Path2D includes CanvasPath;

To maintain compatibility with existing web content, user agents need to enumerate methods defined in CanvasUserInterface immediately after the stroke() method on CanvasRenderingContext2D objects.

Returns a CanvasRenderingContext2D object that is permanently bound to a particular canvas element.

If the alpha member is false, then the context is forced to always be opaque.

If the desynchronized member is true, then the context might be desynchronized.

The colorSpace member specifies the color space of the rendering context.

If the willReadFrequently member is true, then the context is marked for readback optimization.
Support in all current engines.

Firefox 1.5+ Safari 3+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the `canvas` element.

\[ \text{attributes} = \text{context}.\text{getContextAttributes}() \]

Returns an object whose:

- \textit{alpha} member is true if the context has an alpha channel, or false if it was forced to be opaque.
- \textit{desynchronized} member is true if the context can be \textit{desynchronized}.
- \textit{colorSpace} member is a string indicating the context’s \textit{color space}.
- \textit{willReadFrequently} member is true if the context is marked for \textit{readback optimization}.

A \text{CanvasRenderingContext2D} object has an \textit{output bitmap} that is initialized when the object is created.

The \textit{output bitmap} has an \textit{origin-clean} flag, which can be set to true or false. Initially, when one of these bitmaps is created, its \textit{origin-clean} flag must be set to true.

The \text{CanvasRenderingContext2D} object also has an \textit{alpha} boolean. When a \text{CanvasRenderingContext2D} object’s \textit{alpha} is false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

Thus, the bitmap of such a context starts off as \textit{opaque black} instead of \textit{transparent black}; \text{clearRect()} always results in \textit{opaque black} pixels, every fourth byte from \text{getImageData()} is always 255, the \text{putImageData()} method effectively ignores every fourth byte in its input, and so on. However, the alpha component of styles and images drawn onto the canvas are still honoured up to the point where they would impact the \textit{output bitmap}’s alpha channel; for instance, drawing a 50% transparent white square on a freshly created \textit{output bitmap} with its \textit{alpha} set to false will result in a fully-opaque gray square.

The \text{CanvasRenderingContext2D} object also has a \textit{desynchronized} boolean. When a \text{CanvasRenderingContext2D} object’s \textit{desynchronized} is true, then the user agent may optimize the rendering of the canvas to reduce the latency, as measured from input events to rasterization, by desynchronizing the canvas paint cycle from the event loop, bypassing the ordinary user agent rendering algorithm, or both. Insofar as this mode involves bypassing the usual paint mechanisms, rasterization, or both, it might introduce visible tearing artifacts.
The user agent usually renders on a buffer which is not being displayed, quickly swapping it and the one being scanned out for presentation; the former buffer is called back buffer and the latter front buffer. A popular technique for reducing latency is called front buffer rendering, also known as single buffer rendering, where rendering happens in parallel and racily with the scanning out process. This technique reduces the latency at the price of potentially introducing tearing artifacts and can be used to implement in total or part of the desynchronized boolean. [MULTIPLEBUFFERING]

The desynchronized boolean can be useful when implementing certain kinds of applications, such as drawing applications, where the latency between input and rasterization is critical.

The `CanvasRenderingContext2D` object also has a will read frequently boolean. When a `CanvasRenderingContext2D` object’s will read frequently is true, the user agent may optimize the canvas for readback operations.

On most devices the user agent needs to decide whether to store the canvas’s output bitmap on the GPU (this is also called "hardware accelerated"), or on the CPU (also called "software"). Most rendering operations are more performant for accelerated canvases, with the major exception being readback with `getImageData()`, `toDataURL()`, or `toBlob()`.

`CanvasRenderingContext2D` objects with will read frequently equal to true tell the user agent that the webpage is likely to perform many readback operations and that it is advantageous to use a software canvas.

The `CanvasRenderingContext2D` object also has a color space setting of type `PredefinedColorSpace`. The `CanvasRenderingContext2D` object’s color space indicates the color space for the output bitmap.

The `getContextAttributes()` method steps are to return «[ "alpha" → this’s alpha, “desynchronized” → this’s desynchronized, “colorSpace” → this’s color space, “willReadFrequently” → this’s will read frequently ]».

The `CanvasRenderingContext2D` 2D rendering context represents a flat linear Cartesian surface whose origin (0,0) is at the top left corner, with the coordinate space having x values increasing when going right, and y values increasing when going down. The x-coordinate of the right-most edge is equal to the width of the rendering context’s output bitmap in CSS pixels; similarly, the y-coordinate of the bottom-most edge is equal to the height of the rendering context’s output bitmap in CSS pixels.

The size of the coordinate space does not necessarily represent the size of the actual bitmaps that the user agent will use internally or during rendering. On high-definition displays, for instance, the user agent may internally use bitmaps with four device pixels per unit in the coordinate space, so that the rendering remains at high quality throughout. Anti-aliasing can similarly be implemented using oversampling with bitmaps of a higher resolution than the final image on the display.

Using CSS pixels to describe the size of a rendering context’s output bitmap does not mean that
when rendered the canvas will cover an equivalent area in CSS pixels. CSS pixels are reused for ease of integration with CSS features, such as text layout.

In other words, the canvas element below’s rendering context has a 200x200 output bitmap (which internally uses CSS pixels as a unit for ease of integration with CSS) and is rendered as 100x100 CSS pixels:

```html
<canvas width=200 height=200 style=width:100px;height:100px>
```

The 2D context creation algorithm, which is passed a target (a canvas element) and options, consists of running these steps:

1. Let settings be the result of converting options to the dictionary type CanvasRenderingContext2DSettings. (This can throw an exception.).
2. Let context be a new CanvasRenderingContext2D object.
3. Initialize context’s canvas attribute to point to target.
4. Set context’s output bitmap to the same bitmap as target’s bitmap (so that they are shared).
5. Set bitmap dimensions to the numeric values of target’s width and height content attributes.
6. Set context’s alpha to settings["alpha"].
7. Set context’s desynchronized to settings["desynchronized"].
8. Set context’s color space to settings["colorSpace"].
9. Set context’s will read frequently to settings["willReadFrequently"].
10. Return context.

When the user agent is to set bitmap dimensions to width and height, it must run these steps:

1. Reset the rendering context to its default state.
2. Resize the output bitmap to the new width and height.
3. Let canvas be the canvas element to which the rendering context’s canvas attribute was initialized.
4. If the numeric value of canvas’s width content attribute differs from width, then set
canvas's width content attribute to the shortest possible string representing width as a valid non-negative integer.

5. If the numeric value of canvas's height content attribute differs from height, then set canvas's height content attribute to the shortest possible string representing height as a valid non-negative integer.

Only one square appears to be drawn in the following example:

```javascript
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');
context.fillRect(0, 0, 50, 50);
canvas.setAttribute('width', '300'); // clears the canvas
context.fillRect(0, 100, 50, 50);
canvas.width = canvas.width; // clears the canvas
context.fillRect(100, 0, 50, 50); // only this square remains
```

The canvas attribute must return the value it was initialized to when the object was created.

The PredefinedColorSpace enumeration is used to specify the color space of the canvas’s backing store.

The "srgb" value indicates the ‘srgb’ color space.

The “display-p3” value indicates the ‘display-p3’ color space.

Algorithms for converting between color spaces are found in the Predefined color spaces section of CSS Color. [CSSCOLOR]

The CanvasFillRule enumeration is used to select the fill rule algorithm by which to determine if a point is inside or outside a path.

The value "nonzero" value indicates the nonzero winding rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape’s path going in one direction is equal to the number of times it crosses the path going in the other direction.

The “evenodd” value indicates the even-odd rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape’s path is even.

If a point is not outside a shape, it is inside the shape.
The `ImageSmoothingQuality` enumeration is used to express a preference for the interpolation quality to use when smoothing images.

The "low" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "medium" value indicates a preference for a medium level of image interpolation quality.

The "high" value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-smoothing algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used.

4.12.5.1.1 Implementation notes

This section is non-normative.

The output bitmap, when it is not directly displayed by the user agent, implementations can, instead of updating this bitmap, merely remember the sequence of drawing operations that have been applied to it until such time as the bitmap’s actual data is needed (for example because of a call to `drawImage()`, or the `createImageBitmap()` factory method). In many cases, this will be more memory efficient.

The bitmap of a canvas element is the one bitmap that’s pretty much always going to be needed in practice. The output bitmap of a rendering context, when it has one, is always just an alias to a canvas element’s bitmap.

Additional bitmaps are sometimes needed, e.g. to enable fast drawing when the canvas is being painted at a different size than its intrinsic size, or to enable double buffering so that graphics updates, like page scrolling for example, can be processed concurrently while canvas draw commands are being executed.

4.12.5.1.2 The canvas state

Objects that implement the `CanvasState` interface maintain a stack of drawing states. Drawing states consist of:

- The current transformation matrix.
- The current clipping region.
- The current values of the following attributes: `strokeStyle`, `fillStyle`, `globalAlpha`, `lineWidth`, `lineCap`, `lineJoin`, `miterLimit`, `lineDashOffset`, `shadowOffsetX`, `shadowOffsetY`, `shadowBlur`, `shadowColor`, `filter`, `globalCompositeOperation`, `font`, `textAlign`, `textBaseline`, `direction`,
The rendering context’s bitmaps are not part of the drawing state, as they depend on whether and how the rendering context is bound to a `canvas` element.

Objects that implement the `CanvasState` mixin have a `context lost` boolean, that is initialized to false when the object is created. The `context lost` value is updated in the `context lost steps`.

```javascript
context.save()
```

Support in all current engines.

- Firefox 1.5+
- Safari 2+
- Chrome 1+
- Opera 12.1+
- Edge 79+
- Edge (Legacy) 12+
- Internet Explorer 9+
- Firefox Android 4+
- Safari iOS 1+
- Chrome Android 18+
- WebView Android 1+
- Samsung Internet 1.0+
- Opera Android 12.1+

Pushes the current state onto the stack.

```javascript
context.restore()
```

Support in all current engines.

- Firefox 1.5+
- Safari 2+
- Chrome 1+
- Opera 12.1+
- Edge 79+
- Edge (Legacy) 12+
- Internet Explorer 9+
- Firefox Android 4+
- Safari iOS 1+
- Chrome Android 18+
- WebView Android 1+
- Samsung Internet 1.0+
- Opera Android 12.1+

Pops the top state on the stack, restoring the context to that state.

```javascript
context.reset()
```

Resets the rendering context, which includes the backing buffer, the drawing state stack, path, and styles.
**context.isContextLost()**

Returns true if the rendering context was lost. Context loss can occur due to driver crashes, running out of memory, etc. In these cases, the canvas loses its backing storage and takes steps to reset the rendering context to its default state.

The `save()` method steps are to push a copy of the current drawing state onto the drawing state stack.

The `restore()` method steps are to pop the top entry in the drawing state stack, and reset the drawing state it describes. If there is no saved state, then the method must do nothing.

The `reset()` method steps are to reset the rendering context to its default state.

To reset the rendering context to its default state:

1. Clear canvas's bitmap to transparent black.
2. Empty the list of subpaths in context’s current default path.
3. Clear the context’s drawing state stack.
4. Reset everything that drawing state consists of to their initial values.

The `isContextLost()` method steps are to return this’s context lost.

4.12.5.1.3 Line styles

**context.lineWidth [ = value ]**

CanvasRenderingContext2D/lineWidth

Support in all current engines.

<table>

</tbody>
</table>

**styles.lineWidth [ = value ]**

Returns the current line width.

Can be set, to change the line width. Values that are not finite values greater than zero are ignored.
`context.lineCap` [ = value ]

CanvasRenderingContext2D/lineCap

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

`styles.lineCap` [ = value ]

Returns the current line cap style.

Can be set, to change the line cap style.

The possible line cap styles are "butt", "round", and "square". Other values are ignored.

`context.lineJoin` [ = value ]

CanvasRenderingContext2D/lineJoin

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

`styles.lineJoin` [ = value ]

Returns the current line join style.

Can be set, to change the line join style.

The possible line join styles are "bevel", "round", and "miter". Other values are ignored.

`context.miterLimit` [ = value ]

CanvasRenderingContext2D/miterLimit

Support in all current engines.
Returns the current miter limit ratio.

Can be set, to change the miter limit ratio. Values that are not finite values greater than zero are ignored.

```plaintext
context.setStyleLineDash(segments)
```

Sets the current line dash pattern (as used when stroking). The argument is a list of distances for which to alternately have the line on and the line off.

```plaintext
segments = context.getLineDash()
```

Returns a copy of the current line dash pattern. The array returned will always have an even number of entries (i.e. the pattern is normalized).
context. `lineDashOffset`

CanvasRenderingContext2D/lineDashOffset

Support in all current engines.

Firefox 27+ Safari 7+ Chrome 23+
Opera 15+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 11
Firefox Android 27+ Safari iOS 7+ Chrome Android 25+ WebView Android 37+ Samsung Internet 1.5+ Opera Android 14+

`styles. lineDashOffset`

Returns the phase offset (in the same units as the line dash pattern).

Can be set, to change the phase offset. Values that are not finite values are ignored.

Objects that implement the CanvasPathDrawingStyles interface have attributes and methods (defined in this section) that control how lines are treated by the object.

The `lineWidth` attribute gives the width of lines, in coordinate space units. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the CanvasPathDrawingStyles interface is created, the `lineWidth` attribute must initially have the value 1.0.

The `lineCap` attribute defines the type of endings that UAs will place on the end of lines. The three valid values are "butt", "round", and "square".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the CanvasPathDrawingStyles interface is created, the `lineCap` attribute must initially have the value "butt".

The `lineJoin` attribute defines the type of corners that UAs will place where two lines meet. The three valid values are "bevel", "round", and "miter".

On getting, it must return the current value. On setting, the current value must be changed to the new value.
When the object implementing the `CanvasPathDrawingStyles` interface is created, the `lineJoin` attribute must initially have the value "miter".

When the `lineJoin` attribute has the value "miter", strokes use the miter limit ratio to decide how to render joins. The miter limit ratio can be explicitly set using the `miterLimit` attribute. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `miterLimit` attribute must initially have the value 10.0.

Each `CanvasPathDrawingStyles` object has a `dash list`, which is either empty or consists of an even number of non-negative numbers. Initially, the `dash list` must be empty.

The `setLineDash(segments)` method, when invoked, must run these steps:

1. If any value in `segments` is not finite (e.g. an Infinity or a NaN value), or if any value is negative (less than zero), then return (without throwing an exception; user agents could show a message on a developer console, though, as that would be helpful for debugging).

2. If the number of elements in `segments` is odd, then let `segments` be the concatenation of two copies of `segments`.

3. Let the object’s `dash list` be `segments`.

When the `getLineDash()` method is invoked, it must return a sequence whose values are the values of the object’s `dash list`, in the same order.

It is sometimes useful to change the “phase” of the dash pattern, e.g. to achieve a “marching ants” effect. The phase can be set using the `lineDashOffset` attribute. On getting, it must return the current value. On setting, infinite and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `lineDashOffset` attribute must initially have the value 0.0.

When a user agent is to `trace a path`, given an object `style` that implements the `CanvasPathDrawingStyles` interface, it must run the following algorithm. This algorithm returns a new `path`.

1. Let `path` be a copy of the path being traced.
2. Prune all zero-length line segments from path.

3. Remove from path any subpaths containing no lines (i.e. subpaths with just one point).

4. Replace each point in each subpath of path other than the first point and the last point of each subpath by a join that joins the line leading to that point to the line leading out of that point, such that the subpaths all consist of two points (a starting point with a line leading out of it, and an ending point with a line leading into it), one or more lines (connecting the points and the joins), and zero or more joins (each connecting one line to another), connected together such that each subpath is a series of one or more lines with a join between each one and a point on each end.

5. Add a straight closing line to each closed subpath in path connecting the last point and the first point of that subpath; change the last point to a join (from the previously last line to the newly added closing line), and change the first point to a join (from the newly added closing line to the first line).

6. If style’s dash list is empty, then jump to the step labeled convert.

7. Let pattern width be the concatenation of all the entries of style’s dash list, in coordinate space units.

8. For each subpath subpath in path, run the following substeps. These substeps mutate the subpaths in path in vivo.

   1. Let subpath width be the length of all the lines of subpath, in coordinate space units.
   2. Let offset be the value of style’s LineDashOffset, in coordinate space units.
   3. While offset is greater than pattern width, decrement it by pattern width.

      While offset is less than zero, increment it by pattern width.

   4. Define L to be a linear coordinate line defined along all lines in subpath, such that the start of the first line in the subpath is defined as coordinate 0, and the end of the last line in the subpath is defined as coordinate subpath width.

   5. Let position be zero minus offset.

   6. Let index be 0.

   7. Let current state be off (the other states being on and zero-on).

   8. Dash on: Let segment length be the value of style’s dash list’s indexth entry.

   9. Increment position by segment length.
10. If $position$ is greater than $subpath \ width$, then end these substeps for this subpath and start them again for the next subpath; if there are no more subpaths, then jump to the step labeled convert instead.

11. If $segment \ length$ is nonzero, then let $current \ state$ be on.

12. Increment $index$ by one.

13. Dash off: Let $segment \ length$ be the value of $style$’s dash list’s $index$th entry.

14. Let $start$ be the offset $position$ on $L$.

15. Increment $position$ by $segment \ length$.

16. If $position$ is less than zero, then jump to the step labeled post-cut.

17. If $start$ is less than zero, then let $start$ be zero.

18. If $position$ is greater than $subpath \ width$, then let $end$ be the offset $subpath \ width$ on $L$. Otherwise, let $end$ be the offset $position$ on $L$.

19. Jump to the first appropriate step:

   **If $segment \ length$ is zero and $current \ state$ is off**

   Do nothing, just continue to the next step.

   **If $current \ state$ is off**

   Cut the line on which $end$ finds itself short at $end$ and place a point there, cutting in two the subpath that it was in; remove all line segments, joins, points, and subpaths that are between $start$ and $end$; and finally place a single point at $start$ with no lines connecting to it.

   The point has a directionality for the purposes of drawing line caps (see below). The directionality is the direction that the original line had at that point (i.e. when $L$ was defined above).

   **Otherwise**

   Cut the line on which $start$ finds itself into two at $start$ and place a point there, cutting in two the subpath that it was in, and similarly cut the line on which $end$ finds itself short at $end$ and place a point there, cutting in two the subpath that it was in, and then remove all line segments, joins, points, and subpaths that are between $start$ and $end$.

   If $start$ and $end$ are the same point, then this results in just the line being cut in two and two points being inserted there, with nothing being removed,
unless a join also happens to be at that point, in which case the join must be removed.

20. **Post-cut**: If position is greater than subpath width, then jump to the step labeled convert.

21. If segment length is greater than zero, then let positioned-at-on-dash be false.

22. Increment index by one. If it is equal to the number of entries in style's dash list, then let index be 0.

23. Return to the step labeled dash on.

9. **Convert**: This is the step that converts the path to a new path that represents its stroke.

Create a new path that describes the edge of the areas that would be covered if a straight line of length equal to style's lineWidth was swept along each subpath in path while being kept at an angle such that the line is orthogonal to the path being swept, replacing each point with the end cap necessary to satisfy style's lineCap attribute as described previously and elaborated below, and replacing each join with the join necessary to satisfy style's lineJoin type, as defined below.

**Caps**: Each point has a flat edge perpendicular to the direction of the line coming out of it. This is then augmented according to the value of style's lineCap. The “butt” value means that no additional line cap is added. The “round” value means that a semi-circle with the diameter equal to style's lineWidth width must additionally be placed on to the line coming out of each point. The “square” value means that a rectangle with the length of style's lineWidth width and the width of half style's lineWidth width, placed flat against the edge perpendicular to the direction of the line coming out of the point, must be added at each point.

Points with no lines coming out of them must have two caps placed back-to-back as if it was really two points connected to each other by an infinitesimally short straight line in the direction of the point’s directionality (as defined above).

**Joins**: In addition to the point where a join occurs, two additional points are relevant to each join, one for each line: the two corners found half the line width away from the join point, one perpendicular to each line, each on the side furthest from the other line.

A triangle connecting these two opposite corners with a straight line, with the third point of the triangle being the join point, must be added at all joins. The lineJoin attribute controls whether anything else is rendered. The three aforementioned values have the following meanings:

The “bevel” value means that this is all that is rendered at joins.

The “round” value means that an arc connecting the two aforementioned corners of the
join, abutting (and not overlapping) the aforementioned triangle, with the diameter equal to the line width and the origin at the point of the join, must be added at joins.

The "miter" value means that a second triangle must (if it can given the miter length) be added at the join, with one line being the line between the two aforementioned corners, abutting the first triangle, and the other two being continuations of the outside edges of the two joining lines, as long as required to intersect without going over the miter length.

The miter length is the distance from the point where the join occurs to the intersection of the line edges on the outside of the join. The miter limit ratio is the maximum allowed ratio of the miter length to half the line width. If the miter length would cause the miter limit ratio (as set by style's miterLimit attribute) to be exceeded, then this second triangle must not be added.

The subpaths in the newly created path must be oriented such that for any point, the number of times a half-infinite straight line drawn from that point crosses a subpath is even if and only if the number of times a half-infinite straight line drawn from that same point crosses a subpath going in one direction is equal to the number of times it crosses a subpath going in the other direction.

10. Return the newly created path.

4.12.5.1.4 Text styles

context.font [ = value ]

CanvasRenderingContext2D/font

Support in all current engines.

Firefox3.5+Safari4+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS3.2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android12.1+

styles.font [ = value ]

Returns the current font settings.

Can be set, to change the font. The syntax is the same as for the CSS 'font' property; values that cannot be parsed as CSS font values are ignored.

Relative keywords and lengths are computed relative to the font of the canvas element.
**context**. `textAlign` [ = value ]

CanvasRenderingContext2D/textAlign

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung
Internet 1.0+ Opera Android 12.1+

**styles**. `textAlign` [ = value ]

Returns the current text alignment settings.

Can be set, to change the alignment. The possible values are and their meanings are given below. Other values are ignored. The default is "start".

**context**. `textBaseline` [ = value ]

CanvasRenderingContext2D/textBaseline

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung
Internet 1.0+ Opera Android 12.1+

**styles**. `textBaseline` [ = value ]

Returns the current baseline alignment settings.

Can be set, to change the baseline alignment. The possible values and their meanings are given below. Other values are ignored. The default is "alphabetic".

**context**. `direction` [ = value ]

CanvasRenderingContext2D/direction

Firefox No Safari 9+ Chrome 77+
Opera 64+ Edge 79+
Returns the current directionality.

Can be set, to change the directionality. The possible values and their meanings are given below. Other values are ignored. The default is "inherit".

Guardian.**[LetterSpacing]** [ = value ]

Returns the current spacing between characters in the text.

Can be set, to change spacing between characters. Postive values spreads characters further apart, while negative values brings them closer together. The default is 0.

Guardian.**[FontKerning]** [ = value ]

Returns the current font kerning settings.

Can be set, to change the font kerning. The possible values and their meanings are given below. Other values are ignored. The default is "auto".

Guardian.**[FontStretch]** [ = value ]

Returns the current font stretch settings.

Can be set, to change the font stretch. The possible values and their meanings are given below. Other values are ignored. The default is "normal".

Guardian.**[FontVariantCaps]** [ = value ]

Returns the current font variant caps settings.

Can be set, to change the font variant caps. The possible values and their meanings are given below. Other values are ignored. The default is "normal".

Guardian.**[TextRendering]** [ = value ]

Returns the current text rendering settings.
Can be set, to change the text rendering. The possible values and their meanings are given below. Other values are ignored. The default is "auto".

```
context.wordSpacing [ = value ]
styles.wordSpacing [ = value ]
```

Returns the current spacing between words in the text.

Can be set, to change spacing between words. Positive values spreads words further apart, while negative values brings them closer together. The default is 0.

Objects that implement the CanvasTextDrawingStyles interface have attributes (defined in this section) that control how text is laid out (rasterized or outlined) by the object. Such objects can also have a font style source object. For CanvasRenderingContext2D objects, this is the canvas element given by the value of the context's canvas attribute. For OffscreenCanvasRenderingContext2D objects, this is the associated OffscreenCanvas object.

Font resolution for the font style source object requires a font source. This is determined for a given object implementing CanvasTextDrawingStyles by the following steps:

1. If object's font style source object is a canvas element, return the element's node document.
2. Otherwise, object's font style source object is an OffscreenCanvas object:
   1. Let global be object's relevant global object.
   2. If global is a Window object, then return global's associated Document.
   3. Assert: global implements WorkerGlobalScope.
   4. Return global.

