `ProcessingInstruction` node whose target name contains a U+003A COLON (:).
- A `ProcessingInstruction` node whose data contains the string "?=".

**Note**

These are the only ways to make a DOM unserialisable. The DOM enforces all the other XML constraints; for example, trying to append two elements to a `Document` node will throw a "HierarchyRequestError" `DOMException`.
The XML fragment parsing algorithm either returns a Document or throws a "SyntaxError" DOMException. Given a string input and a context element context, the algorithm is as follows:

1. Create a new XML parser.
2. Feed the parser just created the string corresponding to the start tag of the context element, declaring all the namespace prefixes that are in scope on that element in the DOM, as well as declaring the default namespace (if any) that is in scope on that element in the DOM.

A namespace prefix is in scope if the DOM lookupNamespaceURI() method on the element would return a non-null value for that prefix.

The default namespace is the namespace for which the DOM isDefaultNamespace() method on the element would return true.

3. Feed the parser just created the string input.
4. Feed the parser just created the string corresponding to the end tag of the context element.
5. If there is an XML well-formedness or XML namespace well-formedness error, then throw a "SyntaxError" DOMException.
6. If the document element of the resulting Document has any sibling nodes, then throw a "SyntaxError" DOMException.
7. Return the child nodes of the document element of the resulting Document, in tree order.
14 Rendering

User agents are not required to present HTML documents in any particular way. However, this section provides a set of suggestions for rendering HTML documents that, if followed, are likely to lead to a user experience that closely resembles the experience intended by the documents' authors. So as to avoid confusion regarding the normativity of this section, "must" has not been used. Instead, the term "expected" is used to indicate behavior that will lead to this experience. For the purposes of conformance for user agents designated as supporting the suggested default rendering, the term "expected" in this section has the same conformance implications as "must".

14.1 Introduction

In general, user agents are expected to support CSS, and many of the suggestions in this section are expressed in CSS terms. User agents that use other presentation mechanisms can derive their expected behavior by translating from the CSS rules given in this section.

In the absence of style-layer rules to the contrary (e.g. author style sheets), user agents are expected to render an element so that it conveys to the user the meaning that the element represents, as described by this specification.

The suggestions in this section generally assume a visual output medium with a resolution of 96dpi or greater, but HTML is intended to apply to multiple media (it is a media-independent language). User agent implementers are encouraged to adapt the suggestions in this section to their target media.

An element is being rendered if it has any associated CSS layout boxes, SVG layout boxes, or some equivalent in other styling languages.

Note

Just being off-screen does not mean the element is not being rendered. The presence of the hidden attribute normally means the element is not being rendered, though this might be overridden by the style sheets.

User agents that do not honor author-level CSS style sheets are nonetheless expected to act as if they applied the CSS rules given in these sections in a manner consistent with this specification and the relevant CSS and Unicode specifications. [CSS] [UNICODE]

Note

This is especially important for issues relating to the 'display', 'unicode-bidi', and 'direction' properties.

14.2 The CSS user agent style sheet and presentational hints

The CSS rules given in these subsections are, except where otherwise specified, expected to be used as part of the user-agent level style sheet defaults for all documents that contain HTML elements.

Some rules are intended for the author-level zero-specificity presentational hints part of the CSS cascade; these are explicitly called out as presentational hints.

When the text below says that an attribute attribute on an element element maps to the pixel length property (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute's value using the rules for parsing non-negative integers doesn't generate an error, then the user agent is expected to use the parsed value as a pixel length for a presentational hint for properties.

When the text below says that an attribute attribute on an element element maps to the dimension property (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute's value using the rules for parsing
doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a
presentational hint for properties, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When the text below says that an attribute attribute on an element element maps to the dimension property (ignoring zero) (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute’s value using the rules for parsing nonzero dimension values doesn’t generate an error, then the user agent is expected to use the parsed dimension as the value for a presentational hint for properties, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When a user agent is to align descendants of a node, the user agent is expected to align only those descendants that have both their margin-inline-start and margin-inline-end properties computing to a value other than ‘auto’, that are over-constrained and that have one of those two margins with a used value forced to a greater value, and that do not themselves have an applicable align attribute. When multiple elements are to align a particular descendant, the most deeply nested such element is expected to override the others. Aligned elements are expected to be aligned by having the used values of their margins on the line-left and line-right sides be set accordingly. [CSSLOGICAL] [CSSWM]

### 14.3 Non-replaced elements

#### 14.3.1 Hidden elements

```css
@namespace url(http://www.w3.org/1999/xhtml);

[hidden], area, base, basefont, datalist, head, link, meta, noembed, noframes, param, rp, script, source, style, template, track, title {
  display: none;
}

embed[hidden] { display: inline; height: 0; width: 0; }

input[type=hidden i] { display: none !important; }

@media (scripting) {
  noscript { display: none !important; }
}
```

#### 14.3.2 The page

```css
@namespace url(http://www.w3.org/1999/xhtml);

html, body { display: block; }
```

For each property in the table below, given a body element, the first attribute that exists maps to the pixel length property on the body element. If none of the attributes for a property are found, or if the value of the attribute that was found cannot be parsed successfully, then a default value of 8px is expected to be used for that property instead.

<table>
<thead>
<tr>
<th>Property</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>'margin-top'</td>
<td>The body element's marginheight attribute</td>
</tr>
<tr>
<td></td>
<td>The body element's toprightmargin attribute</td>
</tr>
<tr>
<td></td>
<td>The body element's container frame element's marginheight attribute</td>
</tr>
<tr>
<td>'margin-right'</td>
<td>The body element's marginwidth attribute</td>
</tr>
<tr>
<td></td>
<td>The body element's rightmargin attribute</td>
</tr>
<tr>
<td></td>
<td>The body element's container frame element's marginwidth attribute</td>
</tr>
<tr>
<td>'margin-bottom'</td>
<td>The body element's marginheight attribute</td>
</tr>
<tr>
<td></td>
<td>The body element's bottommargin attribute</td>
</tr>
</tbody>
</table>
If the body element's node document's browsing context is a nested browsing context, and the browsing context container of that nested browsing context is a frame or iframe element, then the container frame element of the body element is that frame or iframe element. Otherwise, there is no container frame element.

⚠Warning!
The above requirements imply that a page can change the margins of another page (including one from another origin) using, for example, an iframe. This is potentially a security risk, as it might in some cases allow an attack to contrive a situation in which a page is rendered not as the author intended, possibly for the purposes of phishing or otherwise misleading the user.

If a Document is in a nested browsing context, it is expected to be positioned and sized to fit inside the content box of its browsing context container. If a browsing context's browsing context container is not being rendered, the browsing context is expected to have a viewport with zero width and zero height.

If the Document is in a nested browsing context, and the browsing context container of that nested browsing context is a frame or iframe element, and that element has a scrolling attribute, and that attribute's value is an ASCII case-insensitive match for the string "off", "noscroll", or "no", then the user agent is expected to prevent any scroll bars from being shown for the viewport of the nested browsing context, regardless of the 'overflow' property that applies to that viewport.

When a body has a background attribute set to a non-empty value, the new value is expected to be parsed relative to the element's node document, and if this is successful, the user agent is expected to treat the attribute as a presentational hint setting the element’s ‘background-image’ property to the resulting URL string.

When a body element has a background-color attribute set, the new value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s ‘background-color’ property to the resulting color.

When a body has a text attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s ‘color’ property to the resulting color.

When a body element has a link attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the ‘color’ property of any element in the Document matching the :link pseudo-class to the resulting color.

When a body element has a vlink attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the ‘color’ property of any element in the Document matching the :visited pseudo-class to the resulting color.

When a body element has an alink attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the ‘color’ property of any element in the Document matching the :active pseudo-class and either the :link pseudo-class or the :visited pseudo-class to the resulting color.

### 14.3.3 Flow content

```
@namespace url(http://www.w3.org/1999/xhtml);

address, blockquote, center, dialog, div, figure, figcaption, footer, form,
header, hr, legend, listing, main, p, plaintext, pre, xmp {
  display: block;
}
```
The following rules are also expected to apply, as presentational hints:

CSS

```css
@namespace url(http://www.w3.org/1999/xhtml);
pre[wrap] { white-space: pre-wrap; }
```

In quirks mode, the following rules are also expected to apply:

CSS

```css
@namespace url(http://www.w3.org/1999/xhtml);
form { margin-block-end: 1em; }
```

The `center` element, and the `div` element when it has an `align` attribute whose value is an ASCII case-insensitive match for either the string "center" or the string "middle", are expected to center text within themselves, as if they had their `text-align` property set to 'center' in a presentational hint, and to align descendants to the center.

The `div` element, when it has an `align` attribute whose value is an ASCII case-insensitive match for the string "left", is expected to left-align text within itself, as if it had its `text-align` property set to 'left' in a presentational hint, and to align descendants to the left.

The `div` element, when it has an `align` attribute whose value is an ASCII case-insensitive match for the string "right", is expected to right-align text within itself, as if it had its `text-align` property set to 'right' in a presentational hint, and to align descendants to the right.

The `div` element, when it has an `align` attribute whose value is an ASCII case-insensitive match for the string "justify", is expected to full-justify text within itself, as if it had its `text-align` property set to 'justify' in a presentational hint, and to align descendants to the left.
The following rules are also expected to apply, as presentational hints.

For the purposes of the CSS ruby model, runs of children of `ruby` elements that are not `rt` or `rp` elements are expected to be wrapped in anonymous boxes whose `display` property has the value `ruby-base`. [CSSRUBY]

When a particular part of a ruby has more than one annotation, the annotations should be distributed on both sides of the base text so as to minimize the stacking of ruby annotations on one side.

User agents that do not support correct ruby rendering are expected to render parentheses around the text of `rt` elements in the absence of `rp` elements.
User agents are expected to support the `clear` property on inline elements (in order to render br elements with clear attributes) in the manner described in the non-normative note to this effect in the CSS specification.

The initial value for the `color` property is expected to be black. The initial value for the `background-color` property is expected to be 'transparent'. The canvas's background is expected to be white.

When a font element has a color attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s `color` property to the resulting color.

The font element is expected to override the color of any text decoration that spans the text of the element to the used value of the element’s `color` property.

When a font element has a face attribute, the user agent is expected to treat the attribute as a presentational hint setting the element’s `font-family` property to the attribute’s value.

When a font element has a size attribute, the user agent is expected to use the following steps, known as the rules for parsing a legacy font size, to treat the attribute as a presentational hint setting the element’s `font-size` property:

1. Let input be the attribute's value.
2. Let position be a pointer into input, initially pointing at the start of the string.
3. Skip ASCII whitespace within input given position.
4. If position is past the end of input, there is no presentational hint. Return.
5. If the character at position is a U+002B PLUS SIGN character (+), then let mode be relative-plus, and advance position to the next character. Otherwise, if the character at position is a U+002D HYPHEN-MINUS character (-), then let mode be relative-minus, and advance position to the next character. Otherwise, let mode be absolute.
6. Collect a sequence of code points that are ASCII digits from input given position, and let the resulting sequence be digits.
7. If digits is the empty string, there is no presentational hint. Return.
8. Interpret digits as a base-ten integer. Let value be the resulting number.
9. If mode is relative-plus, then increment value by 3. If mode is relative-minus, then let value be the result of subtracting value from 3.
10. If value is greater than 7, let it be 7.
11. If value is less than 1, let it be 1.
12. Set `font-size` to the keyword corresponding to the value of value according to the following table:

<table>
<thead>
<tr>
<th>value</th>
<th><code>font-size</code> keyword</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>'x-small'</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>'small'</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>'medium'</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>'large'</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>'x-large'</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>'xx-large'</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>'xxx-large'</td>
<td>see below</td>
</tr>
</tbody>
</table>

The 'xxx-large' value is a non-CSS value used here to indicate a font size 50% larger than 'xx-large'.

---

**14.3.5 Bidirectional text**

```css
@namespace url(http://www.w3.org/1999/xhtml);
[dir]:dir(ltr), bdi:dir(ltr), input[type=tel]:dir(ltr) { direction: ltr; }
[dir]:dir(rtl), bdi:dir(rtl) { direction: rtl; }
```
When an `input` element's `dir` attribute is in the `auto` state and its `type` attribute is in the `Text`, `Search`, `Telephone`, `URL`, or `E-mail` state, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the `unicode-bidi` property to `plaintext`.

Input fields (i.e. `textarea` elements, and `input` elements when their `type` attribute is in the `Text`, `Search`, `Telephone`, `URL`, or `E-mail` state) are expected to present an editing user interface with a directionality that matches the element's `direction` property.

When the document's character encoding is [ISO-8859-8](https://en.wikipedia.org/wiki/ISO/IEC_8859-8), the following rules are additionally expected to apply, following those above: [ENCODING]1122

### 14.3.6 Quotes §39

This block is automatically generated from the Unicode Common Locale Data Repository. [CLDR]1122

User agents are expected to use either the block below (which will be regularly updated) or to automatically generate their own copy directly from the source material. The language codes are derived from the CLDR file names. The quotes are derived from the delimiter blocks, with fallback handled as specified in the CLDR documentation.
14.3.7 Sections and headings

In the following CSS block, \( x \) is shorthand for the following selector: \( \text{matches(article, aside, nav, section)} \)

```css
@namespace url(http://www.w3.org/1999/xhtml);

article, aside, h1, h2, h3, h4, h5, h6, hgroup, nav, section {
    display: block;
}

h1 { margin-block-start: 0.67em; margin-block-end: 0.67em; font-size: 2.00em; font-weight: bold; }
h2 { margin-block-start: 0.83em; margin-block-end: 0.83em; font-size: 1.50em; font-weight: bold; }
h3 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; font-weight: bold; }
h4 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; font-weight: bold; }
h5 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; font-weight: bold; }
h6 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; font-weight: bold; }
```
The following rules are also expected to apply, as presentational hints:

```css
ol[type="1"], li[type="1"] { list-style-type: decimal; }
ol[type=a], li[type=a] { list-style-type: lower-alpha; }
ol[type=A], li[type=A] { list-style-type: upper-alpha; }
ol[type=i], li[type=i] { list-style-type: lower-roman; }
ol[type=I], li[type=I] { list-style-type: upper-roman; }
ul[type=none i], li[type=none i] { list-style-type: none; }
ul[type=disc i], li[type=disc i] { list-style-type: disc; }
ul[type=circle i], li[type=circle i] { list-style-type: circle; }
```
In the above style sheet, the attribute selectors for the \[ol\] and \[li\] elements are expected to be treated as case-sensitive.

When rendering \[li\] elements, non-CSS user agents are expected to use the ordinal value of the \[li\] element to render the counter in the list item marker.

This specification does not yet define the CSS-specific rules for rendering \[li\] elements, because CSS doesn't yet provide sufficient hooks for this purpose.