This is an example of font resolution with a regular canvas element with ID c1.

```javascript
const font = new FontFace("MyCanvasFont", "url(mycanvasfont.ttf)");
documents.fonts.add(font);

const context = document.getElementById("c1").getContext("2d");
document.fonts.ready.then((function() {
  context.font = "64px MyCanvasFont";
  context.fillText("hello", 0, 0);
}));
```

In this example, the canvas will display text using mycanvasfont.ttf as its font.
This is an example of how font resolution can happen using `OffscreenCanvas`. Assuming a `canvas` element with ID `c2` which is transferred to a worker like so:

```javascript
const offscreenCanvas = document.getElementById("c2").transferControlToOffscreen;
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker:

```javascript
self.onmessage = function(ev) {
    const transferredCanvas = ev.data;
    const context = transferredCanvas.getContext("2d");
    const font = new FontFace("MyFont", "url(myfont.ttf)");
    self.fonts.add(font);
    self.fonts.ready.then(function() {
        context.font = "64px MyFont";
        context.fillText("hello", 0, 0);
    });
};
```

In this example, the canvas will display a text using `myfont.ttf`. Notice that the font is only loaded inside the worker, and not in the document context.

The `font` IDL attribute, on setting, must be parsed as a CSS `<font>` value (but without supporting property-independent style sheet syntax like ‘inherit’), and the resulting font must be assigned to the context, with the ‘line-height’ component forced to ‘normal’, with the ‘font-size’ component converted to CSS pixels, and with system fonts being computed to explicit values. If the new value is syntactically incorrect (including using property-independent style sheet syntax like ‘inherit’ or ‘initial’), then it must be ignored, without assigning a new font value. [CSS]

Font family names must be interpreted in the context of the font style source object when the font is to be used; any fonts embedded using `@font-face` or loaded using `FontFace` objects that are visible to the font style source object must therefore be available once they are loaded. (Each font style source object has a font source, which determines what fonts are available.) If a font is used before it is fully loaded, or if the font style source object does not have that font in scope at the time the font is to be used, then it must be treated as if it was an unknown font, falling back to another as described by the relevant CSS specifications. [CSSFONTS] [CSSFONTLOAD]

On getting, the `font` attribute must return the serialized form of the current font of the context (with no ‘line-height’ component). [CSSOM]

For example, after the following statement:

```javascript
context.font = 'italic 400 12px/2 Unknown Font, sans-serif';
```

...the expression `context.font` would evaluate to the string
/*italic 12px "Unknown Font", sans-serif*. The "400" font-weight doesn't appear because that is the default value. The line-height doesn't appear because it is forced to "normal", the default value.

When the object implementing the CanvasTextDrawingStyles interface is created, the font of the context must be set to 10px sans-serif. When the 'font-size' component is set to lengths using percentages, 'em' or 'ex' units, or the 'larger' or 'smaller' keywords, these must be interpreted relative to the computed value of the 'font-size' property of the font style source object at the time that the attribute is set, if it is an element. When the 'font-weight' component is set to the relative values 'bolder' and 'lighter', these must be interpreted relative to the computed value of the 'font-weight' property of the font style source object at the time that the attribute is set, if it is an element. If the computed values are undefined for a particular case (e.g. because the font style source object is not an element or is not being rendered), then the relative keywords must be interpreted relative to the normal-weight 10px sans-serif default.

The textAlign IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles interface is created, the textAlign attribute must initially have the value start.

The textBaseline IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles interface is created, the textBaseline attribute must initially have the value alphabetic.

The direction IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles interface is created, the direction attribute must initially have the value "inherit".

The letterSpacing IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value, where values may be positive or negative. When the object implementing the CanvasTextDrawingStyles interface is created, the letterSpacing attribute must initially have the value 0.

The fontKerning IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles interface is created, the fontKerning attribute must initially have the value "auto".

The fontStretch IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles interface is created, the fontStretch attribute must initially have the value "normal".

The fontVariantCaps IDL attribute, on getting, must return the current value. On setting,
the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles interface is created, the fontVariantCaps attribute must initially have the value "normal".

The textRendering IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles interface is created, the textRendering attribute must initially have the value "auto".

The wordSpacing IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value, where values may be positive or negative. When the object implementing the CanvasTextDrawingStyles interface is created, the wordSpacing attribute must initially have the value 0.

The textAlign attribute’s allowed keywords are as follows:

**start**

Align to the start edge of the text (left side in left-to-right text, right side in right-to-left text).

**end**

Align to the end edge of the text (right side in left-to-right text, left side in right-to-left text).

**left**

Align to the left.

**right**

Align to the right.

**center**

Align to the center.

The textBaseline attribute’s allowed keywords correspond to alignment points in the font:
The keywords map to these alignment points as follows:

**top**
The top of the em square

**hanging**
The hanging baseline

**middle**
The middle of the em square

**alphabetic**
The alphabetic baseline

**ideographic**
The ideographic-under baseline

**bottom**
The bottom of the em square

The **direction** attribute’s allowed keywords are as follows:

**ltr**
Treat input to the text preparation algorithm as left-to-right text.

**rtl**
Treat input to the text preparation algorithm as right-to-left text.
\textit{inherit}

Default to the directionality of the \texttt{canvas} element or \texttt{Document} as appropriate.

The \texttt{fontKerning} attribute’s allowed keywords are as follows:

\texttt{auto}

Kerning is applied at the discretion of the user agent.

\texttt{normal}

Kerning is applied.

\texttt{none}

Kerning is not applied.

The \texttt{fontStretch} attribute’s allowed keywords are as follows:

\texttt{ultra-condensed}

Same as CSS ‘\texttt{font-stretch} ‘ultra-condensed’ setting.

\texttt{extra-condensed}

Same as CSS ‘\texttt{font-stretch} ‘extra-condensed’ setting.

\texttt{condensed}

Same as CSS ‘\texttt{font-stretch} ‘condensed’ setting.

\texttt{semi-condensed}

Same as CSS ‘\texttt{font-stretch} ‘semi-condensed’ setting.

\texttt{normal}

The default setting, where width of the glyphs is at 100%.

\texttt{semi-expanded}

Same as CSS ‘\texttt{font-stretch} ‘semi-expanded’ setting.

\texttt{expanded}

Same as CSS ‘\texttt{font-stretch} ‘expanded’ setting.
**extra-expanded**

Same as CSS `font-stretch` 'extra-expanded' setting.

**ultra-expanded**

Same as CSS `font-stretch` 'ultra-expanded' setting.

The `fontVariantCaps` attribute’s allowed keywords are as follows:

**normal**

None of the features listed below are enabled.

**small-caps**

Same as CSS `font-variant-caps` 'small-caps' setting.

**all-small-caps**

Same as CSS `font-variant-caps` 'all-small-caps' setting.

**petite-caps**

Same as CSS `font-variant-caps` 'petite-caps' setting.

**all-petite-caps**

Same as CSS `font-variant-caps` 'all-petite-caps' setting.

**unicase**

Same as CSS `font-variant-caps` 'unicase' setting.

**titling-caps**

Same as CSS `font-variant-caps` 'titling-caps' setting.

The `textRendering` attribute’s allowed keywords are as follows:

**auto**

Same as 'auto' in SVG text-rendering property.

**optimizeSpeed**

Same as 'optimizeSpeed' in SVG text-rendering property.
optimizeLegibility

Same as ‘optimizeLegibility’ in SVG text-rendering property.

genericPrecision

Same as ‘genericPrecision’ in SVG text-rendering property.

The text preparation algorithm is as follows. It takes as input a string text, a CanvasTextDrawingStyles object target, and an optional length maxWidth. It returns an array of glyph shapes, each positioned on a common coordinate space, a physical alignment whose value is one of left, right, and center, and an inline box. (Most callers of this algorithm ignore the physical alignment and the inline box.)

1. If maxWidth was provided but is less than or equal to zero or equal to NaN, then return an empty array.

2. Replace all ASCII whitespace in text with U+0020 SPACE characters.

3. Let font be the current font of target, as given by that object’s font attribute.

4. Apply the appropriate step from the following list to determine the value of direction:

   If the target object’s direction attribute has the value "ltr"
   Let direction be ‘ltr’.

   If the target object’s direction attribute has the value "rtl"
   Let direction be ‘rtl’.

   If the target object’s font style source object is an element
   Let direction be the directionality of the target object’s font style source object.

   If the target object’s font style source object is a Document with a non-null document element
   Let direction be the directionality of the target object’s font style source object’s document element.

   Otherwise
   Let direction be ‘ltr’.

5. Form a hypothetical infinitely-wide CSS line box containing a single inline box containing the text text, with its CSS properties set as follows:

<table>
<thead>
<tr>
<th>Property</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘direction’</td>
<td>direction</td>
</tr>
<tr>
<td>‘font’</td>
<td>font</td>
</tr>
<tr>
<td>‘font-kerning’</td>
<td>target’s fontKerning</td>
</tr>
</tbody>
</table>
6. If $\text{maxWidth}$ was provided and the hypothetical width of the inline box in the hypothetical line box is greater than $\text{maxWidth CSS pixels}$, then change $\text{font}$ to have a more condensed font (if one is available or if a reasonably readable one can be synthesized by applying a horizontal scale factor to the font) or a smaller font, and return to the previous step.

7. The anchor point is a point on the inline box, and the physical alignment is one of the values left, right, and center. These variables are determined by the $\text{textAlign}$ and $\text{textBaseline}$ values as follows:

Horizontal position:

If $\text{textAlign}$ is left
If $\text{textAlign}$ is start and direction is ‘ltr’
If $\text{textAlign}$ is end and direction is ‘rtl’
    Let the anchor point’s horizontal position be the left edge of the inline box, and let physical alignment be left.

If $\text{textAlign}$ is right
If $\text{textAlign}$ is end and direction is ‘ltr’
If $\text{textAlign}$ is start and direction is ‘rtl’
    Let the anchor point’s horizontal position be the right edge of the inline box, and let physical alignment be right.

If $\text{textAlign}$ is center
    Let the anchor point’s horizontal position be half way between the left and right edges of the inline box, and let physical alignment be center.

Vertical position:

If $\text{textBaseline}$ is top
    Let the anchor point’s vertical position be the top of the em box of the first available font of the inline box.

If $\text{textBaseline}$ is hanging
    Let the anchor point’s vertical position be the hanging baseline of the first available
Let the anchor point’s vertical position be half way between the bottom and the top of the em box of the first available font of the inline box.

If textBaseline is alphabetic
Let the anchor point’s vertical position be the alphabetic baseline of the first available font of the inline box.

If textBaseline is ideographic
Let the anchor point’s vertical position be the ideographic-under baseline of the first available font of the inline box.

If textBaseline is bottom
Let the anchor point’s vertical position be the bottom of the em box of the first available font of the inline box.

8. Let result be an array constructed by iterating over each glyph in the inline box from left to right (if any), adding to the array, for each glyph, the shape of the glyph as it is in the inline box, positioned on a coordinate space using CSS pixels with its origin is at the anchor point.

9. Return result, physical alignment, and the inline box.

4.12.5.1.5 Building paths

Objects that implement the CanvasPath interface have a path. A path has a list of zero or more subpaths. Each subpath consists of a list of one or more points, connected by straight or curved line segments, and a flag indicating whether the subpath is closed or not. A closed subpath is one where the last point of the subpath is connected to the first point of the subpath by a straight line. Subpaths with only one point are ignored when painting the path.

Paths have a need new subpath flag. When this flag is set, certain APIs create a new subpath rather than extending the previous one. When a path is created, its need new subpath flag must be set.

When an object implementing the CanvasPath interface is created, its path must be initialized to zero subpaths.

context.moveTo(x, y)  

CanvasRenderingContext2D/moveTo

Support in all current engines.
path.moveTo(x, y)

Creates a new subpath with the given point.

context.closePath()

CanvasRenderingContext2D/closePath

Support in all current engines.

path.closePath()

Marks the current subpath as closed, and starts a new subpath with a point the same as the start and end of the newly closed subpath.

context.lineTo(x, y)

CanvasRenderingContext2D/lineTo

Support in all current engines.

path.lineTo(x, y)

Adds the given point to the current subpath, connected to the previous one by a straight line.
Support in all current engines.

**CanvasRenderingContext2D/quadraticCurveTo**

```javascript
context.quadraticCurveTo(cpx, cpy, x, y)
```

Adds the given point to the current subpath, connected to the previous one by a quadratic Bézier curve with the given control point.

**CanvasRenderingContext2D/bezierCurveTo**

Support in all current engines.

```javascript
context.bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)
```

Adds the given point to the current subpath, connected to the previous one by a cubic Bézier curve with the given control points.

**CanvasRenderingContext2D/arcTo**

Support in all current engines.

```javascript
context.arcTo(x1, y1, x2, y2, radius)
```

Adds an arc with the given control points and radius to the current subpath, connected to
the previous point by a straight line.

Throws an "IndexSizeError" DOMException if the given radius is negative.
`context.arc(x, y, radius, startAngle, endAngle [, counterclockwise ])

CanvasRenderingContext2D/arc

Support in all current engines.

Firefox 1.5+, Safari 3+, Chrome 1+
Opera 11.6+, Edge 79+
Edge (Legacy) 12+, Internet Explorer 9+
Firefox Android 4+, Safari iOS 1+, Chrome Android 18+, WebView Android 1+, Samsung Internet 1.0+

`path.arc(x, y, radius, startAngle, endAngle [, counterclockwise ])`

Adds points to the subpath such that the arc described by the circumference of the circle described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an "`IndexSizeError`" `DOMException` if the given radius is negative.

```html
// the thick line corresponds to:
context.moveTo(x0, y0)
context.arc(x, y, radius, α, β)
context.stroke()
```

`context.ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle [, counterclockwise])`

CanvasRenderingContext2D/ellipse

Support in all current engines.

Firefox 48+, Safari 9+, Chrome 31+
Opera 18+, Edge 79+
adds points to the subpath such that the arc described by the circumference of the ellipse described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an "IndexSizeError" DOMException if the given radius is negative.

**context.rect(x, y, w, h)**

Support in all current engines.

Firefox1.5+Safari2+Chrome1+
Opera11.6+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android12+

**path.ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle [, counterclockwise])**

Adds a new closed subpath to the path representing the given rectangle.

**context.roundRect(x, y, w, h, radii)**

**path.roundRect(x, y, w, h, radii)**

Adds a new closed subpath to the path representing the given rounded rectangle. `radii` represents a list of radii for the corners of the rectangle, in pixels. The number and order of these radii function in the same way as the CSS `border-radius` property.

If `w` and `h` are both greater than or equal to 0, or if both are smaller than 0, then the path is drawn clockwise. Otherwise, it is drawn counterclockwise.

When `w` is negative, the rounded rectangle is flipped horizontally, which means that the radius values that normally apply to the left corners are used on the right and vice versa. Similarly, when `h` is negative, the rounded rect is flipped vertically.

When a value `r` in `radii` is a number, the corresponding corner(s) are drawn as circular arcs of radius `r`.

When a value `r` in `radii` is an object with `{ x, y }` properties, the corresponding corner(s)
are drawn as elliptical arcs whose \(x\) and \(y\) radii are equal to \(r.x\) and \(r.y\), respectively.

When the sum of the \(radii\) of two corners of the same edge is greater than the length of the edge, all the \(radii\) of the rounded rectangle are scaled by a factor of length \(/(r1 + r2)\). If multiple edges have this property, the scale factor of the edge with the smallest scale factor is used. This is consistent with CSS behavior.

Throws a \text{RangeError} if \(radii\) not a list of size one, two, three, or four.

Throws a \text{RangeError} if a value in \(radii\) is a negative number, or is an \{ \text{x, y} \} object whose \(x\) or \(y\) properties are negative numbers.

The following methods allow authors to manipulate the \text{paths} of objects implementing the \text{CanvasPath} interface.

For objects implementing the \text{CanvasDrawPath} and \text{CanvasTransform} interfaces, the points passed to the methods, and the resulting lines added to \text{current default path} by these methods, must be transformed according to the \text{current transformation matrix} before being added to the path.

The \text{moveTo}(x, y)\) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.

2. Create a new subpath with the specified point as its first (and only) point.

When the user agent is to \text{ensure there is a subpath} for a coordinate \((x, y)\) on a \text{path}, the user agent must check to see if the \text{path} has its \text{need new subpath} flag set. If it does, then the user agent must create a new subpath with the point \((x, y)\) as its first (and only) point, as if the \text{moveTo()} method had been called, and must then unset the \text{path’s need new subpath} flag.

The \text{closePath()} method, when invoked, must do nothing if the object’s path has no subpaths. Otherwise, it must mark the last subpath as closed, create a new subpath whose first point is the same as the previous subpath’s first point, and finally add this new subpath to the path.

If the last subpath had more than one point in its list of points, then this is equivalent to adding a straight line connecting the last point back to the first point of the last subpath, thus “closing” the subpath.

New points and the lines connecting them are added to subpaths using the methods described below. In all cases, the methods only modify the last subpath in the object’s path.

The \text{lineTo}(x, y)\) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. If the object’s path has no subpaths, then ensure there is a subpath for (x, y).

3. Otherwise, connect the last point in the subpath to the given point (x, y) using a straight line, and then add the given point (x, y) to the subpath.

The `quadraticCurveTo(cpx, cpy, x, y)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. **Ensure there is a subpath** for (cpx, cpy)

3. Connect the last point in the subpath to the given point (x, y) using a quadratic Bézier curve with control point (cpx, cpy). [BEZIER]

4. Add the given point (x, y) to the subpath.

The `bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. **Ensure there is a subpath** for (cp1x, cp1y).

3. Connect the last point in the subpath to the given point (x, y) using a cubic Bézier curve with control points (cp1x, cp1y) and (cp2x, cp2y). [BEZIER]

4. Add the point (x, y) to the subpath.

The `arcTo(x1, y1, x2, y2, radius)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. **Ensure there is a subpath** for (x1, y1).

3. If radius is negative, then throw an **“IndexSizeError” DOMException**.

4. Let the point (x0, y0) be the last point in the subpath, transformed by the inverse of the current transformation matrix (so that it is in the same coordinate system as the points passed to the method).

5. If the point (x0, y0) is equal to the point (x1, y1), or if the point (x1, y1) is equal to the point (x2, y2), or if radius is zero, then add the point (x1, y1) to the subpath, and connect that point to the previous point (x0, y0) by a straight line.

6. Otherwise, if the points (x0, y0), (x1, y1), and (x2, y2) all lie on a single straight line, then add the point (x1, y1) to the subpath, and connect that point to the previous point (x0, y0) by a straight line.
7. Otherwise, let *The Arc* be the shortest arc given by circumference of the circle that has radius \( r \), and that has one point tangent to the half-infinite line that crosses the point \((x_0, y_0)\) and ends at the point \((x_1, y_1)\), and that has a different point tangent to the half-infinite line that ends at the point \((x_1, y_1)\) and crosses the point \((x_2, y_2)\). The points at which this circle touches these two lines are called the start and end tangent points respectively. Connect the point \((x_0, y_0)\) to the start tangent point by a straight line, adding the start tangent point to the subpath, and then connect the start tangent point to the end tangent point by *The Arc*, adding the end tangent point to the subpath.

The \( \text{arc}(x, y, r, \text{startAngle}, \text{endAngle}, \text{counterclockwise}) \) method, when invoked, must run the \( \text{ellipse method steps} \) with this, \( x, y, r, \text{radius}, 0, \text{startAngle}, \text{endAngle}, \text{and counterclockwise} \).

This makes it equivalent to \( \text{ellipse}() \) except that both radii are equal and \( \text{rotation} \) is 0.

The \( \text{ellipse}(x, y, rX, rY, \text{rotation}, \text{startAngle}, \text{endAngle}, \text{counterclockwise}) \) method, when invoked, must run the \( \text{ellipse method steps} \) with this, \( x, y, rX, rY, \text{rotation}, \text{startAngle}, \text{endAngle}, \text{and counterclockwise} \).

The \( \text{ellipse method steps} \), given \( \text{canvasPath, x, y, rX, rY, rotation, startAngle, endAngle, and counterclockwise} \), are:

1. If any of the arguments are infinite or NaN, then return.
2. If either \( rX \) or \( rY \) are negative, then throw an “IndexSizeError” \( \text{DOMException} \).
3. If \( \text{canvasPath}'s\) path has any subpaths, then add a straight line from the last point in the subpath to the start point of the arc.
4. Add the start and end points of the arc to the subpath, and connect them with an arc.

The arc and its start and end points are defined as follows:

Consider an ellipse that has its origin at \((x, y)\), that has a major-axis radius \( rX \) and a minor-axis radius \( rY \), and that is rotated about its origin such that its semi-major axis is inclined \( \text{rotation} \) radians clockwise from the x-axis.

If \( \text{counterclockwise} \) is false and \( \text{endAngle}-\text{startAngle} \) is equal to or greater than \( 2\pi \), or, if \( \text{counterclockwise} \) is true and \( \text{startAngle}-\text{endAngle} \) is equal to or greater than \( 2\pi \), then the arc is the whole circumference of this ellipse, and the point at \( \text{startAngle} \) along this circle’s circumference, measured in radians clockwise from the ellipse’s semi-major axis, acts as both the start point and the end point.

Otherwise, the points at \( \text{startAngle} \) and \( \text{endAngle} \) along this circle’s circumference, measured in radians clockwise from the ellipse’s semi-major axis, are the start and end points respectively, and the arc is the path along the circumference of this ellipse from
the start point to the end point, going counterclockwise if \textit{counterclockwise} is true, and clockwise otherwise. Since the points are on the ellipse, as opposed to being simply angles from zero, the arc can never cover an angle greater than \(2\pi\) radians.

Even if the arc covers the entire circumference of the ellipse and there are no other points in the subpath, the path is not closed unless the \texttt{closePath()} method is appropriately invoked.

The \texttt{rect(x, y, w, h)} method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Create a new subpath containing just the four points \((x, y), (x+w, y), (x+w, y+h), (x, y+h)\), in that order, with those four points connected by straight lines.
3. Mark the subpath as closed.
4. Create a new subpath with the point \((x, y)\) as the only point in the subpath.

The \texttt{roundRect(x, y, w, h, radii)} method steps are:

1. If any of \(x, y, w,\) or \(h\) are infinite or NaN, then return.
2. If \(\text{radii}\) is not a list of size one, two, three, or four, then throw a \texttt{RangeError}.
3. Let \(\text{normalizedRadii}\) be an empty list.
4. For each \text{radius} of \text{radii}:
   1. If \text{radius} is a \texttt{DOMPointInit}:
      1. If \text{radius}["x"] or \text{radius}["y"] is infinite or NaN, then return.
      2. If \text{radius}["x"] or \text{radius}["y"] is negative, then throw a \texttt{RangeError}.
      3. Otherwise, append \text{radius} to \text{normalizedRadii}.
   2. If \text{radius} is a \texttt{unrestricted\_double}:
      1. If \text{radius} is infinite or NaN, then return.
      2. If \text{radius} is negative, then throw a \texttt{RangeError}.
      3. Otherwise append «[ "x" → radius, "y" → radius ]» to \text{normalizedRadii}.
5. Let upperLeft, upperRight, lowerRight, and lowerLeft be null.
6. If \( \text{normalizedRadii}'s \) size is 4, then set \( \text{upperLeft} \) to \( \text{normalizedRadii}[0] \), set \( \text{upperRight} \) to \( \text{normalizedRadii}[1] \), set \( \text{lowerRight} \) to \( \text{normalizedRadii}[2] \), and set \( \text{lowerLeft} \) to \( \text{normalizedRadii}[3] \).

7. If \( \text{normalizedRadii}'s \) size is 3, then set \( \text{upperLeft} \) to \( \text{normalizedRadii}[0] \), set \( \text{upperRight} \) and \( \text{lowerLeft} \) to \( \text{normalizedRadii}[1] \), and set \( \text{lowerRight} \) to \( \text{normalizedRadii}[2] \).

8. If \( \text{normalizedRadii}'s \) size is 2, then set \( \text{upperLeft} \) and \( \text{lowerRight} \) to \( \text{normalizedRadii}[0] \) and set \( \text{upperRight} \) and \( \text{lowerLeft} \) to \( \text{normalizedRadii}[1] \).

9. If \( \text{normalizedRadii}'s \) size is 1, then set \( \text{upperLeft} \), \( \text{upperRight} \), \( \text{lowerRight} \), and \( \text{lowerLeft} \) to \( \text{normalizedRadii}[0] \).

10. Corner curves must not overlap. Scale all radii to prevent this:
    1. Let \( \text{top} \) be \( \text{upperLeft}[^x] + \text{upperRight}[^x] \).
    2. Let \( \text{right} \) be \( \text{upperRight}[^y] + \text{lowerRight}[^y] \).
    3. Let \( \text{bottom} \) be \( \text{lowerRight}[^x] + \text{lowerLeft}[^x] \).
    4. Let \( \text{left} \) be \( \text{upperLeft}[^y] + \text{lowerLeft}[^y] \).
    5. Let \( \text{scale} \) be the minimum value of the ratios \( \frac{w}{\text{top}} \), \( \frac{h}{\text{right}} \), \( \frac{w}{\text{bottom}} \), \( \frac{h}{\text{left}} \).
    6. If \( \text{scale} \) is less than 1, then set the \( x \) and \( y \) members of \( \text{upperLeft} \), \( \text{upperRight} \), \( \text{lowerLeft} \), and \( \text{lowerRight} \) to their current values multiplied by \( \text{scale} \).

11. Create a new subpath:
    1. Move to the point \((x + \text{upperLeft}[^x], y)\).
    2. Draw a straight line to the point \((x + w - \text{upperRight}[^x], y)\).
    3. Draw an arc to the point \((x + w, y + \text{upperRight}[^y])\).
    4. Draw a straight line to the point \((x + w, y + h - \text{lowerRight}[^y])\).
    5. Draw an arc to the point \((x + w - \text{lowerRight}[^x], y + h)\).
    6. Draw a straight line to the point \((x + \text{lowerLeft}[^x], y + h)\).
    7. Draw an arc to the point \((x, y + h - \text{lowerLeft}[^y])\).
    8. Draw a straight line to the point \((x, y + \text{upperLeft}[^y])\).
    9. Draw an arc to the point \((x + \text{upperLeft}[^y], y)\).
12. Mark the subpath as closed.

13. Create a new subpath with the point \((x, y)\) as the only point in the subpath.

This is designed to behave similarly to the CSS `border-radius` property.

4.12.5.1.6 `Path2D` objects

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>31+</td>
</tr>
<tr>
<td>Safari</td>
<td>8+</td>
</tr>
<tr>

</tr>
<tr>
<td>Opera Android</td>
<td>24+</td>
</tr>
</tbody>
</table>

`Path2D` objects can be used to declare paths that are then later used on objects implementing the `CanvasDrawPath` interface. In addition to many of the APIs described in earlier sections, `Path2D` objects have methods to combine paths, and to add text to paths.

```javascript
path = new Path2D()
```

Support in all current engines.

<table>

</table>

Adds to the path the path given by the argument.

The **Path2D**(path) constructor, when invoked, must run these steps:

1. Let output be a new Path2D object.
2. If path is not given, then return output.
3. If path is a Path2D object, then add all subpaths of path to output and return output. (In other words, it returns a copy of the argument.)
4. Let svgPath be the result of parsing and interpreting path according to SVG 2’s rules for path data. [SVG]
   The resulting path could be empty. SVG defines error handling rules for parsing and applying path data.
5. Let (x, y) be the last point in svgPath.
6. Add all the subpaths, if any, from svgPath to output.
7. Create a new subpath in output with (x, y) as the only point in the subpath.
8. Return output.

The **addPath**(path, transform) method, when invoked on a Path2D object a, must run these steps:

1. If the Path2D object path has no subpaths, then return.
2. Let matrix be the result of creating a DOMMatrix from the 2D dictionary transform.
3. If one or more of matrix’s m11 element, m12 element, m21 element, m22 element, m41
element, or \texttt{m42 element} are infinite or NaN, then return.

4. Create a copy of all the subpaths in \emph{path}. Let this copy be known as \emph{c}.

5. Transform all the coordinates and lines in \emph{c} by the transform matrix \emph{matrix}.

6. Let \((x, y)\) be the last point in the last subpath of \emph{c}.

7. Add all the subpaths in \emph{c} to \emph{a}.

8. Create a new subpath in \emph{a} with \((x, y)\) as the only point in the subpath.

4.12.5.1.7 Transformations

Objects that implement the \texttt{CanvasTransform} interface have a \emph{current transformation matrix}, as well as methods (described in this section) to manipulate it. When an object implementing the \texttt{CanvasTransform} interface is created, its transformation matrix must be initialized to the identity matrix.

The \emph{current transformation matrix} is applied to coordinates when creating the \emph{current default path}, and when painting text, shapes, and \texttt{Path2D} objects, on objects implementing the \texttt{CanvasTransform} interface.

The transformations must be performed in reverse order.

For instance, if a scale transformation that doubles the width is applied to the canvas, followed by a rotation transformation that rotates drawing operations by a quarter turn, and a rectangle twice as wide as it is tall is then drawn on the canvas, the actual result will be a square.

\begin{verbatim}
context.scale(x, y)
\end{verbatim}

\texttt{CanvasRenderingContext2D/scale}

Support in all current engines.

\begin{tabular}{ll}
Firefox & 1.5+ \textit{Safari} & 2+ \textit{Chrome} & 1+ \\
Opera & 12.1+ & Edge & 79+ \\
Edge (Legacy) & 12+ & Internet Explorer & 9+ \\
Firefox Android & 4+ & Safari iOS & 1+ & Chrome Android & 18+ & WebView & 1+ & Samsung \\
Internet & 1.0+ & Opera & Android & 12.1+ \\
\end{tabular}

Changes the \emph{current transformation matrix} to apply a scaling transformation with the given characteristics.

\begin{verbatim}
context.rotate(angle)
\end{verbatim}
CanvasRenderingContext2D/rotate

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung
Internet 1.0+ Opera Android 12.1+

Changes the current transformation matrix to apply a rotation transformation with the given characteristics. The angle is in radians.

context.translate(x, y)

CanvasRenderingContext2D/translate

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung
Internet 1.0+ Opera Android 12.1+

Changes the current transformation matrix to apply a translation transformation with the given characteristics.

context.transform(a, b, c, d, e, f)

CanvasRenderingContext2D/transform

Support in all current engines.

Firefox 3+ Safari 3.1+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 2+ Chrome Android 18+ WebView Android 1+ Samsung
Internet 1.0+ Opera Android 12.1+

Changes the current transformation matrix to apply the matrix given by the arguments as
described below.