### 14.3.9 Tables

```css
@namespace url(http://www.w3.org/1999/xhtml);

table { display: table; }
caption { display: table-caption; }
colgroup, colgroup[hidden] { display: table-column-group; }
col, col[hidden] { display: table-column; }
thead, thead[hidden] { display: table-header-group; }
tbody, tbody[hidden] { display: table-row-group; }
tfoot, tfoot[hidden] { display: table-footer-group; }
tr, tr[hidden] { display: table-row; }
td, th { display: table-cell; }

colgroup[hidden], col[hidden], thead[hidden], tbody[hidden],
tfoot[hidden], tr[hidden] {
  visibility: collapse;
}

table {
  box-sizing: border-box;
  border-spacing: 2px;
  border-collapse: separate;
  text-indent: initial;
}

td, th { padding: 1px; }
th { font-weight: bold; }
caption { text-align: center; }
thead, tbody, tfoot, table > tr { vertical-align: middle; }
tr, td, th { vertical-align: inherit; }

table, td, th { border-color: gray; }
thead, tbody, tfoot, tr { border-color: inherit; }
table[rules=none i], table[rules=groups i], table[rules=rows i],
table[rules=cols i], table[rules=all i], table[frame=void i],
table[frame=above i], table[frame=below i], table[frame=hsides i],
table[frame=lhs i], table[frame=rhs i], table[frame=vsides i],
table[frame=box i], table[frame=border i],
table[rules=none i] > tr > td, table[rules=none i] > tr > th,
table[rules=groups i] > tr > td, table[rules=groups i] > tr > th,
table[rules=rows i] > tr > td, table[rules=rows i] > tr > th,
table[rules=cols i] > tr > td, table[rules=cols i] > tr > th,
table[rules=all i] > tr > td, table[rules=all i] > tr > th,
table[rules=none i] > thead > tr > td, table[rules=none i] > thead > tr > th,
table[rules=groups i] > thead > tr > td, table[rules=groups i] > thead > tr > th,
table[rules=rows i] > thead > tr > td, table[rules=rows i] > thead > tr > th,
table[rules=cols i] > thead > tr > td, table[rules=cols i] > thead > tr > th,
```
The following rules are also expected to apply, as presentational hints:

css
```css
@namespace url(http://www.w3.org/1999/xhtml);

table[align=left i] { float: left; }
table[align=right i] { float: right; }
table[align=center i] { margin-inline-start: auto; margin-inline-end: auto; }
thead[align=absmiddle i], tbody[align=absmiddle i], tfoot[align=absmiddle i],
tr[align=absmiddle i], td[align=absmiddle i], th[align=absmiddle i] {
  text-align: center;
}
caption[align=bottom i] { caption-side: bottom; }
p[align=left i], h1[align=left i], h2[align=left i], h3[align=left i], h4[align=left i], h5[align=left i], h6[align=left i] {
  text-align: left;
}
p[align=right i], h1[align=right i], h2[align=right i], h3[align=right i], h4[align=right i], h5[align=right i], h6[align=right i] {
  text-align: right;
}
p[align=center i], h1[align=center i], h2[align=center i], h3[align=center i], h4[align=center i], h5[align=center i], h6[align=center i] {
  text-align: center;
}
p[align=justify i], h1[align=justify i], h2[align=justify i], h3[align=justify i], h4[align=justify i], h5[align=justify i], h6[align=justify i] {
  text-align: justify;
}
thead[valign=top i], tbody[valign=top i], tfoot[valign=top i],
tr[valign=top i], td[valign=top i], th[valign=top i] {
  vertical-align: top;
}
thead[valign=middle i], tbody[valign=middle i], tfoot[valign=middle i],
tr[valign=middle i], td[valign=middle i], th[valign=middle i] {
  vertical-align: middle;
}
thead[valign=bottom i], tbody[valign=bottom i], tfoot[valign=bottom i],
tr[valign=bottom i], td[valign=bottom i], th[valign=bottom i] {
  vertical-align: bottom;
}
thead[valign=baseline i], tbody[valign=baseline i], tfoot[valign=baseline i],
tr[valign=baseline i], td[valign=baseline i], th[valign=baseline i] {
  vertical-align: baseline;
}
td[nowrap], th[nowrap] { white-space: nowrap; }
```
```css
table[rules=none i], table[rules=groups i], table[rules=rows i],
table[rules=cols i], table[rules=all i] {
    border-style: hidden;
    border-collapse: collapse;
}
table[border] { border-style: outset; } /* only if border is not equivalent to zero */
table[frame=void i] { border-style: hidden; }
table[frame=above i] { border-style: outset hidden hidden hidden; }
table[frame=below i] { border-style: hidden hidden outset hidden; }
table[frame=hsides i] { border-style: outset hidden outset hidden; }
table[frame=lhs i] { border-style: hidden hidden hidden outset; }
table[frame=rhs i] { border-style: hidden outset hidden hidden; }
table[frame=vsides i] { border-style: outset; }
table[frame=box i], table[frame=border i] { border-style: outset; }

table[border] > tr > td, table[border] > tr > th,
table[border] > thead > tr > td, table[border] > thead > tr > th,
table[border] > tbody > tr > td, table[border] > tbody > tr > th,
table[border] > tfoot > tr > td, table[border] > tfoot > tr > th {
    /* only if border is not equivalent to zero */
    border-width: 1px;
    border-style: inset;
}
table[rules=none i] > tr > td, table[rules=none i] > tr > th,
table[rules=none i] > thead > tr > td, table[rules=none i] > thead > tr > th,
table[rules=none i] > tbody > tr > td, table[rules=none i] > tbody > tr > th,
table[rules=none i] > tfoot > tr > td, table[rules=none i] > tfoot > tr > th,
table[rules=groups i] > tr > td, table[rules=groups i] > tr > th,
table[rules=groups i] > thead > tr > td, table[rules=groups i] > thead > tr > th,
table[rules=groups i] > tbody > tr > td, table[rules=groups i] > tbody > tr > th,
table[rules=groups i] > tfoot > tr > td, table[rules=groups i] > tfoot > tr > th,
table[rules=rows i] > tr > td, table[rules=rows i] > tr > th,
table[rules=rows i] > thead > tr > td, table[rules=rows i] > thead > tr > th,
table[rules=rows i] > tbody > tr > td, table[rules=rows i] > tbody > tr > th,
table[rules=rows i] > tfoot > tr > td, table[rules=rows i] > tfoot > tr > th {
    border-width: 1px;
    border-block-start-style: none;
    border-inline-end-style: solid;
    border-block-end-style: none;
    border-inline-start-style: solid;
}
table[rules=all i] > tr > td, table[rules=all i] > tr > th,
table[rules=all i] > thead > tr > td, table[rules=all i] > thead > tr > th,
table[rules=all i] > tbody > tr > td, table[rules=all i] > tbody > tr > th,
table[rules=all i] > tfoot > tr > td, table[rules=all i] > tfoot > tr > th {
    border-width: 1px;
    border-style: solid;
}
table[rules=groups i] > colgroup {
    border-inline-start-width: 1px;
    border-inline-start-style: solid;
    border-inline-end-width: 1px;
    border-inline-end-style: solid;
}
```
In quirks mode, the following rules are also expected to apply:

```css
@namespace url(http://www.w3.org/1999/xhtml);

table {
  font-weight: initial;
  font-style: initial;
  font-variant: initial;
  font-size: initial;
  line-height: initial;
  white-space: initial;
  text-align: initial;
}
```

For the purposes of the CSS table model, the `col` element is expected to be treated as if it was present as many times as its `span` attribute specifies.

For the purposes of the CSS table model, the `colgroup` element, if it contains no `col` element, is expected to be treated as if it had as many such children as its `span` attribute specifies.

For the purposes of the CSS table model, the `colspan` and `rowspan` attributes on `td` and `th` elements are expected to provide the special knowledge regarding cells spanning rows and columns.

In HTML documents, the following rules are also expected to apply:

```css
@namespace url(http://www.w3.org/1999/xhtml);

:matches(table, thead, tbody, tfoot, tr) > form {
  display: none !important;
}
```

The `table` element's `cellspacing` attribute maps to the pixel length property 'border-spacing' on the element.

The `table` element's `cellpadding` attribute maps to the pixel length properties 'padding-top', 'padding-right', 'padding-bottom', and 'padding-left' of any `td` and `th` elements that have corresponding `cells` in the `table`, corresponding to the `table` element.

The `table` element's `height` attribute maps to the dimension property (ignoring zero) 'height' on the `table` element.

The `table` element's `width` attribute maps to the dimension property (ignoring zero) 'width' on the `table` element.

The `col` element's `width` attribute maps to the dimension property (ignoring zero) 'width' on the `col` element.

The `tr` element's `height` attribute maps to the dimension property (ignoring zero) 'height' on the `tr` element.
The `td`\(^{446}\) and `th`\(^{451}\) elements' `height`\(^{4175}\) attributes map to the dimension property (ignoring zero)\(^{4134}\) `height` on the element.

The `td`\(^{446}\) and `th`\(^{451}\) elements' `width`\(^{4175}\) attributes map to the dimension property (ignoring zero)\(^{4134}\) `width` on the element.

The `thead`\(^{446}\), `tbody`\(^{445}\), `tfoot`\(^{447}\), `tr`\(^{448}\), `td`\(^{449}\), and `th`\(^{451}\) elements, when they have an align attribute whose value is an ASCII case-insensitive match for either the string "center" or the string "middle", are expected to center text within themselves, as if they had their `text-align` property set to 'center' in a presentational hint\(^{4133}\), and to align descendants\(^{4134}\) to the center.

The `thead`\(^{446}\), `tbody`\(^{445}\), `tfoot`\(^{447}\), `tr`\(^{448}\), `td`\(^{449}\), and `th`\(^{451}\) elements, when they have an align attribute whose value is an ASCII case-insensitive match for the string "left", are expected to left-align text within themselves, as if they had their `text-align` property set to 'left' in a presentational hint\(^{4133}\), and to align descendants\(^{4134}\) to the left.

The `thead`\(^{446}\), `tbody`\(^{445}\), `tfoot`\(^{447}\), `tr`\(^{448}\), `td`\(^{449}\), and `th`\(^{451}\) elements, when they have an align attribute whose value is an ASCII case-insensitive match for the string "right", are expected to right-align text within themselves, as if they had their `text-align` property set to 'right' in a presentational hint\(^{4133}\), and to align descendants\(^{4134}\) to the right.

The `thead`\(^{446}\), `tbody`\(^{445}\), `tfoot`\(^{447}\), `tr`\(^{448}\), `td`\(^{449}\), and `th`\(^{451}\) elements, when they have an align attribute whose value is an ASCII case-insensitive match for the string "justify", are expected to full-justify text within themselves, as if they had their `text-align` property set to 'justify' in a presentational hint\(^{4133}\), and to align descendants\(^{4134}\) to the left.

User agents are expected to have a rule in their user agent style sheet that matches `th`\(^{451}\) elements that have a parent node whose computed value for the `text-align` property is its initial value, whose declaration block consists of just a single declaration that sets the `text-align` property to the value 'center'.

When a `table`\(^{435}\), `thead`\(^{446}\), `tbody`\(^{445}\), `tfoot`\(^{447}\), `tr`\(^{448}\), `td`\(^{449}\), or `th`\(^{451}\) element has a `background`\(^{4175}\) attribute set to a non-empty value, the new value is expected to be parsed relative to the element's node document, and if this is successful, the user agent is expected to treat the attribute as a presentational hint\(^{4133}\) setting the element's `background-image` property to the resulting URL string\(^{486}\).

When a `table`\(^{435}\), `thead`\(^{446}\), `tbody`\(^{445}\), `tfoot`\(^{447}\), `tr`\(^{448}\), `td`\(^{449}\), or `th`\(^{451}\) element has a bgcolor attribute set, the new value is expected to be parsed using the rules for parsing a legacy color value\(^{483}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint\(^{4133}\) setting the element's `background-color` property to the resulting color.

When a `table`\(^{435}\) element has a bordercolor\(^{4175}\) attribute, its value is expected to be parsed using the rules for parsing a legacy color value\(^{483}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint\(^{4133}\) setting the element's `border-top-color`, `border-right-color`, `border-bottom-color`, and `border-left-color` properties to the resulting color.

The `table`\(^{435}\) element's `border`\(^{4175}\) attribute maps to the pixel length properties\(^{4113}\) `border-top-width`, `border-right-width`, `border-bottom-width`, and `border-left-width`, on the element. If the attribute is present but parsing the attribute's value using the rules for parsing non-negative integers\(^{466}\) generates an error, a default value of 1px is expected to be used for that property instead.

Rules marked "only if border is not equivalent to zero" in the CSS block above is expected to only be applied if the `border`\(^{4175}\) attribute mentioned in the selectors for the rule is not only present but, when parsed using the rules for parsing non-negative integers\(^{466}\), is also found to have a value other than zero or to generate an error.

In quirks mode, a `td`\(^{449}\) element or a `th`\(^{451}\) element that has a nowrap\(^{4175}\) attribute but also has a `width`\(^{4175}\) attribute whose value, when parsed using the rules for parsing nonzero dimension values\(^{469}\), is found to be a length (not an error or a number classified as a percentage), is expected to have a presentational hint\(^{4133}\) setting the element's `white-space` property to 'normal', overriding the rule in the CSS block above that sets it to 'nowrap'.

### 14.3.10 Margin collapsing quirks

A node is substantial if it is a text node that is not inter-element whitespace\(^{4125}\), or if it is an element node.

A node is blank if it is an element that contains no substantial\(^{4151}\) nodes.

The elements with default margins are the following elements: `blockquote`\(^{410}\), `dir`\(^{41170}\), `dl`\(^{429}\), `h1`\(^{4183}\), `h2`\(^{4183}\), `h3`\(^{4183}\), `h4`\(^{4183}\), `h5`\(^{4183}\).
In quirks mode, any element with default margins that is the child of a body, td, or th element and has no substantial previous siblings is expected to have a user-agent level style sheet rule that sets its 'margin-block-start' property to zero.

In quirks mode, any element with default margins that is the child of a body, td, or th element, has no substantial previous siblings, and is blank, is expected to have a user-agent level style sheet rule that sets its 'margin-block-end' property to zero also.

In quirks mode, any element with default margins that is the child of a td or th element, has no substantial following siblings, and is blank, is expected to have a user-agent level style sheet rule that sets its 'margin-block-start' property to zero.

In quirks mode, any element that is the child of a td or th element and has no substantial following siblings, is expected to have a user-agent level style sheet rule that sets its 'margin-block-end' property to zero.

### 14.3.11 Form controls

```css
@namespace url(http://www.w3.org/1999/xhtml);

input, select, option, optgroup, button, textarea {
  text-indent: initial;
}

input:matches([type=radio i], [type=checkbox i], [type=reset i], [type=button i], [type=submit i], [type=search i]), select, button {
  box-sizing: border-box;
}

textarea { white-space: pre-wrap; }
```

In quirks mode, the following rules are also expected to apply:

```css
@namespace url(http://www.w3.org/1999/xhtml);

input:not([type=image i]), textarea { box-sizing: border-box; }
```

Each kind of form control is also described in the *Widgets* section, which describes the look and feel of the control.

### 14.3.12 The hr element

```css
@namespace url(http://www.w3.org/1999/xhtml);

hr {
  color: gray;
  border-style: inset;
  border-width: 1px;
  margin-block-start: 0.5em;
  margin-inline-end: auto;
  margin-block-end: 0.5em;
  margin-inline-start: auto;
  overflow: hidden;
}
```

The following rules are also expected to apply, as *presentational hints*:

```css
@namespace url(http://www.w3.org/1999/xhtml);
```
If an `hr` element has either a `color` attribute or a `noshade` attribute, and furthermore also has a `size` attribute, and parsing that attribute's value using the `rules for parsing non-negative integers` doesn't generate an error, then the user agent is expected to use the parsed value divided by two as a pixel length for `presentational hints` for the properties `'border-top-width'`, `'border-right-width'`, `'border-bottom-width'`, and `'border-left-width'` on the element.

Otherwise, if an `hr` element has neither a `color` attribute nor a `noshade` attribute, but does have a `size` attribute, and parsing that attribute's value using the `rules for parsing non-negative integers` doesn't generate an error, then: if the parsed value is one, then the user agent is expected to use the attribute as a `presentational hint` setting the element's `'border-bottom-width'` to 0; otherwise, if the parsed value is greater than one, then the user agent is expected to use the parsed value minus two as a pixel length for `presentational hints` for the `'height'` property on the element.

The `width` attribute on an `hr` element maps to the dimension property `'width'` on the element.

When an `hr` element has a `color` attribute, its value is expected to be parsed using the `rules for parsing a legacy color value`, and if that does not return an error, the user agent is expected to treat the attribute as a `presentational hint` setting the element's `'color'` property to the resulting color.

### 14.3.13 The `fieldset` and `legend` elements

The `fieldset` element is expected to establish a new block formatting context.

If the `fieldset` element has a `child` that matches the conditions in the list below, then the first such child is the `fieldset` element's `rendered legend`:

- The child is a `legend` element.
- The child is not `out-of-flow` (e.g. not absolutely positioned or floated).
- The child is generating a box (e.g. it is not `display:none` or `display:contents`).

A `fieldset` element's `rendered legend`, if any, is expected to be rendered over the `block-start border edge` of the `fieldset` element as a `block box` (overriding any explicit `'display'` value). In the absence of an explicit `inline size`, the box should shrink-wrap. The element is expected to establish a new block formatting context. If the `legend` element in question has an `align` attribute, and its value is an `ASCII case-insensitive` match for one of the strings in the first column of the following table, then the `legend` is expected to be rendered aligned in the inline direction over the `border edge` in the position given in the corresponding cell on the same row in the second column. If the attribute is absent or has a value that doesn't match any of the cases in the table, then the position is expected to be on the `inline-start` side. [CSSWM]
14.4 Replaced elements

The following elements can be replaced elements: audio, canvas, embed, iframe, img, input, object, and video.

14.4.1 Embedded content

The embed, iframe, and video elements are expected to be treated as replaced elements.

A canvas element that represents embedded content is expected to be treated as a replaced element; the contents of such elements are the element's bitmap, if any, or else a transparent black bitmap with the same intrinsic dimensions as the element. Other canvas elements are expected to be treated as ordinary elements in the rendering model.

An object element that represents an image, plugin, or nested browsing context is expected to be treated as a replaced element. Other object elements are expected to be treated as ordinary elements in the rendering model.

The audio element, when it is exposing a user interface, is expected to be treated as a replaced element about one line high, as wide as is necessary to expose the user agent's user interface features. When an audio element is not exposing a user interface, the user agent is expected to force its 'display' property to compute to 'none', irrespective of CSS rules.

Whether a video element is exposing a user interface is not expected to affect the size of the rendering; controls are expected to be overlaid above the page content without causing any layout changes, and are expected to disappear when the user agent does not need them.

When a video element represents a poster frame or frame of video, the poster frame or frame of video is expected to be rendered at the largest size that maintains the aspect ratio of that poster frame or frame of video without being taller or wider than the video element itself, and is expected to be centered in the video element.