```javascript
matrix = context.getTransform()
```

CanvasRenderingContext2D/getTransform

Support in all current engines.

Firefox 70+ Safari 11+ Chrome 68+
Opera 55+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android No Safari iOS 11+ Chrome Android 68+ WebView Android 68+ Samsung Internet 10.0+ Opera Android 48+

Returns a copy of the current transformation matrix, as a newly created DOMMatrix object.

```javascript
canvas.setTransform(a, b, c, d, e, f)
```

CanvasRenderingContext2D/setTransform

Support in all current engines.

Firefox 3+ Safari 4+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Changes the current transformation matrix to the matrix given by the arguments as described below.

```javascript
canvas.setTransform(transform)
```

Changes the current transformation matrix to the matrix represented by the passed DOMMatrix2DInit dictionary.

```javascript
canvas.resetTransform()
```

CanvasRenderingContext2D/resetTransform

Support in all current engines.
Changes the current transformation matrix to the identity matrix.

The scale(\textit{x, y}) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.

2. Add the scaling transformation described by the arguments to the current transformation matrix. The \textit{x} argument represents the scale factor in the horizontal direction and the \textit{y} argument represents the scale factor in the vertical direction. The factors are multiples.

The rotate(\textit{angle}) method, when invoked, must run these steps:

1. If \textit{angle} is infinite or NaN, then return.

2. Add the rotation transformation described by the argument to the current transformation matrix. The \textit{angle} argument represents a clockwise rotation angle expressed in radians.

The translate(\textit{x, y}) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.

2. Add the translation transformation described by the arguments to the current transformation matrix. The \textit{x} argument represents the translation distance in the horizontal direction and the \textit{y} argument represents the translation distance in the vertical direction. The arguments are in coordinate space units.

The transform(\textit{a, b, c, d, e, f}) method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Replace the current transformation matrix with the result of multiplying the current transformation matrix with the matrix described by:

\[
\begin{bmatrix}
  a & c & e \\
  b & d & f \\
  0 & 0 & 1 \\
\end{bmatrix}
\]

The arguments \textit{a, b, c, d, e, and f} are sometimes called \textit{m11, m12, m21, m22, dx, and dy} or \textit{m11, m21, m12, m22, dx, and dy}. Care ought to be taken in particular with the order of the second
and third arguments \((b \text{ and } c)\) as their order varies from API to API and APIs sometimes use the notation \(m12/m21\) and sometimes \(m21/m12\) for those positions.

The \textit{getTransform()} method, when invoked, must return a newly created \texttt{DOMMatrix} representing a copy of the \texttt{current transformation matrix} matrix of the context.

This returned object is not live, so updating it will not affect the \texttt{current transformation matrix}, and updating the \texttt{current transformation matrix} will not affect an already returned \texttt{DOMMatrix}.

The \textit{setTransform}(a, b, c, d, e, f) method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Reset the \texttt{current transformation matrix} to the identity matrix.
3. Invoke the \texttt{transform}(a, b, c, d, e, f) method with the same arguments.

The \textit{setTransform(transform)} method, when invoked, must run these steps:

1. Let \texttt{matrix} be the result of \texttt{creating a DOMMatrix from the 2D dictionary transform}.
2. If one or more of \texttt{matrix}'s \texttt{m11 element}, \texttt{m12 element}, \texttt{m21 element}, \texttt{m22 element}, \texttt{m41 element}, or \texttt{m42 element} are infinite or NaN, then return.
3. Reset the \texttt{current transformation matrix} to \texttt{matrix}.

The \textit{resetTransform()} method, when invoked, must reset the \texttt{current transformation matrix} to the identity matrix.

Given a matrix of the form created by the \texttt{transform()} and \texttt{setTransform()} methods, i.e.,

\[
\begin{pmatrix}
a & c & e \\
b & d & f \\
0 & 0 & 1
\end{pmatrix}
\]

the resulting transformed coordinates after transform matrix multiplication will be

\[
\begin{align*}
x_{\text{new}} &= a \times + c \times y + e \\
y_{\text{new}} &= b \times + d \times y + f
\end{align*}
\]

Some methods on the \texttt{CanvasDrawImage} and \texttt{CanvasFillStrokeStyles} interfaces take the union type \texttt{CanvasImageSource} as an argument.
This union type allows objects implementing any of the following interfaces to be used as image sources:

- **HTMLImageElement** *(img or SVG image elements)*
- **HTMLVideoElement** *(video elements)*
- **HTMLCanvasElement** *(canvas elements)*
- **ImageBitmap**
- **VideoFrame**

Although not formally specified as such, **SVG image** elements are expected to be implemented nearly identical to **img** elements. That is, **SVG image** elements share the fundamental concepts and features of **img** elements.

The **ImageBitmap** interface can be created from a number of other image-representing types, including **ImageData**.

To check the usability of the image argument, where **image** is a **CanvasImageSource** object, run these steps:

1. Switch on **image**:

   **HTMLImageElement**

   If **image's** current request’s state is **broken**, then throw an *"InvalidStateError"* DOMException.

   If **image** is not **fully decodable**, then return **bad**.

   If **image** has an **intrinsic width** or **intrinsic height** (or both) equal to zero, then return **bad**.

   **HTMLVideoElement**

   If **image's** readyState attribute is either **HAVE_NOTHING** or **HAVE_METADATA**, then return **bad**.

   **HTMLCanvasElement**

   **OffscreenCanvas**

   If **image** has either a horizontal dimension or a vertical dimension equal to zero, then throw an *"InvalidStateError"* DOMException.

   **ImageBitmap**

   **VideoFrame**

   If **image's** [[Detached]] internal slot value is set to true, then throw an *"InvalidStateError"* DOMException.
2. Return good.

When a `CanvasImageSource` object represents an `HTMLOrSVGImageElement`, the element’s image must be used as the source image.

Specifically, when a `CanvasImageSource` object represents an animated image in an `HTMLOrSVGImageElement`, the user agent must use the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation, when rendering the image for `CanvasRenderingContext2D` APIs.

When a `CanvasImageSource` object represents an `HTMLVideoElement`, then the frame at the current playback position when the method with the argument is invoked must be used as the source image when rendering the image for `CanvasRenderingContext2D` APIs, and the source image’s dimensions must be the intrinsic width and intrinsic height of the media resource (i.e., after any aspect-ratio correction has been applied).

When a `CanvasImageSource` object represents an `HTMLCanvasElement`, the element’s bitmap must be used as the source image.

When a `CanvasImageSource` object represents an element that is being rendered and that element has been resized, the original image data of the source image must be used, not the image as it is rendered (e.g. width and height attributes on the source element have no effect on how the object is interpreted when rendering the image for `CanvasRenderingContext2D` APIs).

When a `CanvasImageSource` object represents an `ImageBitmap`, the object’s bitmap image data must be used as the source image.

When a `CanvasImageSource` object represents a `VideoFrame`, the object’s pixel data must be used as the source image, and the source image’s dimensions must be the object’s `[[display width]]` and `[[display height]].`

An object image is not origin-clean if, switching on image’s type:

- **HTMLOrSVGImageElement**
  - image’s current request’s image data is CORS-cross-origin.

- **HTMLVideoElement**
  - image’s media data is CORS-cross-origin.

- **HTMLCanvasElement**

- **ImageBitmap**
  - image’s bitmap’s origin-clean flag is false.
4.12.5.1.9 Fill and stroke styles

**context.fillStyle** [ = value ]

CanvasRenderingContext2D/fillStyle

Support in all current engines.

<table>
<thead>

</tr>
</tbody>
</table>

Returns the current style used for stroking shapes.

Can be set, to change the stroke style.

The style can be either a string containing a CSS color, or a CanvasGradient or CanvasPattern object. Invalid values are ignored.

Objects that implement the CanvasFillStrokeStyles interface have attributes and methods (defined in this section) that control how shapes are treated by the object.

Such objects have associated fill style and stroke style values, which are either CSS colors,
CanvasPattern, or CanvasGradient. Initially, both must be the result of parsing the string “#000000”.

When the value is a CSS color, it must not be affected by the transformation matrix when used to draw on bitmaps.

When set to a CanvasPattern or CanvasGradient object, changes made to the object after the assignment do affect subsequent stroking or filling of shapes.

The fillStyle getter steps are:

1. If this’s fill style is a CSS color, then return the serialization of that color.
2. Return this’s fill style.

The fillStyle setter steps are:

1. If the given value is a string, then:
   1. Let parsedValue be the result of parsing the given value with this’s canvas attribute’s value.
   2. If parsedValue is failure, then return.
   3. Set this’s fill style to parsedValue.
   4. Return.
2. If the given value is a CanvasPattern object that is marked as not origin-clean, then set this’s origin-clean flag to false.
3. Set this’s fill style to the given value.

The strokeStyle getter steps are:

1. If this’s stroke style is a CSS color, then return the serialization of that color.
2. Return this’s stroke style.

The strokeStyle setter steps are:

1. If the given value is a string, then:
   1. Let parsedValue be the result of parsing the given value with this’s canvas attribute’s value.
   2. If parsedValue is failure, then return.
3. Set this’s stroke style to parsedValue.

4. Return.

2. If the given value is a CanvasPattern object that is marked as not origin-clean, then set this’s origin-clean flag to false.

3. Set this’s stroke style to the given value.

The serialization of a color for a color value is a string, computed as follows: if it has alpha equal to 1.0, then the string is a lowercase six-digit hex value, prefixed with a "#" character (U+0023 NUMBER SIGN), with the first two digits representing the red component, the next two digits representing the green component, and the last two digits representing the blue component, the digits being ASCII lower hex digits. Otherwise, the color value has alpha less than 1.0, and the string is the color value in the CSS rgba() functional-notation format: the literal string "rgba" (U+0072 U+0067 U+0062 U+0061) followed by a U+0028 LEFT PARENTHESES, a base-ten integer in the range 0-255 representing the red component (using ASCII digits in the shortest form possible), a literal U+002C COMMA and U+0020 SPACE, an integer for the green component, a comma and a space, an integer for the blue component, another comma and space, a U+0030 DIGIT ZERO, if the alpha value is greater than zero then a U+002E FULL STOP (representing the decimal point), if the alpha value is greater than zero then one or more ASCII digits representing the fractional part of the alpha, and finally a U+0029 RIGHT PARENTHESES. User agents must express the fractional part of the alpha value, if any, with the level of precision necessary for the alpha value, when reparsed, to be interpreted as the same alpha value.

There are three types of gradients, linear gradients, radial gradients, and conic gradients, represented by objects implementing the opaque CanvasGradient interface.

Once a gradient has been created (see below), stops are placed along it to define how the colors are distributed along the gradient. The color of the gradient at each stop is the color specified for that stop. Between each such stop, the colors and the alpha component must be linearly interpolated over the RGBA space without premultiplying the alpha value to find the color to use at that offset. Before the first stop, the color must be the color of the first stop. After the last stop, the color must be the color of the last stop. When there are no stops, the gradient is transparent black.

```
gradient.addColorStop(offset, color)
```

CanvasGradient/addColorStop

Support in all current engines.

Firefox3.6+Safari5.1+Chrome6+
Opera9+Edge79+
Adds a color stop with the given color to the gradient at the given offset. 0.0 is the offset at one end of the gradient, 1.0 is the offset at the other end.

Throws an "IndexSizeError" DOMException if the offset is out of range. Throws a "SyntaxError" DOMException if the color cannot be parsed.

\[
\text{gradient} = \text{context}.\text{createLinearGradient}(x0, y0, x1, y1)
\]

CanvasRenderingContext2D/createLinearGradient

Support in all current engines.

</table>

Returns a CanvasGradient object that represents a conic gradient that paints clockwise along the rotation around the center represented by the arguments.

The `addColorStop(offset, color)` method on the CanvasGradient, when invoked, must run these steps:

1. If the `offset` is less than 0 or greater than 1, then throw an "IndexSizeError" DOMException.

2. Let `parsed color` be the result of parsing `color`.

   No element is passed to the parser because CanvasGradient objects are canvas-neutral — a CanvasGradient object created by one canvas can be used by another, and there is therefore no way to know which is the "element in question" at the time that the color is specified.

3. If `parsed color` is failure, throw a "SyntaxError" DOMException.

4. Place a new stop on the gradient, at offset `offset` relative to the whole gradient, and with the color `parsed color`.

   If multiple stops are added at the same offset on a gradient, then they must be placed in the order added, with the first one closest to the start of the gradient, and each subsequent one infinitesimally further along towards the end point (in effect causing all but the first and last stop added at each point to be ignored).

The `createLinearGradient(x0, y0, x1, y1)` method takes four arguments that represent the start point \((x0, y0)\) and end point \((x1, y1)\) of the gradient. The method, when invoked, must return a linear CanvasGradient initialized with the specified line.

Linear gradients must be rendered such that all points on a line perpendicular to the line that crosses the start and end points have the color at the point where those two lines cross (with the colors coming from the interpolation and extrapolation described above). The points in the linear gradient must be transformed as described by the current transformation matrix when rendering.
If \( x_0 = x_1 \) and \( y_0 = y_1 \), then the linear gradient must paint nothing.

The \texttt{createRadialGradient}(\( x_0 \), \( y_0 \), \( r_0 \), \( x_1 \), \( y_1 \), \( r_1 \)) method takes six arguments, the first three representing the start circle with origin \((x_0, y_0)\) and radius \(r_0\), and the last three representing the end circle with origin \((x_1, y_1)\) and radius \(r_1\). The values are in coordinate space units. If either of \(r_0\) or \(r_1\) are negative, then an "IndexSizeError" \texttt{DOMException} must be thrown. Otherwise, the method, when invoked, must return a radial \texttt{CanvasGradient} initialized with the two specified circles.

Radial gradients must be rendered by following these steps:

1. If \( x_0 = x_1 \) and \( y_0 = y_1 \) and \( r_0 = r_1 \), then the radial gradient must paint nothing. Return.

2. Let \( x(\omega) = (x_1-x_0)\omega + x_0 \)
   
   Let \( y(\omega) = (y_1-y_0)\omega + y_0 \)
   
   Let \( r(\omega) = (r_1-r_0)\omega + r_0 \)

   Let the color at \( \omega \) be the color at that position on the gradient (with the colors coming from the interpolation and extrapolation described above).

3. For all values of \( \omega \) where \( r(\omega) > 0 \), starting with the value of \( \omega \) nearest to positive infinity and ending with the value of \( \omega \) nearest to negative infinity, draw the circumference of the circle with radius \( r(\omega) \) at position \((x(\omega), y(\omega))\), with the color at \( \omega \), but only painting on the parts of the bitmap that have not yet been painted on by earlier circles in this step for this rendering of the gradient.

This effectively creates a cone, touched by the two circles defined in the creation of the gradient, with the part of the cone before the start circle \((0.0)\) using the color of the first offset, the part of the cone after the end circle \((1.0)\) using the color of the last offset, and areas outside the cone untouched by the gradient (transparent black).

The resulting radial gradient must then be transformed as described by the \texttt{current transformation matrix} when rendering.

The \texttt{createConicGradient}(\( \text{startAngle} \), \( x \), \( y \)) method takes three arguments, the first argument, \( \text{startAngle} \), represents the angle in radians at which the gradient begins, and the last two arguments, \((x, y)\), represent the center of the gradient in \texttt{CSS pixels}. The method, when invoked, must return a conic \texttt{CanvasGradient} initialized with the specified center and angle.

It follows the same rendering rule as CSS 'conic-gradient' and it is equivalent to CSS 'conic-gradient(from \text{adjustedStartAngle}\,\text{rad at xpx ypx, angularColorStopList}'). Here:

- \( \text{adjustedStartAngle} \) is given by \( \text{startAngle} + \pi/2 \);
- \( \text{angularColorStopList} \) is given by the color stops that have been added to the
CanvasGradient using addColorStop(), with the color stop offsets interpreted as percentages.

Gradients must be painted only where the relevant stroking or filling effects requires that they be drawn.

Patterns are represented by objects implementing the opaque CanvasPattern interface.

\[
pattern = context.createPattern(image, repetition)
\]

CanvasRenderingContext2D/createPattern

Returns a CanvasPattern object that uses the given image and repeats in the direction(s) given by the repetition argument.

The allowed values for repetition are repeat (both directions), repeat-x (horizontal only), repeat-y (vertical only), and no-repeat (neither). If the repetition argument is empty, the value repeat is used.

If the image isn’t yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an ‘InvalidStateError’ DOMException.

\[

</table>

Sets the transformation matrix that will be used when rendering the pattern during a fill or
stroke painting operation.

The `createPattern(image, repetition)` method, when invoked, must run these steps:

1. Let `usability` be the result of checking the usability of `image`.
2. If `usability` is `bad`, then return null.
3. Assert: `usability` is `good`.
4. If `repetition` is the empty string, then set it to "repeat".
5. If `repetition` is not identical to one of "repeat", "repeat-x", "repeat-y", or "no-repeat", then throw a "SyntaxError" DOMException.
6. Let `pattern` be a new `CanvasPattern` object with the image `image` and the repetition behavior given by `repetition`.
7. If `image` is not origin-clean, then mark `pattern` as not origin-clean.
8. Return `pattern`.

Modifying the `image` used when creating a `CanvasPattern` object after calling the `createPattern()` method must not affect the pattern(s) rendered by the `CanvasPattern` object.

Patterns have a transformation matrix, which controls how the pattern is used when it is painted. Initially, a pattern’s transformation matrix must be the identity matrix.

The `setTransform(transform)` method, when invoked, must run these steps:

1. Let `matrix` be the result of creating a DOMMatrix from the 2D dictionary `transform`.
2. If one or more of `matrix`'s `m11` element, `m12` element, `m21` element, `m22` element, `m41` element, or `m42` element are infinite or NaN, then return.
3. Reset the pattern’s transformation matrix to `matrix`.

When a pattern is to be rendered within an area, the user agent must run the following steps to determine what is rendered:

1. Create an infinite transparent black bitmap.
2. Place a copy of the image on the bitmap, anchored such that its top left corner is at the origin of the coordinate space, with one coordinate space unit per CSS pixel of the image, then place repeated copies of this image horizontally to the left and right, if the repetition behavior is "repeat-x", or vertically up and down, if the repetition behavior is "repeat-y", or in all four directions all over the bitmap, if the repetition behavior is
"repeat".

If the original image data is a bitmap image, then the value painted at a point in the area of the repetitions is computed by filtering the original image data. When scaling up, if the `imageSmoothingEnabled` attribute is set to false, then the image must be rendered using nearest-neighbor interpolation. Otherwise, the user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). User agents which support multiple filtering algorithms may use the value of the `imageSmoothingQuality` attribute to guide the choice of filtering algorithm. When such a filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from wrapping the pixel’s coordinates to the original image’s dimensions. (That is, the filter uses ‘repeat’ behavior, regardless of the value of the pattern’s repetition behavior.)

3. Transform the resulting bitmap according to the pattern’s transformation matrix.

4. Transform the resulting bitmap again, this time according to the current transformation matrix.

5. Replace any part of the image outside the area in which the pattern is to be rendered with transparent black.

6. The resulting bitmap is what is to be rendered, with the same origin and same scale.

If a radial gradient or repeated pattern is used when the transformation matrix is singular, then the resulting style must be transparent black (otherwise the gradient or pattern would be collapsed to a point or line, leaving the other pixels undefined). Linear gradients and solid colors always define all points even with singular transformation matrices.

4.12.5.1.10 Drawing rectangles to the bitmap

Objects that implement the `CanvasRect` interface provide the following methods for immediately drawing rectangles to the bitmap. The methods each take four arguments; the first two give the x and y coordinates of the top left of the rectangle, and the second two give the width w and height h of the rectangle, respectively.

The current transformation matrix must be applied to the following four coordinates, which form the path that must then be closed to get the specified rectangle: (x, y), (x+w, y), (x+w, y+h), (x, y+h).

Shapes are painted without affecting the current default path, and are subject to the clipping region, and, with the exception of `clearRect()`, also shadow effects, global alpha, and global composition operators.

`context.clearRect(x, y, w, h)`
**CanvasRenderingContext2D/clearRect**

Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android10.1+

Paints the given rectangle onto the bitmap, using the current fill style.

```javascript
context.strokeRect(x, y, w, h)
```

**CanvasRenderingContext2D/strokeRect**

Support in all current engines.

Firefox1.5+Safari2+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android12.1+

Paints the box that outlines the given rectangle onto the bitmap, using the current stroke style.
The `clearRect(x, y, w, h)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Let `pixels` be the set of pixels in the specified rectangle that also intersect the current clipping region.

3. Clear the pixels in `pixels` to a transparent black, erasing any previous image.

If either height or width are zero, this method has no effect, since the set of pixels would be empty.

The `fillRect(x, y, w, h)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. If either `w` or `h` are zero, then return.

3. Paint the specified rectangular area using this’s fill style.

The `strokeRect(x, y, w, h)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Take the result of tracing the path described below, using the `CanvasPathDrawingStyles` interface’s line styles, and fill it with this’s stroke style.

If both `w` and `h` are zero, the path has a single subpath with just one point `(x, y)`, and no lines, and this method thus has no effect (the trace a path algorithm returns an empty path in that case).

If just one of either `w` or `h` is zero, then the path has a single subpath consisting of two points, with coordinates `(x, y)` and `(x+w, y+h)`, in that order, connected by a single straight line.

Otherwise, the path has a single subpath consisting of four points, with coordinates `(x, y)`, `(x+w, y)`, `(x+w, y+h)`, and `(x, y+h)`, connected to each other in that order by straight lines.

**TextMetrics/ideographicBaseline**

MDN

TextMetrics/ideographicBaseline
Returns the measurement described below.

Objects that implement the `CanvasText` interface provide the following methods for rendering text.

The `fillText(text, x, y, maxWidth)` and `strokeText(text, x, y, maxWidth)` methods render the given `text` at the given `(x, y)` coordinates ensuring that the text isn’t wider than `maxWidth` if specified, using the current `font`, `textAlign`, and `textBaseline` values. Specifically, when the methods are invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Run the text preparation algorithm, passing it `text`, the object implementing the `CanvasText` interface, and, if the `maxWidth` argument was provided, that argument. Let `glyphs` be the result.

3. Move all the shapes in `glyphs` to the right by `x` CSS pixels and down by `y` CSS pixels.

4. Paint the shapes given in `glyphs`, as transformed by the current transformation matrix, with each CSS pixel in the coordinate space of `glyphs` mapped to one coordinate space unit.

   For `fillText()`, this’s fill style must be applied to the shapes and this’s stroke style must be ignored. For `strokeText()`, the reverse holds: this’s stroke style must be applied to the result of tracing the shapes using the object implementing the `CanvasText` interface for the line styles, and this’s fill style must be ignored.

   These shapes are painted without affecting the current path, and are subject to shadow effects, global alpha, the clipping region, and global composition operators.

   (This is a tracking vector.)

The `measureText(text)` method steps are to run the text preparation algorithm, passing it `text` and the object implementing the `CanvasText` interface, and then using the returned inline box must return a new `TextMetrics` object with members behaving as described in the following list: [CSS]

**width attribute**

The width of that inline box, in CSS pixels. (The text’s advance width.)
**actualBoundingBoxLeft** attribute

The distance parallel to the baseline from the alignment point given by the `textAlign` attribute to the left side of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going left from the given alignment point.

The sum of this value and the next (`actualBoundingBoxRight`) can be wider than the width of the inline box (`width`), in particular with slanted fonts where characters overhang their advance width.

**actualBoundingBoxRight** attribute

The distance parallel to the baseline from the alignment point given by the `textAlign` attribute to the right side of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going right from the given alignment point.

**fontBoundingBoxAscent** attribute

The distance from the horizontal line indicated by the `textBaseline` attribute to the ascent metric of the first available font, in CSS pixels; positive numbers indicating a distance going up from the given baseline.

This value and the next are useful when rendering a background that have to have a consistent height even if the exact text being rendered changes. The `actualBoundingBoxAscent` attribute (and its corresponding attribute for the descent) are useful when drawing a bounding box around specific text.

**fontBoundingBoxDescent** attribute

The distance from the horizontal line indicated by the `textBaseline` attribute to the descent metric of the first available font, in CSS pixels; positive numbers indicating a distance going down from the given baseline.

**actualBoundingBoxAscent** attribute

The distance from the horizontal line indicated by the `textBaseline` attribute to the top of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going up from the given baseline.

This number can vary greatly based on the input text, even if the first font specified covers all the characters in the input. For example, the `actualBoundingBoxAscent` of a lowercase “o” from an alphabetic baseline would be less than that of an uppercase “F”. The value can easily be negative; for example, the distance from the top of the em box (`textBaseline` value “top”) to the top of the bounding rectangle when the given text is just a single comma “,” would likely (unless the font is quite unusual) be negative.
**actualBoundingBoxDescent** attribute

The distance from the horizontal line indicated by the **textBaseline** attribute to the bottom of the bounding rectangle of the given text, in **CSS pixels**; positive numbers indicating a distance going down from the given baseline.

**emHeightAscent** attribute

The distance from the horizontal line indicated by the **textBaseline** attribute to the highest top of the em squares in the **inline box**, in **CSS pixels**; positive numbers indicating that the given baseline is below the top of that em square (so this value will usually be positive). Zero if the given baseline is the top of that em square; half the font size if the given baseline is the middle of that em square.

**emHeightDescent** attribute

The distance from the horizontal line indicated by the **textBaseline** attribute to the lowest bottom of the em squares in the **inline box**, in **CSS pixels**; positive numbers indicating that the given baseline is above the bottom of that em square. (Zero if the given baseline is the bottom of that em square.)

**hangingBaseline** attribute

The distance from the horizontal line indicated by the **textBaseline** attribute to the **hanging baseline** of the **inline box**, in **CSS pixels**; positive numbers indicating that the given baseline is below the **hanging baseline**. (Zero if the given baseline is the **hanging baseline**.)

**alphabeticBaseline** attribute

The distance from the horizontal line indicated by the **textBaseline** attribute to the **alphabetic baseline** of the **inline box**, in **CSS pixels**; positive numbers indicating that the given baseline is below the **alphabetic baseline**. (Zero if the given baseline is the **alphabetic baseline**.)

**ideographicBaseline** attribute

The distance from the horizontal line indicated by the **textBaseline** attribute to the **ideographic-under baseline** of the **inline box**, in **CSS pixels**; positive numbers indicating that the given baseline is below the **ideographic-under baseline**. (Zero if the given baseline is the **ideographic-under baseline**.)

Glyphs rendered using **fillText()** and **strokeText()** can spill out of the box given by the font size (the em square size) and the width returned by **measureText()** (the text width). Authors are encouraged to use the bounding box values described above if this is an issue.

A future version of the 2D context API might provide a way to render fragments of documents, rendered using CSS, straight to the canvas. This would be provided in preference to a dedicated...
way of doing multiline layout.

4.12.5.1.12 Drawing paths to the canvas

Objects that implement the CanvasDrawPath interface have a current default path. There is only one current default path, it is not part of the drawing state. The current default path is a path, as described above.

context.beginPath()

CanvasRenderingContext2D/beginPath

Support in all current engines.

Firefox1.5+Safari2+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android12.1+

Resets the current default path.

context.fill([ fillRule ])

CanvasRenderingContext2D/fill

Support in all current engines.

Firefox1.5+Safari2+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android12.1+

context.fill(path [, fillRule ])

Fills the subpaths of the current default path or the given path with the current fill style, obeying the given fill rule.

context.stroke()

CanvasRenderingContext2D/stroke
Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

**context.stroke(path)**

Strokes the subpaths of the current default path or the given path with the current stroke style.

**context.clip([ fillRule ])**

✔️MDN

CanvasRenderingContext2D/clip

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

**context.clip(path [, fillRule ])**

Further constrains the clipping region to the current default path or the given path, using the given fill rule to determine what points are in the path.

**context.isPointInPath(x, y [, fillRule ])**

✔️MDN

CanvasRenderingContext2D/isPointInPath

Support in all current engines.

Firefox 2+ Safari 3.1+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 2+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

**context.isPointInPath(path, x, y [, fillRule ])**

Returns true if the given point is in the current default path or the given path, using the given fill rule to determine what points are in the path.
`context.isPresentInStroke(x, y)`

CanvasRenderingContext2D/isPointInStroke

Support in all current engines.

`context.isPresentInStroke(path, x, y)`

Returns true if the given point would be in the region covered by the stroke of the current default path or the given path, given the current stroke style.

The `beginPath()` method steps are to empty the list of subpaths in this’s current default path so that it once again has zero subpaths.

Where the following method definitions use the term intended path for a Path2D-or-null path, it means path itself if it is a Path2D object, or the current default path otherwise.

When the intended path is a Path2D object, the coordinates and lines of its subpaths must be transformed according to the current transformation matrix on the object implementing the CanvasTransform interface when used by these methods (without affecting the Path2D object itself). When the intended path is the current default path, it is not affected by the transform. (This is because transformations already affect the current default path when it is constructed, so applying it when it is painted as well would result in a double transformation.)

The `fill(fillRule)` method steps are to run the fill steps given this, null, and fillRule.

The `fill(path, fillRule)` method steps are to run the fill steps given this, path, and fillRule.

The fill steps, given a CanvasDrawPath context, a Path2D-or-null path, and a fill rule fillRule, are to fill all the subpaths of the intended path for path, using context’s fill style, and using the fill rule indicated by fillRule. Open subpaths must be implicitly closed when being filled (without affecting the actual subpaths).

The `stroke()` method steps are to run the stroke steps given this and null.

The `stroke(path)` method steps are to run the stroke steps given this and path.

The stroke steps, given a CanvasDrawPath context and a Path2D-or-null path, are to trace the intended path for path, using context’s line styles as set by its
**CanvasPathDrawingStyles** mixin, and then fill the resulting path using *context's stroke style*, using the *nonzero winding rule*.

As a result of how the algorithm to *trace a path* is defined, overlapping parts of the paths in one stroke operation are treated as if their union was what was painted.

The stroke *style* is affected by the transformation during painting, even if the *current default path* is used.

Paths, when filled or stroked, must be painted without affecting the *current default path* or any Path2D objects, and must be subject to *shadow effects*, *global alpha*, the *clipping region*, and *global composition operators*. (The effect of transformations is described above and varies based on which path is being used.)

The `clip(fillRule)` method steps are to run the `clip steps` given *this*, null, and *fillRule*.

The `clip(path, fillRule)` method steps are to run the `clip steps` given *this*, *path*, and *fillRule*.

The `clip steps`, given a CanvasDrawPath context, a Path2D-or-null *path*, and a fill rule *fillRule*, are to create a new *clipping region* by calculating the intersection of *context's current clipping region* and the area described by the intended path for *path*, using the fill rule indicated by *fillRule*. Open subpaths must be implicitly closed when computing the clipping region, without affecting the actual subpaths. The new clipping region replaces the current clipping region.

When the context is initialized, its current clipping region must be set to the largest infinite surface (i.e. by default, no clipping occurs).

The `isPointInPath(x, y, fillRule)` method steps are to return the result of the *is point in path steps* given *this*, null, *x*, *y*, and *fillRule*.

The `isPointInPath(path, x, y, fillRule)` method steps are to return the result of the *is point in path steps* given *this*, null, *x*, *y*, and *fillRule*.

The *is point in path steps*, given a CanvasDrawPath context, a Path2D-or-null *path*, two numbers *x* and *y*, and a fill rule *fillRule*, are:

1. If *x* or *y* are infinite or NaN, then return false.

2. If the point given by the *x* and *y* coordinates, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the intended path for *path* as determined by the fill rule indicated by *fillRule*, then return true. Open subpaths must be implicitly closed when computing the area inside the path, without affecting the actual subpaths. Points on the path itself must be considered to be inside
the path.

3. Return false.

The \texttt{isPointInStroke(x, y)} method steps are to return the result of the is point in stroke steps given this, null, x, and y.

The \texttt{isPointInStroke(path, x, y)} method steps are to return the result of the is point in stroke steps given this, path, x, and y.

The is point in stroke steps, given a \texttt{CanvasDrawPath} context, a \texttt{Path2D}-or-null path, and two numbers \texttt{x} and \texttt{y}, are:

1. If \texttt{x} or \texttt{y} are infinite or NaN, then return false.

2. If the point given by the \texttt{x} and \texttt{y} coordinates, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the path that results from tracing the intended path for \texttt{path}, using the nonzero winding rule, and using \texttt{context}'s line styles as set by its \texttt{CanvasPathDrawingStyles} mixin, then return true. Points on the resulting path must be considered to be inside the path.

3. Return false.

This \texttt{canvas} element has a couple of checkboxes. The path-related commands are highlighted:

\begin{verbatim}
<canvas height=400 width=750>
  <label><input type=checkbox id=showA> Show As</label>
  <label><input type=checkbox id=showB> Show Bs</label>
</canvas>

<script>
  function drawCheckbox(context, element, x, y, paint) {
    context.save();
    context.font = '10px sans-serif';
    context.textAlign = 'left';
    context.textBaseline = 'middle';
    var metrics = context.measureText(element.labels[0].textContent);
    if (paint) {
      context.beginPath();
      context.strokeStyle = 'black';
      context.rect(x-5, y-5, 10, 10);
      context.stroke();
      if (element.checked) {
        context.fillStyle = 'black';
        context.fill();
      }
    }
  }
\end{verbatim}
```javascript
function drawBase() {
    /* ... */
}
function drawAs() {
    /* ... */
}
function drawBs() {
    /* ... */
}
function redraw() {