Any subtitles or captions are expected to be overlayed directly on top of their video element, as defined by the relevant rendering rules; for WebVTT, those are the rules for updating the display of WebVTT text tracks. [WEBVTT]

When the user agent starts exposing a user interface for a video element, the user agent should run the rules for updating the text track rendering of each of the text tracks in the video element's list of text tracks that are showing and whose text track kind is one of subtitles or captions (e.g., for text tracks based on WebVTT, the rules for updating the display of WebVTT text tracks). [WEBVTT]

Resizing video and canvas elements does not interrupt video playback or clear the canvas.

The following CSS rules are expected to apply:

```css
css
@namespace url(http://www.w3.org/1999/xhtml);

iframe { border: 2px inset; }
video { object-fit: contain; }
```
User agents are expected to render `img` elements and `input` elements whose `type` attributes are in the Image Button state, according to the first applicable rules from the following list:

↪ If the element represents an image

The user agent is expected to treat the element as a replaced element and render the image according to the rules for doing so defined in CSS.

↪ If the element does not represent an image, but the element already has intrinsic dimensions (e.g. from the dimension attributes or CSS rules), and either:
• the user agent has reason to believe that the image will become available and be rendered in due course, or
• the element has no alt attribute, or
• the Document is in quirks mode

The user agent is expected to treat the element as a replaced element whose content is the text that the element represents, if any, optionally alongside an icon indicating that the image is being obtained (if applicable). For `input` elements, the element is expected to appear button-like to indicate that the element is a button.

↪ If the element is an `img` element that represents some text and the user agent does not expect this to change

The user agent is expected to treat the element as a non-replaced phrasing element whose content is the text, optionally with an icon indicating that an image is missing, so that the user can request the image be displayed or investigate why it is not rendering. In non-graphical contexts, such an icon should be omitted.

↪ If the element is an `img` element that represents nothing and the user agent does not expect this to change

The user agent is expected to treat the element as an empty inline element. (In the absence of further styles, this will cause the element to essentially not be rendered.)

↪ If the element is an `input` element that does not represent an image and the user agent does not expect this to change

The user agent is expected to treat the element as a replaced element consisting of a button whose content is the element’s alternative text. The intrinsic dimensions of the button are expected to be about one line in height and whatever width is necessary to render the text on one line.

The icons mentioned above are expected to be relatively small so as not to disrupt most text but be easily clickable. In a visual environment, for instance, icons could be 16 pixels by 16 pixels square, or 1em by 1em if the images are scalable. In an audio environment, the icon could be a short bleep. The icons are intended to indicate to the user that they can be used to get to whatever options the UA provides for images, and, where appropriate, are expected to provide access to the context menu that would have come up if the user interacted with the actual image.

All animated images with the same absolute URL and the same image data are expected to be rendered synchronized to the same timeline as a group, with the timeline starting at the time of the least recent addition to the group.

In other words, when a second image with the same absolute URL and animated image data is inserted into a document, it jumps to the point in the animation cycle that is currently being displayed by the first image.

When a user agent is to restart the animation for an `img` element showing an animated image, all animated images with the same absolute URL and the same image data in that `img` element's node document are expected to restart their animation from the beginning.

The following CSS rules are expected to apply when the Document is in quirks mode:

```
<css>
@namespace url(http://www.w3.org/1999/xhtml);

img[align=left] { margin-right: 3px; }
img[align=right] { margin-left: 3px; }
</css>
```
The following CSS rules are expected to apply as presentational hints:

```css
@namespace url(http://www.w3.org/1999/xhtml);

iframe[frameborder=0], iframe[frameborder=no i] { border: none; }
embed[align=left i], iframe[align=left i], img[align=left i],
input[type=image i][align=left i], object[align=left i] {
  float: left;
}
embed[align=right i], iframe[align=right i], img[align=right i],
input[type=image i][align=right i], object[align=right i] {
  float: right;
}
embed[align=top i], iframe[align=top i], img[align=top i],
input[type=image i][align=top i], object[align=top i] {
  vertical-align: top;
}
embed[align=baseline i], iframe[align=baseline i], img[align=baseline i],
input[type=image i][align=baseline i], object[align=baseline i] {
  vertical-align: baseline;
}
embed[align=texttop i], iframe[align=texttop i], img[align=texttop i],
input[type=image i][align=texttop i], object[align=texttop i] {
  vertical-align: text-top;
}
embed[align=absmiddle i], iframe[align=absmiddle i], img[align=absmiddle i],
input[type=image i][align=absmiddle i], object[align=absmiddle i],
embed[align=abscenter i], iframe[align=abscenter i], img[align=abscenter i],
input[type=image i][align=abscenter i], object[align=abscenter i] {
  vertical-align: middle;
}
embed[align=bottom i], iframe[align=bottom i], img[align=bottom i],
input[type=image i][align=bottom i], object[align=bottom i] {
  vertical-align: bottom;
}
```

When an `embed`, `iframe`, `img`, or `object` element, or an `input` element whose `type` attribute is in the Image Button state, has an align attribute whose value is an ASCII case-insensitive match for the string "center" or the string "middle", the user agent is expected to act as if the element's `vertical-align` property was set to a value that aligns the vertical middle of the element with the parent element's baseline.

The `hspace` attribute of `embed`, `iframe`, `img`, or `object` elements, and `input` elements with a `type` attribute in the Image Button state, maps to the dimension properties `margin-left` and `margin-right` on the element.

The `vspace` attribute of `embed`, `iframe`, `img`, or `object` elements, and `input` elements with a `type` attribute in the Image Button state, maps to the dimension properties `margin-top` and `margin-bottom` on the element.

When an `img` element, `object`, or `input` element with a `type` attribute in the Image Button state has a border attribute whose value, when parsed using the rules for parsing non-negative integers, is found to be a number greater than zero, the user agent is expected to use the parsed value for eight presentational hints: four setting the parsed value as a pixel length for the element's `border-top-width`, `border-right-width`, `border-bottom-width`, and `border-left-width` properties, and four setting the element's `border-top-style`, `border-right-style`, `border-bottom-style`, and `border-left-style` properties to the value 'solid'.

The `width` and `height` attributes on `embed`, `iframe`, `img`, `object`, and `video` elements, and `input` elements...
with a \texttt{type}\textsuperscript{p478} attribute in the \texttt{ImageButton}\textsuperscript{p501} state and that either represents an image or that the user expects will eventually represent an image, \texttt{map to the dimension properties}\textsuperscript{p1133} \texttt{'width'} and \texttt{'height'} on the element respectively.

14.4.4 Image maps \textsuperscript{p11}

Shapes on an \texttt{image map}\textsuperscript{p430} are expected to act, for the purpose of the CSS cascade, as elements independent of the original \texttt{area}\textsuperscript{p428} element that happen to match the same style rules but inherit from the \texttt{img}\textsuperscript{p307} or \texttt{object}\textsuperscript{p358} element.

For the purposes of the rendering, only the \texttt{'cursor'} property is expected to have any effect on the shape.

\textbf{Example}

Thus, for example, if an \texttt{area}\textsuperscript{p428} element has a \texttt{style}\textsuperscript{p141} attribute that sets the \texttt{'cursor'} property to 'help', then when the user designates that shape, the cursor would change to a Help cursor.

\textbf{Example}

Similarly, if an \texttt{area}\textsuperscript{p428} element had a CSS rule that set its \texttt{'cursor'} property to 'inherit' (or if no rule setting the \texttt{'cursor'} property matched the element at all), the shape's cursor would be inherited from the \texttt{img}\textsuperscript{p307} or \texttt{object}\textsuperscript{p358} element of the \texttt{image map}\textsuperscript{p430}, not from the parent of the \texttt{area}\textsuperscript{p428} element.

14.5 Widgets \textsuperscript{p11}

14.5.1 Introduction \textsuperscript{p11}

The elements defined in this section can be rendered in a variety of manners, within the guidelines provided below. User agents are encouraged to set the \texttt{appearance} CSS property appropriately to achieve platform-native appearances for widgets, and are expected to implement any relevant animations, etc., that are appropriate for the platform.

14.5.2 The \texttt{button}\textsuperscript{p518} element \textsuperscript{p11}

The \texttt{button}\textsuperscript{p518} element expected to render as a \texttt{'inline-block'} box depicting a button whose contents are the contents of the element.

14.5.3 The \texttt{details}\textsuperscript{p584} and \texttt{summary}\textsuperscript{p588} elements \textsuperscript{p11}

\begin{verbatim}
@namespace url(http://www.w3.org/1999/xhtml);

summary {
    display: list-item;
    counter-increment: list-item 0;
    list-style: disclosure-closed inside;
}
details[open] > summary {
    list-style-type: disclosure-open;
}
\end{verbatim}

The \texttt{details}\textsuperscript{p584} element is expected to render as a \texttt{block box}. The element's shadow tree is expected to take the element's first \texttt{summary}\textsuperscript{p588} element child, if any, and place it in a first \texttt{block box} container, and then take the element's remaining descendants, if any, and place them in a second \texttt{block box} container.

The first container is expected to allow the user to request the details be shown or hidden.

The second container is expected to be removed from the rendering when the \texttt{details}\textsuperscript{p584} element does not have an \texttt{open}\textsuperscript{p585} attribute.
### 14.5.4 The `input` element as a text entry widget

An `input` element whose `type` attribute is in the `Text`, `Search`, `Telephone`, `URL`, or `E-mail` state, is expected to render as an `inline-block` box depicting a text control. Additionally, the `line-height` property, if it has a computed value equivalent to a value that is less than 1.0, must have a `used value` of 1.0.

An `input` element whose `type` attribute is in the `Password` state is expected to render as an `inline-block` box depicting a text control that obscures data entry.

If these text controls provide a text selection, then, when the user changes the current selection, the user agent is expected to queue a task, using the user interaction task source, to fire an event named `select` at the element, with the `bubbles` attribute initialized to true.

If an `input` element whose `type` attribute is in one of the above states has a `size` attribute, and parsing that attribute's value using the rules for parsing non-negative integers doesn't generate an error, then the user agent is expected to use the attribute as a presentational hint for the `width` property on the element, with the value obtained from applying the `converting a character width to pixels` algorithm to the value of the attribute.

If an `input` element whose `type` attribute is in one of the above states does not have a `size` attribute, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the `width` property on the element to the number 20.

The `converting a character width to pixels` algorithm returns \((size-1) \times \text{avg} + \text{max}\), where `size` is the character width to convert, `avg` is the average character width of the primary font for the element for which the algorithm is being run, in pixels, and `max` is the maximum character width of that same font, also in pixels. (The element's `letter-spacing` property does not affect the result.)

### 14.5.5 The `input` element as domain-specific widgets

An `input` element whose `type` attribute is in the `Date` state is expected to render as an `inline-block` box depicting a date control.

An `input` element whose `type` attribute is in the `Month` state is expected to render as an `inline-block` box depicting a month control.

An `input` element whose `type` attribute is in the `Week` state is expected to render as an `inline-block` box depicting a week control.

An `input` element whose `type` attribute is in the `Time` state is expected to render as an `inline-block` box depicting a time control.

An `input` element whose `type` attribute is in the `Local Date and Time` state is expected to render as an `inline-block` box depicting a local date and time control.

An `input` element whose `type` attribute is in the `Number` state is expected to render as an `inline-block` box depicting a number control.

These controls are all expected to be about one line high, and about as wide as necessary to show the widest possible value.

### 14.5.6 The `input` element as a range control

An `input` element whose `type` attribute is in the `Range` state is expected to render as an `inline-block` box depicting a slider control.

When the control is wider than it is tall (or square), the control is expected to be a horizontal slider, with the lowest value on the right if the `direction` property on this element has a computed value of `rtl`, and on the left otherwise. When the control is taller than it is wide, it is expected to be a vertical slider, with the lowest value on the bottom.

Predefined suggested values (provided by the `list` attribute) are expected to be shown as tick marks on the slider, which the slider can snap to.
User agents are expected to use the used value of the 'direction' property on the element to determine the direction in which the slider operates. Typically, a left-to-right ('ltr') horizontal control would have the lowest value on the left and the highest value on the right, and vice versa.

### 14.5.7 The **input** element as a color well

An **input** element whose type attribute is in the Color state is expected to render as an 'inline-block' box depicting a color well, which, when activated, provides the user with a color picker (e.g., a color wheel or color palette) from which the color can be changed.

Predefined suggested values (provided by the list attribute) are expected to be shown in the color picker interface, not on the color well itself.

### 14.5.8 The **input** element as a checkbox and radio button widgets

An **input** element whose type attribute is in the Checkbox state is expected to render as an 'inline-block' box containing a single checkbox control, with no label.

An **input** element whose type attribute is in the Radio Button state is expected to render as an 'inline-block' box containing a single radio button control, with no label.

### 14.5.9 The **input** element as a file upload control

An **input** element whose type attribute is in the File Upload state is expected to render as an 'inline-block' box containing a span of text giving the file name(s) of the selected files, if any, followed by a button that, when activated, provides the user with a file picker from which the selection can be changed.

### 14.5.10 The **input** element as a button

An **input** element whose type attribute is in the Submit Button, Reset Button, or Button state is expected to render as an 'inline-block' box depicting a button, about one line high, containing the contents of the element's value attribute, if any, or text derived from the element's type attribute in a user-agent-defined (and probably locale-specific) fashion, if not.

### 14.5.11 The **marquee** element

The **marquee** element, while turned on, is expected to render in an animated fashion according to its attributes as follows:

**If the element’s behavior attribute is in the scroll state**

Slide the contents of the element in the direction described by the direction attribute as defined below, such that it begins off the start side of the marquee, and ends flush with the inner end side.

**Example**

For example, if the direction attribute is left (the default), then the contents would start such that their left edge are off the side of the right edge of the marquee's content area, and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the marquee's content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index. If the element is still turned on after this, then the user agent is expected to restart the animation.

**If the element’s behavior attribute is in the slide state**

Slide the contents of the element in the direction described by the direction attribute as defined below, such that it begins off
the start side of the `marquee` element, and ends off the end side of the `marquee` element.

Example

For example, if the `direction` attribute is `left` (the default), then the contents would start such that their left edge are off the right side of the `marquee` element's content area, and the contents would then slide up to the point where the right edge of the contents are flush with the left inner edge of the `marquee` element's content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index. If the element is still turned on after this, then the user agent is expected to restart the animation.

If the element's `behavior` attribute is in the alternate state

When the `marquee current loop index` is even (or zero), slide the contents of the element in the direction described by the `direction` attribute as defined below, such that it begins flush with the start side of the `marquee`, and ends flush with the end side of the `marquee` element.

When the `marquee current loop index` is odd, slide the contents of the element in the opposite direction than that described by the `direction` attribute as defined below, such that it begins flush with the end side of the `marquee`, and ends flush with the start side of the `marquee` element.

Example

For example, if the `direction` attribute is `left` (the default), then the contents would start such that their left edge are off the right side of the `marquee` element's content area, and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the `marquee` element's content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index. If the element is still turned on after this, then the user agent is expected to continue the animation.

The `direction` attribute has the meanings described in the following table:

<table>
<thead>
<tr>
<th><code>direction</code> attribute state</th>
<th>Direction of animation</th>
<th>Start edge</th>
<th>End edge</th>
<th>Opposite direction</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>left</code></td>
<td>← Right to left</td>
<td>Right</td>
<td>Left</td>
<td>→ Left to Right</td>
</tr>
<tr>
<td><code>right</code></td>
<td>→ Left to Right</td>
<td>Left</td>
<td>Right</td>
<td>← Right to left</td>
</tr>
<tr>
<td><code>up</code></td>
<td>↑ Up (Bottom to Top)</td>
<td>Bottom</td>
<td>Top</td>
<td>↓ Down (Top to Bottom)</td>
</tr>
<tr>
<td><code>down</code></td>
<td>↓ Down (Top to Bottom)</td>
<td>Top</td>
<td>Bottom</td>
<td>↑ Up (Bottom to Top)</td>
</tr>
</tbody>
</table>

In any case, the animation should proceed such that there is a delay given by the `marquee scroll interval` between each frame, and such that the content moves at most the distance given by the `marquee scroll distance` with each frame.

When a `marquee` element has a `bgcolor` attribute set, the value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element's `background-color` property to the resulting color.

The `width` and `height` attributes on a `marquee` element map to the dimension properties 'width' and 'height' on the element respectively.

The `intrinsic height` of a `marquee` element with its `direction` attribute in the `up` or `down` states is 200 CSS pixels.

The `vspace` attribute of a `marquee` element maps to the dimension properties 'margin-top' and 'margin-bottom' on the element. The `hspace` attribute of a `marquee` element maps to the dimension properties 'margin-left' and 'margin-right' on the element.

The `overflow` property on the `marquee` element is expected to be ignored; overflow is expected to always be hidden.

14.5.12 The `meter` element

The `meter` element is expected to render as an 'inline-block' box with a 'height' of '1em' and a 'width' of '5em', a 'vertical-align' of '0.2em', and with its contents depicting a gauge.