    var context = canvas.getContext('2d');
    context.clearRect(0, 0, canvas.width, canvas.height);
    drawCheckbox(context, document.getElementById('showA'), 20, 40, true);
    drawCheckbox(context, document.getElementById('showB'), 20, 60, true);
    drawBase();
    if (document.getElementById('showA').checked)
        drawAs();
    if (document.getElementById('showB').checked)
        drawBs();
}
function processClick(event) {
    var canvas = document.getElementsByTagName('canvas')[0];
    var context = canvas.getContext('2d');
    var x = event.clientX;
    var y = event.clientY;
    var node = event.target;
    while (node) {
        x -= node.offsetLeft - node.scrollLeft;
        y -= node.offsetTop - node.scrollTop;
        node = node.offsetParent;
    }
    drawCheckbox(context, document.getElementById('showA'), 20, 40, false);
    if (context.isPointInPath(x, y))
        document.getElementById('showA').checked = !!(document.getElementById('showA').checked);
    drawCheckbox(context, document.getElementById('showB'), 20, 60, false);
    if (context.isPointInPath(x, y))
        document.getElementById('showB').checked = !!(document.getElementById('showB').checked);
    redraw();
}
document.getElementsByTagName('canvas')[0].addEventListener('focus', redraw, false);
document.getElementsByTagName('canvas')[0].addEventListener('blur', redraw, false);
document.getElementsByTagName('canvas')[0].addEventListener('change', redraw, false);
document.getElementsByTagName('canvas')[0].addEventListener('click', processClick);
```
4.12.5.1.13 Drawing focus rings and scrolling paths into view

**context.drawFocusIfNeeded(element)**

Support in all current engines.

Firefox 32+ Safari 8+ Chrome 37+
Opera 24+ Edge 79+
Edge (Legacy) 14+ Internet Explorer No
Firefox Android 32+ Safari iOS 8+ Chrome Android 37+ WebView Android 37+ Samsung

`context.drawFocusIfNeeded(path, element)`

If the given element is focused, draws a focus ring around the current default path or the given path, following the platform conventions for focus rings.

**context.scrollPathIntoView()**

Support in one engine only.

Firefox No Safari No Chrome 36+
Opera 23+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android No Safari iOS No Chrome Android 36+ WebView Android No Samsung Internet No Opera Android No

`context.scrollPathIntoView(path)`

Scrolls the current default path or the given path into view. This is especially useful on devices with small screens, where the whole canvas might not be visible at once.

Objects that implement the [CanvasUserInterface](https://developer.mozilla.org/en-US/docs/Web/API/CanvasUserInterface) interface provide the following methods to control drawing focus rings and scrolling paths into view.

The `drawFocusIfNeeded(element)` method, when invoked, must run these steps:

1. If `element` is not focused or is not a descendant of the element with whose context the
method is associated, then return.

2. Draw a focus ring of the appropriate style along the intended path, following platform conventions.

Some platforms only draw focus rings around elements that have been focused from the keyboard, and not those focused from the mouse. Other platforms simply don’t draw focus rings around some elements at all unless relevant accessibility features are enabled. This API is intended to follow these conventions. User agents that implement distinctions based on the manner in which the element was focused are encouraged to classify focus driven by the `focus()` method based on the kind of user interaction event from which the call was triggered (if any).

The focus ring should not be subject to the shadow effects, the global alpha, the global composition operators, or any of the members in the `CanvasFillStrokeStyles`, `CanvasPathDrawingStyles`, `CanvasTextDrawingStyles` interfaces, but should be subject to the clipping region. (The effect of transformations is described above and varies based on which path is being used.)

3. Inform the user that the focus is at the location given by the intended path. User agents may wait until the next time the event loop reaches its update the rendering step to optionally inform the user.

User agents should not implicitly close open subpaths in the intended path when drawing the focus ring.

This might be a moot point, however. For example, if the focus ring is drawn as an axis-aligned bounding rectangle around the points in the intended path, then whether the subpaths are closed or not has no effect. This specification intentionally does not specify precisely how focus rings are to be drawn: user agents are expected to honor their platform’s native conventions.

The `scrollPathIntoView()` method, when invoked, must run these steps:

1. Let `specifiedRectangle` be the rectangle of the bounding box of the intended path.

2. Let `notionalChild` be a hypothetical element that is a rendered child of the canvas element whose dimensions are those of `specifiedRectangle`.

3. Scroll `notionalChild` into view with behavior set to “auto”, block set to “start”, and inline set to “nearest”.

4. Optionally, inform the user that the caret or selection (or both) cover `specifiedRectangle` of the canvas. The user agent may wait until the next time the event loop reaches its update the rendering step to optionally inform the user.

“Inform the user”, as used in this section, does not imply any persistent state change. It could mean, for instance, calling a system accessibility API to notify assistive technologies such as
magnification tools so that the user’s magnifier moves to the given area of the canvas. However, it does not associate the path with the element, or provide a region for tactile feedback, etc.

4.12.5.1.14 Drawing images

Objects that implement the `CanvasDrawImage` interface have the `drawImage` method to draw images.

This method can be invoked with three different sets of arguments:

- `drawImage(image, dx, dy)`
- `drawImage(image, dx, dy, dw, dh)`
- `drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`

`context.drawImage(image, dx, dy)`

CanvasRenderingContext2D/drawImage

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 9+ Edge 9+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 10.1+

`context.drawImage(image, dx, dy, dw, dh)`
`context.drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`

Draws the given image onto the canvas. The arguments are interpreted as follows:
If the image isn’t yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an “InvalidStateError” DOMException.

When the `drawImage()` method is invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Let `usability` be the result of checking the usability of `image`.

3. If `usability` is `bad`, then return (without drawing anything).

4. Establish the source and destination rectangles as follows:

   If not specified, the `dw` and `dh` arguments must default to the values of `sw` and `sh`, interpreted such that one CSS pixel in the image is treated as one unit in the output bitmap’s coordinate space. If the `sx`, `sy`, `sw`, and `sh` arguments are omitted, then they must default to 0, 0, the image’s intrinsic width in image pixels, and the image’s intrinsic height in image pixels, respectively. If the image has no intrinsic dimensions, then the concrete object size must be used instead, as determined using the CSS “Concrete Object Size Resolution” algorithm, with the specified size having neither a definite width nor height, nor any additional constraints, the object’s intrinsic properties being those of the `image` argument, and the default object size being the size of the output bitmap. [CSSIMAGES]

   The source rectangle is the rectangle whose corners are the four points `(sx, sy), (sx+sw, sy), (sx+sw, sy+sh), (sx, sy+sh)`.

   The destination rectangle is the rectangle whose corners are the four points `(dx, dy),...
When the source rectangle is outside the source image, the source rectangle must be clipped to the source image and the destination rectangle must be clipped in the same proportion.

When the destination rectangle is outside the destination image (the output bitmap), the pixels that land outside the output bitmap are discarded, as if the destination was an infinite canvas whose rendering was clipped to the dimensions of the output bitmap.

5. If one of the sw or sh arguments is zero, then return. Nothing is painted.

6. Paint the region of the image argument specified by the source rectangle on the region of the rendering context’s output bitmap specified by the destination rectangle, after applying the current transformation matrix to the destination rectangle.

The image data must be processed in the original direction, even if the dimensions given are negative.

When scaling up, if the imageSmoothingEnabled attribute is set to true, the user agent should attempt to apply a smoothing algorithm to the image data when it is scaled. User agents which support multiple filtering algorithms may use the value of the imageSmoothingQuality attribute to guide the choice of filtering algorithm when the imageSmoothingEnabled attribute is set to true. Otherwise, the image must be rendered using nearest-neighbor interpolation.

This specification does not define the precise algorithm to use when scaling an image down, or when scaling an image up when the imageSmoothingEnabled attribute is set to true.

When a canvas element is drawn onto itself, the drawing model requires the source to be copied before the image is drawn, so it is possible to copy parts of a canvas element onto overlapping parts of itself.

If the original image data is a bitmap image, then the value painted at a point in the destination rectangle is computed by filtering the original image data. The user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). When the filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from the nearest edge pixel. (That is, the filter uses ‘clamp-to-edge’ behavior.) When the filtering algorithm requires a pixel value from outside the source rectangle but inside the original image data, then the value from the original image data must be used.

Thus, scaling an image in parts or in whole will have the same effect. This does mean that when sprites coming from a single sprite sheet are to be scaled, adjacent images in the sprite sheet can interfere. This can be avoided by ensuring each sprite in the sheet is surrounded by a border of transparent black, or by copying sprites to be scaled into
temporary canvas elements and drawing the scaled sprites from there.

Images are painted without affecting the current path, and are subject to shadow effects, global alpha, the clipping region, and global composition operators.

7. If `image` is not origin-clean, then set the CanvasRenderingContext2D's origin-clean flag to false.

4.12.5.15 Pixel manipulation

```javascript
imagedata = new ImageData(sw, sh [, settings])
```

ImageData/ImageData

Support in all current engines.

<table>
<thead>
<tr>
<th></th>
<th>Firefox 29+</th>
<th>Safari 7+</th>
<th>Chrome 42+</th>
<th>Opera 29+</th>
<th>Edge 79+</th>
<th>Edge (Legacy) 14+</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns an `ImageData` object with the given dimensions and the color space indicated by `settings`. All the pixels in the returned object are transparent black.

Throws an "IndexSizeError" DOMException if either of the width or height arguments are zero.

```javascript
imagedata = new ImageData(data, sw [, sh [, settings ] ])
```

Returns an `ImageData` object using the data provided in the Uint8ClampedArray argument, interpreted using the given dimensions and the color space indicated by `settings`.

As each pixel in the data is represented by four numbers, the length of the data needs to be a multiple of four times the given width. If the height is provided as well, then the length needs to be exactly the width times the height times 4.

Throws an "IndexSizeError" DOMException if the given data and dimensions can't be interpreted consistently, or if either dimension is zero.

```javascript
imagedata = context.createImageData(imagedata)
```

Returns an `ImageData` object with the same dimensions and color space as the argument. All the pixels in the returned object are transparent black.
```javascript
imagedata = context.createImageData(sw, sh [, settings])
```

**CanvasRenderingContext2D/createImageData**

Support in all current engines.

</table>

Returns an `ImageData` object containing the image data for the given rectangle of the bitmap. The color space of the returned object is the color space of `context` unless overridden by `settings`.

Throws an "IndexSizeError" DOMException if the either of the width or height arguments are zero.

```javascript
imagedata.width
```

**ImageData/width**

- MDN
Support in all current engines.

Firefox14+Safari3.1+Chrome1+
Opera9+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android14+Safari iOS2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android10.1+

**ImageData.height**

returns the actual dimensions of the data in the `ImageData` object, in pixels.

**ImageData/data**

returns the one-dimensional array containing the data in RGBA order, as integers in the range 0 to 255.

**ImageData.colorSpace**

Returns the color space of the pixels.
Support in all current engines.

Firefox 2+ Safari 4+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Paints the data from the given ImageData object onto the bitmap. If a dirty rectangle is provided, only the pixels from that rectangle are painted.

The globalAlpha and globalCompositeOperation attributes, as well as the shadow attributes, are ignored for the purposes of this method call; pixels in the canvas are replaced wholesale, with no composition, alpha blending, no shadows, etc.

Throws an "InvalidStateError" DOMException if the imagedata object’s data attribute value’s [[ViewedArrayBuffer]] internal slot is detached.

Objects that implement theCanvasImageData interface provide the following methods for reading and writing pixel data to the bitmap.

The new ImageData(sw, sh, settings) constructor steps are:

1. If one or both of sw and sh are zero, then throw an "IndexSizeError" DOMException.
2. Initialize this given sw, sh, and settings set to settings.
3. Initialize the image data of this to transparent black.

The new ImageData(data, sw, sh, settings) constructor steps are:

1. Let length be the number of bytes in data.
2. If length is not a nonzero integral multiple of four, then throw an "InvalidStateError" DOMException.
3. Let length be length divided by four.
4. If length is not an integral multiple of sw, then throw an "IndexSizeError" DOMException.

At this step, the length is guaranteed to be greater than zero (otherwise the second step above would have aborted the steps), so if sw is zero, this step will throw the exception and return.
5. Let $height$ be $length$ divided by $sw$.

6. If $sh$ was given and its value is not equal to $height$, then throw an "IndexSizeError" DOMException.

7. Initialize this given $sw$, $sh$, $settings$ set to $settings$, and $source$ set to $data$.

   This step does not set this’s data to a copy of $data$. It sets it to the actual Uint8ClampedArray object passed as $data$.

The `createImageData($sw$, $sh$, $settings$)` method steps are:

1. If one or both of $sw$ and $sh$ are zero, then throw an "IndexSizeError" DOMException.

2. Let $newImageData$ be a new ImageData object.

3. Initialize $newImageData$ given the absolute magnitude of $sw$, the absolute magnitude of $sh$, $settings$ set to $settings$, and $defaultColorSpace$ set to this’s color space.

4. Initialize the image data of $newImageData$ to transparent black.

5. Return $newImageData$.

The `createImageData($imagedata$)` method steps are:

1. Let $newImageData$ be a new ImageData object.

2. Initialize $newImageData$ given the value of $imagedata$’s width attribute, the value of $imagedata$’s height attribute, and $defaultColorSpace$ set to the value of $imagedata$’s colorSpace attribute.

3. Initialize the image data of $newImageData$ to transparent black.

4. Return $newImageData$.

The `getImageData($sx$, $sy$, $sw$, $sh$, $settings$)` method steps are:

1. If either the $sw$ or $sh$ arguments are zero, then throw an "IndexSizeError" DOMException.

2. If the CanvasRenderingContext2D’s origin-clean flag is set to false, then throw a "SecurityError" DOMException.

3. Let $imageData$ be a new ImageData object.

4. Initialize $imageData$ given $sw$, $sh$, $settings$ set to $settings$, and $defaultColorSpace$ set to
Let the source rectangle whose corners are the four points \((sx, sy), (sx+sw, sy), (sx+sw, sy+sh), (sx, sy+sh)\).

Set the pixel values of \(\text{imageData}\) to be the pixels of \(\text{this’s output bitmap}\) in the area specified by the source rectangle in the bitmap’s coordinate space units, converted from \(\text{this’s color space}\) to \(\text{imageData’s colorSpace}\) using ‘relative-colorimetric’ rendering intent.

Set the pixels values of \(\text{imageData}\) for areas of the source rectangle that are outside of the \(\text{output bitmap}\) to transparent black.

Return \(\text{imageData}\).

To initialize an \(\text{ImageData}\) object \(\text{imageData}\), given a positive integer number of rows \(\text{rows}\), a positive integer number of pixels per row \(\text{pixelsPerRow}\), an optional \(\text{ImageDataSettings settings}\), an optional \(\text{Uint8ClampedArray source}\), and an optional \(\text{PredefinedColorSpace defaultColorSpace}\):

1. If \(\text{source}\) was given, then initialize the \(\text{data}\) attribute of \(\text{imageData}\) to \(\text{source}\).

2. Otherwise (\(\text{source}\) was not given), initialize the \(\text{data}\) attribute of \(\text{imageData}\) to a new \(\text{Uint8ClampedArray}\) object. The \(\text{Uint8ClampedArray}\) object must use a new \(\text{Canvas Pixel ArrayBuffer}\) for its storage, and must have a zero start offset and a length equal to the length of its storage, in bytes. The \(\text{Canvas Pixel ArrayBuffer}\) must have the correct size to store \(\text{rows} \times \text{pixelsPerRow}\) pixels.

   If the \(\text{Canvas Pixel ArrayBuffer}\) cannot be allocated, then rethrow the \(\text{RangeError}\) thrown by JavaScript, and return.

3. Initialize the \(\text{width}\) attribute of \(\text{imageData}\) to \(\text{pixelsPerRow}\).

4. Initialize the \(\text{height}\) attribute of \(\text{imageData}\) to \(\text{rows}\).

5. If \(\text{settings}\) was given and \(\text{settings["colorSpace"] exists}\), then initialize the \(\text{colorSpace}\) attribute of \(\text{imageData}\) to \(\text{settings["colorSpace"]}\).

6. Otherwise, if \(\text{defaultColorSpace}\) was given, then initialize the \(\text{colorSpace}\) attribute of \(\text{imageData}\) to \(\text{defaultColorSpace}\).

7. Otherwise, initialize the \(\text{colorSpace}\) attribute of \(\text{imageData}\) to "srgb".

\(\text{ImageData}\) objects are \(\text{serializable objects}\). Their \(\text{serialization steps}\), given \(\text{value}\) and \(\text{serialized}\), are:

1. Set \(\text{serialized.[[Data]]}\) to the \(\text{sub-serialization}\) of the value of \(\text{value’s data}\) attribute.
2. Set `serialized.[[Width]]` to the value of `value`'s `width` attribute.

3. Set `serialized.[[Height]]` to the value of `value`'s `height` attribute.

4. Set `serialized.[[ColorSpace]]` to the value of `value`'s `colorSpace` attribute.

Their deserialization steps, given `serialized` and `value`, are:

1. Initialize `value`'s `data` attribute to the sub-deserialization of `serialized.[[Data]]`.

2. Initialize `value`'s `width` attribute to `serialized.[[Width]]`.

3. Initialize `value`'s `height` attribute to `serialized.[[Height]]`.

4. Initialize `value`'s `colorSpace` attribute to `serialized.[[ColorSpace]]`.

A Canvas Pixel `ArrayBuffer` is an `ArrayBuffer` whose data is represented in left-to-right order, row by row top to bottom, starting with the top left, with each pixel's red, green, blue, and alpha components being given in that order for each pixel. Each component of each pixel represented in this array must be in the range 0..255, representing the 8 bit value for that component. The components must be assigned consecutive indices starting with 0 for the top left pixel’s red component.

The `putImageData()` method writes data from `ImageData` structures back to the rendering context’s output bitmap. Its arguments are: `imagedata`, `dx`, `dy`, `dirtyX`, `dirtyY`, `dirtyWidth`, and `dirtyHeight`.

When the last four arguments to this method are omitted, they must be assumed to have the values 0, 0, the `width` member of the `imagedata` structure, and the `height` member of the `imagedata` structure, respectively.

The method, when invoked, must act as follows:

1. Let `buffer` be `imagedata`'s `data` attribute value's `[[ViewedArrayBuffer]]` internal slot.

2. If `IsDetachedBuffer(buffer)` is true, then throw an "`InvalidStateError`" `DOMException`.

3. If `dirtyWidth` is negative, then let `dirtyX` be `dirtyX+dirtyWidth`, and let `dirtyWidth` be equal to the absolute magnitude of `dirtyWidth`

   If `dirtyHeight` is negative, then let `dirtyY` be `dirtyY+dirtyHeight`, and let `dirtyHeight` be equal to the absolute magnitude of `dirtyHeight`.

4. If `dirtyX` is negative, then let `dirtyWidth` be `dirtyWidth+dirtyX`, and let `dirtyX` be zero.

   If `dirtyY` is negative, then let `dirtyHeight` be `dirtyHeight+dirtyY`, and let `dirtyY` be zero.
5. If dirtyX + dirtyWidth is greater than the width attribute of the imagedata argument, then let dirtyWidth be the value of that width attribute, minus the value of dirtyX.

If dirtyY + dirtyHeight is greater than the height attribute of the imagedata argument, then let dirtyHeight be the value of that height attribute, minus the value of dirtyY.

6. If, after those changes, either dirtyWidth or dirtyHeight are negative or zero, then return without affecting any bitmaps.

7. For all integer values of x and y where dirtyX ≤ x < dirtyX + dirtyWidth and dirtyY ≤ y < dirtyY + dirtyHeight, copy the four channels of the pixel with coordinate (x, y) in the imagedata data structure’s Canvas Pixel ArrayBuffer to the pixel with coordinate (dx+x, dy+y) in the rendering context’s output bitmap.

Due to the lossy nature of converting between color spaces and converting to and from premultiplied alpha color values, pixels that have just been set using putImageData(), and are not completely opaque, might be returned to an equivalent getImageData() as different values.

The current path, transformation matrix, shadow attributes, global alpha, the clipping region, and global composition operator must not affect the methods described in this section.

In the following example, the script generates an ImageData object so that it can draw onto it.

```javascript
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');

// create a blank slate
var data = context.createImageData(canvas.width, canvas.height);

// create some plasma
FillPlasma(data, 'green'); // green plasma

// add a cloud to the plasma
AddCloud(data, data.width/2, data.height/2); // put a cloud in the middle

// paint the plasma+cloud on the canvas
context.putImageData(data, 0, 0);

// support methods
function FillPlasma(data, color) { ... }  
function AddCloud(data, x, y) { ... }  
```

Here is an example of using getImageData() and putImageData() to implement an edge detection filter.
var image = new Image();
function init() {
    image.onload = demo;
    image.src = "image.jpeg";
}
function demo() {
    var canvas = document.getElementsByTagName('canvas')[0];
    var context = canvas.getContext('2d');

    // draw the image onto the canvas
    context.drawImage(image, 0, 0);

    // get the image data to manipulate
    var input = context.getImageData(0, 0, canvas.width, canvas.height);

    // get an empty slate to put the data into
    var output = context.createImageData(canvas.width, canvas.height);

    // alias some variables for convenience
    // In this case input.width and input.height
    // match canvas.width and canvas.height
    // but we'll use the former to keep the code generic.
    var w = input.width, h = input.height;
    var inputData = input.data;
    var outputData = output.data;

    // edge detection
    for (var y = 1; y < h-1; y++) {
        for (var x = 1; x < w-1; x++) {
            for (var c = 0; c < 3; c++) {
                var i = (y*w + x)*4 + c;
                outputData[i] = 127 + -inputData[i - w*4 - 4] - inputData[i - w*4]
                    -inputData[i - 4] + 8*inputData[i]
                    -inputData[i + w*4 - 4] - inputData[i + w*4]
            }
            outputData[(y*w + x)*4 + 3] = 255; // alpha
        }
    }

    // put the image data back after manipulation
    context.putImageData(output, 0, 0);
Here is an example of color space conversion applied when drawing a solid color and reading the result back using and `getImageData()`.