When the element is wider than it is tall (or square), the depiction is expected to be of a horizontal gauge, with the minimum value on the right if the `direction` property on this element has a computed value of 'rtl', and on the left otherwise. When the element is taller
than it is wide, it is expected to depict a vertical gauge, with the minimum value on the bottom.

User agents are expected to use a presentation consistent with platform conventions for gauges, if any.

**Note**

Requirements for what must be depicted in the gauge are included in the definition of the `meter` element.

### 14.5.13 The `progress` element

The `progress` element is expected to render as an `inline-block` box with a `height` of `1em` and a `width` of `10em`, and a `vertical-align` of `-0.2em`.

![Progress Bars (80%)](image)

When the element is wider than it is tall, the element is expected to be depicted as a horizontal progress bar, with the start on the right and the end on the left if the `direction` property on this element has a computed value of `rtl`, and with the start on the left and the end on the right otherwise. When the element is taller than it is wide, it is expected to be depicted as a vertical progress bar, with the lowest value on the bottom. When the element is square, it is expected to be depicted as a direction-independent progress widget (e.g. a circular progress ring).

User agents are expected to use a presentation consistent with platform conventions for progress bars. In particular, user agents are expected to use different presentations for determinate and indeterminate progress bars. User agents are also expected to vary the presentation based on the dimensions of the element.

**Example**

For example, on some platforms for showing indeterminate progress there is a "spinner" progress indicator with square dimensions, which could be used when the element is square, and an indeterminate progress bar, which could be used when the element is wide.

**Note**

Requirements for how to determine if the progress bar is determinate or indeterminate, and what progress a determinate progress bar is to show, are included in the definition of the `progress` element.

### 14.5.14 The `select` element

A `select` element whose `multiple` attribute is present is expected to render as a multi-select list box.

A `select` element whose `multiple` attribute is absent, and whose `display size` is greater than 1, is expected to render as a single-select list box.

When the element renders as a list box, it is expected to render as an `inline-block` box whose `height` is the height necessary to contain as many rows for items as given by the element's `display size`, or four rows if the attribute is absent, and whose `width` is the *width of the select's labels* plus the width of a scrollbar.

A `select` element whose `multiple` attribute is absent, and whose `display size` is 1, is expected to render as a one-line drop down box whose width is the *width of the select's labels*.

In either case (list box or drop-down box), the element's items are expected to be the element's *list of options*, with the element's `optgroup` children providing headers for groups of options where applicable.

An `optgroup` element is expected to be rendered by displaying the element's `label` attribute.

An `option` element is expected to be rendered by displaying the element's `label`, indented under its `optgroup` element if it has one.
The width of the `select`'s labels is the wider of the width necessary to render the widest `optgroup`, and the width necessary to render the widest `option` element in the element's list of options (including its indent, if any).

If a `select` element contains a placeholder label option, the user agent is expected to render that `option` in a manner that conveys that it is a label, rather than a valid option of the control. This can include preventing the `placeholder label option` from being explicitly selected by the user. When the `placeholder label option`'s `selectedness` is true, the control is expected to be displayed in a fashion that indicates that no valid option is currently selected.

User agents are expected to render the labels in a `select` in such a manner that any alignment remains consistent whether the label is being displayed as part of the page or in a menu control.

### 14.5.15 The `textarea` element

The `textarea` element is expected to render as an `inline-block` box depicting a multiline text control. If this multilime text control provides a selection, then, when the user changes the current selection, the user agent is expected to queue a task, using the `user interaction task source`, to fire an event named `select` at the element, with the `bubbles` attribute initialized to true.

If the element has a `cols` attribute, and parsing that attribute's value using the rules for parsing non-negative integers doesn't generate an error, then the user agent is expected to use the attribute as a `presentational hint` for the 'width' property on the element, with the value being the `textarea effective width` (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'width' property on the element to the `textarea effective width`.

The `textarea effective width` of a `textarea` element is `size×avg + sbw`, where `size` is the element's `character width`, `avg` is the average character width of the primary font of the element, in CSS pixels, and `sbw` is the width of a scroll bar, in CSS pixels. (The element's 'letter-spacing' property does not affect the result.)

If the element has a `rows` attribute, and parsing that attribute's value using the rules for parsing non-negative integers doesn't generate an error, then the user agent is expected to use the attribute as a `presentational hint` for the 'height' property on the element, with the value being the `textarea effective height` (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'height' property on the element to the `textarea effective height`.

The `textarea effective height` of a `textarea` element is the height in CSS pixels of the number of lines specified the element's `character height`, plus the height of a scrollbar in CSS pixels.

User agents are expected to apply the 'white-space' CSS property to `textarea` elements. For historical reasons, if the element has a `wrap` attribute whose value is an ASCII case-insensitive match for the string "off", then the user agent is expected to treat the attribute as a `presentational hint`, setting the element's 'white-space' property to 'pre'.

### 14.6 Frames and framesets

User agent are expected to render `frameset` elements as a box with the height and width of the `viewport`, with a surface rendered according to the following layout algorithm:

1. The `cols` and `rows` variables are lists of zero or more pairs consisting of a number and a unit, the unit being one of `percentage`, `relative`, and `absolute`.

   Use the rules for parsing a list of dimensions to parse the value of the element's `cols` attribute, if there is one. Let `cols` be the result, or an empty list if there is no such attribute.

   Use the rules for parsing a list of dimensions to parse the value of the element's `rows` attribute, if there is one. Let `rows` be the result, or an empty list if there is no such attribute.

2. For any of the entries in `cols` or `rows` that have the number zero and the unit `relative`, change the entry's number to one.

3. If `cols` has no entries, then add a single entry consisting of the value 1 and the unit `relative` to `cols`.

   If `rows` has no entries, then add a single entry consisting of the value 1 and the unit `relative` to `rows`.

4. Invoke the algorithm defined below to convert a list of dimensions to a list of pixel values using `cols` as the input list, and the width of the surface that the `frameset` is being rendered into, in CSS pixels, as the input dimension. Let sized `cols` be
the resulting list.

Invoke the algorithm defined below to convert a list of dimensions to a list of pixel values using rows as the input list, and the height of the surface that the frameset is being rendered into, in CSS pixels, as the input dimension. Let sized rows be the resulting list.

5. Split the surface into a grid of \( w \times h \) rectangles, where \( w \) is the number of entries in sized cols and \( h \) is the number of entries in sized rows.

Size the columns so that each column in the grid is as many CSS pixels wide as the corresponding entry in the sized cols list.

Size the rows so that each row in the grid is as many CSS pixels high as the corresponding entry in the sized rows list.

6. Let \( \text{children} \) be the list of frame and frameset elements that are children of the frameset element for which the algorithm was invoked.

7. For each row of the grid of rectangles created in the previous step, from top to bottom, run these substeps:

   1. For each rectangle in the row, from left to right, run these substeps:
      
      1. If there are any elements left in \( \text{children} \), take the first element in the list, and assign it to the rectangle. If this is a frameset element, then recurse the entire frameset layout algorithm for that frameset element, with the rectangle as the surface. Otherwise, it is a frame element; render its nested browsing context, positioned and sized to fit the rectangle.

      2. If there are any elements left in \( \text{children} \), remove the first element from \( \text{children} \).

8. If the frameset element has a border, draw an outer set of borders around the rectangles, using the element’s frame border color.

   For each rectangle, if there is an element assigned to that rectangle, and that element has a border, draw an inner set of borders around that rectangle, using the element’s frame border color.

   For each (visible) border that does not abut a rectangle that is assigned a frame element with a noresize attribute (including rectangles in further nested frameset elements), the user agent is expected to allow the user to move the border, resizing the rectangles within, keeping the proportions of any nested frameset grids.

A frameset or frame element has a border if the following algorithm returns true:

   1. If the element has a frameborder attribute whose value is not the empty string and whose first character is either a U+0031 DIGIT ONE (1) character, a U+0079 LATIN SMALL LETTER Y character (y), or a U+0059 LATIN CAPITAL LETTER Y character (Y), then return true.

   2. Otherwise, if the element has a frameborder attribute, return false.

   3. Otherwise, if the element has a parent element that is a frameset element, then return true if that element has a border, and false if it does not.

   4. Otherwise, return true.

The frame border color of a frameset or frame element is the color obtained from the following algorithm:

   1. If the element has a bordercolor attribute, and applying the rules for parsing a legacy color value to that attribute’s value does not result in an error, then return the color so obtained.

   2. Otherwise, if the element has a parent element that is a frameset element, then return the frame border color of that element.

   3. Otherwise, return gray.

The algorithm to convert a list of dimensions to a list of pixel values consists of the following steps:

1. Let \( \text{input list} \) be the list of numbers and units passed to the algorithm.

   Let \( \text{output list} \) be a list of numbers the same length as \( \text{input list} \), all zero.

   Entries in \( \text{output list} \) correspond to the entries in \( \text{input list} \) that have the same position.
2. Let \( \text{input dimension} \) be the size passed to the algorithm.

3. Let \( \text{count percentage} \) be the number of entries in \( \text{input list} \) whose unit is \( \text{percentage} \).
   Let \( \text{total percentage} \) be the sum of all the numbers in \( \text{input list} \) whose unit is \( \text{percentage} \).
   Let \( \text{count relative} \) be the number of entries in \( \text{input list} \) whose unit is \( \text{relative} \).
   Let \( \text{total relative} \) be the sum of all the numbers in \( \text{input list} \) whose unit is \( \text{relative} \).
   Let \( \text{count absolute} \) be the number of entries in \( \text{input list} \) whose unit is \( \text{absolute} \).
   Let \( \text{total absolute} \) be the sum of all the numbers in \( \text{input list} \) whose unit is \( \text{absolute} \).
   Let \( \text{remaining space} \) be the value of \( \text{input dimension} \).

4. If \( \text{total absolute} \) is greater than \( \text{remaining space} \), then for each entry in \( \text{input list} \) whose unit is \( \text{absolute} \), set the corresponding value in \( \text{output list} \) to the number of the entry in \( \text{input list} \) multiplied by \( \text{remaining space} \) and divided by \( \text{total absolute} \). Then, set \( \text{remaining space} \) to zero.
   Otherwise, for each entry in \( \text{input list} \) whose unit is \( \text{absolute} \), set the corresponding value in \( \text{output list} \) to the number of the entry in \( \text{input list} \). Then, decrement \( \text{remaining space} \) by \( \text{total absolute} \).

5. If \( \text{total percentage} \) multiplied by the \( \text{input dimension} \) and divided by 100 is greater than \( \text{remaining space} \), then for each entry in \( \text{input list} \) whose unit is \( \text{percentage} \), set the corresponding value in \( \text{output list} \) to the number of the entry in \( \text{input list} \) multiplied by \( \text{remaining space} \) and divided by \( \text{total percentage} \). Then, set \( \text{remaining space} \) to zero.
   Otherwise, for each entry in \( \text{input list} \) whose unit is \( \text{percentage} \), set the corresponding value in \( \text{output list} \) to the number of the entry in \( \text{input list} \) multiplied by the \( \text{input dimension} \) and divided by 100. Then, decrement \( \text{remaining space} \) by \( \text{total percentage} \) multiplied by the \( \text{input dimension} \) and divided by 100.

6. For each entry in \( \text{input list} \) whose unit is \( \text{relative} \), set the corresponding value in \( \text{output list} \) to the number of the entry in \( \text{input list} \) multiplied by \( \text{remaining space} \) and divided by \( \text{total relative} \).

7. Return \( \text{output list} \).

User agents working with integer values for frame widths (as opposed to user agents that can lay frames out with subpixel accuracy) are expected to distribute the remainder first to the last entry whose unit is \( \text{relative} \), then equally (not proportionally) to each entry whose unit is \( \text{percentage} \), then equally (not proportionally) to each entry whose unit is \( \text{absolute} \), and finally, failing all else, to the last entry.

The contents of a \( \text{frame} \) element that does not have a \( \text{frameset} \) parent are expected to be rendered as transparent black; the user agent is expected to not render the nested browsing context in this case, and that nested browsing context is expected to have a viewport with zero width and zero height.

### 14.7 Interactive media

#### 14.7.1 Links, forms, and navigation

User agents are expected to allow the user to control aspects of hyperlink activation and form submission, such as which browsing context is to be used for the subsequent navigation.

User agents are expected to allow users to discover the destination of hyperlinks and of forms before triggering their navigation.

User agents are expected to inform the user of whether a hyperlink includes hyperlink auditing, and to let them know at a minimum which domains will be contacted as part of such auditing.

User agents may allow users to navigate to browsing contexts to the URLs indicated by the cite attributes on q, blockquote, ins, and del elements.

User agents may surface hyperlinks created by link elements in their user interface.
14.7.2 The title attribute

User agents are expected to expose the advisory information of elements upon user request, and to make the user aware of the presence of such information.

On interactive graphical systems where the user can use a pointing device, this could take the form of a tooltip. When the user is unable to use a pointing device, then the user agent is expected to make the content available in some other fashion, e.g. by making the element a focusable area and always displaying the advisory information of the currently focused element, or by showing the advisory information of the elements under the user’s finger on a touch device as the user pans around the screen.

U+000A LINE FEED (LF) characters are expected to cause line breaks in the tooltip; U+0009 CHARACTER TABULATION (tab) characters are expected to render as a nonzero horizontal shift that lines up the next glyph with the next tab stop, with tab stops occurring at points that are multiples of 8 times the width of a U+0020 SPACE character.

Example

For example, a visual user agent could make elements with a title attribute focusable, and could make any focused element with a title attribute show its tooltip under the element while the element has focus. This would allow a user to tab around the document to find all the advisory text.

Example

As another example, a screen reader could provide an audio cue when reading an element with a tooltip, with an associated key to read the last tooltip for which a cue was played.

14.7.3 Editing hosts

The current text editing caret (i.e. the active range, if it is empty and in an editing host), if any, is expected to act like an inline replaced element with the vertical dimensions of the caret and with zero width for the purposes of the CSS rendering model.

Note

This means that even an empty block can have the caret inside it, and that when the caret is in such an element, it prevents margins from collapsing through the element.

14.7.4 Text rendered in native user interfaces

User agents are expected to honor the Unicode semantics of text that is exposed in user interfaces, for example supporting the bidirectional algorithm in text shown in dialogs, title bars, pop-up menus, and tooltips. Text from the contents of elements is expected to be rendered in a manner that honors the directionality of the element from which the text was obtained. Text from attributes is expected to be rendered in a manner that honors the directionality of the attribute.

Example

Consider the following markup, which has Hebrew text asking for a programming language, the languages being text for which a left-to-right direction is important given the punctuation in some of their names:

```html
<p dir="rtl" lang="he">
  <label>
```

A string provided by a script (e.g. the argument to `window.alert()`)
is expected to be treated as an independent set of one or more
bidirectional algorithm paragraphs when displayed, as defined by the bidirectional algorithm, including, for instance, supporting the
paragraph-breaking behavior of U+000A LINE FEED (LF) characters. For the purposes of determining the paragraph level of such text in
the bidirectional algorithm, this specification does not provide a higher-level override of rules P2 and P3. [BIDI]

When necessary, authors can enforce a particular direction for a given paragraph by starting it with the Unicode U+200E LEFT-TO-
RIGHT MARK or U+200F RIGHT-TO-LEFT MARK characters.

Example

The directionality of attributes depends on the attribute and on the element’s `dir` attribute, as the following example
demonstrates. Consider this markup:

```html
<table>
  <tr>
    <th abbr="(A" dir=ltr>A
    <th abbr="(A" dir=rtl>A
    <th abbr="(A" dir=auto>A
  </tr>
</table>
```

If the `abbr` attributes are rendered, e.g. in a tooltip or other user interface, the first will have a left parenthesis (because the
direction is 'ltr'), the second will have a right parenthesis (because the direction is 'rtl'), and the third will have a right parenthesis
(because the direction is determined from the attribute value to be 'rtl').

However, if instead the attribute was not a directionality-capable attribute, the results would be different:

```html
<table>
  <tr>
    <th data-abbr="(A" dir=ltr>A
    <th data-abbr="(A" dir=rtl>A
    <th data-abbr="(A" dir=auto>A
  </tr>
</table>
```

In this case, if the user agent were to expose the `data-abbr` attribute in the user interface (e.g. in a debugging environment), the
last case would be rendered with a left parenthesis, because the direction would be determined from the element’s contents.

If the `select` element was rendered as a drop down box, a correct rendering would ensure that the punctuation was the same
both in the drop down, and in the box showing the current selection.

Example

The directionality of attributes depends on the attribute and on the element’s `dir` attribute, as the following example
demonstrates. Consider this markup:

```html
<select>
  <option dir="ltr">C++</option>
  <option dir="ltr">C#</option>
  <option dir="ltr">FreePascal</option>
  <option dir="ltr">F#</option>
</select>
```
Thus, the following script:

```javascript
alert('יומם HTML' + ' ' + 'Yom ' + 'שומשום HTML' + ' ' + 'Yom ' + 'שומשום!')
```

...would always result in a message reading "יומם HTML שומשום HTML!"), regardless of the language of the user agent interface or the direction of the page or any of its elements.

**Example**

For a more complex example, consider the following script:

```javascript
/* Warning: this script does not handle right-to-left scripts correctly */
var s;
if (s = prompt('What is your name?')) {
  alert(s + ' Ok, Fred, ' + s + ', and Wilma will get the car.');
}
```

When the user enters "Kitty", the user agent would alert "Kitty! Ok, Fred, Kitty, and Wilma will get the car.". However, if the user enters "אفهم לא", then the bidirectional algorithm will determine that the direction of the paragraph is right-to-left, and so the output will be the following unintended mess: "ואחרי ...Wilma will get the car, אفهم לא, Ok, Fred! אفهم לא"

To force an alert that starts with user-provided text (or other text of unknown directionality) to render left-to-right, the string can be prefixed with a U+200E LEFT-TO-RIGHT MARK character:

```javascript
var s;
if (s = prompt('What is your name?')) {
  alert('‎' + s + ' Ok, Fred, ' + s + ', and Wilma will get the car.');
}
```

### 14.8 Print media

User agents are expected to allow the user to request the opportunity to **obtain a physical form** (or a representation of a physical form) of a Document. For example, selecting the option to print a page or convert it to PDF format. [PDF]

When the user actually **obtains a physical form** (or a representation of a physical form) of a Document, the user agent is expected to create a new rendering of the Document for the print media.

### 14.9 Unstyled XML documents

HTML user agents may, in certain circumstances, find themselves rendering non-HTML documents that use vocabularies for which they lack any built-in knowledge. This section provides for a way for user agents to handle such documents in a somewhat useful manner.

While a Document is an **unstyled document**, the user agent is expected to render an **unstyled document view** while it matches the following conditions:

A Document is an **unstyled document** while it matches the following conditions:

- The Document has no author style sheets (whether referenced by HTTP headers, processing instructions, elements like `link`, inline elements like `style`, or any other mechanism).
- None of the elements in the Document have any **presentational hints**.
- None of the elements in the Document have any **style attributes**.
- None of the elements in the Document are in any of the following namespaces: **HTML namespace**, **SVG namespace**.
MathML namespace

• The Document has no focusable area (e.g. from XLink) other than the viewport.

• The Document has no hyperlinks (e.g. from XLink).

• There exists no script whose settings object specifies this Document as the responsible document.

• None of the elements in the Document have any registered event listeners.

An unstyled document view is one where the DOM is not rendered according to CSS (which would, since there are no applicable styles in this context, just result in a wall of text), but is instead rendered in a manner that is useful for a developer. This could consist of just showing the Document object's source, maybe with syntax highlighting, or it could consist of displaying just the DOM tree, or simply a message saying that the page is not a styled document.

Note

If a Document stops being an unstyled document, then the conditions above stop applying, and thus a user agent following these requirements will switch to using the regular CSS rendering.
15 Obsolete features

15.1 Obsolete but conforming features

Features listed in this section will trigger warnings in conformance checkers.

Authors should not specify a border attribute on an img element. If the attribute is present, its value must be the string "0". CSS should be used instead.

Authors should not specify a charset attribute on a script element. If the attribute is present, its value must be an ASCII case-insensitive match for "utf-8". (This has no effect in a document that conforms to the requirements elsewhere in this standard of being encoded as UTF-8.)

Authors should not specify a language attribute on a script element. If the attribute is present, its value must be an ASCII case-insensitive match for the string "JavaScript" and either the type attribute must be omitted or its value must be an ASCII case-insensitive match for the string "text/javascript". The attribute should be entirely omitted instead (with the value "JavaScript", it has no effect), or replaced with use of the type attribute.

Authors should not specify a value for the type attribute on script elements that is the empty string or a JavaScript MIME type essence match. Instead, they should omit the attribute, which has the same effect.

Authors should not specify a type attribute on a style element. If the attribute is present, its value must be an ASCII case-insensitive match for "text/css".

Authors should not specify a name attribute on a p elements. If the attribute is present, its value must not be the empty string and must neither be equal to the value of any of the IDs in the element's tree other than the element's own ID, if any, nor be equal to the value of any of the other name attributes on a p elements in the element's tree. If this attribute is present and the element has an ID, then the attribute's value must be equal to the element's ID. In earlier versions of the language, this attribute was intended as a way to specify possible targets for fragments in URLs. The id attribute should be used instead.

Authors should not, but may despite requirements to the contrary elsewhere in this specification, specify the maxlength and size attributes on input elements whose type attributes are in the Number state. One valid reason for using these attributes regardless is to help legacy user agents that do not support input elements with type="number" to still render the text control with a useful width.

15.1.1 Warnings for obsolete but conforming features

To ease the transition from HTML4 Transitional documents to the language defined in this specification, and to discourage certain features that are only allowed in very few circumstances, conformance checkers must warn the user when the following features are used in a document. These are generally old obsolete features that have no effect, and are allowed only to distinguish between likely mistakes (regular conformance errors) and mere vestigial markup or unusual and discouraged practices (these warnings).

The following features must be categorized as described above:

- The presence of a border attribute on an img element if its value is the string "0".
- The presence of a charset attribute on a script element if its value is an ASCII case-insensitive match for "utf-8".
- The presence of a language attribute on a script element if its value is an ASCII case-insensitive match for the string "JavaScript" and there is no type attribute or there is and its value is an ASCII case-insensitive match for the string "text/javascript".
- The presence of a type attribute on a script element if its value is a JavaScript MIME type essence match.
- The presence of a type attribute on a style element if its value is an ASCII case-insensitive match for "text/css".
- The presence of a name attribute on a p element, if its value is not the empty string.
- The presence of a maxlength attribute on an input element whose type attribute is in the Number state.
• The presence of a `size` attribute on an `input` element whose `type` attribute is in the `Number` state.

Conformance checkers must distinguish between pages that have no conformance errors and have none of these obsolete features, and pages that have no conformance errors but do have some of these obsolete features.

Example

For example, a validator could report some pages as "Valid HTML" and others as "Valid HTML with warnings".

### 15.2 Non-conforming features

Elements in the following list are entirely obsolete, and must not be used by authors:

- **applet**
  - Use `embed` or `object` instead.

- **acronym**
  - Use `abbr` instead.

- **bgsound**
  - Use `audio` instead.

- **dir**
  - Use `ul` instead.

- **frame**
  - **frameset**
  - **noframes**
    - Either use `iframe` and CSS instead, or use server-side includes to generate complete pages with the various invariant parts merged in.

- **isindex**
  - Use an explicit `form` and `text control` combination instead.

- **keygen**
  - For enterprise device management use cases, use native on-device management capabilities.

    For certificate enrollment use cases, use the Web Cryptography API to generate a keypair for the certificate, and then export the certificate and key to allow the user to install them manually. [WEBCRYPTO]

- **listing**
  - Use `pre` and `code` instead.

- **menuitem**
  - To implement a custom context menu, use script to handle the `contextmenu` event.

- **nextid**
  - Use GUIDs instead.

- **noembed**
  - Use `object` instead of `embed` when fallback is necessary.

- **plaintext**
  - Use the "text/plain" MIME type instead.

- **rb**

- **rtc**
  - Providing the ruby base directly inside the `ruby` element or using nested `ruby` elements is sufficient.
**strike**

Use `del` instead if the element is marking an edit, otherwise use `s` instead.

**xmp**

Use `pre` and `code` instead, and escape "<" and "&" characters as "&lt;" and "&amp;" respectively.

**basefont**

**big**

**blink**

**center**

**font**

**marquee**

**multicol**

**nobr**

**spacer**

**tt**

Use appropriate elements or CSS instead.

Where the `tt` element would have been used for marking up keyboard input, consider the `kbd` element; for variables, consider the `var` element; for computer code, consider the `code` element; and for computer output, consider the `samp` element.

Similarly, if the `big` element is being used to denote a heading, consider using the `h1` element; if it is being used for marking up important passages, consider the `strong` element; and if it is being used for highlighting text for reference purposes, consider the `mark` element.

See also the [text-level semantics usage summary](#) for more suggestions with examples.

The following attributes are obsolete (though the elements are still part of the language), and must not be used by authors:

**charset** on `a` elements

**charset** on `link` elements

Use an HTTP `Content-Type` header on the linked resource instead.

**charset** on `script` elements (except as noted in the previous section)

Omit the attribute. Both documents and scripts are required to use UTF-8, so it is redundant to specify it on the `script` element since it inherits from the document.

**coords** on `a` elements

**shape** on `a` elements

Use `area` instead of `a` for image maps.

**methods** on `a` elements

**methods** on `link` elements

Use the HTTP OPTIONS feature instead.

**name** on `a` elements (except as noted in the previous section)

**name** on `embed` elements

**name** on `img` elements

**name** on `option` elements

Use the `id` attribute instead.

**rev** on `a` elements

**rev** on `link` elements

Use the `rel` attribute instead, with an opposite term. (For example, instead of `rev="made"`, use `rel="author"`.)
urn on a\textsuperscript{p328} elements
urn on link\textsuperscript{p353} elements

Specify the preferred persistent identifier using the $\texttt{href}$\textsuperscript{p274} attribute instead.

accept on form\textsuperscript{p474} elements

Use the $\texttt{accept}$\textsuperscript{p480} attribute directly on the $\texttt{input}$\textsuperscript{p476} elements instead.

hreflang on area\textsuperscript{p428} elements
type on area\textsuperscript{p428} elements

These attributes do not do anything useful, and for historical reasons there are no corresponding IDL attributes on area\textsuperscript{p428} elements. Omit them altogether.

nohref on area\textsuperscript{p428} elements

Omitting the $\texttt{href}$\textsuperscript{p274} attribute is sufficient; the $\texttt{nohref}$\textsuperscript{p1172} attribute is unnecessary. Omit it altogether.

profile on head\textsuperscript{p149} elements

Unnecessary. Omit it altogether.

version on html\textsuperscript{p148} elements

Unnecessary. Omit it altogether.

ismap on input\textsuperscript{p476} elements

Unnecessary. Omit it altogether. All input\textsuperscript{p476} elements with a type\textsuperscript{p478} attribute in the Image Button\textsuperscript{p561} state are processed as server-side image maps.

usemap on input\textsuperscript{p476} elements

Use $\texttt{img}$\textsuperscript{p307} instead of input\textsuperscript{p476} for image maps.

longdesc on iframe\textsuperscript{p347} elements

longdesc on img\textsuperscript{p307} elements

Use a regular a\textsuperscript{p328} element to link to the description, or (in the case of images) use an image map\textsuperscript{p430} to provide a link from the image to the image's description.

lowsrc on img\textsuperscript{p307} elements

Use a progressive JPEG image (given in the src\textsuperscript{p307} attribute), instead of using two separate images.

target on link\textsuperscript{p153} elements

Unnecessary. Omit it altogether.

type on menu\textsuperscript{p216} elements

To implement a custom context menu, use script to handle the contextmenu\textsuperscript{p1217} event. For toolbar menus, omit the attribute.

label on menu\textsuperscript{p216} elements

contextmenu on all elements

onshow on all elements

To implement a custom context menu, use script to handle the contextmenu\textsuperscript{p1217} event.

scheme on meta\textsuperscript{p158} elements

Use only one scheme per field, or make the scheme declaration part of the value.

archive on object\textsuperscript{p338} elements
classid on object\textsuperscript{p338} elements
code on object\textsuperscript{p338} elements
codebase on object\textsuperscript{p338} elements
codetype on object\textsuperscript{p338} elements

Use the data\textsuperscript{p358} and type\textsuperscript{p359} attributes to invoke plugins\textsuperscript{p45}. To set parameters with these names in particular, the param\textsuperscript{p363} element can be used.

declare on object\textsuperscript{p338} elements

Repeat the object\textsuperscript{p338} element completely each time the resource is to be reused.
standby on object elements
Optimize the linked resource so that it loads quickly or, at least, incrementally.

type on param elements

type on script elements (except as noted in the previous section)
Omit the attribute for JavaScript; for data blocks, use the type attribute instead.

valuetype on param elements
Use the name and value attributes without declaring value types.

event on script elements
Use DOM events mechanisms to register event listeners. [DOM]

type on style elements (except as noted in the previous section)
Omit the attribute for CSS; for resource blocks, use script as the container instead of style.

datapagesize on table elements
Unnecessary. Omit it altogether.

summary on table elements
Use one of the techniques for describing tables given in the table section instead.

abbr on td elements
Use text that begins in an unambiguous and terse manner, and include any more elaborate text after that. The title attribute can also be useful in including more detailed text, so that the cell's contents can be made terse. If it's a heading, use th (which has an abbr attribute).

axis on td and th elements
Use the scope attribute on the relevant th.

scope on td elements
Use th elements for heading cells.

data on a, button, div, img, input, label, legend, marquee, object, option, select, span, and table elements
Use script and a mechanism such as XMLHttpRequest to populate the page dynamically. [XHR]

dropzone on all elements
Use script to handle the dragenter and dragover events instead.
alink on body.elements
bgcolor on body.elements
bottommargin on body.elements
leftmargin on body.elements
link on body.elements
marginheight on body.elements
marginwidth on body.elements
rightmargin on body.elements
text on body.elements
topmargin on body.elements
vlink on body.elements
clear on br.elements
align on caption.elements
align on col.elements
char on col.elements
charoff on col.elements
valign on col.elements
width on col.elements
align on div.elements
compact on dl.elements
align on embed.elements
hspace on embed.elements
vspace on embed.elements
align on hr.elements
color on hr.elements
noshade on hr.elements
size on hr.elements
width on hr.elements
align on h1–h6.elements
align on iframe.elements
allowtransparency on iframe.elements
frameborder on iframe.elements
framespacing on iframe.elements
hspace on iframe.elements
marginheight on iframe.elements
marginwidth on iframe.elements
scrolling on iframe.elements
vspace on iframe.elements
align on input.elements
border on input.elements
hspace on input.elements
vspace on input.elements
align on img.elements
border on img.elements (except as noted in the previous section)
hspace on img.elements
vspace on img.elements
align on legend.elements
type on li.elements
compact on menu.elements
align on menu.elements
border on object.elements
hspace on object.elements
vspace on object.elements
compact on ol elements
align on pre elements
width on pre elements
align on table elements
bgcolor on table elements
border on table elements
bordercolor on table elements
cellpadding on table elements
cells spacing on table elements
frame on table elements
height on table elements
rules on table elements
width on table elements
align on tbody, thead, and tfoot elements
char on tbody, thead, and tfoot elements
charoff on tbody, thead, and tfoot elements
valign on tbody, thead, and tfoot elements
align on td and th elements
bgcolor on td and th elements
char on td and th elements
charoff on td and th elements
height on td and th elements
nowrap on td and th elements
valign on td and th elements
width on td and th elements
align on tr elements
bgcolor on tr elements
char on tr elements
charoff on tr elements
height on tr elements
valign on tr elements
compact on ul elements
type on ul elements

Use CSS instead.

15.3 Requirements for implementations

15.3.1 The marquee element

The marquee element is a presentational element that animates content. CSS transitions and animations are a more appropriate mechanism. [CSSANIMATIONS] [CSSTRANSITIONS]

The task source for tasks mentioned in this section is the DOM manipulation task source.

The marquee element must implement the HTMLMarqueeElement interface.

```
IDL
[Exposed=Window, HTMLConstructor]
interface HTMLMarqueeElement : HTMLElement {
    [CEReactions] attribute DOMString behavior;
    [CEReactions] attribute DOMString bgColor;
    [CEReactions] attribute DOMString direction;
}
```
A **marquee** element can be turned on or turned off. When it is created, it is turned on.

When the `start()` method is called, the **marquee** element must be turned on.

When the `stop()` method is called, the **marquee** element must be turned off.

When a **marquee** element is created, the user agent must queue a task to fire an event named `start` at the element.

The **behavior** content attribute on **marquee** elements is an enumerated attribute with the following keywords (all non-conforming):

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>scroll</td>
<td>scroll</td>
</tr>
<tr>
<td>slide</td>
<td>slide</td>
</tr>
<tr>
<td>alternate</td>
<td>alternate</td>
</tr>
</tbody>
</table>

The *missing value default* and *invalid value default* are the `scroll` state.

The **direction** content attribute on **marquee** elements is an enumerated attribute with the following keywords (all non-conforming):

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>left</td>
</tr>
<tr>
<td>right</td>
<td>right</td>
</tr>
<tr>
<td>up</td>
<td>up</td>
</tr>
<tr>
<td>down</td>
<td>down</td>
</tr>
</tbody>
</table>

The *missing value default* and *invalid value default* are the `left` state.

The **trueSpeed** content attribute on **marquee** elements is a boolean attribute.

A **marquee** element has a **marquee scroll interval**, which is obtained as follows:

1. If the element has a `scrollDelay` attribute, and parsing its value using the rules for parsing non-negative integers does not return an error, then let `delay` be the parsed value. Otherwise, let `delay` be 85.