```html
<!DOCTYPE HTML>
<html lang="en">
<title>Color space image data demo</title>

<canvas></canvas>

<script>
const canvas = document.querySelector('canvas');
const context = canvas.getContext('2d', {colorSpace:'display-p3'}); 

// Draw a red rectangle. Note that the hex color notation specifies sRGB colors.
context.fillStyle = "#FF0000";
context.fillRect(0, 0, 64, 64);

// Get the image data.
const pixels = context.getImageData(0, 0, 1, 1);

// This will print 'display-p3', reflecting the default behavior of returning image data in the canvas's color space.
console.log(pixels.colorSpace);

// This will print the values 234, 51, and 35, reflecting the red fill color, converted to 'display-p3'.
console.log(pixels.data[0]);
console.log(pixels.data[1]);
console.log(pixels.data[2]);
</script>
```

4.12.5.1.16 Compositing

`context.globalAlpha [ = value ]`

[MDN](https://developer.mozilla.org/en-US/docs/Web/API/CanvasRenderingContext2D/globalAlpha)
Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the current alpha value applied to rendering operations.

Can be set, to change the alpha value. Values outside of the range 0.0 .. 1.0 are ignored.

```javascript
context.globalCompositeOperation [ = value ]
``` MDN

CanvasRenderingContext2D/globalCompositeOperation

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 9+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 10.1+

Returns the current composition operation, from the values defined in Compositing and Blending. [COMPOSITE].

Can be set, to change the composition operation. Unknown values are ignored.

All drawing operations on an object which implements the CanvasCompositing interface are affected by the global compositing attributes, globalAlpha and globalCompositeOperation.

The globalAlpha attribute gives an alpha value that is applied to shapes and images before they are composited onto the output bitmap. The value must be in the range from 0.0 (fully transparent) to 1.0 (no additional transparency). If an attempt is made to set the attribute to a value outside this range, including Infinity and Not-a-Number (NaN) values, then the attribute must retain its previous value. When the context is created, the globalAlpha attribute must initially have the value 1.0.

The globalCompositeOperation attribute sets the current composition operator, which controls how shapes and images are drawn onto the output bitmap, once they have had globalAlpha and the current transformation matrix applied. The possible values are those defined in Compositing and Blending, and include the values source-over and copy. [COMPOSITE]
These values are all case-sensitive — they must be used exactly as defined. User agents must not recognize values that are not identical to one of the values given in Compositing and Blending. [COMPOSITE]

On setting, if the user agent does not recognize the specified value, it must be ignored, leaving the value of globalCompositeOperation unaffected. Otherwise, the attribute must be set to the given new value.

When the context is created, the globalCompositeOperation attribute must initially have the value source-over.

4.12.5.1.17 Image smoothing

```
context.imageSmoothingEnabled [ = value ]
```

Support in all current engines.

Firefox51+ Safari9.1+ Chrome30+
Opera17+ Edge79+
Edge (Legacy)15+ Internet Explorer11
Firefox Android51+ Safari iOS9.3+ Chrome Android30+ WebView Android4.4+ Samsung
Internet2.0+ Opera Android18+

Returns whether pattern fills and the drawImage() method will attempt to smooth images if their pixels don’t line up exactly with the display, when scaling images up.

Can be set, to change whether images are smoothed (true) or not (false).

```
context.imageSmoothingQuality [ = value ]
```

Firefox No Safari9.1+ Chrome54+
Opera41+ Edge79+
Edge (Legacy) No Internet Explorer No
Firefox Android No Safari iOS9.3+ Chrome Android54+ WebView Android54+ Samsung
Internet6.0+ Opera Android41+

Returns the current image-smoothing-quality preference.

Can be set, to change the preferred quality of image smoothing. The possible values are
"low", "medium" and "high". Unknown values are ignored.

Objects that implement the CanvasImageSmoothing interface have attributes that control how image smoothing is performed.

The imageSmoothingEnabled attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the CanvasImageSmoothing interface is created, the attribute must be set to true.

The imageSmoothingQuality attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the CanvasImageSmoothing interface is created, the attribute must be set to "low".

4.12.5.1.18 Shadows

All drawing operations on an object which implements the CanvasShadowStyles interface are affected by the four global shadow attributes.

context.shadowColor [ = value ]

CanvasRenderingContext2D/shadowColor

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 4+Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the current shadow color.

Can be set, to change the shadow color. Values that cannot be parsed as CSS colors are ignored.

context.shadowOffsetX [ = value ]

CanvasRenderingContext2D/shadowOffsetX

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+
 Returns the current shadow offset.

Can be set, to change the shadow offset. Values that are not finite numbers are ignored.

`context.shadowOffsetY [ = value ]`

`CanvasRenderingContext2D/shadowOffsetY`

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+

Returns the current level of blur applied to shadows.

Can be set, to change the blur level. Values that are not finite numbers greater than or equal to zero are ignored.

`context.shadowBlur [ = value ]`

`CanvasRenderingContext2D/shadowBlur`

Support in all current engines.

Firefox 1.5+ Safari 2+ Chrome 1+
Opera 12.1+ Edge 79+

The `shadowColor` attribute sets the color of the shadow.

When the context is created, the `shadowColor` attribute initially must be `transparent black`.

On getting, the serialization of the color must be returned.

On setting, the new value must be parsed with this canvas element and the color assigned. If parsing the value results in failure then it must be ignored, and the attribute must retain its
previous value. [CSSCOLOR]

The `shadowOffsetX` and `shadowOffsetY` attributes specify the distance that the shadow will be offset in the positive horizontal and positive vertical distance respectively. Their values are in coordinate space units. They are not affected by the current transformation matrix.

When the context is created, the shadow offset attributes must initially have the value 0.

On getting, they must return their current value. On setting, the attribute being set must be set to the new value, except if the value is infinite or NaN, in which case the new value must be ignored.

The `shadowBlur` attribute specifies the level of the blurring effect. (The units do not map to coordinate space units, and are not affected by the current transformation matrix.)

When the context is created, the `shadowBlur` attribute must initially have the value 0.

On getting, the attribute must return its current value. On setting the attribute must be set to the new value, except if the value is negative, infinite or NaN, in which case the new value must be ignored.

*Shadows are only drawn if* the opacity component of the alpha component of the color of `shadowColor` is nonzero and either the `shadowBlur` is nonzero, or the `shadowOffsetX` is nonzero, or the `shadowOffsetY` is nonzero.

**When shadows are drawn**, they must be rendered as follows:

1. Let $A$ be an infinite transparent black bitmap on which the source image for which a shadow is being created has been rendered.

2. Let $B$ be an infinite transparent black bitmap, with a coordinate space and an origin identical to $A$.

3. Copy the alpha channel of $A$ to $B$, offset by `shadowOffsetX` in the positive $x$ direction, and `shadowOffsetY` in the positive $y$ direction.

4. If `shadowBlur` is greater than 0:
   
   1. Let $\sigma$ be half the value of `shadowBlur`.
   
   2. Perform a 2D Gaussian Blur on $B$, using $\sigma$ as the standard deviation.

   User agents may limit values of $\sigma$ to an implementation-specific maximum value to avoid exceeding hardware limitations during the Gaussian blur operation.

5. Set the red, green, and blue components of every pixel in $B$ to the red, green, and blue components (respectively) of the color of `shadowColor`. 
6. Multiply the alpha component of every pixel in $B$ by the alpha component of the color of `shadowColor`.

7. The shadow is in the bitmap $B$, and is rendered as part of the drawing model described below.

If the current composition operation is `copy`, then shadows effectively won’t render (since the shape will overwrite the shadow).

4.12.5.1.19 Filters

All drawing operations on an object which implements the CanvasFilters interface are affected by the global `filter` attribute.

```
context.filter [ = value ]
```

Returns the current filter.

Can be set, to change the filter. Values that cannot be parsed as a `<filter-value-list>` value are ignored.

The `filter` attribute, on getting, must return the last value it was successfully set to. The value must not be re-serialized. On setting, if the new value is ‘none’ (not the empty string, null, or undefined), filters must be disabled for the context. Otherwise, the value must be parsed as a `<filter-value-list>` value. If the value cannot be parsed as a `<filter-value-list>` value, where using property-independent style sheet syntax like ‘inherit’ or ‘initial’ is considered an invalid value, then it must be ignored, and the attribute must retain its previous value. When creating the object implementing the CanvasFilters interface, the attribute must be set to ‘none’.

A `<filter-value-list>` value consists of a sequence of one or more filter functions or references to SVG filters. The input to the filter is used as the input to the first item in the list. Subsequent items take the output of the previous item as their input. [FILTERS]

Coordinates used in the value of the `filter` attribute are interpreted such that one pixel is equivalent to one SVG user space unit and to one canvas coordinate space unit. Filter coordinates are not affected by the current transformation matrix. The current transformation matrix affects only the input to the filter. Filters are applied in the output bitmap’s coordinate
space.

When the value of the `filter` attribute defines lengths using percentages or using ‘em’ or ‘ex’ units, these must be interpreted relative to the computed value of the ‘font-size’ property of the font style source object at the time that the attribute is set, if it is an element. If the computed values are undefined for a particular case (e.g. because the font style source object is not an element or is not being rendered), then the relative keywords must be interpreted relative to the default value of the `font` attribute. The ‘larger’ and ‘smaller’ keywords are not supported.

If the value of the `filter` attribute refers to an SVG filter in the same document, and this SVG filter changes, then the changed filter is used for the next draw operation.

If the value of the `filter` attribute refers to an SVG filter in an external resource document and that document is not loaded when a drawing operation is invoked, then the drawing operation must proceed with no filtering.

4.12.5.1.20 Working with externally-defined SVG filters

This section is non-normative.

Since drawing is performed using filter value ‘none’ until an externally-defined filter has finished loading, authors might wish to determine whether such a filter has finished loading before proceeding with a drawing operation. One way to accomplish this is to load the externally-defined filter elsewhere within the same page in some element that sends a load event (for example, an SVG `use` element), and wait for the load event to be dispatched.

4.12.5.1.21 Drawing model

When a shape or image is painted, user agents must follow these steps, in the order given (or act as if they do):

1. Render the shape or image onto an infinite transparent black bitmap, creating image A, as described in the previous sections. For shapes, the current fill, stroke, and line styles must be honored, and the stroke must itself also be subjected to the current transformation matrix.

2. When the filter attribute is set to a value other than ‘none’ and all the externally-defined filters it references, if any, are in documents that are currently loaded, then use image A as the input to the `filter`, creating image B. Otherwise, let B be an alias for A.

3. When shadows are drawn, render the shadow from image B, using the current shadow styles, creating image C.

4. When shadows are drawn, multiply the alpha component of every pixel in C by `globalAlpha`. 
5. **When shadows are drawn**, composite $C$ within the **clipping region** over the current **output bitmap** using the **current composition operator**.

6. Multiply the alpha component of every pixel in $B$ by $\text{globalAlpha}$.

7. Composite $B$ within the **clipping region** over the current **output bitmap** using the **current composition operator**.

When compositing onto the **output bitmap**, pixels that would fall outside of the **output bitmap** must be discarded.

### 4.12.5.1.22 Best practices

When a canvas is interactive, authors should include **focusable** elements in the element’s fallback content corresponding to each **focusable** part of the canvas, as in the **example above**.

When rendering focus rings, to ensure that focus rings have the appearance of native focus rings, authors should use the `drawFocusIfNeeded()` method, passing it the element for which a ring is being drawn. This method only draws the focus ring if the element is **focused**, so that it can simply be called whenever drawing the element, without checking whether the element is focused or not first.

In addition to drawing focus rings, authors should use the `scrollPathIntoView()` method when an element in the canvas is focused, to make sure it is visible on the screen (if applicable).

Authors should avoid implementing text editing controls using the **canvas** element. Doing so has a large number of disadvantages:

- Mouse placement of the caret has to be reimplemented.
- Keyboard movement of the caret has to be reimplemented (possibly across lines, for multiline text input).
- Scrolling of the text control has to be implemented (horizontally for long lines, vertically for multiline input).
- Native features such as copy-and-paste have to be reimplemented.
- Native features such as spell-checking have to be reimplemented.
- Native features such as drag-and-drop have to be reimplemented.
- Native features such as page-wide text search have to be reimplemented.
- Native features specific to the user, for example custom text services, have to be reimplemented. This is close to impossible since each user might have different services installed, and there is an unbounded set of possible such services.
- Bidirectional text editing has to be reimplemented.
- For multiline text editing, line wrapping has to be implemented for all relevant languages.
- Text selection has to be reimplemented.
- Dragging of bidirectional text selections has to be reimplemented.
- Platform-native keyboard shortcuts have to be reimplemented.
- Platform-native input method editors (IMEs) have to be reimplemented.
• Undo and redo functionality has to be reimplemented.
• Accessibility features such as magnification following the caret or selection have to be reimplemented.

This is a huge amount of work, and authors are most strongly encouraged to avoid doing any of it by instead using the input element, the textarea element, or the contenteditable attribute.

4.12.5.1.23 Examples

This section is non-normative.

Here is an example of a script that uses canvas to draw pretty glowing lines.

<canvas width="800" height="450"></canvas>
<script>

var context = document.getElementsByTagName('canvas')[0].getContext('2d');

var lastX = context.canvas.width * Math.random();
var lastY = context.canvas.height * Math.random();
var hue = 0;
function line() {
  context.save();
  context.translate(context.canvas.width/2, context.canvas.height/2);
  context.scale(0.9, 0.9);
  context.translate(-context.canvas.width/2, -context.canvas.height/2);
  context.beginPath();
  context.lineWidth = 5 + Math.random() * 10;
  context.moveTo(lastX, lastY);
  lastX = context.canvas.width * Math.random();
  lastY = context.canvas.height * Math.random();
  context.bezierCurveTo(context.canvas.width * Math.random(),
                        context.canvas.height * Math.random(),
                        context.canvas.width * Math.random(),
                        context.canvas.height * Math.random(),
                        lastX, lastY);

  hue = hue + 10 * Math.random();
  context.strokeStyle = 'hsl(' + hue + ', 50%, 50%)';
  context.shadowColor = 'white';
  context.shadowBlur = 10;
  context.stroke();
  context.restore();
}
setInterval(line, 50);
The 2D rendering context for canvas is often used for sprite-based games. The following example demonstrates this:

```javascript
function blank() {
  context.fillStyle = 'rgba(0,0,0,0.1)';
  context.fillRect(0, 0, context.canvas.width, context.canvas.height);
}
setInterval(blank, 40);
</script>

Here is the source for this example:

```html
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Blue Robot Demo</title>
<style>
  html { overflow: hidden; min-height: 200px; min-width: 380px; }
  body { height: 200px; position: relative; margin: 8px; }
  .buttons { position: absolute; bottom: 0px; left: 0px; margin: 4px; }
</style>
<canvas width="380" height="200"></canvas>
<script>
var Landscape = function (context, width, height) {
  this.offset = 0;
  this.width = width;
  this.advance = function (dx) {
    this.offset += dx;
  };
  this.horizon = height * 0.7;
  // This creates the sky gradient (from a darker blue to white at the bottom)
  this.sky = context.createLinearGradient(0, 0, 0, this.horizon);
  this.sky.addColorStop(0.0, 'rgb(55,121,179)');</n  this.sky.addColorStop(0.7, 'rgb(121,194,245)');</n```
this.sky.addColorStop(1.0, 'rgb(164,200,214)');
// this creates the grass gradient (from a darker green to a lighter green)
this.earth = context.createLinearGradient(0, this.horizon, 0, height);
this.earth.addColorStop(0.0, 'rgb(81,140,20)');
this.earth.addColorStop(1.0, 'rgb(123,177,57)');

this.paintBackground = function (context, width, height) {
  // first, paint the sky and grass rectangles
  context.fillStyle = this.sky;
  context.fillRect(0, 0, width, this.horizon);
  context.fillStyle = this.earth;
  context.fillRect(0, this.horizon, width, height-this.horizon);
  // then, draw the cloudy banner
  // we make it cloudy by having the draw text off the top of the
  // canvas, and just having the blurred shadow shown on the canvas
  context.save();
  context.translate(width-((this.offset+(this.width*3.2)) % (this.width*4.0)));
  context.shadowColor = 'white';
  context.shadowOffsetY = 30+this.horizon/3; // offset down on canvas
  context.shadowBlur = '5';
  context.fillStyle = 'white';
  context.textAlign = 'left';
  context.textBaseline = 'top';
  context.font = '20px sans-serif';
  context.fillText('WHATWG ROCKS', 10, -30); // text up above canvas
  context.restore();
  // then, draw the background tree
  context.save();
  context.translate(width-((this.offset+(this.width*0.2)) % (this.width*1.1)));
  context.beginPath();
  context.fillStyle = 'rgb(143,89,2)';
  context.strokeStyle = 'rgb(10,10,10)';

4.12.5.2 The **ImageBitmap** rendering context

4.12.5.2.1 Introduction

**ImageBitmapRenderingContext** is a performance-oriented interface that provides a low overhead method for displaying the contents of **ImageBitmap** objects. It uses transfer semantics to reduce overall memory consumption. It also streamlines performance by avoiding intermediate compositing, unlike the **drawImage()** method of **CanvasRenderingContext2D**.

Using an **img** element as an intermediate for getting an image resource into a canvas, for example, would result in two copies of the decoded image existing in memory at the same time: the **img** element’s copy, and the one in the canvas’s backing store. This memory cost can be prohibitive when dealing with extremely large images. This can be avoided by using **ImageBitmapRenderingContext**.

Using **ImageBitmapRenderingContext**, here is how to transcode an image to the JPEG format in a memory- and CPU-efficient way:

```javascript
createImageBitmap(inputImageBlob).then(image => {
    const canvas = document.createElement('canvas');
    const context = canvas.getContext('bitmaprenderer');
    context.transferFromImageBitmap(image);

    canvas.toBlob(outputJPEGBlob => {
        // Do something with outputJPEGBlob.
    }, 'image/jpeg');
});
```

4.12.5.2.2 The **ImageBitmapRenderingContext** interface

Exposed=(Window,Worker])

interface ImageBitmapRenderingContext {
    readonly attribute (HTMLCanvasElement or OffscreenCanvas) canvas;
    undefined transferFromImageBitmap(ImageBitmap? bitmap);
};

dictionary ImageBitmapRenderingContextSettings {
    boolean alpha = true;
};

canvas = context = canvas.getContext('bitmaprenderer' [, { [ alpha: false ] }])

Returns an ImageBitmapRenderingContext object that is permanently bound to a particular canvas element.

If the alpha setting is provided and set to false, then the canvas is forced to always be opaque.

canvas = context.canvas

Returns the canvas element that the context is bound to.

context.transferFromImageBitmap(imageBitmap)

Transfers the underlying bitmap data from imageBitmap to context, and the bitmap becomes the contents of the canvas element to which context is bound.

context.transferFromImageBitmap(null)

Replaces contents of the canvas element to which context is bound with a transparent black bitmap whose size corresponds to the width and height content attributes of the canvas element.

The canvas attribute must return the value it was initialized to when the object was created.
An **ImageBitmapRenderingContext** object has an *output bitmap*, which is a reference to bitmap data.

An **ImageBitmapRenderingContext** object has a *bitmap mode*, which can be set to *valid* or *blank*. A value of *valid* indicates that the context’s *output bitmap* refers to bitmap data that was acquired via `transferFromImageBitmap()`. A value *blank* indicates that the context’s *output bitmap* is a default transparent bitmap.

An **ImageBitmapRenderingContext** object also has an *alpha* flag, which can be set to true or false. When an **ImageBitmapRenderingContext** object has its *alpha* flag set to false, the contents of the **canvas** element to which the context is bound are obtained by compositing the context’s *output bitmap* onto an opaque black bitmap of the same size using the source-over composite operation. If the *alpha* flag is set to true, then the *output bitmap* is used as the contents of the **canvas** element to which the context is bound. [COMPOSITE]

The step of compositing over an opaque black bitmap ought to be elided whenever equivalent results can be obtained more efficiently by other means.

When a user agent is required to *set an ImageBitmapRenderingContext*’s *output bitmap*, with a *context* argument that is an **ImageBitmapRenderingContext** object and an optional argument *bitmap* that refers to **bitmap data**, it must run these steps:

1. If a *bitmap* argument was not provided, then:
   1. Set *context*’s *bitmap mode* to *blank*.
   2. Let **canvas** be the **canvas** element to which *context* is bound.
   3. Set *context*’s *output bitmap* to be transparent black with an intrinsic width equal to the numeric value of **canvas**’s *width* attribute and an intrinsic height equal to the numeric value of **canvas**’s *height* attribute, those values being interpreted in CSS pixels.
   4. Set the *output bitmap*’s *origin-clean* flag to true.

2. If a *bitmap* argument was provided, then:
   1. Set *context*’s *bitmap mode* to *valid*.
   2. Set *context*’s *output bitmap* to refer to the same underlying bitmap data as *bitmap*, without making a copy.

   The *origin-clean* flag of *bitmap* is included in the bitmap data to be referenced by *context*’s *output bitmap*. 
The `ImageBitmapRenderingContext` creation algorithm, which is passed a `target` and `options`, consists of running these steps:

1. Let `settings` be the result of converting `options` to the dictionary type `ImageBitmapRenderingContextSettings`. (This can throw an exception.)

2. Let `context` be a new `ImageBitmapRenderingContext` object.

3. Initialize `context`'s `canvas` attribute to point to `target`.

4. Set `context`'s `output bitmap` to the same bitmap as `target`'s bitmap (so that they are shared).

5. Run the steps to set an `ImageBitmapRenderingContext`'s output bitmap with `context`.

6. Initialize `context`'s `alpha` flag to true.

7. Process each of the members of `settings` as follows:

   - **alpha**
     - If false, then set `context`'s `alpha` flag to false.

8. Return `context`.

The `transferFromImageBitmap(bitmap)` method, when invoked, must run these steps:

1. Let `bitmapContext` be the `ImageBitmapRenderingContext` object on which the `transferFromImageBitmap()` method was called.

2. If `bitmap` is null, then run the steps to set an `ImageBitmapRenderingContext`'s output bitmap, with `bitmapContext` as the `context` argument and no `bitmap` argument, then return.

3. If the value of `bitmap`'s `[[Detached]]` internal slot is set to true, then throw an "`InvalidStateError` DOMException".

4. Run the steps to set an `ImageBitmapRenderingContext`'s output `bitmap`, with the `context` argument equal to `bitmapContext`, and the `bitmap` argument referring to `bitmap`'s underlying `bitmap data`.

5. Set the value of `bitmap`'s `[[Detached]]` internal slot to true.

6. Unset `bitmap`'s `bitmap data`.
4.12.5.3 The **OffscreenCanvas** interface

⚠️ MDN

**OffscreenCanvas**

Support in one engine only.

    Promis€<**Blob**> **convertToBlob**(optional **ImageEncodeOptions** **options** = {});

    attribute **EventHandler** **oncontextlost**;
    attribute **EventHandler** **oncontextrestored**;
};

**OffscreenCanvas** is an **EventTarget**, so both **OffscreenCanvasRenderingContext2D** and WebGL can fire events at it. **OffscreenCanvasRenderingContext2D** can fire **contextlost** and **contextrestored**, and WebGL can fire **webglcontextlost** and **webglcontextrestored**. **[WEBGL]**

**OffscreenCanvas** objects are used to create rendering contexts, much like an **HTMLCanvasElement**, but with no connection to the DOM. This makes it possible to use canvas rendering contexts in **workers**.
WebGLRenderingContext/commit

Support in one engine only.

Firefox 🔰 44+ Safari No Chrome No
Opera No Edge No
Edge (Legacy) No Internet Explorer No
Firefox Android No Safari iOS No Chrome Android No WebView Android No Samsung
Internet No Opera Android No

An `OffscreenCanvas` object may hold a weak reference to a *placeholder canvas element*, which is typically in the DOM, whose embedded content is provided by the `OffscreenCanvas` object. The bitmap of the `OffscreenCanvas` object is pushed to the *placeholder canvas element* by calling the `commit()` method of the `OffscreenCanvas` object’s rendering context. All rendering context types that can be created by an `OffscreenCanvas` object must implement a `commit()` method. The exact behavior of the `commit` method (e.g. whether it copies or transfers bitmaps) may vary, as defined by the rendering contexts’ respective specifications. Only the 2D context for offscreen canvases is defined in this specification.

```javascript
offscreenCanvas = new OffscreenCanvas(width, height)
```

Support in one engine only.

Firefox 🔰 46+ Safari No Chrome 69+
Opera 56+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 🔰 46+ Safari iOS No Chrome Android 69+ WebView Android No Samsung
Internet 10.0+ Opera Android Yes

Returns a new `OffscreenCanvas` object that is not linked to a *placeholder canvas element*, and whose bitmap’s size is determined by the `width` and `height` arguments.