2. If the element does not have a `trueSpeed` attribute, and the `delay` value is less than 60, then let `delay` be 60 instead.

3. The **marquee scroll interval** is `delay`, interpreted in milliseconds.
A `marquee` element has a **marquee scroll distance**, which, if the element has a `scrollamount` attribute, and parsing its value using the rules for parsing non-negative integers does not return an error, is the parsed value interpreted in CSS pixels, and otherwise is 6 CSS pixels.

A `marquee` element has a **marquee loop count**, which, if the element has a `loop` attribute, and parsing its value using the rules for parsing integers does not return an error or a number less than 1, is the parsed value, and otherwise is −1.

The `loop` IDL attribute, on getting, must return the element’s `marquee loop count`, and on setting, if the new value is different than the element’s `marquee loop count` and either greater than zero or equal to −1, must set the element’s `loop` content attribute (adding it if necessary) to the valid integer that represents the new value. (Other values are ignored.)

A `marquee` element also has a **marquee current loop index**, which is zero when the element is created.

The rendering layer will occasionally increment the **marquee current loop index**, which must cause the following steps to be run:

1. If the `marquee loop count` is −1, then return.
2. Increment the `marquee current loop index` by one.
3. If the `marquee current loop index` is now equal to or greater than the element’s `marquee loop count`, turn off the `marquee` element and queue a task to fire an event named `finish` at the `marquee` element.
   
   Otherwise, if the `behavior` attribute is in the `alternate` state, then queue a task to fire an event named `bounce` at the `marquee` element.

   Otherwise, queue a task to fire an event named `start` at the `marquee` element.

The following are the `event handlers` (and their corresponding `event handler event types`) that must be supported, as `event handler content attributes` and `event handler IDL attributes`, by `marquee` elements:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onbounce</td>
<td>bounce</td>
</tr>
<tr>
<td>onfinish</td>
<td>finish</td>
</tr>
<tr>
<td>onstart</td>
<td>start</td>
</tr>
</tbody>
</table>

The `behavior`, `direction`, `height`, `hspace`, `vspace`, and `width` IDL attributes must `reflect` the respective content attributes of the same name.

The `bgColor` IDL attribute must `reflect` the `bgcolor` content attribute.

The `scrollAmount` IDL attribute must `reflect` the `scrollamount` content attribute. The default value is 6.

The `scrollDelay` IDL attribute must `reflect` the `scrolldelay` content attribute. The default value is 85.

The `trueSpeed` IDL attribute must `reflect` the `truespeed` content attribute.

### 15.3.2 Frames

The `frameset` element acts as the `body element` in documents that use frames.

The `frameset` element must implement the `HTMLFrameSetElement` interface.

```
IDL [Exposed=Window, HTMLConstructor]
interface HTMLFrameSetElement : HTMLElement {
  [CEReactions] attribute DOMString cols;
  [CEReactions] attribute DOMString rows;
};
```
The **cols** and **rows** IDL attributes of the **frameset** element must reflect the respective content attributes of the same name.

The **frameset** element exposes as event handler content attributes a number of the event handlers of the **Window** object. It also mirrors their event handler IDL attributes.

The event handlers of the **Window** object named by the **Window-reflecting body element event handler set**, exposed on the **frameset** element, replace the generic event handlers with the same names normally supported by HTML elements.

The **frame** element defines a nested browsing context similar to the **iframe** element, but rendered within a **frameset** element.

A **frame** element is said to be an active frame element when it is in a document.

When a **frame** element is created as an active frame element, or becomes an active frame element after not having been one, the user agent must create a new browsing context, set the element's nested browsing context to the newly-created browsing context, and then process the frame attributes for the first time. If the element has a name attribute, the browsing context name must be set to the value of this attribute; otherwise, the browsing context name must be set to the empty string.

When a **frame** element stops being an active frame element, the user agent must discard the element's nested browsing context, and then set the element's nested browsing context to null.

Whenever a **frame** element with a non-null nested browsing context has its src attribute set, changed, or removed, the user agent must process the frame attributes.

When the user agent is to process the frame attributes, it must run the first appropriate steps from the following list:

- **If the element has no src attribute specified, and the user agent is processing the frame's attributes for the first time**
  
  Queue a task to fire an event named **Load** at the frame element using the DOM manipulation task source.

- **Otherwise**

  Run the otherwise steps for iframe or frame elements.

Any **navigation** required of the user agent in the process the frame attributes algorithm must use the frame element's node document's browsing context as the source browsing context.

Furthermore, if the active document of the element's nested browsing context, before such a navigation was not completely loaded at the time of the new navigation, then the navigation must be completed with replacement enabled.

Similarly, if the nested browsing context's session history contained only one Document when the process the frame attributes algorithm was invoked, and that was the about:blank Document created when the nested browsing context was created, then any navigation required of the user agent in that algorithm must be completed with replacement enabled.

When a Document in a frame is marked as completely loaded, the user agent must fire an event named **Load** at the frame element.

When a **frame** element has a non-null nested browsing context, and its nested browsing context's active document is not ready for post-load tasks, and when anything is delaying the load event of the **frame** element's browsing context, and when the **frame** element's browsing context is in the delaying load events mode, the **frame** element must delay the load event, of its document.

Whenever the name attribute is set and the frame element's nested browsing context is non-null, the nested browsing context's name must be changed to the new value. If the attribute is removed, the browsing context name must be set to the empty string.

The **frame** element must implement the **HTMLFrameElement** interface.
The `name`, `scrolling`, and `src` IDL attributes of the `frame` element must \(\text{reflect}\) the respective content attributes of the same name. For the purposes of reflection, the `frame` element's `src` content attribute is defined as containing a URL.

The `frameBorder` IDL attribute of the `frame` element must \(\text{reflect}\) the element's `frameborder` content attribute.

The `longDesc` IDL attribute of the `frame` element must \(\text{reflect}\) the element's `longdesc` content attribute, which for the purposes of reflection is defined as containing a URL.

The `noResize` IDL attribute of the `frame` element must \(\text{reflect}\) the element's `noresize` content attribute.

The `contentDocument` IDL attribute, on getting, must return the `frame` element's `content document`.

The `contentWindow` IDL attribute must return the `WindowProxy` object of the `frame` element's `nested browsing context`, if the element's `nested browsing context` is non-null, or return null otherwise.

The `marginHeight` IDL attribute of the `frame` element must \(\text{reflect}\) the element's `marginheight` content attribute.

The `marginWidth` IDL attribute of the `frame` element must \(\text{reflect}\) the element's `marginwidth` content attribute.

### 15.3.3 Other elements, attributes and APIs

User agents must treat `acronym` elements in a manner equivalent to `abbr` elements in terms of semantics and for purposes of rendering.

The `coords`, `charset`, `name`, `rev`, and `shape` IDL attributes of the `a` element must \(\text{reflect}\) the respective content attributes of the same name.

The `noHref` IDL attribute of the `area` element must \(\text{reflect}\) the element's `nohref` content attribute.
The **text** IDL attribute of the `body` element must `reflect` the element's `text` content attribute.

The **link** IDL attribute of the `body` element must `reflect` the element's `link` content attribute.

The **aLink** IDL attribute of the `body` element must `reflect` the element's `alink` content attribute.

The **vLink** IDL attribute of the `body` element must `reflect` the element's `vlink` content attribute.

The **bgColor** IDL attribute of the `body` element must `reflect` the element's `bgcolor` content attribute.

The **background** IDL attribute of the `body` element must `reflect` the element's `background` content attribute. (The `background` content is *not* defined to contain a URL, despite rules regarding its handling in the rendering section above.)

The **clear** IDL attribute of the `br` element must `reflect` the content attribute of the same name.

The **align** IDL attribute of the `caption` element must `reflect` the content attribute of the same name.

The **align** and **width** IDL attributes of the `col` element must `reflect` the respective content attributes of the same name.

The **ch** IDL attribute of the `col` element must `reflect` the element's `char` content attribute.

The **chOff** IDL attribute of the `col` element must `reflect` the element's `charoff` content attribute.

The **vAlign** IDL attribute of the `col` element must `reflect` the element's `valign` content attribute.

User agents must treat `dir` elements in a manner equivalent to `ul` elements in terms of semantics and for purposes of rendering.

The **dir** element must implement the `HTMLDirectoryElement` interface.
The **compact** IDL attribute of the `dir` element must reflect the content attribute of the same name.

The **align** IDL attribute of the `div` element must reflect the content attribute of the same name.

The **compact** IDL attribute of the `dl` element must reflect the content attribute of the same name.

The **name** and **align** IDL attributes of the `embed` element must reflect the respective content attributes of the same name.

The **font** element must implement the `HTMLFontElement` interface.

The **color**, **face**, and **size** IDL attributes of the `font` element must reflect the respective content attributes of the same name.

The **align** IDL attribute of the `h1`–`h6` elements must reflect the content attribute of the same name.

**Note**

The **profile** IDL attribute on `head` elements (with the `HTMLHeadElement` interface) is intentionally omitted. Unless so required by another applicable specification, implementations would therefore not support this attribute. (It is mentioned here as it was defined in a previous version of the DOM specifications.)
The `align`, `color`, `size`, and `width` IDL attributes of the `hr` element must reflect the respective content attributes of the same name.

The `noShade` IDL attribute of the `hr` element must reflect the element's `noshade` content attribute.

The `version` IDL attribute of the `html` element must reflect the content attribute of the same name.

The `align` and `scrolling` IDL attributes of the `iframe` element must reflect the respective content attributes of the same name.

The `frameBorder` IDL attribute of the `iframe` element must reflect the element's `frameborder` content attribute.

The `longDesc` IDL attribute of the `iframe` element must reflect the element's `longdesc` content attribute, which for the purposes of reflection is defined as containing a URL.

The `marginHeight` IDL attribute of the `iframe` element must reflect the element's `marginheight` content attribute.

The `marginWidth` IDL attribute of the `iframe` element must reflect the element's `marginwidth` content attribute.

The `name`, `align`, `border`, `hspace`, and `vspace` IDL attributes of the `img` element must reflect the respective content attributes of the same name.

The `longDesc` IDL attribute of the `img` element must reflect the element's `longdesc` content attribute, which for the purposes of reflection is defined as containing a URL.

The `lowsrc` IDL attribute of the `img` element must reflect the element's `lowsrc` content attribute, which for the purposes of
reflection is defined as containing a URL.

Partial interface HTMLInputElement {
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString useMap;
};

The `align` IDL attribute of the `input` element must reflect the content attribute of the same name.

The `useMap` IDL attribute of the `input` element must reflect the element's `usemap` content attribute.

Partial interface HTMLLegendElement {
    [CEReactions] attribute DOMString align;
};

The `align` IDL attribute of the `legend` element must reflect the content attribute of the same name.

Partial interface HTMLLIElement {
    [CEReactions] attribute DOMString type;
};

The `type` IDL attribute of the `li` element must reflect the content attribute of the same name.

Partial interface HTMLLinkElement {
    [CEReactions] attribute DOMString charset;
    [CEReactions] attribute DOMString rev;
    [CEReactions] attribute DOMString target;
};

The `charset`, `rev`, and `target` IDL attributes of the `link` element must reflect the respective content attributes of the same name.

User agents must treat `listing` elements in a manner equivalent to `pre` elements in terms of semantics and for purposes of rendering.

Partial interface HTMLMenuElement {
    [CEReactions] attribute boolean compact;
};

The `compact` IDL attribute of the `menu` element must reflect the content attribute of the same name.

Partial interface HTMLMetaElement {
    [CEReactions] attribute DOMString scheme;
};

User agents may treat the `scheme` content attribute on the `meta` element as an extension of the element's `name` content attribute when processing a `meta` element with a `name` attribute whose value is one that the user agent recognizes as supporting the `scheme` attribute.

User agents are encouraged to ignore the `scheme` attribute and instead process the value given to the metadata name as if it had been specified for each expected value of the `scheme` attribute.
For example, if the user agent acts on `meta` elements with `name` attributes having the value "eGMS.subject.keyword", and knows that the `scheme` attribute is used with this metadata name, then it could take the `scheme` attribute into account, acting as if it was an extension of the `name` attribute. Thus the following two `meta` elements could be treated as two elements giving values for two different metadata names, one consisting of a combination of "eGMS.subject.keyword" and "LGCL", and the other consisting of a combination of "eGMS.subject.keyword" and "ORLY":

```html
<!-- this markup is invalid -->
<meta name="eGMS.subject.keyword" scheme="LGCL" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" scheme="ORLY" content="Mah car: kthxbye">
```

The suggested processing of this markup, however, would be equivalent to the following:

```html
<meta name="eGMS.subject.keyword" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" content="Mah car: kthxbye">
```

The `scheme` IDL attribute of the `meta` element must reflect the content attribute of the same name.

```idl
partial interface HTMLObjectElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString archive;
  [CEReactions] attribute DOMString code;
  [CEReactions] attribute boolean declare;
  [CEReactions] attribute unsigned long hspace;
  [CEReactions] attribute DOMString standby;
  [CEReactions] attribute unsigned long vspace;
  [CEReactions] attribute DOMString codeBase;
  [CEReactions] attribute DOMString codeType;
  [CEReactions] attribute [TreatNullAs=EmptyString] DOMString border;
};
```

The `align`, `archive`, `border`, `code`, `declare`, `hspace`, and `standby` IDL attributes of the `object` element must reflect the respective content attributes of the same name.

The `codeBase` IDL attribute of the `object` element must reflect the element's `codebase` content attribute, which for the purposes of reflection is defined as containing a URL.

The `codeType` IDL attribute of the `object` element must reflect the element's `codetype` content attribute.

```idl
partial interface HTMLListElement {
  [CEReactions] attribute boolean compact;
};
```

The `compact` IDL attribute of the `ol` element must reflect the content attribute of the same name.

```idl
partial interface HTMLParagraphElement {
  [CEReactions] attribute DOMString align;
};
```

The `align` IDL attribute of the `p` element must reflect the content attribute of the same name.
The `type` IDL attribute of the `param` element must reflect the content attribute of the same name.

The `valueType` IDL attribute of the `param` element must reflect the element's `valuetype` content attribute.

User agents must treat `plaintext` elements in a manner equivalent to `pre` elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element, though.)

The `width` IDL attribute of the `pre` element must reflect the content attribute of the same name.

The `type` IDL attribute of the `style` element must reflect the element's `type` content attribute.

The `charset` and `event` IDL attributes of the `script` element must reflect the respective content attributes of the same name.

The `htmlFor` IDL attribute of the `script` element must reflect the element's `for` content attribute.

The `align`, `border`, `frame`, `summary`, `rules`, and `width`, IDL attributes of the `table` element must reflect the respective content attributes of the same name.

The `bgColor` IDL attribute of the `table` element must reflect the element's `bgcolor` content attribute.

The `cellPadding` IDL attribute of the `table` element must reflect the element's `cellpadding` content attribute.

The `cellSpacing` IDL attribute of the `table` element must reflect the element's `cellspacing` content attribute.
The `align` IDL attribute of the `tbody`, `thead`, and `tfoot` elements must reflect the content attribute of the same name.

The `ch` IDL attribute of the `tbody`, `thead`, and `tfoot` elements must reflect the elements' `char` content attributes.

The `chOff` IDL attribute of the `tbody`, `thead`, and `tfoot` elements must reflect the elements' `charoff` content attributes.

The `vAlign` IDL attribute of the `tbody`, `thead`, and `tfoot` element must reflect the elements' `valign` content attributes.

The `align`, `axis`, `height`, and `width` IDL attributes of the `td` and `th` elements must reflect the respective content attributes of the same name.

The `ch` IDL attribute of the `td` and `th` elements must reflect the elements' `char` content attributes.

The `chOff` IDL attribute of the `td` and `th` elements must reflect the elements' `charoff` content attributes.

The `noWrap` IDL attribute of the `td` and `th` elements must reflect the elements' `nowrap` content attributes.

The `vAlign` IDL attribute of the `td` and `th` elements must reflect the elements' `valign` content attributes.

The `bgColor` IDL attribute of the `td` and `th` elements must reflect the elements' `bgcolor` content attributes.

The `align` IDL attribute of the `tr` element must reflect the content attribute of the same name.

The `ch` IDL attribute of the `tr` element must reflect the element's `char` content attribute.

The `chOff` IDL attribute of the `tr` element must reflect the element's `charoff` content attribute.
The `vAlign` IDL attribute of the `tr` element must reflect the element’s `valign` content attribute.

The `bgColor` IDL attribute of the `tr` element must reflect the element’s `bgcolor` content attribute.

```idl
partial interface HTMLUListElement {
  [CEReactions] attribute boolean compact;
  [CEReactions] attribute DOMString type;
};
```

The `compact` and `type` IDL attributes of the `ul` element must reflect the respective content attributes of the same name.

User agents must treat `xmp` elements in a manner equivalent to `pre` elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element though.)

```idl
partial interface Document {
  [CEReactions] attribute [TreatNullAs=EmptyString] DOMString fgColor;
  [CEReactions] attribute [TreatNullAs=EmptyString] DOMString linkColor;
  [CEReactions] attribute [TreatNullAs=EmptyString] DOMString vlinkColor;
  [CEReactions] attribute [TreatNullAs=EmptyString] DOMString alinkColor;
  [CEReactions] attribute [TreatNullAs=EmptyString] DOMString bgColor;

  [SameObject] readonly attribute HTMLCollection anchors;
  [SameObject] readonly attribute HTMLCollection applets;

  void clear();
  void captureEvents();
  void releaseEvents();

  [SameObject] readonly attribute HTMLAllCollection all;
};
```

The attributes of the `Document` object listed in the first column of the following table must reflect the content attribute on the `body` element with the name given in the corresponding cell in the second column on the same row, if the `body` element is a `body` element (as opposed to a `frameset` element). When there is no `body` element or if it is a `frameset` element, the attributes must instead return the empty string on getting and do nothing on setting.

<table>
<thead>
<tr>
<th>IDL attribute</th>
<th>Content attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>fgColor</td>
<td><code>text</code></td>
</tr>
<tr>
<td>linkColor</td>
<td><code>link</code></td>
</tr>
<tr>
<td>vlinkColor</td>
<td><code>vlink</code></td>
</tr>
<tr>
<td>alinkColor</td>
<td><code>alink</code></td>
</tr>
<tr>
<td>bgColor</td>
<td><code>bgcolor</code></td>
</tr>
</tbody>
</table>

The `anchors` attribute must return an `HTMLCollection` rooted at the `Document` node, whose filter matches only `a` elements with `name` attributes.

The `applets` attribute must return an `HTMLCollection` rooted at the `Document` node, whose filter matches nothing. (It exists for historical reasons.)

The `clear()`, `captureEvents()`, and `releaseEvents()` methods must do nothing.

The `all` attribute must return an `HTMLAllCollection` rooted at the `Document` node, whose filter matches all elements.
The `captureEvents()` and `releaseEvents()` methods must do nothing.

The `external` attribute of the `Window` interface must return an instance of the `External` interface:

```idl
[Exposed=Window,
 NoInterfaceObject]
interface External {
    void AddSearchProvider();
    void IsSearchProviderInstalled();
};
```

The `AddSearchProvider()` and `IsSearchProviderInstalled()` methods must do nothing.
16 IANA considerations

16.1 text/html

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
  text

Subtype name:
  html

Required parameters:
  No required parameters

Optional parameters:
  charset

The charset parameter may be provided to specify the document's character encoding, overriding any character encoding declarations in the document other than a Byte Order Mark (BOM). The parameter's value must be an ASCII case-insensitive match for the string "utf-8". [ENCODING]

Encoding considerations:
  8bit (see the section on character encoding declarations)

Security considerations:
Entire novels have been written about the security considerations that apply to HTML documents. Many are listed in this document, to which the reader is referred for more details. Some general concerns bear mentioning here, however:

HTML is a scripted language, and has a large number of APIs (some of which are described in this document). Script can expose the user to potential risks of information leakage, credential leakage, cross-site scripting attacks, cross-site request forgeries, and a host of other problems. While the designs in this specification are intended to be safe if implemented correctly, a full implementation is a massive undertaking and, as with any software, user agents are likely to have security bugs.

Even without scripting, there are specific features in HTML which, for historical reasons, are required for broad compatibility with legacy content but that expose the user to unfortunate security problems. In particular, the img element can be used in conjunction with some other features as a way to effect a port scan from the user's location on the Internet. This can expose local network topologies that the attacker would otherwise not be able to determine.

HTML relies on a compartmentalization scheme sometimes known as the same-origin policy. An origin in most cases consists of all the pages served from the same host, on the same port, using the same protocol.

It is critical, therefore, to ensure that any untrusted content that forms part of a site be hosted on a different origin than any sensitive content on that site. Untrusted content can easily spoof any other page on the same origin, read data from that origin, cause scripts in that origin to execute, submit forms to and from that origin even if they are protected from cross-site request forgery attacks by unique tokens, and make use of any third-party resources exposed to or rights granted to that origin.

Interoperability considerations:
Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:
This document is the relevant specification. Labeling a resource with the text/html type asserts that the resource is an HTML document using the HTML syntax.

Applications that use this media type:
Web browsers, tools for processing Web content, HTML authoring tools, search engines, validators.

Additional information:
Magic number(s):
  No sequence of bytes can uniquely identify an HTML document. More information on detecting HTML documents is available in the WHATWG MIME Sniffing standard. [MIMESNIFF]

File extension(s):
  "html" and "htm" are commonly, but certainly not exclusively, used as the extension for HTML documents.
Macintosh file type code(s):
   TEXT

Person & email address to contact for further information:
   Ian Hickson <ian@hixie.ch>

Intended usage:
   Common

Restrictions on usage:
   No restrictions apply.

Author:
   Ian Hickson <ian@hixie.ch>

Change controller:
   W3C

Fragments used with text/html resources either refer to the indicated part of the document or provide state information for in-page scripts.

16.2 multipart/x-mixed-replace

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
   multipart

Subtype name:
   x-mixed-replace

Required parameters:
   • boundary (defined in RFC2046) [RFC2046]

Optional parameters:
   No optional parameters.

Encoding considerations:
   binary

Security considerations:
   Subresources of a multipart/x-mixed-replace resource can be of any type, including types with non-trivial security implications such as text/html.

Interoperability considerations:
   None.

Published specification:
   This specification describes processing rules for Web browsers. Conformance requirements for generating resources with this type are the same as for multipart/mixed [RFC2046].

Applications that use this media type:
   This type is intended to be used in resources generated by Web servers, for consumption by Web browsers.

Additional information:
   Magic number(s):
      No sequence of bytes can uniquely identify a multipart/x-mixed-replace resource.

   File extension(s):
      No specific file extensions are recommended for this type.

   Macintosh file type code(s):
      No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:
   Ian Hickson <ian@hixie.ch>
16.3 application/xhtml+xml

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
application

Subtype name:
xhtml+xml

Required parameters:
Same as for application/xml [RFC7303]

Optional parameters:
Same as for application/xml [RFC7303]

Encoding considerations:
Same as for application/xml [RFC7303]

Security considerations:
Same as for application/xml [RFC7303]

Interoperability considerations:
Same as for application/xml [RFC7303]

Published specification:
Labeling a resource with the application/xhtml+xml type asserts that the resource is an XML document that likely has a document element from the HTML namespace. Thus, the relevant specifications are the XML specification, the Namespaces in XML specification, and this specification. [XML] [XMLNS]

Applications that use this media type:
Same as for application/xml [RFC7303]

Additional information:
Magic number(s):
Same as for application/xml [RFC7303]

File extension(s):
"xhtml" and "xht" are sometimes used as extensions for XML resources that have a document element from the HTML namespace.

Macintosh file type code(s):
TEXT

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:
Common
Restrictions on usage:
No restrictions apply.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments used with application/xhtml+xml resources have the same semantics as with any XML MIME type. [RFC7303]

16.4 text/cache-manifest

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
text

Subtype name:
cache-manifest

Required parameters:
No parameters

Optional parameters:
charset
The charset parameter may be provided. The parameter's value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:
8bit (always UTF-8)

Security considerations:
Cache manifests themselves pose no immediate risk unless sensitive information is included within the manifest. Implementations, however, are required to follow specific rules when populating a cache based on a cache manifest, to ensure that certain origin-based restrictions are honored. Failure to correctly implement these rules can result in information leakage, cross-site scripting attacks, and the like.

Interoperability considerations:
Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:
This document is the relevant specification.

Applications that use this media type:
Web browsers.

Additional information:
Magic number(s):
Cache manifests begin with the string "CACHE MANIFEST", followed by either a U+0020 SPACE character, a U+0009 CHARACTER TABULATION (tab) character, a U+000A LINE FEED (LF) character, or a U+000D CARRIAGE RETURN (CR) character.

File extension(s):
"appcache"

Macintosh file type code(s):
No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:
Common
Restrictions on usage:
No restrictions apply.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments have no meaning with text/cache-manifest resources.

16.5 text/ping

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
  text

Subtype name:
  ping

Required parameters:
  No parameters

Optional parameters:
  charset
    The charset parameter may be provided. The parameter's value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:
Not applicable.

Security considerations:
If used exclusively in the fashion described in the context of hyperlink auditing, this type introduces no new security concerns.

Interoperability considerations:
Rules applicable to this type are defined in this specification.

Published specification:
This document is the relevant specification.

Applications that use this media type:
Web browsers.

Additional information:
  Magic number(s):
    text/ping resources always consist of the four bytes 0x50 0x49 0x4E 0x47 ("PING").
  File extension(s):
    No specific file extension is recommended for this type.
  Macintosh file type code(s):
    No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:
Common

Restrictions on usage:
Only intended for use with HTTP POST requests generated as part of a Web browser's processing of the ping attribute.

Author:
Ian Hickson <ian@hixie.ch>
Change controller:
W3C

Fragments have no meaning with text/ping resources.

16.6 application/microdata+json

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
application

Subtype name:
microdata+json

Required parameters:
Same as for application/json

Optional parameters:
Same as for application/json

Encoding considerations:
8bit (always UTF-8)

Security considerations:
Same as for application/json

Interoperability considerations:
Same as for application/json

Published specification:
Labeling a resource with the application/microdata+json type asserts that the resource is a JSON text that consists of an object with a single entry called "items" consisting of an array of entries, each of which consists of an object with an entry called "id" whose value is a string, an entry called "type" whose value is another string, and an entry called "properties" whose value is an object whose entries each have a value consisting of an array of either objects or strings. The objects being of the same form as the objects in the aforementioned "items" entry. Thus, the relevant specifications are the JSON specification and this specification.

Applications that use this media type:
Applications that transfer data intended for use with HTML's microdata feature, especially in the context of drag-and-drop, are the primary application class for this type.

Additional information:

Magic number(s):
Same as for application/json

File extension(s):
Same as for application/json

Macintosh file type code(s):
Same as for application/json

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:
Common

Restrictions on usage:
No restrictions apply.

Author:
Ian Hickson <ian@hixie.ch>
Change controller:
W3C

Fragments used with application/microdata+json resources have the same semantics as when used with application/json (namely, at the time of writing, no semantics at all). [JSON]

16.7 text/event-stream

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

text

Subtype name:
event-stream

Required parameters:
No parameters

Optional parameters:
charset

The charset parameter may be provided. The parameter's value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:

8bit (always UTF-8)

Security considerations:

An event stream from an origin distinct from the origin of the content consuming the event stream can result in information leakage. To avoid this, user agents are required to apply CORS semantics. [FETCH]

Event streams can overwhelm a user agent; a user agent is expected to apply suitable restrictions to avoid depleting local resources because of an overabundance of information from an event stream.

Servers can be overwhelmed if a situation develops in which the server is causing clients to reconnect rapidly. Servers should use a 5xx status code to indicate capacity problems, as this will prevent conforming clients from reconnecting automatically.

Interoperability considerations:

Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:
This document is the relevant specification.

Applications that use this media type:
Web browsers and tools using Web services.

Additional information:

Magic number(s):
No sequence of bytes can uniquely identify an event stream.

File extension(s):
No specific file extensions are recommended for this type.

Macintosh file type code(s):
No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:
Common

Restrictions on usage:
This format is only expected to be used by dynamic open-ended streams served using HTTP or a similar protocol. Finite resources are not expected to be labeled with this type.
Fragments have no meaning with `text/event-stream` resources.

16.8 `Ping-From`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

**Header field name:**
Ping-From

**Applicable protocol:**
http

**Status:**
standard

**Author/Change controller:**
W3C

**Specification document(s):**
This document is the relevant specification.

**Related information:**
None.

16.9 `Ping-To`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

**Header field name:**
Ping-To

**Applicable protocol:**
http

**Status:**
standard

**Author/Change controller:**
W3C

**Specification document(s):**
This document is the relevant specification.

**Related information:**
None.

16.10 `Refresh`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]
Applicable protocol:
  http

Status:
  standard

Author/Change controller:
  WHATWG

Specification document(s):
  This document is the relevant specification.

Related information:
  None.

16.11 `Last-Event-ID`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
  Last-Event-ID

Applicable protocol:
  http

Status:
  standard

Author/Change controller:
  W3C

Specification document(s):
  This document is the relevant specification.

Related information:
  None.

16.12 web+ scheme prefix

This section describes a convention for use with the IANA URI scheme registry. It does not itself register a specific scheme. [RFC7595]

Scheme name:
  Schemes starting with the four characters "web+" followed by one or more letters in the range a-z.

Status:
  Permanent

Scheme syntax:
  Scheme-specific.

Scheme semantics:
  Scheme-specific.

Encoding considerations:
  All "web+" schemes should use UTF-8 encodings where relevant.

Applications/protocols that use this scheme name:
  Scheme-specific.

Interoperability considerations:
  The scheme is expected to be used in the context of Web applications.
Security considerations:

Any Web page is able to register a handler for all "web+" schemes. As such, these schemes must not be used for features intended to be core platform features (e.g. network transfer protocols like HTTP or FTP). Similarly, such schemes must not store confidential information in their URLs, such as usernames, passwords, personal information, or confidential project names.

Contact:
Ian Hickson <ian@hixie.ch>

Change controller:
Ian Hickson <ian@hixie.ch>

References:
Custom scheme handlers, HTML Living Standard: https://html.spec.whatwg.org/#custom-handlers
The following sections only cover conforming elements and features.

**Elements**

This section is non-normative.

<table>

</tbody>
</table>

An asterisk (*) in a cell indicates that the actual rules are more complicated than indicated in the table above.

† Categories in the “Parents” column refer to parents that list the given categories in their content model, not to elements that themselves are in those categories. For example, the a element’s “Parents” column says “phrasing”, so any element whose content model contains the “phrasing” category could be a parent of an a element. Since the “flow” category includes all the “phrasing” elements, that means the th element could be a parent of an a element.

### Element content categories

This section is non-normative.

<td>-----------------------</td>
<td>---------------------</td>
<td>---------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>close</td>
<td>Event</td>
<td>dialog[^55] elements, WebSocket[^55]</td>
<td>Fired at dialog[^55] elements when they are closed, and at WebSocket[^55] elements when the connection is terminated</td>
<td></td>
</tr>
<tr>
<td>connect</td>
<td>MessageEvent[^62]</td>
<td>SharedWorkerGlobalScope[^61]</td>
<td>Fired at a shared worker’s global scope when a new client connects</td>
<td></td>
</tr>
<tr>
<td>contextmenu</td>
<td>MouseEvent</td>
<td>Elements</td>
<td>Fired at elements when the user requests their context menu</td>
<td></td>
</tr>
<tr>
<td>copy</td>
<td>Event</td>
<td>Elements</td>
<td>Fired at elements when the user copies data to the clipboard</td>
<td></td>
</tr>
<tr>
<td>cut</td>
<td>Event</td>
<td>Elements</td>
<td>Fired at elements when the user copies the selected data on the clipboard and removes the selection from the document</td>
<td></td>
</tr>
<tr>
<td>error</td>
<td>Event or ErrorEvent[^61]</td>
<td>Global scope objects, Worker[^60] elements, networking-related objects</td>
<td>Fired when unexpected errors occur (e.g. networking errors, script errors, decoding errors)</td>
<td></td>
</tr>
<tr>
<td>focus</td>
<td>Event</td>
<td>Window[^5] elements</td>
<td>Fired at nodes gaining focus[^4]</td>
<td></td>
</tr>
<tr>
<td>hashchange</td>
<td>HashChangeEvent[^63]</td>
<td>Window[^5]</td>
<td>Fired at the Window[^5] when the fragment part of the document’s URL changes</td>
<td></td>
</tr>
<tr>
<td>input</td>
<td>Event</td>
<td>Form controls</td>
<td>Fired at controls when the user changes the value (see also the change[^3] event)</td>
<td></td>
</tr>
<tr>
<td>invalid</td>
<td>Event</td>
<td>Form controls</td>
<td>Fired at controls during form validation if they do not satisfy their constraints</td>
<td></td>
</tr>
<tr>
<td>languagechange</td>
<td>Event</td>
<td>Global scope objects</td>
<td>Fired at the global scope object when the user’s preferred languages change</td>
<td></td>
</tr>
<tr>
<td>load</td>
<td>Event</td>
<td>Window[^5] elements</td>
<td>Fired at the Window[^5] when the document has finished loading; fired at an element containing a resource (e.g. img[^5] embed[^5]) when its resource has finished loading</td>
<td></td>
</tr>
<tr>
<td>loadend</td>
<td>Event or ProgressEvent</td>
<td>img[^5] elements</td>
<td>Fired at img[^5] elements after a successful load</td>
<td></td>
</tr>
<tr>
<td>loadstart</td>
<td>ProgressEvent</td>
<td>img[^5] elements</td>
<td>Fired at img[^5] elements when a load begins (see also media element events[^3])</td>
<td></td>
</tr>
<tr>
<td>message</td>
<td>MessageEvent[^65]</td>
<td>Window[^5], EventSource[^5], WebSocket[^5], MessagePort[^5], BroadcastChannel[^5], DedicatedWorkerGlobalScope[^6], Worker[^5], ServiceWorkerContainer</td>
<td>Fired at an object when it receives a message</td>
<td></td>
</tr>
<tr>
<td>messageerror</td>
<td>MessageEvent[^65]</td>
<td>Window[^5], MessagePort[^5], BroadcastChannel[^5], DedicatedWorkerGlobalScope[^6], Worker[^5], ServiceWorkerContainer</td>
<td>Fired at an object when it receives a message that cannot be deserialized</td>
<td></td>
</tr>
<tr>
<td>offline</td>
<td>Event</td>
<td>Global scope objects</td>
<td>Fired at the global scope object when the network connections fail</td>
<td></td>