```javascript
context = offscreenCanvas.getContext(contextId [, options ])
```

Support in one engine only.

Firefox 🔰 44+ Safari No Chrome 69+
Returns an object that exposes an API for drawing on the `OffscreenCanvas` object. `contextId` specifies the desired API: "2d", "bitmaprenderer", "webgl", "webgl2", or "webgpu". options is handled by that API.

This specification defines the "2d" context below, which is similar but distinct from the "2d" context that is created from a `canvas` element. The WebGL specifications define the "webgl" and "webgl2" contexts. WebGPU defines the "webgpu" context. [WEBGL] [WEBGPU]

Returns null if the canvas has already been initialized with another context type (e.g., trying to get a "2d" context after getting a "webgl" context).

An `OffscreenCanvas` object has an internal `bitmap` that is initialized when the object is created. The width and height of the `bitmap` are equal to the values of the `width` and `height` attributes of the `OffscreenCanvas` object. Initially, all the bitmap's pixels are `transparent black`.

An `OffscreenCanvas` object can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, an `OffscreenCanvas` object also has a `context mode`, which is initially `none` but can be changed to either `2d`, `bitmaprenderer`, `webgl`, `webgl2`, `webgpu`, or `detached` by algorithms defined in this specification.

The constructor `OffscreenCanvas(width, height)`, when invoked, must create a new `OffscreenCanvas` object with its `bitmap` initialized to a rectangular array of `transparent black` pixels of the dimensions specified by `width` and `height`, and its `width` and `height` attributes initialized to `width` and `height` respectively.

`OffscreenCanvas` objects are `transferable`. Their `transfer steps`, given `value` and `dataHolder`, are as follows:

1. If `value's context mode` is not equal to `none`, then throw an "[DOMException] InvalidStateError".
2. Set `value's context mode` to `detached`.
3. Let `width` and `height` be the dimensions of `value's bitmap`.
4. Unset `value's bitmap`.
5. Set `dataHolder.[[Width]]` to `width` and `dataHolder.[[Height]]` to `height`. 
6. Set `dataHolder.([PlaceholderCanvas])` to be a weak reference to `value`'s `placeholder canvas` element, if `value` has one, or null if it does not.

Their **transfer-receiving steps**, given `dataHolder` and `value`, are:

1. Initialize `value`'s `bitmap` to a rectangular array of transparent black pixels with width given by `dataHolder.([Width])` and height given by `dataHolder.([Height])`.

2. If `dataHolder.([PlaceholderCanvas])` is not null, set `value`'s `placeholder canvas` element to `dataHolder.([PlaceholderCanvas])` (while maintaining the weak reference semantics).

---

The `getContext(contextId, options)` method of an `OffscreenCanvas` object, when invoked, must run these steps:

1. If `options` is not an `object`, then set `options` to null.

2. Set `options` to the result of **converting** `options` to a JavaScript value.

3. Run the steps in the cell of the following table whose column header matches this `OffscreenCanvas` object's `context mode` and whose row header matches `contextId`:

<table>
<thead>
<tr>
<th><code>contextId</code></th>
<th><code>options</code></th>
<th><code>context mode</code></th>
<th><code>2d</code></th>
<th><code>bitmaprenderer</code></th>
<th><code>webgl</code></th>
<th><code>webgl2</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
<td>Return the same object as was returned the last time the method was invoked with this same first argument.</td>
<td>Return null.</td>
<td>Return null.</td>
<td>Return null.</td>
</tr>
<tr>
<td>2d</td>
<td></td>
<td></td>
<td>Follow the <strong>offscreen 2D context creation algorithm</strong> defined in the section below, passing it this <code>OffscreenCanvas</code> object and <code>options</code>, to obtain an <code>OffscreenCanvasRenderingContext2D</code> object; if this does not throw an exception, then set this <code>OffscreenCanvas</code> object's <code>context mode</code> to 2d, and return the new <code>OffscreenCanvasRenderingContext2D</code> object.</td>
<td>Return null.</td>
<td>Return null.</td>
<td>Return null.</td>
</tr>
<tr>
<td>bitmaprenderer</td>
<td></td>
<td></td>
<td>Follow the <strong>ImageBitmapRenderingContext creation algorithm</strong> defined in the section above, passing it this <code>OffscreenCanvas</code> object and <code>options</code>, to obtain an <code>ImageBitmapRenderingContext</code> object; if this does not throw an exception, then set this <code>OffscreenCanvas</code> object's <code>context mode</code> to bitmaprenderer, and return the new <code>ImageBitmapRenderingContext</code> object.</td>
<td>Return null.</td>
<td>Return null.</td>
<td>Return null.</td>
</tr>
</tbody>
</table>
Follow the instructions given in the WebGL specifications’ Context Creation sections to obtain either a WebGLRenderingContext, WebGL2RenderingContext, or null; if the returned value is null, then return null; otherwise, set this OffscreenCanvas object’s context mode to webgl or webgl2, and return the WebGLRenderingContext or WebGL2RenderingContext object. [WEBGL]

Follow the instructions given in WebGPU’s Canvas Rendering section to obtain a GPUCanvasContext or null; if the returned value is null, then return null; otherwise, set this OffscreenCanvas object’s context mode to webgpu and return the GPUCanvasContext object. [WEBGPU]

OffscreenCanvas.width [ = value ]

Support in one engine only.

Firefox 44+ Safari No Chrome 69+
Opera 56+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 44+ Safari iOS No Chrome Android 69+ WebView Android No Samsung
Internet 10.0+ Opera Android 48+

OffscreenCanvas.height [ = value ]
These attributes return the dimensions of the `OffscreenCanvas` object’s bitmap.

They can be set, to replace the bitmap with a new, transparent black bitmap of the specified dimensions (effectively resizing it).

If either the `width` or `height` attributes of an `OffscreenCanvas` object are set (to a new value or to the same value as before) and the `OffscreenCanvas` object’s context mode is 2d, then reset the rendering context to its default state and resize the `OffscreenCanvas` object’s bitmap to the new values of the `width` and `height` attributes.

The resizing behavior for "webgl" and "webgl2" contexts is defined in the WebGL specifications. [WEBGL]

The resizing behavior for "webgpu" context is defined in WebGPU. [WEBGPU]

If an `OffscreenCanvas` object whose dimensions were changed has a placeholder canvas element, then the placeholder canvas element’s intrinsic size will only be updated via the `commit()` method of the `OffscreenCanvas` object’s rendering context.

```javascript
promise = offscreenCanvas.convertToBlob([options])
```

Returns a promise that will fulfill with a new `Blob` object representing a file containing the image in the `OffscreenCanvas` object.

The argument, if provided, is a dictionary that controls the encoding options of the image file to be created. The `type` field specifies the file format and has a default value of "image/png"; that type is also used if the requested type isn’t supported. If the image
format supports variable quality (such as "image/jpeg"), then the quality field is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

```javascript
canvas.transferToImageBitmap()
```

[MDN](https://developer.mozilla.org)

**OffscreenCanvas/transferToImageBitmap**

Support in one engine only.

<table>

</tbody>
</table>

Returns a newly created `ImageBitmap` object with the image in the `OffscreenCanvas` object. The image in the `OffscreenCanvas` object is replaced with a new blank image.

The `convertToBlob(options)` method, when invoked, must run the following steps:

1. If the value of this `OffscreenCanvas` object’s [[Detached]] internal slot is set to true, then return a promise rejected with an "[InvalidStateError]

2. If this `OffscreenCanvas` object’s context mode is 2d and the rendering context’s bitmap’s origin-clean flag is set to false, then return a promise rejected with a "[SecurityError"

3. If this `OffscreenCanvas` object’s bitmap has no pixels (i.e., either its horizontal dimension or its vertical dimension is zero) then return a promise rejected with an "[IndexSizeError"

4. Let bitmap be a copy of this `OffscreenCanvas` object’s bitmap.

5. Let result be a new promise object.

6. Run these steps in parallel:

   1. Let file be a serialization of bitmap as a file, with options’s type and quality if present.

   2. Queue an element task on the canvas blob serialization task source given the canvas element to run these steps:

      1. If file is null, then reject result with an "[EncodingError"

```javascript
```
DOMException.

2. Otherwise, resolve result with a new Blob object, created in the relevant Realm of this OffscreenCanvas object, representing file. [FILEAPI]

7. Return result.

The transferToImageBitmap() method, when invoked, must run the following steps:

1. If the value of this OffscreenCanvas object’s [[Detached]] internal slot is set to true, then throw an "InvalidStateError" DOMException.

2. If this OffscreenCanvas object’s context mode is set to none, then throw an "InvalidStateError" DOMException.

3. Let image be a newly created ImageBitmap object that references the same underlying bitmap data as this OffscreenCanvas object’s bitmap.

4. Set this OffscreenCanvas object’s bitmap to reference a newly created bitmap of the same dimensions and color space as the previous bitmap, and with its pixels initialized to transparent black, or opaque black if the rendering context’s alpha flag is set to false.

   This means that if the rendering context of this OffscreenCanvas is a WebGLRenderingContext, the value of preserveDrawingBuffer will have no effect. [WEBGL]

5. Return image.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the OffscreenCanvas interface:

   Event handler  Event handler event type
   oncontextlost  contextlost
   oncontextrestored contextrestored

4.12.5.3.1 The offscreen 2D rendering context

[Exposed=(Window,Worker)]
interface OffscreenCanvasRenderingContext2D {
  undefined commit();
  readonly attribute OffscreenCanvas canvas;
};

OffscreenCanvasRenderingContext2D includes CanvasState;
OffscreenCanvasRenderingContext2D includes CanvasTransform;
The `OffscreenCanvasRenderingContext2D` object is a rendering context for drawing to the bitmap of an `OffscreenCanvas` object. It is similar to the `CanvasRenderingContext2D` object, with the following differences:

- there is no support for user interface features;
- its `canvas` attribute refers to an `OffscreenCanvas` object rather than a `canvas` element;
- it has a `commit()` method for pushing the rendered image to the context’s `OffscreenCanvas` object’s placeholder `canvas` element.

An `OffscreenCanvasRenderingContext2D` object has a `bitmap` that is initialized when the object is created.

The `bitmap` has an `origin-clean` flag, which can be set to true or false. Initially, when one of these bitmaps is created, its `origin-clean` flag must be set to true.

An `OffscreenCanvasRenderingContext2D` object also has an `alpha` flag, which can be set to true or false. Initially, when the context is created, its alpha flag must be set to true. When an `OffscreenCanvasRenderingContext2D` object has its alpha flag set to false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

An `OffscreenCanvasRenderingContext2D` object also has a `color space` setting of type `PredefinedColorSpace`. The color space for the context’s `bitmap` is set to the context’s `color space`.

An `OffscreenCanvasRenderingContext2D` object has an associated `OffscreenCanvas` object, which is the `OffscreenCanvas` object from which the `OffscreenCanvasRenderingContext2D` object was created.
**offscreenCanvasRenderingContext2D.commit()**

Copies the rendering context’s bitmap to the bitmap of the placeholder canvas element of the associated OffscreenCanvas object. The copy operation is synchronous. Calling this method is not needed for the transfer, since it happens automatically during the event loop execution.

**offscreenCanvas = offscreenCanvasRenderingContext2D.canvas**

Returns the associated OffscreenCanvas object.

The offscreen 2D context creation algorithm, which is passed a target (an OffscreenCanvas object) and optionally some arguments, consists of running the following steps:

1. If the algorithm was passed some arguments, let arg be the first such argument. Otherwise, let arg be undefined.

2. Let settings be the result of converting arg to the dictionary type CanvasRenderingContext2DSettings. (This can throw an exception.).

3. Let context be a new OffscreenCanvasRenderingContext2D object.

4. Set context’s associated OffscreenCanvas object to target.

5. If settings["alpha"] is false, then set context’s alpha flag to false.

6. Set context’s color space to settings["colorSpace"].

7. Set context’s bitmap to a newly created bitmap with the dimensions specified by the width and height attributes of target, and set target’s bitmap to the same bitmap (so that they are shared).

8. If context’s alpha flag is set to true, initialize all the pixels of context’s bitmap to transparent black. Otherwise, initialize the pixels to opaque black.

9. Return context.

The commit() method, when invoked, must run the following steps:

1. If this OffscreenCanvasRenderingContext2D’s associated OffscreenCanvas object does not have a placeholder canvas element, then return.

2. Let image be a copy of this OffscreenCanvasRenderingContext2D’s bitmap, including the value of its origin-clean flag.

3. Queue an element task on the DOM manipulation task source given the placeholder canvas element to set the placeholder canvas element’s output bitmap to be a
reference to image.

If image has different dimensions than the bitmap previously referenced as the placeholder canvas element’s output bitmap, then this task will result in a change in the placeholder canvas element’s intrinsic size, which can affect document layout.

Implementations are encouraged to short-circuit the graphics update steps of the window event loop for the purposes of updating the contents of a placeholder canvas element to the display. This could mean, for example, that the commit() method can copy the bitmap contents directly to a graphics buffer that is mapped to the physical display location of the placeholder canvas element. This or similar short-circuiting approaches can significantly reduce display latency, especially in cases where the commit() method is invoked from a worker event loop and the window event loop of the placeholder canvas element is busy. However, such shortcuts cannot have any script-observable side-effects. This means that the committed bitmap still needs to be sent to the placeholder canvas element, in case the element is used as a CanvasImageSource, as an ImageBitmapSource, or in case toDataURL() or toBlob() are called on it.

The canvas attribute, on getting, must return this OffscreenCanvasRenderingContext2D’s associated OffscreenCanvas object.

4.12.5.4 Color spaces and color space conversion

The canvas APIs provide mechanisms for specifying the color space of the canvas’s backing store. The default backing store color space for all canvas APIs is ‘srgb’.

Color space conversion must be applied to the canvas’s backing store when rendering the canvas to the output device. This color space conversion must be identical to the color space conversion that would be applied to an img element with a color profile that specifies the same color space as the canvas’s backing store.

When drawing content to a 2D context, all inputs must be converted to the context’s color space before drawing. Interpolation of gradient color stops must be performed on color values after conversion to the context’s color space. Alpha blending must be performed on values after conversion to the context’s color space.

There do not exist any inputs to a 2D context for which the color space is undefined. The color space for CSS colors is defined in CSS Color. The color space for images that specify no color profile information is assumed to be ‘srgb’, as specified in the Color Spaces of Untagged Colors section of CSS Color. [CSSCOLOR]

4.12.5.5 Serializing bitmaps to a file

When a user agent is to create a serialization of the bitmap as a file, given a type and an optional quality, it must create an image file in the format given by type. If an error occurs during the creation of the image file (e.g. an internal encoder error), then the result of the serialization is null. [PNG]
The image file’s pixel data must be the bitmap’s pixel data scaled to one image pixel per coordinate space unit, and if the file format used supports encoding resolution metadata, the resolution must be given as 96dpi (one image pixel per CSS pixel).

If type is supplied, then it must be interpreted as a MIME type giving the format to use. If the type has any parameters, then it must be treated as not supported.

For example, the value "image/png" would mean to generate a PNG image, the value "image/jpeg" would mean to generate a JPEG image, and the value "image/svg+xml" would mean to generate an SVG image (which would require that the user agent track how the bitmap was generated, an unlikely, though potentially awesome, feature).

User agents must support PNG ("image/png"). User agents may support other types. If the user agent does not support the requested type, then it must create the file using the PNG format. [PNG]

User agents must convert the provided type to ASCII lowercase before establishing if they support that type.

For image types that do not support an alpha channel, the serialized image must be the bitmap image composited onto an opaque black background using the source-over operator.

For image types that support color profiles, the serialized image must include a color profile indicating the color space of the underlying bitmap. For image types that do not support color profiles, the serialized image must be converted to the 'srgb' color space using 'relative-colorimetric' rendering intent.

Thus, in the 2D context, calling the drawImage() method to render the output of the toDataURL() or toBlob() method to the canvas, given the appropriate dimensions, has no visible effect beyond, at most, clipping colors of the canvas to a more narrow gamut.

If type is an image format that supports variable quality (such as "image/jpeg"), quality is given, and type is not "image/png", then, if Type(quality) is Number, and quality is in the range 0.0 to 1.0 inclusive, the user agent must treat quality as the desired quality level. Otherwise, the user agent must use its default quality value, as if the quality argument had not been given.

The use of type-testing here, instead of simply declaring quality as a Web IDL double, is a historical artifact.

Different implementations can have slightly different interpretations of "quality". When the quality is not specified, an implementation-specific default is used that represents a reasonable compromise between compression ratio, image quality, and encoding time.

4.12.5.6 Security with canvas elements

This section is non-normative.
**Information leakage** can occur if scripts from one *origin* can access information (e.g. read pixels) from images from another origin (one that isn’t the *same*).

To mitigate this, bitmaps used with *canvas* elements and *ImageBitmap* objects are defined to have a flag indicating whether they are *origin-clean*. All bitmaps start with their *origin-clean* set to true. The flag is set to false when cross-origin images are used.

The `toDataURL()`, `toBlob()`, and `getImageData()` methods check the flag and will throw a “SecurityError” *DOMException* rather than leak cross-origin data.

The value of the *origin-clean* flag is propagated from a source *canvas* element’s bitmap to a new *ImageBitmap* object by `createImageBitmap()`. Conversely, a destination *canvas* element’s bitmap will have its *origin-clean* flags set to false by `drawImage` if the source image is an *ImageBitmap* object whose bitmap has its *origin-clean* flag set to false.

The flag can be reset in certain situations; for example, when changing the value of the *width* or the *height* content attribute of the *canvas* element to which a *CanvasRenderingContext2D* is bound, the bitmap is cleared and its *origin-clean* flag is reset.

When using an *ImageBitmapRenderingContext*, the value of the *origin-clean* flag is propagated from *ImageBitmap* objects when they are transferred to the *canvas* via `transferFromImageBitmap()`.

### 4.12.5.7 Premultiplied alpha and the 2D rendering context

**Premultiplied alpha** refers to one way of representing transparency in an image, the other being non-premultiplied alpha.

Under non-premultiplied alpha, the red, green, and blue channels of a pixel represent that pixel’s color, and its alpha channel represents that pixel’s opacity.

Under premultiplied alpha, however, the red, green, and blue channels of a pixel represent the amounts of color that the pixel adds to the image, and its alpha channel represents the amount that the pixel obscures whatever is behind it.

For instance, assuming the color channels range from 0 (off) to 255 (full intensity), these example colors are represented in the following ways:
<table>
<thead>
<tr>
<th>CSS color representation</th>
<th>Premultiplied representation</th>
<th>Non-premultiplied representation</th>
<th>Description of color</th>
<th>Image of color blended above other content</th>
</tr>
</thead>
<tbody>
<tr>
<td>rgba(255, 127, 0, 1)</td>
<td>255, 127, 0, 255 255, 127, 0, 255</td>
<td>Completely-opaque orange</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rgba(255, 255, 0, 0.5)</td>
<td>127, 127, 0, 127 255, 255, 0, 127</td>
<td>Halfway-opaque yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Unrepresentable 255, 127, 0, 127</td>
<td>Unrepresentable</td>
<td>Additive halfway-opaque orange</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Unrepresentable 255, 127, 0, 0</td>
<td>Unrepresentable</td>
<td>Additive fully-transparent orange</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rgba(255, 127, 0, 0)</td>
<td>0, 0, 0, 0 255, 127, 0, 0</td>
<td>Fully-transparent (“invisible”) orange</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rgba(0, 127, 255, 0)</td>
<td>0, 0, 0, 0 255, 127, 0, 0</td>
<td>Fully-transparent (“invisible”) turquoise</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Converting a color value from a non-premultiplied representation to a premultiplied one involves multiplying the color’s red, green, and blue channels by its alpha channel (remapping the range of the alpha channel such that “fully transparent” is 0, and “fully opaque” is 1).

Converting a color value from a premultiplied representation to a non-premultiplied one involves the inverse: dividing the color’s red, green, and blue channels by its alpha channel.

As certain colors can only be represented under premultiplied alpha (for instance, additive colors), and others can only be represented under non-premultiplied alpha (for instance, “invisible” colors which hold certain red, green, and blue values even with no opacity); and division and multiplication on 8-bit integers (which is how canvas’s colors are currently stored)
entails a loss of precision, converting between premultiplied and non-premultiplied alpha is a lossy operation on colors that are not fully opaque.

A CanvasRenderingContext2D’s output bitmap and an OffscreenCanvasRenderingContext2D’s bitmap must use premultiplied alpha to represent transparent colors.

It is important for canvas bitmaps to represent colors using premultiplied alpha because it affects the range of representable colors. While additive colors cannot currently be drawn onto canvases directly because CSS colors are non-premultiplied and cannot represent them, it is still possible to, for instance, draw additive colors onto a WebGL canvas and then draw that WebGL canvas onto a 2D canvas via `drawImage()`.

4.13 Custom elements

Support in all current engines.

Firefox 63+ Safari 10.1+ Chrome 54+
Opera 41+ Edge 79+

Edge (Legacy) No

Internet Explorer No

Firefox Android 63+ Safari iOS 10.3+ Chrome Android 54+ WebView Android 54+
Samsung Internet 6.0+ Opera Android 41+

4.13.1 Introduction

This section is non-normative.

Custom elements provide a way for authors to build their own fully-featured DOM elements. Although authors could always use non-standard elements in their documents, with application-specific behavior added after the fact by scripting or similar, such elements have historically been non-conforming and not very functional. By defining a custom element, authors can inform the parser how to properly construct an element and how elements of that class should react to changes.

Custom elements are part of a larger effort to "rationalise the platform", by explaining existing platform features (like the elements of HTML) in terms of lower-level author-exposed extensibility points (like custom element definition). Although today there are many limitations on the capabilities of custom elements—both functionally and semantically—that prevent them from fully explaining the behaviors of HTML’s existing elements, we hope to shrink this gap over time.
4.13.1.1 Creating an autonomous custom element

This section is non-normative.

For the purposes of illustrating how to create an autonomous custom element, let's define a custom element that encapsulates rendering a small icon for a country flag. Our goal is to be able to use it like so:

```html
<flag-icon country="nl"></flag-icon>
```

To do this, we first declare a class for the custom element, extending HTMLElement:

```javascript
class FlagIcon extends HTMLElement {
  constructor() {
    super();
    this._countryCode = null;
  }

  static observedAttributes = ["country"];

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "country" due to observedAttributes
    this._countryCode = newValue;
    this._updateRendering();
  }

  connectedCallback() {
    this._updateRendering();
  }

  get country() {
    return this._countryCode;
  }

  set country(v) {
    this.setAttribute("country", v);
  }

  _updateRendering() {
    // Left as an exercise for the reader. But, you'll probably want to
    // check this.ownerDocument.defaultView to see if we've been
    // inserted into a document with a browsing context, and avoid
    // doing any work if not.
  }
}
```

We then need to use this class to define the element:

```javascript
customElements.define("flag-icon", FlagIcon);
```
At this point, our above code will work! The parser, whenever it sees the flag-icon tag, will construct a new instance of our FlagIcon class, and tell our code about its new country attribute, which we then use to set the element’s internal state and update its rendering (when appropriate).

You can also create flag-icon elements using the DOM API:

```javascript
const flagIcon = document.createElement("flag-icon")
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

Finally, we can also use the custom element constructor itself. That is, the above code is equivalent to:

```javascript
const flagIcon = new FlagIcon()
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

4.13.1.2 Creating a form-associated custom element

This section is non-normative.

Adding a static formAssociated property, with a true value, makes an autonomous custom element a form-associated custom element. The ElementInternals interface helps you to implement functions and properties common to form control elements.

```javascript
class MyCheckbox extends HTMLElement {
  static formAssociated = true;
  static observedAttributes = ['checked'];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this.addEventListener('click', this._onClick.bind(this));
  }

  get form() { return this._internals.form; }
  get name() { return this.getAttribute('name'); }
  get type() { return this.localName; }

  get checked() { return this.hasAttribute('checked'); }
  set checked(flag) { this.toggleAttribute('checked', Boolean(flag)); }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "checked" due to observedAttributes
    this._internals.setFormValue(this.checked ? 'on' : null);
  }
}
```
customElements.define('my-checkbox', MyCheckbox);

You can use the custom element my-checkbox like a built-in form-associated element. For example, putting it in form or label associates the my-checkbox element with them, and submitting the form will send data provided by my-checkbox implementation.

<form action="..." method="...">
  <label><my-checkbox name="agreed"></my-checkbox> I read the agreement.</label>
  <input type="submit">
</form>

4.13.1.3 Creating a custom element with default accessible roles, states, and properties

This section is non-normative.

By using the appropriate properties of ElementInternals, your custom element can have default accessibility semantics. The following code expands our form-associated checkbox from the previous section to properly set its default role and checkedness, as viewed by accessibility technology:

class MyCheckbox extends HTMLElement {
  static formAssociated = true;
  static observedAttributes = ['checked'];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this.addEventListener('click', this._onClick.bind(this));

    this._internals.role = 'checkbox';
    this._internals.ariaChecked = false;
  }

  get form() { return this._internals.form; }
  get name() { return this.getAttribute('name'); }
  get type() { return this.localName; }

  get checked() { return this.getAttribute('checked'); }
  set checked(flag) { this.toggleAttribute('checked', Boolean(flag)); }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "checked" due to observedAttributes
```javascript
  this._internals.setFormValue(this.checked ? 'on' : null);
  this._internals.ariaChecked = this.checked;
}

_onClick(event) {
  this.checked = !this.checked;
}
}
customElements.define('my-checkbox', MyCheckbox);
```

Note that, like for built-in elements, these are only defaults, and can be overridden by the page author using the `role` and `aria-*` attributes:

```html
<!-- This markup is non-conforming -->
<input type="checkbox" checked role="button" aria-checked="false">

<!-- This markup is probably not what the custom element author intended -->
<my-checkbox role="button" checked aria-checked="false">
```

Custom element authors are encouraged to state what aspects of their accessibility semantics are strong native semantics, i.e., should not be overridden by users of the custom element. In our example, the author of the `my-checkbox` element would state that its `role` and `aria-checked` values are strong native semantics, thus discouraging code such as the above.

4.13.1.4 Creating a customized built-in element

This section is non-normative.

Customized built-in elements are a distinct kind of custom element, which are defined slightly differently and used very differently compared to autonomous custom elements. They exist to allow reuse of behaviors from the existing elements of HTML, by extending those elements with new custom functionality. This is important since many of the existing behaviors of HTML elements can unfortunately not be duplicated by using purely autonomous custom elements. Instead, customized built-in elements allow the installation of custom construction behavior, lifecycle hooks, and prototype chain onto existing elements, essentially “mixing in” these capabilities on top of the already-existing element.

Customized built-in elements require a distinct syntax from autonomous custom elements because user agents and other software key off an element’s local name in order to identify the element’s semantics and behavior. That is, the concept of customized built-in elements building on top of existing behavior depends crucially on the extended elements retaining their original local name.

In this example, we’ll be creating a customized built-in element named `plastic-button`, which behaves like a normal button but gets fancy animation effects added whenever you click on it. We start by defining a class, just like before, although this time we extend `HTMLButtonElement` instead of `HTMLElement`:
class PlasticButton extends HTMLButtonElement {
    constructor() {
        super();

        this.addEventListener("click", () => {
            // Draw some fancy animation effects!
        });
    }
}

When defining our custom element, we have to also specify the `extends` option:

customElements.define("plastic-button", PlasticButton, { extends: "button" })

In general, the name of the element being extended cannot be determined simply by looking at what element interface it extends, as many elements share the same interface (such as `q` and `blockquote` both sharing `HTMLQuoteElement`).

To construct our customized built-in element from parsed HTML source text, we use the `is` attribute on a `button` element:

```html
<button is="plastic-button">Click Me!</button>
```

Trying to use a customized built-in element as an autonomous custom element will *not* work; that is, `<plastic-button>Click me?</plastic-button>` will simply create an `HTMLElement` with no special behavior.

If you need to create a customized built-in element programmatically, you can use the following form of `createElement()`:

```javascript
const plasticButton = document.createElement("button", { is: "plastic-button" });
plasticButton.textContent = "Click me!";
```

And as before, the constructor will also work:

```javascript
const plasticButton2 = new PlasticButton();
console.log(plasticButton2.localName); // will output "button"
console.assert(plasticButton2 instanceof PlasticButton);
console.assert(plasticButton2 instanceof HTMLButtonElement);
```

Note that when creating a customized built-in element programmatically, the `is` attribute will not be present in the DOM, since it was not explicitly set. However, it will be added to the output when serializing:

```javascript
console.assert(!plasticButton.hasAttribute("is"));
console.log(plasticButton.outerHTML); // will output '<button is="plastic-button"'>Click me!</button>'
```
Regardless of how it is created, all of the ways in which button is special apply to such "plastic buttons" as well: their focus behavior, ability to participate in form submission, the disabled attribute, and so on.

Customized built-in elements are designed to allow extension of existing HTML elements that have useful user-agent supplied behavior or APIs. As such, they can only extend existing HTML elements defined in this specification, and cannot extend legacy elements such as bgsound, blink, isindex, keygen, multicol, nextid, or spacer that have been defined to use HTMLUnknownElement as their element interface.

One reason for this requirement is future-compatibility: if a customized built-in element was defined that extended a currently-unknown element, for example combobox, this would prevent this specification from defining a combobox element in the future, as consumers of the derived customized built-in element would have come to depend on their base element having no interesting user-agent-supplied behavior.

4.13.1.5 Drawbacks of autonomous custom elements

This section is non-normative.

As specified below, and alluded to above, simply defining and using an element called taco-button does not mean that such elements represent buttons. That is, tools such as web browsers, search engines, or accessibility technology will not automatically treat the resulting element as a button just based on its defined name.

To convey the desired button semantics to a variety of users, while still using an autonomous custom element, a number of techniques would need to be employed:

- The addition of the tabindex attribute would make the taco-button focusable. Note that if the taco-button were to become logically disabled, the tabindex attribute would need to be removed.

- The addition of an ARIA role and various ARIA states and properties helps convey semantics to accessibility technology. For example, setting the role to "button" will convey the semantics that this is a button, enabling users to successfully interact with the control using usual button-like interactions in their accessibility technology. Setting the aria-label property is necessary to give the button an accessible name, instead of having accessibility technology traverse its child text nodes and announce them. And setting the aria-disabled state to "true" when the button is logically disabled conveys to accessibility technology the button’s disabled state.

- The addition of event handlers to handle commonly-expected button behaviors helps convey the semantics of the button to web browser users. In this case, the most relevant event handler would be one that proxies appropriate keydown events to become click events, so that you can activate the button both with keyboard and by clicking.

- In addition to any default visual styling provided for taco-button elements, the
visual styling will also need to be updated to reflect changes in logical state, such as becoming disabled; that is, whatever style sheet has rules for **taco-button** will also need to have rules for **taco-button[disabled]**.

With these points in mind, a full-featured **taco-button** that took on the responsibility of conveying button semantics (including the ability to be disabled) might look something like this:

class TacoButton extends HTMLElement {
    static observedAttributes = ["disabled"];

    constructor() {
        super();
        this._internals = this.attachInternals();
        this._internals.role = "button";

        this.addEventListener("keydown", e => {
            if (e.code === "Enter" || e.code === "Space") {
                this.dispatchEvent(new PointerEvent("click", {
                    bubbles: true,
                    cancelable: true
                }));
            }
        });

        this.addEventListener("click", e => {
            if (this.disabled) {
                e.preventDefault();
                e.stopImmediatePropagation();
            }
        });

        this._observer = new MutationObserver(() => {
            this._internals.ariaLabel = this.textContent;
        });
    }

    connectedCallback() {
        this.setAttribute("tabindex", "0");

        this._observer.observe(this, {
            childList: true,
            characterData: true,
            subtree: true
        });
    }
}
disconnectedCallback() {
  this._observer.disconnect();
}

get disabled() {
  return this.hasAttribute("disabled");
}

set disabled(flag) {
  this.toggleAttribute("disabled", Boolean(flag));
}

attributeChangedCallback(name, oldValue, newValue) {
  // name will always be "disabled" due to observedAttributes
  if (this.disabled) {
    this.removeAttribute("tabindex");
    this._internals.ariaDisabled = "true";
  } else {
    this.setAttribute("tabindex", "0");
    this._internals.ariaDisabled = "false";
  }
}

Even with this rather-complicated element definition, the element is not a pleasure to use for consumers: it will be continually “sprouting” `tabindex` attributes of its own volition, and its choice of `tabindex="0"` focusability behavior may not match the `button` behavior on the current platform. This is because as of now there is no way to specify default focus behavior for custom elements, forcing the use of the `tabindex` attribute to do so (even though it is usually reserved for allowing the consumer to override default behavior).

In contrast, a simple customized built-in element, as shown in the previous section, would automatically inherit the semantics and behavior of the `button` element, with no need to implement these behaviors manually. In general, for any elements with nontrivial behavior and semantics that build on top of existing elements of HTML, customized built-in elements will be easier to develop, maintain, and consume.

4.13.1.6 Upgrading elements after their creation

This section is non-normative.

Because element definition can occur at any time, a non-custom element could be created, and then later become a custom element after an appropriate definition is registered. We call this process “upgrading” the element, from a normal element into a custom element.

Upgrades enable scenarios where it may be preferable for custom element definitions to be registered after relevant elements have been initially created, such as by the parser. They allow progressive enhancement of the content in the custom element. For example, in the following
HTML document the element definition for `<img-viewer>` is loaded asynchronously:

```html
<!DOCTYPE html>
<html lang="en">
<title>Image viewer example</title>

<img-viewer filter="Kelvin">
  <img src="images/tree.jpg" alt="A beautiful tree towering over an empty savanna">
</img-viewer>

<script src="js/elements/img-viewer.js" async></script>
```

The definition for the `<img-viewer>` element here is loaded using a `<script>` element marked with the `async` attribute, placed after the `<img-viewer>` tag in the markup. While the script is loading, the `<img-viewer>` element will be treated as an undefined element, similar to a `<span>`. Once the script loads, it will define the `<img-viewer>` element, and the existing `<img-viewer>` element on the page will be upgraded, applying the custom element’s definition (which presumably includes applying an image filter identified by the string "Kelvin", enhancing the image’s visual appearance).

Note that upgrades only apply to elements in the document tree. (Formally, elements that are connected.) An element that is not inserted into a document will stay un-upgraded. An example illustrates this point:

```html
<!DOCTYPE html>
<html lang="en">
<title>Upgrade edge-cases example</title>

<example-element></example-element>

<script>
  "use strict";

  const inDocument = document.querySelector("example-element");
  const outOfDocument = document.createElement("example-element");

  // Before the element definition, both are HTMLElement:
  console.assert(inDocument instanceof HTMLElement);
  console.assert(outOfDocument instanceof HTMLElement);

  class ExampleElement extends HTMLElement {}
  customElements.define("example-element", ExampleElement);

  // After element definition, the in-document element was upgraded:
  console.assert(inDocument instanceof ExampleElement);
  console.assert(!(outOfDocument instanceof ExampleElement));
</script>
```
4.13.2 Requirements for custom element constructors and reactions

When authoring custom element constructors, authors are bound by the following conformance requirements:

- A parameter-less call to `super()` must be the first statement in the constructor body, to establish the correct prototype chain and `this` value before any further code is run.
- A `return` statement must not appear anywhere inside the constructor body, unless it is a simple early-return (`return` or `return this`).
- The constructor must not use the `document.write()` or `document.open()` methods.
- The element's attributes and children must not be inspected, as in the non-upgrade case none will be present, and relying on upgrades makes the element less usable.
- The element must not gain any attributes or children, as this violates the expectations of consumers who use the `createElement` or `createElementNS` methods.
- In general, work should be deferred to `connectedCallback` as much as possible—especially work involving fetching resources or rendering. However, note that `connectedCallback` can be called more than once, so any initialization work that is truly one-time will need a guard to prevent it from running twice.
- In general, the constructor should be used to set up initial state and default values, and to set up event listeners and possibly a shadow root.

Several of these requirements are checked during element creation, either directly or indirectly, and failing to follow them will result in a custom element that cannot be instantiated by the parser or DOM APIs. This is true even if the work is done inside a constructor-initiated microtask, as a microtask checkpoint can occur immediately after construction.

When authoring custom element reactions, authors should avoid manipulating the node tree as this can lead to unexpected results.

An element's `connectedCallback` can be queued before the element is disconnected, but as the callback queue is still processed, it results in a `connectedCallback` for an element that is no longer connected:
class CParent extends HTMLElement {
    connectedCallback() {
        this.firstChild.remove();
    }
}
customElements.define("c-parent", CParent);

class CChild extends HTMLElement {
    connectedCallback() {
        console.log("CChild connectedCallback: isConnected = ", this.isConnected);
    }
}
customElements.define("c-child", CChild);

const parent = new CParent(),
    child = new CChild();
parent.append(child);
document.body.append(parent);

// Logs:
// CChild connectedCallback: isConnected = false

4.13.3 Core concepts

A custom element is an element that is custom. Informally, this means that its constructor and
prototype are defined by the author, instead of by the user agent. This author-supplied
constructor function is called the custom element constructor.

Two distinct types of custom elements can be defined:

1. An autonomous custom element, which is defined with no extends option. These types
   of custom elements have a local name equal to their defined name.

2. A customized built-in element, which is defined with an extends option. These types
   of custom elements have a local name equal to the value passed in their extends option,
   and their defined name is used as the value of the is attribute, which therefore must be

MDN

Global_attributes/is

Internet9.0+Opera Android48+
a valid custom element name.

After a custom element is created, changing the value of the is attribute does not change the element’s behavior, as it is saved on the element as its is value.

Autonomous custom elements have the following element definition:

**Categories:**
- Flow content.
- Phrasing content.
- Palpable content.

For form-associated custom elements: Listed, labelable, submittable, and resettable form-associated element.

**Contexts in which this element can be used:**
- Where phrasing content is expected.

**Content model:**
- Transparent.

**Content attributes:**
- Global attributes, except the is attribute
  - form, for form-associated custom elements — Associates the element with a form element
  - disabled, for form-associated custom elements — Whether the form control is disabled
  - readonly, for form-associated custom elements — Affects willValidate, plus any behavior added by the custom element author
  - name, for form-associated custom elements — Name of the element to use for form submission and in the form.elements API

Any other attribute that has no namespace (see prose).

**Accessibility considerations:**
- For form-associated custom elements: for authors; for implementers.

Otherwise: for authors; for implementers.

**DOM interface:**
- Supplied by the element’s author (inherits from HTMLElement)

An autonomous custom element does not have any special meaning; it represents its children. A customized built-in element inherits the semantics of the element that it extends.
Any namespace-less attribute that is relevant to the element’s functioning, as determined by the element’s author, may be specified on an autonomous custom element, so long as the attribute name is XML-compatible and contains no ASCII upper alphas. The exception is the is attribute, which must not be specified on an autonomous custom element (and which will have no effect if it is).

Customized built-in elements follow the normal requirements for attributes, based on the elements they extend. To add custom attribute-based behavior, use data-* attributes.

An autonomous custom element is called a form-associated custom element if the element is associated with a custom element definition whose form-associated field is set to true.

The name attribute represents the form-associated custom element’s name. The disabled attribute is used to make the form-associated custom element non-interactive and to prevent its submission value from being submitted. The form attribute is used to explicitly associate the form-associated custom element with its form owner.

The readonly attribute of form-associated custom elements specifies that the element is barred from constraint validation. User agents don’t provide any other behavior for the attribute, but custom element authors should, where possible, use its presence to make their control non-editable in some appropriate fashion, similar to the behavior for the readonly attribute on built-in form controls.

Constraint validation: If the readonly attribute is specified on a form-associated custom element, the element is barred from constraint validation.

The reset algorithm for form-associated custom elements is to enqueue a custom element callback reaction with the element, callback name "formResetCallback", and an empty argument list.

A valid custom element name is a sequence of characters name that meets all of the following requirements:

- name must match the PotentialCustomElementName production:

```
PotentialCustomElementName ::= [a-z] (PCENChar)* '-' (PCENChar)*
```

```
PCENChar ::= "-" | "." | [0-9] | "_" | [a-z] | #xB7 | [#xC0-#xD6] | [#xD8-#xF6] | [#xF8-#x37D] | [#x37F-#x1FFF] | [#x200C-#x200D] | [#x203F-#x2040] | [#x2070-#x218F] | [#x2C00-#x2DF] | [#x3001-#xD7FF] | [#xF900-#xFD] | [#xFDF0-#xFFFD] | [#x10000-#x1FFFF]
```
This uses the EBNF notation from the XML specification. [XML]

• *name* must not be any of the following:
  
  ◦ annotation-xml  
  ◦ color-profile  
  ◦ font-face  
  ◦ font-face-src  
  ◦ font-face-uri  
  ◦ font-face-format  
  ◦ font-face-name  
  ◦ missing-glyph  

The list of names above is the summary of all hyphen-containing element names from the applicable specifications, namely SVG 2 and MathML. [SVG] [MATHML]

These requirements ensure a number of goals for valid custom element names:

• They start with an [ASCII lower alpha](https://en.wikipedia.org/wiki/Latin_1#Lowercase), ensuring that the HTML parser will treat them as tags instead of as text.

• They do not contain any [ASCII upper alphas](https://en.wikipedia.org/wiki/Latin_1#Uppercase), ensuring that the user agent can always treat HTML elements ASCII-case-insensitively.

• They contain a hyphen, used for namespacing and to ensure forward compatibility (since no elements will be added to HTML, SVG, or MathML with hyphen-containing local names in the future).

• They can always be created with `createElement()` and `createElementNS()`, which have restrictions that go beyond the parser’s.

Apart from these restrictions, a large variety of names is allowed, to give maximum flexibility for use cases like `<math-α>` or `<emotion-😍>`.

A custom element definition describes a custom element and consists of:

A name

A [valid custom element name](https://en.wikipedia.org/wiki/Valid_custom_element_name)

A local name

A local name

A constructor

A Web IDL [CustomElementConstructor](https://html.spec.whatwg.org/multipage/custom-element-api.html#custom-element-constructor) callback function type value wrapping the custom element constructor

A list of observed attributes

A sequence<DOMString>
A collection of lifecycle callbacks
A map, whose keys are the strings "connectedCallback", "disconnectedCallback", "adoptedCallback", "attributeChangedCallback", "formAssociatedCallback", "formDisabledCallback", "formResetCallback", and "formStateRestoreCallback". The corresponding values are either a Web IDL Function callback function type value, or null. By default the value of each entry is null.

A construction stack
A list, initially empty, that is manipulated by the upgrade an element algorithm and the HTML element constructors. Each entry in the list will be either an element or an already constructed marker.

A form-associated boolean
If this is true, user agent treats elements associated to this custom element definition as form-associated custom elements.

A disable internals boolean
Controls attachInternals().

A disable shadow boolean
Controls attachShadow().

To look up a custom element definition, given a document, namespace, localName, and is, perform the following steps. They will return either a custom element definition or null:

1. If namespace is not the HTML namespace, return null.
2. If document's browsing context is null, return null.
3. Let registry be document's relevant global object's CustomElementRegistry object.
4. If there is custom element definition in registry with name and local name both equal to localName, return that custom element definition.
5. If there is a custom element definition in registry with name equal to is and local name equal to localName, return that custom element definition.
6. Return null.

4.13.4 The CustomElementRegistry interface

CustomElementRegistry

Support in all current engines.
Each `Window` object is associated with a unique instance of a `CustomElementRegistry` object, allocated when the `Window` object is created.

Custom element registries are associated with `Window` objects, instead of `Document` objects, since each `custom element constructor` inherits from the `HTMLElement` interface, and there is exactly one `HTMLElement` interface per `Window` object.

Support in all current engines.

The `customElements` attribute of the `Window` interface must return the `CustomElementRegistry` object for that `Window` object.

```javascript
[Exposed=Window]
interface CustomElementRegistry {
  [CEReactions] undefined define(DOMString name, CustomElementConstructor constructor) (CustomElementConstructor or undefined) get(DOMString name);
  Promise<CustomElementConstructor> whenDefined(DOMString name);
  [CEReactions] undefined upgrade(Node root);
};

callback CustomElementConstructor = HTMLElement ();

dictionary ElementDefinitionOptions {
  DOMString extends;
};
```

Every `CustomElementRegistry` has a set of `custom element definitions`, initially empty. In general, algorithms in this specification look up elements in the registry by any of `name`, `local name`, or `constructor`.

Retrieves the *custom element constructor* defined for the given `name`. Returns undefined if there is no *custom element definition* with the given `name`.

```javascript
window.customElements.whenDefined(name)
```

`MDN`
CustomElementRegistry/whenDefined

Support in all current engines.

Firefox63+Safari10.1+Chrome67+
Opera54+Edge79+
Edge (Legacy)NoInternet ExplorerNo

Firefox Android63+Safari iOS10.3+Chrome Android67+WebView Android67+Samsung
Internet9.0+Opera Android48+

Returns a promise that will be fulfilled with the custom element’s constructor when a custom element becomes defined with the given name. (If such a custom element is already defined, the returned promise will be immediately fulfilled.) Returns a promise rejected with a "SyntaxError" DOMException if not given a valid custom element name.

window.customElements.upgrade(root)

CustomElementRegistry/upgrade

Support in all current engines.

Firefox63+Safari12.1+Chrome68+
Opera55+Edge79+
Edge (Legacy)NoInternet ExplorerNo

Firefox Android63+Safari iOS12.2+Chrome Android68+WebView Android68+Samsung
Internet10.0+Opera Android48+

Tries to upgrade all shadow-including inclusive descendant elements of root, even if they are not connected.

Element definition is a process of adding a custom element definition to the CustomElementRegistry. This is accomplished by the define() method. When invoked, the define(name, constructor, options) method must run these steps:

1. If IsConstructor(constructor) is false, then throw a TypeError.

2. If name is not a valid custom element name, then throw a "SyntaxError" DOMException.

3. If this CustomElementRegistry contains an entry with name name, then throw a "NotSupportedError" DOMException.

4. If this CustomElementRegistry contains an entry with constructor constructor, then throw a "NotSupportedError" DOMException.

5. Let localName be name.
6. Let extends be the value of the extends member of options, or null if no such member exists.

7. If extends is not null, then:
   1. If extends is a valid custom element name, then throw a “NotSupportedError” DOMException.
   2. If the element interface for extends and the HTML namespace is HTMLUnknownElement (e.g., if extends does not indicate an element definition in this specification), then throw a “NotSupportedError” DOMException.
   3. Set localName to extends.

8. If this CustomElementRegistry’s element definition is running flag is set, then throw a “NotSupportedError” DOMException.

9. Set this CustomElementRegistry’s element definition is running flag.

10. Let formAssociated be false.

11. Let disableInternals be false.

12. Let disableShadow be false.

13. Let observedAttributes be an empty sequence<DOMString>.

14. Run the following substeps while catching any exceptions:
   1. Let prototype be Get(constructor, ”prototype”). Rethrow any exceptions.
   2. If Type(prototype) is not Object, then throw a TypeError exception.
   3. Let lifecycleCallbacks be a map with the keys ”connectedCallback”, ”disconnectedCallback”, ”adoptedCallback”, and ”attributeChangedCallback”, each of which belongs to an entry whose value is null.
   4. For each of the keys callbackName in lifecycleCallbacks, in the order listed in the previous step:
      1. Let callbackValue be Get(prototype, callbackName). Rethrow any exceptions.
      2. If callbackValue is not undefined, then set the value of the entry in lifecycleCallbacks with key callbackName to the result of converting callbackValue to the Web IDL Function callback type. Rethrow any exceptions from the conversion.
5. If the value of the entry in `lifecycleCallbacks` with key "attributeChangedCallback" is not null, then:

   1. Let `observedAttributesIterable` be `Get(constructor, "observedAttributes"). Rethrow any exceptions.

   2. If `observedAttributesIterable` is not undefined, then set `observedAttributes` to the result of converting `observedAttributesIterable` to a sequence<DOMString>. Rethrow any exceptions from the conversion.

6. Let `disabledFeatures` be an empty sequence<DOMString>.

7. Let `disabledFeaturesIterable` be `Get(constructor, "disabledFeatures"). Rethrow any exceptions.

8. If `disabledFeaturesIterable` is not undefined, then set `disabledFeatures` to the result of converting `disabledFeaturesIterable` to a sequence<DOMString>. Rethrow any exceptions from the conversion.

9. Set `disableInternals` to true if `disabledFeatures` contains "internals".

10. Set `disableShadow` to true if `disabledFeatures` contains "shadow".

11. Let `formAssociatedValue` be `Get(constructor, "formAssociated"). Rethrow any exceptions.

12. Set `formAssociated` to the result of converting `formAssociatedValue` to a boolean. Rethrow any exceptions from the conversion.

13. If `formAssociated` is true, for each of "formAssociatedCallback", "formResetCallback", "formDisabledCallback", and "formStateRestoreCallback" callbackName:

   1. Let `callbackValue` be `Get(prototype, callbackName). Rethrow any exceptions.

   2. If `callbackValue` is not undefined, then set the value of the entry in `lifecycleCallbacks` with key `callbackName` to the result of converting `callbackValue` to the Web IDL Function callback type. Rethrow any exceptions from the conversion.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Unset this CustomElementRegistry’s element definition is running flag.
Finally, if the first set of substeps threw an exception, then rethrow that exception (thus terminating this algorithm). Otherwise, continue onward.

15. Let definition be a new custom element definition with name name, local name localName, constructor constructor, observed attributes observedAttributes, lifecycle callbacks lifecycleCallbacks, form-associated formAssociated, disable internals disableInternals, and disable shadow disableShadow.

16. Add definition to this CustomElementRegistry.

17. Let document be this CustomElementRegistry’s relevant global object’s associated Document.

18. Let upgrade candidates be all elements that are shadow-including descendants of document, whose namespace is the HTML namespace and whose local name is localName, in shadow-including tree order. Additionally, if extends is non-null, only include elements whose is value is equal to name.

19. For each element element in upgrade candidates, enqueue a custom element upgrade reaction given element and definition.

20. If this CustomElementRegistry’s when-defined promise map contains an entry with key name:
   1. Let promise be the value of that entry.
   2. Resolve promise with constructor.
   3. Delete the entry with key name from this CustomElementRegistry’s when-defined promise map.

When invoked, the get(name) method must run these steps:

1. If this CustomElementRegistry contains an entry with name name, then return that entry’s constructor.

2. Otherwise, return undefined.

When invoked, the whenDefined(name) method must run these steps:

1. If name is not a valid custom element name, then return a new promise rejected with a “SyntaxError” DOMException.

2. If this CustomElementRegistry contains an entry with name name, then return a new promise resolved with that entry’s constructor.

3. Let map be this CustomElementRegistry’s when-defined promise map.
4. If `map` does not contain an entry with key `name`, create an entry in `map` with key `name` and whose value is a new promise.

5. Let `promise` be the value of the entry in `map` with key `name`.

6. Return `promise`.

The `whenDefined()` method can be used to avoid performing an action until all appropriate custom elements are defined. In this example, we combine it with the `:defined` pseudo-class to hide a dynamically-loaded article’s contents until we’re sure that all of the autonomous custom elements it uses are defined.

```javascript
articleContainer.hidden = true;

fetch(articleURL)
  .then(response => response.text())
  .then(text => {
    articleContainer.innerHTML = text;

    return Promise.all(
      [...articleContainer.querySelectorAll(":not(:defined)")]
        .map(el => customElements.whenDefined(el.localName))
    );
  })
  .then(() => {
    articleContainer.hidden = false;
  });
```

When invoked, the `upgrade(root)` method must run these steps:

1. Let `candidates` be a list of all of `root`'s shadow-including inclusive descendant elements, in shadow-including tree order.

2. For each candidate of candidates, try to upgrade candidate.

The `upgrade()` method allows upgrading of elements at will. Normally elements are automatically upgraded when they become connected, but this method can be used if you need to upgrade before you’re ready to connect the element.

```javascript
const el = document.createElement("spider-man");

class SpiderMan extends HTMLElement {}
customElements.define("spider-man", SpiderMan);

console.assert(!(el instanceof SpiderMan)); // not yet upgraded
customElements.upgrade(el);
```
4.13.5 Upgrades

To upgrade an element, given as input a custom element definition and an element, run the following steps:

1. If element's custom element state is not "undefined" or "uncustomized", then return.

One scenario where this can occur due to reentrant invocation of this algorithm, as in the following example:

```html
<!DOCTYPE html>
<x-foo id="a"></x-foo>
<x-foo id="b"></x-foo>

<script>
// Defining enqueues upgrade reactions for both "a" and "b"
customElements.define("x-foo", class extends HTMLElement {
  constructor() {
    super();

    const b = document.querySelector("#b");
    b.remove();