<tr>
<td>online</td>
<td>Event</td>
<td>Global scope objects</td>
<td>Fired at the global scope object when the network connections returns</td>
<td></td>
</tr>
<tr>
<td>open</td>
<td>Event</td>
<td>EventSource[^5], WebSocket[^5]</td>
<td>Fired at networking-related objects when a connection is established</td>
<td></td>
</tr>
<tr>
<td>pagehide</td>
<td>PageTransitionEvent[^4]</td>
<td>Window[^7]</td>
<td>Fired at the Window[^7] when the page’s entry in the session history[^4] stops being the current entry[^4]</td>
<td></td>
</tr>
<tr>
<td>pageshow</td>
<td>PageTransitionEvent[^4]</td>
<td>Window[^7]</td>
<td>Fired at the Window[^7] when the page’s entry in the session history[^4] becomes the current entry[^4]</td>
<td></td>
</tr>
<tr>
<td>paste</td>
<td>Event</td>
<td>Elements</td>
<td>Fired at elements when the user will insert the clipboard data in the most suitable format (if any) supported for the given context</td>
<td></td>
</tr>
<tr>
<td>popstate</td>
<td>PopStateEvent[^7]</td>
<td>Window[^7]</td>
<td>Fired at the Window[^7] when the user navigates the session history[^7]</td>
<td></td>
</tr>
<tr>
<td>progress</td>
<td>ProgressEvent</td>
<td>img[^7] elements</td>
<td>Fired at img[^7] elements during a CORS-same-origin[^7] image load (see also media element events[^3])</td>
<td></td>
</tr>
<tr>
<td>readystatechange</td>
<td>Event</td>
<td>Document[^1]</td>
<td>Fired at the Document[^1] when it finishes parsing and again when all its subresources have finished loading</td>
<td></td>
</tr>
<tr>
<td>rejectionhandled</td>
<td>PromiseRejectionEvent[^3]</td>
<td>Global scope objects</td>
<td>Fired at global scope objects when a previously-unhandled promise rejection became handled</td>
<td></td>
</tr>
<tr>
<td>reset</td>
<td>Event</td>
<td>form[^7] elements</td>
<td>Fired at a form[^7] element when it is reset[^7]</td>
<td></td>
</tr>
<tr>
<td>securitypolicyviolation</td>
<td>Event</td>
<td>Elements</td>
<td>Fired at elements when a Content Security Policy violation is generated [CSP][^1]</td>
<td></td>
</tr>
<tr>
<td>select</td>
<td>Event</td>
<td>Form controls</td>
<td>Fired at form controls when their text selection is</td>
<td></td>
</tr>

</tr>
<tr>
<td>------------------</td>
<td>----------------------</td>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>storage</td>
<td>StorageEvent</td>
<td>Window</td>
<td>Fired at Windows event when the corresponding localStorage or sessionStorage storage areas change</td>
<td></td>
</tr>
<tr>
<td>submit</td>
<td>Event</td>
<td>form elements</td>
<td>Fired at a form element when it is submitted</td>
<td></td>
</tr>
<tr>
<td>toggle</td>
<td>Event</td>
<td>details element</td>
<td>Fired at details elements when they open or close</td>
<td></td>
</tr>
<tr>
<td>unhandledrejection</td>
<td>PromiseRejectionEvent</td>
<td>Global scope objects</td>
<td>Fired at global scope objects when a promise rejection goes unhandled</td>
<td></td>
</tr>
<tr>
<td>unload</td>
<td>Event</td>
<td>Window</td>
<td>Fired at the Window object when the page is going away</td>
<td></td>
</tr>
</tbody>
</table>

**MIME Types**

This section is non-normative.

The following MIME types are mentioned in this specification:

- application/atom+xml
  - Atom [ATOM]
- application/ecmascript
  - JavaScript (legacy type) [JAVASCRIPT]
- application/javascript
  - JavaScript (legacy type) [JAVASCRIPT]
- application/json
  - JSON [JSON]
- application/x-ecmascript
  - JavaScript (legacy type) [JAVASCRIPT]
- application/x-javascript
  - JavaScript (legacy type) [JAVASCRIPT]
- application/octet-stream
  - Generic binary data [RFC2046]
- application/microdata+json
  - Microdata as JSON
- application/rss+xml
  - RSS
- application/x-www-form-urlencoded
  - Form submission
- application/xhtml+xml
  - HTML
- application/xml
  - XML [XML]
- image/gif
  - GIF images
- image/jpeg
  - JPEG images
**image/png**
PNG images [PNG]

**image/svg+xml**
SVG images [SVG]

**multipart/form-data**
Form submission [RFC7578]

**multipart/mixed**
Generic mixed content [RFC2046]

**multipart/x-mixed-replace**
Streaming server push

**text/cache-manifest**
Offline application cache manifests

**text/css**
CSS [CSS]

**text/ecmascript**
JavaScript (legacy type) [JAVASCRIPT]

**text/event-stream**
Server-sent event streams

**text/javascript**
JavaScript [JAVASCRIPT]

**text/javascript1.0**
JavaScript (legacy type) [JAVASCRIPT]

**text/javascript1.1**
JavaScript (legacy type) [JAVASCRIPT]

**text/javascript1.2**
JavaScript (legacy type) [JAVASCRIPT]

**text/javascript1.3**
JavaScript (legacy type) [JAVASCRIPT]

**text/javascript1.4**
JavaScript (legacy type) [JAVASCRIPT]

**text/javascript1.5**
JavaScript (legacy type) [JAVASCRIPT]

**text/jscript**
JavaScript (legacy type) [JAVASCRIPT]

**text/json**
JSON (legacy type)

**text/livescript**
JavaScript (legacy type) [JAVASCRIPT]

**text/plain**
Generic plain text [RFC2046], [RFC3676]

**text/html**
HTML

**text/ping**
Hyperlink auditing

**text/uri-list**
List of URLs [RFC2483]
text/vcard
  vCard [RFC6350]

text/vtt
  WebVTT [WEBVTT]

text/x-ecmascript
  JavaScript (legacy type) [JAVASCRIPT]

text/x-javascript
  JavaScript (legacy type) [JAVASCRIPT]

text/xml
  XML [XML] [RFC7303]

video/mp4
  MPEG-4 video [RFC4337]

video/mpeg
  MPEG video [RFC2046]

  CSS Logical Properties, R. Atanassov, E. Etemad. W3C.

[CSSOM]
  Cascading Style Sheets Object Model (CSSOM), S. Pieters, G. Adams. W3C.

[CSSOMVIEW]
  CSSOM View Module, S. Pieters, G. Adams. W3C.

[CSSOVERFLOW]
  CSS Overflow Module, L. Baron, F. Rivoal. W3C.

[CSSPOSITION]
  CSS Positioned Layout, R. Atanassov, A. Eicholz. W3C.

[CSSRUBY]
  CSS3 Ruby Module, R. Ishida. W3C.

[CSSTRANSITIONS]
  (Non-normative) CSS Transitions, D. Jackson, D. Hyatt, C. Marrin, L. Baron. W3C.

[CSSUI]
  CSS3 Basic User Interface Module, T. Çelik. W3C.

[CSSSYNTAX]
  CSS Syntax, T. Atkins, S. Sapin. W3C.

[CSSTABLE]
  CSS Table, F. Remy, G. Whitworth. W3C.

[CSSTEXT]
  CSS Text, E. Etemad, K. Ishii. W3C.

[CSSVALUES]
  CSS3 Values and Units, H. Lie, T. Atkins, E. Etemad. W3C.
[CSSWM]
CSS Writing Modes, E. Etemad, K. Ishii. W3C.

[DASH]
Dynamic adaptive streaming over HTTP (DASH), ISO.

[DOM]
DOM, A. van Kesteren, A. Gregor, Ms2ger. WHATWG.

[DOMPARSING]
DOM Parsing and Serialization, T. Leithead. W3C.

[DOT]
(Non-normative) The DOT Language, Graphviz.

[E163]

[ENCODING]
Encoding, A. van Kesteren, J. Bell. WHATWG.

[EXECOMMAND]
execCommand, J. Wilm, A. Gregor. W3C Editing APIs CG.

[EXIF]
(Non-normative) Exchangeable image file format, JEITA.

[FEATUREPOLICY]
Feature Policy, I. Clelland, WICG.

[FETCH]
Fetch, A. van Kesteren. WHATWG.

[FILEAPI]
File API, A. Ranganathan. W3C.

[FILTERS]

[FULLSCREEN]
Fullscreen, A. van Kesteren, T. Çelik. WHATWG.

[GEOMETRY]
Geometry Interfaces Module, S. Pieters, D. Schulze, R. Cabanier. W3C.

[GIF]
(Non-normative) Graphics Interchange Format, CompuServe.

[GRAPHICS]

[GREGORIAN]

[HRT]
High Resolution Time, I. Grigorik, J. Simonsen, J. Mann. W3C.

[HTMLAAM]
HTML Accessibility API Mappings 1.0, S. Faulkner, J. Kiss, A. Surkov. W3C.

[HTTP]
Hypertext Transfer Protocol (HTTP/1.1): Message Syntax and Routing, R. Fielding, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Semantics and Content, R. Fielding, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Conditional Requests, R. Fielding, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Range Requests, R. Fielding, Y. Lafon, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Caching, R. Fielding, M. Nottingham, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Authentication, R. Fielding, J. Reschke. IETF.
[RFC1123]  
Requirements for Internet Hosts -- Application and Support, R. Braden. IETF, October 1989.

[RFC2046]  
Multipurpose Internet Mail Extensions (MIME) Part Two: Media Types, N. Freed, N. Borenstein. IETF.

[RFC2397]  
The "data" URL scheme, L. Masinter. IETF.

[RFC5545]  
Internet Calendaring and Scheduling Core Object Specification (iCalendar), B. Desruisseaux. IETF.

[RFC2483]  
URI Resolution Services Necessary forURN Resolution, M. Mealling, R. Daniel. IETF.

[RFC3676]  
The Text/Plain Format and DelSp Parameters, R. Gellens. IETF.

[RFC3864]  
Registration Procedures for Message Header Fields, G. Klyne, M. Nottingham, J. Mogul. IETF.

[RFC4329]  
(Non-normative) Scripting Media Types, B. Höhrmann. IETF.

[RFC4337]  
(Non-normative) MIME Type Registration for MPEG-4, Y. Lim, D. Singer. IETF.

[RFC7595]  
Guidelines and Registration Procedures for URI Schemes, D. Thaler, T. Hansen, T. Hardie. IETF.

[RFC5322]  
Internet Message Format, P. Resnick. IETF.

[RFC6381]  
The 'Codecs' and 'Profiles' Parameters for "Bucket" Media Types, R. Gellens, D. Singer, P. Frojdh. IETF.

[RFC6266]  
Use of the Content-Disposition Header Field in the Hypertext Transfer Protocol (HTTP), J. Reschke. IETF.

[RFC6350]  
vCard Format Specification, S. Perreault. IETF.

[RFC6596]  
The Canonical Link Relation, M. Ohye, J. Kupke. IETF.

[RFC7303]  
XML Media Types, H. Thompson, C. Lilley. IETF.

[RFC7578]  
Returning Values from Forms: multipart/form-data, L. Masinter. IETF.

[SCREENORIENTATION]  
Screen Orientation API, M. Lamouri, M. Cáceres. W3C.

[SCSU]  

[SECURE-CONTEXTS]  
Secure Contexts, M. West. W3C.

[SELECTION]  
Selection API, R. Niwa. W3C.

[SELECTORS]  

[SMS]  
(Non-normative) URI Scheme for Global System for Mobile Communications (GSM) Short Message Service (SMS), E. Wilde, A. Vaha-Sipila. IETF.
[WEBMCG]
   WebM Container Guidelines. The WebM Project.

[WEBVTT]
   WebVTT. S. Pieters. W3C.

[WHATWGWIki]
   The WHATWG Wiki. WHATWG.

[WORKLETS]
   Worklets. I. Kilpatrick. W3C.

[WSP]
   The WebSocket protocol. I. Fette, A. Melnikov. IETF.

[X121]

[XFN]
   XFN 1.1 profile. T. Çelik, M. Mullenweg, E. Meyer. GMPG.

[XHR]
   XMLHttpRequest. A. van Kesteren. WHATWG.

[XKCD1288]
   (Non-normative) Substitutions. Randall Munroe. xkcd.

[XML]
   Extensible Markup Language. T. Bray, J. Paoli, C. Sperber-McQueen, E. Maler, F. Yergeau. W3C.

[XMLENTITY]
   (Non-normative) XML Entity Definitions for Characters. D. Carlisle, P. Ion. W3C.

[XMLNS]
   Namespaces in XML. T. Bray, D. Hollander, A. Layman, R. Tobin. W3C.

[XMLSSPI]

[XPATH10]
   XML Path Language (XPath) Version 1.0. J. Clark, S. DeRose. W3C.

[XSLT10]
   (Non-normative) XSL Transformations (XSLT) Version 1.0. J. Clark. W3C.

[XSLTP]
   (Non-normative) DOM XSLTProcessor. WHATWG Wiki. WHATWG.
Acknowledgments

Thanks to Tim Berners-Lee for inventing HTML, without which none of this would exist.

Thanks also to everyone who has ever posted about HTML in their blogs, public mailing lists, or forums, including all the contributors to the various W3C HTML WG lists and the various WHATWG lists.

Special thanks to Richard Williamson for creating the first implementation of `canvas` in Safari, from which the canvas feature was
discovered.
designed.

Special thanks also to the Microsoft employees who first implemented the event-based drag-and-drop mechanism, contenteditable, and other features first widely deployed by the Windows Internet Explorer browser.

Special thanks and $10,000 to David Hyatt who came up with a broken implementation of the adoption agency algorithm that the editor had to reverse engineer and fix before using it in the parsing section.

Thanks to the participants of the microdata usability study for allowing us to use their mistakes as a guide for designing the microdata feature.

Thanks to the many sources that provided inspiration for the examples used in the specification.

Thanks also to the Microsoft blogging community for some ideas, to the attendees of the W3C Workshop on Web Applications and Compound Documents for inspiration, to the #mrt crew, the #mrt.no crew, and the #whatwg crew, and to Pillar and Hedral for their ideas and support.

Thanks to Igor Zhbanov for generating PDF versions of the specification.

Special thanks to the RICG for developing the picture element and related features; in particular thanks to Adrian Bateman, Bruce Lawson, David Newton, Ilya Grigorik, John Schoenick, Leon de Rijke, Mat Marquardt, Marcos Cáceres, Tab Atkins, Theresa O’Connor, and Yoav Weiss for their contributions.

Special thanks to the WPWG for incubating the custom elements feature. In particular, thanks to David Hyatt and Ian Hickson for their influence through the XBL specifications, Dimitri Glazkov for the first draft of the custom elements specification, and to Alex Komoroske, Alex Russell, Andres Rios, Boris Zbarsky, Brian Kardell, Daniel Buchner, Dominic Cooney, Erik Arvidsson, Elliott Sprehn, Hajime Morita, Hayato Ito, Jan Miksovsky, Jonas Sicking, Olli Pettay, Rafael Weinstein, Roland Steiner, Ryosuke Niwa, Scott Miles, Steve Faulkner, Steve Orvell, Tab Atkins, Theresa O’Connor, Tim Perry, and William Chen for their contributions.

Part of the revision history of the picture element and related features can be found in the ResponsiveImagesCG/picture-element-repository.

Part of the revision history of the theme-color metadata name can be found in the whatwg/meta-theme-color repository.

Part of the revision history of the custom elements feature can be found in the w3c/webcomponents repository, which is available under the W3C Permissive Document License.

Part of the revision history of the innerText IDL attribute can be found in the rocallahan/innerText-spec repository.

For about ten years starting in 2003, this standard was almost entirely written by Ian Hickson (Google, ian@hixie.ch). More recently, Simon Pieters (Bocoup, zcorpan@gmail.com), Anne van Kesteren (Mozilla, annevk@annevk.nl), Philip Jägenstedt (Google, philip@foolip.org), and Domenic Denicola (Google, d@domenic.me), all previously long-time contributors, have joined Ian in editing the text directly.