    // While this constructor is running for "a", "b" is still undefined, and so inserting it into the document will enqueue a second upgrade reaction for "b" in addition to the one enqueued by defining x-foo.
    document.body.appendChild(b);
  }
})
</script>
```

This step will thus bail out the algorithm early when upgrade an element is invoked with "b" a second time.

2. Set element's custom element definition to definition.

3. Set element's custom element state to "failed".

   It will be set to "custom" after the upgrade succeeds. For now, we set it to "failed" so that any reentrant invocations will hit the above early-exit step.

4. For each attribute in element's attribute list, in order, enqueue a custom element callback reaction with element, callback name "attributeChangedCallback", and
an argument list containing attribute's local name, null, attribute's value, and attribute's namespace.

5. If element is connected, then enqueue a custom element callback reaction with element, callback name "connectedCallback", and an empty argument list.

6. Add element to the end of definition’s construction stack.

7. Let C be definition’s constructor.

8. Run the following substeps while catching any exceptions:

   1. If definition’s disable shadow is true and element’s shadow root is non-null, then throw a "NotSupportedError" DOMException.

      This is needed as attachShadow() does not use look up a custom element definition while attachInternals() does.

   2. Set element’s custom element state to "precustomized".

   3. Let constructResult be the result of constructing C, with no arguments.

      If C non-conformantly uses an API decorated with the [CEReactions] extended attribute, then the reactions enqueued at the beginning of this algorithm will execute during this step, before C finishes and control returns to this algorithm. Otherwise, they will execute after C and the rest of the upgrade process finishes.

   4. If SameValue(constructResult, element) is false, then throw a TypeError.

      This can occur if C constructs another instance of the same custom element before calling super(), or if C uses JavaScript’s return-override feature to return an arbitrary HTMLElement object from the constructor.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Remove the last entry from the end of definition’s construction stack.

Assuming C calls super() (as it will if it is conformant), and that the call succeeds, this will be the already constructed marker that replaced the element we pushed at the beginning of this algorithm. (The HTML element constructor carries out this replacement.)

If C does not call super() (i.e. it is not conformant), or if any step in the HTML element constructor throws, then this entry will still be element.

Finally, if the above steps threw an exception, then:
1. Set element’s custom element definition to null.

2. Empty element’s custom element reaction queue.

3. Rethrow the exception (thus terminating this algorithm).

If the above steps threw an exception, then element’s custom element state will remain "failed" or "precustomized".

9. If element is a form-associated custom element, then:

1. Reset the form owner of element. If element is associated with a form element, then enqueue a custom element callback reaction with element, callback name "formAssociatedCallback", and « the associated form ».

2. If element is disabled, then enqueue a custom element callback reaction with element, callback name “formDisabledCallback” and « true ».

10. Set element’s custom element state to “custom”.

To try to upgrade an element, given as input an element element, run the following steps:

1. Let definition be the result of looking up a custom element definition given element’s node document, element’s namespace, element’s local name, and element’s is value.

2. If definition is not null, then enqueue a custom element upgrade reaction given element and definition.

4.13.6 Custom element reactions

A custom element possesses the ability to respond to certain occurrences by running author code:

- When upgraded, its constructor is run, with no arguments.

- When it becomes connected, its connectedCallback is called, with no arguments.

- When it becomes disconnected, its disconnectedCallback is called, with no arguments.

- When it is adopted into a new document, its adoptedCallback is called, given the old document and new document as arguments.

- When any of its attributes are changed, appended, removed, or replaced, its attributeChangedCallback is called, given the attribute’s local name, old value, new value, and namespace as arguments. (An attribute’s old or new value is considered to be null when the attribute is added or removed, respectively.)
• When the user agent resets the form owner of a form-associated custom element and doing so changes the form owner, its formAssociatedCallback is called, given the new form owner (or null if no owner) as an argument.

• When the form owner of a form-associated custom element is reset, its formResetCallback is called.

• When the disabled state of a form-associated custom element is changed, its formDisabledCallback is called, given the new state as an argument.

• When user agent updates a form-associated custom element’s value on behalf of a user or as part of navigation, its formStateRestoreCallback is called, given the new value and a string indicating a reason, "autocomplete" or "restore", as arguments.

We call these reactions collectively custom element reactions.

The way in which custom element reactions are invoked is done with special care, to avoid running author code during the middle of delicate operations. Effectively, they are delayed until "just before returning to user script". This means that for most purposes they appear to execute synchronously, but in the case of complicated composite operations (like cloning, or range manipulation), they will instead be delayed until after all the relevant user agent processing steps have completed, and then run together as a batch.

Additionally, the precise ordering of these reactions is managed via a somewhat-complicated stack-of-queues system, described below. The intention behind this system is to guarantee that custom element reactions always are invoked in the same order as their triggering actions, at least within the local context of a single custom element. (Because custom element reaction code can perform its own mutations, it is not possible to give a global ordering guarantee across multiple elements.)

Each similar-origin window agent has a custom element reactions stack, which is initially empty. A similar-origin window agent’s current element queue is the element queue at the top of its custom element reactions stack. Each item in the stack is an element queue, which is initially empty as well. Each item in an element queue is an element. (The elements are not necessarily custom yet, since this queue is used for upgrades as well.)

Each custom element reactions stack has an associated backup element queue, which an initially-empty element queue. Elements are pushed onto the backup element queue during operations that affect the DOM without going through an API decorated with [CEReactions], or through the parser’s create an element for the token algorithm. An example of this is a user-initiated editing operation which modifies the descendants or attributes of an editable element. To prevent reentrancy when processing the backup element queue, each custom element reactions stack also has a processing the backup element queue flag, initially unset.

All elements have an associated custom element reaction queue, initially empty. Each item in
the **custom element reaction queue** is of one of two types:

- An *upgrade reaction*, which will **upgrade** the custom element and contains a **custom element definition**; or
- A *callback reaction*, which will call a lifecycle callback, and contains a callback function as well as a list of arguments.

This is all summarized in the following schematic diagram:

To enqueue an element on the appropriate element queue, given an element `element`, run the following steps:

1. Let `reactionsStack` be `element`'s **relevant agent**’s **custom element reactions stack**.
2. If `reactionsStack` is empty, then:
   1. Add `element` to `reactionsStack`'s **backup element queue**.
   2. If `reactionsStack`'s **processing the backup element queue** flag is set, then return.
   3. Set `reactionsStack`'s **processing the backup element queue** flag.
   4. **Queue a microtask** to perform the following steps:
      1. **Invoke custom element reactions** in `reactionsStack`'s **backup element queue**.
2. Unset `reactionsStack`'s processing the backup element queue flag.

3. Otherwise, add `element` to `element`'s relevant agent's current element queue.

To enqueue a custom element callback reaction, given a custom element element, a callback name `callbackName`, and a list of arguments `args`, run the following steps:

1. Let `definition` be `element`'s custom element definition.

2. Let `callback` be the value of the entry in `definition`'s lifecycle callbacks with key `callbackName`.

3. If `callback` is null, then return.

4. If `callbackName` is “attributeChangedCallback”, then:
   1. Let `attributeName` be the first element of `args`.
   2. If `definition`'s observed attributes does not contain `attributeName`, then return.

5. Add a new callback reaction to `element`'s custom element reaction queue, with callback function `callback` and arguments `args`.

6. Enqueue an element on the appropriate element queue given `element`.

To enqueue a custom element upgrade reaction, given an element `element` and custom element definition `definition`, run the following steps:

1. Add a new upgrade reaction to `element`'s custom element reaction queue, with custom element definition `definition`.

2. Enqueue an element on the appropriate element queue given `element`.

To invoke custom element reactions in an element queue queue, run the following steps:

1. While `queue` is not empty:
   1. Let `element` be the result of dequeuing from `queue`.
   2. Let `reactions` be `element`'s custom element reaction queue.
   3. Repeat until `reactions` is empty:
      1. Remove the first element of `reactions`, and let `reaction` be that element. Switch on `reaction`'s type:

         **upgrade reaction**
         Upgrade `element` using `reaction`'s custom element definition.
To ensure custom element reactions are triggered appropriately, we introduce the \textbf{[CEReactions]} IDL extended attribute. It indicates that the relevant algorithm is to be supplemented with additional steps in order to appropriately track and invoke custom element reactions.

The \textbf{[CEReactions]} extended attribute must take no arguments, and must not appear on anything other than an operation, attribute, setter, or deleter. Additionally, it must not appear on readonly attributes.

Operations, attributes, setters, or deleters annotated with the \textbf{[CEReactions]} extended attribute must run the following steps in place of the ones specified in their description:

1. Push a new \textit{element queue} onto this object’s relevant agent’s custom element reactions stack.
2. Run the originally-specified steps for this construct, catching any exceptions. If the steps return a value, let value be the returned value. If they throw an exception, let exception be the thrown exception.
3. Let queue be the result of \textit{popping} from this object’s relevant agent’s custom element reactions stack.
4. Invoke custom element reactions in queue.
5. If an exception exception was thrown by the original steps, rethrow exception.
6. If a value value was returned from the original steps, return value.

The intent behind this extended attribute is somewhat subtle. One way of accomplishing its goals would be to say that every operation, attribute, setter, and deleter on the platform must have these steps inserted, and to allow implementers to optimize away unnecessary cases (where no DOM mutation is possible that could cause custom element reactions to occur).

However, in practice this imprecision could lead to non-interoperable implementations of custom element reactions, as some implementations might forget to invoke these steps in some cases. Instead, we settled on the approach of explicitly annotating all relevant IDL constructs, as a way of ensuring interoperable behavior and helping implementations easily pinpoint all cases where these steps are necessary.

Any nonstandard APIs introduced by the user agent that could modify the DOM in such a way as to cause \textit{enqueuing a custom element callback reaction} or \textit{enqueuing a custom element reaction}
upgrade reaction, for example by modifying any attributes or child elements, must also be
decorated with the `CEReactions` attribute.

As of the time of this writing, the following nonstandard or not-yet-standardized APIs are
known to fall into this category:

- `HTMLInputElement`’s `webkitdirectory` and `incremental` IDL attributes
- `HTMLLinkElement`’s `scope` IDL attribute

### 4.13.7 Element internals

Certain capabilities are meant to be available to a custom element author, but not to a custom
element consumer. These are provided by the `element.attachInternals()` method, which
returns an instance of `ElementInternals`. The properties and methods of
`ElementInternals` allow control over internal features which the user agent provides to all
elements.

**element.attachInternals()**

Returns an `ElementInternals` object targeting the custom element `element`. Throws an
exception if `element` is not a custom element, if the "internals" feature was disabled as
part of the element definition, or if it is called twice on the same element.

Each `HTMLElement` has an `attached internals` boolean, initially false.

<table>
<thead>
<tr>
<th>MDN</th>
<th>HTMLElement/attachInternals</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 93+ Safari No Chrome 77+</td>
<td>Opera 64+ Edge 79+</td>
</tr>
<tr>
<td>Edge (Legacy) No Internet Explorer No</td>
<td>Firefox Android 93+ Safari iOS No Chrome Android 77+ WebView Android 77+ Samsung Internet 12.0+ Opera Android 55+</td>
</tr>
</tbody>
</table>

The `attachInternals()` method steps are:

1. If `this`'s `is value` is not null, then throw a “`NotSupportedError`” `DOMException`.
2. Let `definition` be the result of looking up a custom element definition given this's `node
document`, its namespace, its local name, and null as the `is value`.
3. If `definition` is null, then throw an “`NotSupportedError`” `DOMException`.
4. If `definition`'s `disable internals` is true, then throw a “`NotSupportedError`”
5. If this’s attached internals is true, then throw an "NotSupportedError" DOMException.

6. If this’s custom element state is not "precustomized" or "custom", then throw a "NotSupportedError" DOMException.

7. Set this’s attached internals to true.

8. Return a new ElementInternals instance whose target element is this.

4.13.7.1 The ElementInternals interface

The IDL for the ElementInternals interface is as follows, with the various operations and attributes defined in the following sections:

[Exposed=Window]
interface ElementInternals {

   // Shadow root access
   readonly attribute ShadowRoot? shadowRoot;

   // Form-associated custom elements
   undefined setFormValue((File or USVString or FormData)? value,
                            optional (File or USVString or FormData)? state);

   readonly attribute HTMLFormElement? form;

   undefined setValidity(optional ValidityStateFlags flags = {},
                            optional DOMString message,
                            optional HTMLElement anchor);

   readonly attribute boolean willValidate;
   readonly attribute ValidityState validity;
   readonly attribute DOMString validationMessage;
   boolean checkValidity();
   boolean reportValidity();

}
readonly attribute NodeList labels;
};

// Accessibility semantics
ElementInternals includes ARIAMixin;

dictionary ValidityStateFlags {
    boolean valueMissing = false;
    boolean typeMismatch = false;
    boolean patternMismatch = false;
    boolean tooLong = false;
    boolean tooShort = false;
    boolean rangeUnderflow = false;
    boolean rangeOverflow = false;
    boolean stepMismatch = false;
    boolean badInput = false;
    boolean customError = false;
};

Each ElementInternals has a target element, which is a custom element.

4.13.7.2 Shadow root access

internals.shadowRoot

Returns the ShadowRoot for internals's target element, if the target element is a shadow host, or null otherwise.

<table>
<thead>
<tr>
<th>Browser</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox93+</td>
</tr>
<tr>
<td>Safari</td>
</tr>
<tr>
<td>NoChrome77+</td>
</tr>
<tr>
<td>Opera64+</td>
</tr>
<tr>
<td>Edge79+</td>
</tr>
<tr>
<td>Edge (Legacy)</td>
</tr>
<tr>
<td>NoInternet Explorer</td>
</tr>
<tr>
<td>No</td>
</tr>
<tr>
<td>Firefox Android93+</td>
</tr>
<tr>
<td>Safari iOS</td>
</tr>
<tr>
<td>NoChrome Android77+</td>
</tr>
<tr>
<td>WebView Android77+</td>
</tr>
<tr>
<td>Samsung Internet12.0+</td>
</tr>
<tr>
<td>Opera Android55+</td>
</tr>
</tbody>
</table>

The shadowRoot getter steps are:

1. Let target be this's target element.
2. If target is not a shadow host, then return null.
3. Let shadow be target's shadow root.
4. If shadow’s available to element internals is false, then return null.

5. Return shadow.

4.13.7.3 Form-associated custom elements

**internals.setFormValue(value)**

Sets both the state and submission value of internals’s target element to value.

If value is null, the element won’t participate in form submission.

**internals.setFormValue(value, state)**

Sets the submission value of internals’s target element to value, and its state to state.

If value is null, the element won’t participate in form submission.

**internals.form**

Returns the form owner of internals’s target element.

**internals.setValidity(flags, message [, anchor ])**

Marks internals’s target element as suffering from the constraints indicated by the flags argument, and sets the element’s validation message to message. If anchor is specified, the user agent might use it to indicate problems with the constraints of internals’s target element when the form owner is validated interactively or reportValidity() is called.

**internals.setValidity({})**

Marks internals’s target element as satisfying its constraints.

**internals. willValidate**

Returns true if internals’s target element will be validated when the form is submitted; false otherwise.

**internals. validity**

Returns the ValidityState object for internals’s target element.

**internals. validationMessage**

Returns the error message that would be shown to the user if internals’s target element was to be checked for validity.
valid = internals . checkValidity()

Returns true if internals's target element has no validity problems; false otherwise. Fires an invalid event at the element in the latter case.

valid = internals . reportValidity()

Returns true if internals's target element has no validity problems; otherwise, returns false, fires an invalid event at the element, and (if the event isn’t canceled) reports the problem to the user.

internals.labels

Returns a NodeList of all the label elements that internals's target element is associated with.

Each form-associated custom element has submission value. It is used to provide one or more entries on form submission. The initial value of submission value is null, and submission value can be null, a string, a File, or a list of entries.

Each form-associated custom element has state. It is information with which the user agent can restore a user’s input for the element. The initial value of state is null, and state can be null, a string, a File, or a list of entries.

The setFormValue() method is used by the custom element author to set the element’s submission value and state, thus communicating these to the user agent.

When the user agent believes it is a good idea to restore a form-associated custom element’s state, for example after navigation or restarting the user agent, they may enqueue a custom element callback reaction with that element, callback name “formStateRestoreCallback”, an argument list containing the state to be restored, and “restore”.

If the user agent has a form-filling assist feature, then when the feature is invoked, it may enqueue a custom element callback reaction with a form-associated custom element, callback name “formStateRestoreCallback”, an argument list containing the state value determined by history of state value and some heuristics, and “autocomplete”.

In general, the state is information specified by a user, and the submission value is a value after canonicalization or sanitization, suitable for submission to the server. The following examples makes this concrete:

Suppose that we have a form-associated custom element which asks a user to specify a date. The user specifies "3/15/2019", but the control wishes to submit "2019-03-15" to the server. "3/15/2019" would be a state of the element, and "2019-03-15" would be a submission value.

Suppose you develop a custom element emulating a the behavior of the existing checkbox
**input** type. Its **submission value** would be the value of its **value** content attribute, or the string "on". Its **state** would be one of "checked", "unchecked", "checked/indeterminate", or "unchecked/indeterminate".

---

**ElementInternals/setFormValue**

<table>
<thead>
<tr>
<th>Browser</th>
<th>Compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox® 95+</td>
<td>Safari NoChrome 77+</td>
</tr>
<tr>
<td>Opera 64+</td>
<td>Edge 79+</td>
</tr>
<tr>
<td>Edge (Legacy)</td>
<td>No Internet Explorer No</td>
</tr>
<tr>
<td>Firefox Android</td>
<td>No Safari iOS NoChrome Android 77+ WebView Android 77+ Samsung Internet 12.0+ Opera Android 55+</td>
</tr>
</tbody>
</table>

The **setFormValue**(value, state) method steps are:

1. Let **element** be this's target element.
2. If **element** is not a form-associated custom element, then throw a "**NotSupportedError**" DOMException.
3. Set target element’s submission value to value if value is not a **FormData** object, or to a clone of the entry list associated with value otherwise.
4. If the state argument of the function is omitted, set element’s state to its submission value.
5. Otherwise, if **state** is a **FormData** object, set element’s state to clone of the entry list associated with state.
6. Otherwise, set element’s state to state.

---

Each form-associated custom element has validity flags named **valueMissing**, **typeMismatch**, **patternMismatch**, **tooLong**, **tooShort**, **rangeUnderflow**, **rangeOverflow**, **stepMismatch**, and **customError**. They are false initially.

Each form-associated custom element has a validation message string. It is the empty string initially.

Each form-associated custom element has a validation anchor element. It is null initially.

---

**ElementInternals/setValidity**
Support in one engine only.

Firefox No Safari No Chrome 77+
Opera 64+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android No Safari iOS No Chrome Android 77+ WebView Android 77+ Samsung Internet 12.0+ Opera Android 55+

The `setValidity(flags, message, anchor)` method steps are:

1. Let `element` be this’s target element.
2. If `element` is not a form-associated custom element, then throw a `"NotSupportedError"` DOMException.
3. If `flags` contains one or more true values and `message` is not given or is the empty string, then throw a `TypeError`.
4. For each entry `flag → value` of `flags`, set `element`’s validity flag with the name `flag` to `value`.
5. Set `element`’s validation message to the empty string if `message` is not given or all of `element`’s validity flags are false, or to `message` otherwise.
6. If `element`’s customError validity flag is true, then set `element`’s custom validity error message to `element`’s validation message. Otherwise, set `element`’s custom validity error message to the empty string.
7. Set `element`’s validation anchor to null if `anchor` is not given. Otherwise, if `anchor` is not a shadow-including descendant of `element`, then throw a `"NotFoundError"` DOMException. Otherwise, set `element`’s validation anchor to `anchor`.

⚠️ MDN

Support in one engine only.

Firefox No Safari No Chrome 77+
Opera 64+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android No Safari iOS No Chrome Android 77+ WebView Android 77+ Samsung Internet 12.0+ Opera Android 55+

The `validationMessage` getter steps are:
1. Let `element` be this’s target element.

2. If `element` is not a form-associated custom element, then throw a "NotSupportedException" DOMException.

3. Return `element`’s validation message.

The entry construction algorithm for a form-associated custom element, given an element `element` and a list `entry list`, consists of the following steps:

1. If `element`’s submission value is a list of entries, then append each item of `element`’s submission value to `entry list`, and return.

   In this case, user agent does not refer to the name content attribute value. An implementation of form-associated custom element is responsible to decide names of entries. They can be the name content attribute value, they can be strings based on the name content attribute value, or they can be unrelated to the name content attribute.

2. If the element does not have a name attribute specified, or its name attribute’s value is the empty string, then return.

3. If the element’s submission value is not null, append an entry to `entry list` with the name attribute value and the submission value.

4.13.7.4 Accessibility semantics

   `internals.role` [ = value ]

   Sets or retrieves the default ARIA role for `internals`’s target element, which will be used unless the page author overrides it using the role attribute.

   `internals.aria*` [ = value ]

   Sets or retrieves various default ARIA states or property values for `internals`’s target element, which will be used unless the page author overrides them using the aria-* attributes.

Each custom element has a native accessibility semantics map, which is a map, initially empty. See the Requirements related to ARIA and to platform accessibility APIs section for information on how this impacts platform accessibility APIs.

`ElementInternals` includes the ARIAMixin mixin. The accessors provided by this mixin are used to manipulate the target element’s native accessibility semantics map, as follows:

The ARIAMixin getter steps for `ElementInternals`, given `internals`, idlAttribute, and contentAttribute, are:
1. Let \( \text{map} \) be \text{internals}'s target element's native accessibility semantics map.

2. If \( \text{map}[\text{contentAttribute}] \) exists, then return it.

3. Return null.

The \texttt{ARIAMixin} setter steps for \texttt{ElementInternals}, given \texttt{internals}, \texttt{idlAttribute}, \texttt{contentAttribute}, and \texttt{value}, are:

1. Let \( \text{map} \) be \text{internals}'s target element's native accessibility semantics map.

2. If \texttt{value} is null, then remove \( \text{map}[\text{contentAttribute}] \).

3. Otherwise, set \( \text{map}[\text{contentAttribute}] \) to \texttt{value}.

### 4.14 Common idioms without dedicated elements

#### 4.14.1 Breadcrumb navigation

This specification does not provide a machine-readable way of describing breadcrumb navigation menus. Authors are encouraged to just use a series of links in a paragraph. The \texttt{nav} element can be used to mark the section containing these paragraphs as being navigation blocks.

In the following example, the current page can be reached via two paths.

```html
<nav>
  <p>
    <a href="/">Main</a> ▶
    <a href="/products/">Products</a> ▶
    <a href="/products/dishwashers/">Dishwashers</a> ▶
    <a>Second hand</a>
  </p>
  <p>
    <a href="/">Main</a> ▶
    <a href="/second-hand/">Second hand</a> ▶
    <a>Dishwashers</a>
  </p>
</nav>
```

#### 4.14.2 Tag clouds

This specification does not define any markup specifically for marking up lists of keywords that apply to a group of pages (also known as \textit{tag clouds}). In general, authors are encouraged to either mark up such lists using \texttt{ul} elements with explicit inline counts that are then hidden and turned into a presentational effect using a style sheet, or to use SVG.
Here, three tags are included in a short tag cloud:

```html
<style>
.tag-cloud > li > span { display: none; }
.tag-cloud > li { display: inline; }
.tag-cloud-1 { font-size: 0.7em; }
.tag-cloud-2 { font-size: 0.9em; }
.tag-cloud-3 { font-size: 1.1em; }
.tag-cloud-4 { font-size: 1.3em; }
.tag-cloud-5 { font-size: 1.5em; }

@media speech {
  .tag-cloud > li > span { display:inline }
}
</style>

...<ul class="tag-cloud">
<li class="tag-cloud-4"><a title="28 instances" href="/t/apple">apple</a> <span>
<li class="tag-cloud-2"><a title="6 instances" href="/t/kiwi">kiwi</a> <span>
<li class="tag-cloud-5"><a title="41 instances" href="/t/pear">pear</a> <span>
</ul>
```

The actual frequency of each tag is given using the `title` attribute. A CSS style sheet is provided to convert the markup into a cloud of differently-sized words, but for user agents that do not support CSS or are not visual, the markup contains annotations like “(popular)” or “(rare)” to categorize the various tags by frequency, thus enabling all users to benefit from the information.

The `ul` element is used (rather than `ol`) because the order is not particularly important: while the list is in fact ordered alphabetically, it would convey the same information if ordered by, say, the length of the tag.

The `tag rel`-keyword is not used on these `a` elements because they do not represent tags that apply to the page itself; they are just part of an index listing the tags themselves.

### 4.14.3 Conversations

This specification does not define a specific element for marking up conversations, meeting minutes, chat transcripts, dialogues in screenplays, instant message logs, and other situations where different players take turns in discourse.

Instead, authors are encouraged to mark up conversations using `p` elements and punctuation. Authors who need to mark the speaker for styling purposes are encouraged to use `span` or `b`. Paragraphs with their text wrapped in the `i` element can be used for marking up stage directions.

This example demonstrates this using an extract from Abbot and Costello’s famous sketch,
Who’s on first:

The following extract shows how an IM conversation log could be marked up, using the <code>data</code> element to provide Unix timestamps for each line. Note that the timestamps are provided in a format that the <code>time</code> element does not support, so the <code>data</code> element is used instead (namely, Unix <code>time_t</code> timestamps). Had the author wished to mark up the data using one of the date and time formats supported by the <code>time</code> element, that element could have been used instead of <code>data</code>. This could be advantageous as it would allow data analysis tools to detect the timestamps unambiguously, without coordination with the page author.

<p>&lt;data value="1319898155">14:22&lt;/data&gt;  <b>egof</b>&lt;b&gt; I'm not that nerdy, I've only seen 30% of the star trek episodes</p>

<p>&lt;data value="1319898192">14:23&lt;/data&gt;  <b>kaj</b>&lt;b&gt; if you know what percentage of the star trek episodes you have seen, you are inarguably nerdy</p>

<p>&lt;data value="1319898228">14:23&lt;/data&gt;  &lt;i&gt;* kaj blinks&lt;/i&gt;</p>

<p>&lt;data value="1319898260">14:24&lt;/data&gt;  <b>kaj</b>&lt;b&gt; you are not helping your case</p>

HTML does not have a good way to mark up graphs, so descriptions of interactive conversations from games are more difficult to mark up. This example shows one possible convention using <code>dl</code> elements to list the possible responses at each point in the conversation. Another option to consider is describing the conversation in the form of a DOT file, and outputting the result as an SVG image to place in the document. [DOT]

<p>Next, you meet a fisher. You can say one of several greetings:</p><p>&lt;dl&gt;<br> &lt;dt&gt; "Hello there!"&lt;/dt&gt;<br> &lt;dd&gt; She responds with "Hello, how may I help you?"; you can respond with:<br> &lt;dl&gt;<br> &lt;dt&gt; "I would like to buy a fish."&lt;/dt&gt;<br> &lt;dd&gt; She sells you a fish and the conversation finishes.<br> &lt;dt&gt; "Can I borrow your boat?"&lt;/dt&gt;<br> &lt;dd&gt; She is surprised and asks "What are you offering in return?". <br> &lt;dl&gt; <br> &lt;dt&gt; "Five gold." (if you have enough) <br> &lt;dt&gt; "Ten gold." (if you have enough) <br> &lt;dt&gt; "Fifteen gold." (if you have enough) <br> &lt;dd&gt; She lends you her boat. The conversation ends.<br> &lt;dt&gt; "A fish." (if you have one)
"A newspaper." (if you have one)
"A pebble." (if you have one)
"No thanks", she replies. Your conversation options at this point are the same as they were after asking to borrow her boat, minus any options you've suggested before.

"Vote for me in the next election!"
She turns away. The conversation finishes.
"Madam, are you aware that your fish are running away?"
She looks at you skeptically and says "Fish cannot run, miss".
"You got me!"
The fisher sighs and the conversation ends.
"Only kidding."
"Good one!" she retorts. Your conversation options at this point are the same as those following "Hello there!" above.
"Oh, then what are they doing?"
She looks at her fish, giving you an opportunity to steal her boat, which you do. The conversation ends.

In some games, conversations are simpler: each character merely has a fixed set of lines that they say. In this example, a game FAQ/walkthrough lists some of the known possible responses for each character:

<section>
<h1>Dialogue</h1>
<p><small>Some characters repeat their lines in order each time you interact with them, others randomly pick from amongst their lines. Those who respond in order have numbered entries in the lists below.</small></p>
<h2>The Shopkeeper</h2>
<ul>
<li>How may I help you?</li>
<li>Fresh apples!</li>
<li>A loaf of bread for madam?</li>
</ul>
<h2>The pilot</h2>
<p>Before the accident:</p>
<ul>
<li>I'm about to fly out, sorry!</li>
<li>Sorry, I'm just waiting for flight clearance and then I'll be off!</li>
</ul>
After the accident:

- I'm about to fly out, sorry!
- Ok, I'm not leaving right now, my plane is being cleaned.
- Ok, it's not being cleaned, it needs a minor repair first.
- Ok, ok, stop bothering me! Truth is, I had a crash.

Clan Leader:

During the first clan meeting:

- Hey, have you seen my daughter? I bet she's up to something nefarious again.
- Nice weather we're having today, eh?
- The name is Bailey, Jeff Bailey. How can I help you today?
- A glass of water? Fresh from the well!

After the earthquake:

- Everyone is safe in the shelter, we just have to put out the fire!
- I'll go and tell the fire brigade, you keep hosing it down!

4.14.4 Footnotes

HTML does not have a dedicated mechanism for marking up footnotes. Here are the suggested alternatives.

For short inline annotations, the `title` attribute could be used.

In this example, two parts of a dialogue are annotated with footnote-like content using the `title` attribute.

Customer: Hello! I wish to register a complaint. Hello. Miss?

Shopkeeper: Watcha mean, miss?

Customer: Uh, I'm sorry, I have a cold. I wish to make a complaint.

Shopkeeper: Sorry, This is, of course, a lie."we're closing for lunch.

Unfortunately, relying on the `title` attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

If the `title` attribute is used, CSS can be used to draw the reader’s attention to the elements.
with the attribute.

For example, the following CSS places a dashed line below elements that have a `title` attribute.

```
[title] { border-bottom: thin dashed; }
```

For longer annotations, the `a` element should be used, pointing to an element later in the document. The convention is that the contents of the link be a number in square brackets.

In this example, a footnote in the dialogue links to a paragraph below the dialogue. The paragraph then reciprocally links back to the dialogue, allowing the user to return to the location of the footnote.

```html
<p>Announcer: Number 16: The <i>hand</i>.</p>
<p>Interviewer: Good evening. I have with me in the studio tonight Mr Norman St John Polevaulter, who for the past few years has been contradicting people. Mr Polevaulter, why <em>do</em> you contradict people?</p>
<p>Norman: I don't. <sup><a href="#fn1" id="r1">[1]</a></sup></p>
<p>Interviewer: You told me you did!</p>
```

For side notes, longer annotations that apply to entire sections of the text rather than just specific words or sentences, the `aside` element should be used.

In this example, a sidebar is given after a dialogue, giving it some context.

```html
<p><span class="speaker">Customer</span>: I will not buy this record, it is scratched.</p>
<p><span class="speaker">Shopkeeper</span>: I'm sorry?</p>
<p><span class="speaker">Customer</span>: I will not buy this record, it is scratched.</p>
<p><span class="speaker">Shopkeeper</span>: No no no, this's'a tobacconist's.</p>
```

```html
<aside>
In 1970, the British Empire lay in ruins, and foreign nationalists frequented the streets — many of them Hungarians (not the streets — the foreign nationals). Sadly, Alexander Yalt has been publishing incompetently-written phrase books.
</aside>
```
For figures or tables, footnotes can be included in the relevant `<figcaption>` or `<caption>` element, or in surrounding prose.

In this example, a table has cells with footnotes that are given in prose. A `<figure>` element is used to give a single legend to the combination of the table and its footnotes.

```html
<figure>
  <figcaption>Table 1. Alternative activities for knights.</figcaption>
  <table>
    <tr>
      <th>Activity</th>
      <th>Location</th>
      <th>Cost</th>
    </tr>
    <tr>
      <td>Dance</td>
      <td>Wherever possible</td>
      <td>£0<sup><a href="#fn1">1</a></sup></td>
    </tr>
    <tr>
      <td>Routines, chorus scenes</td>
      <td>Undisclosed</td>
      <td>Undisclosed</td>
    </tr>
    <tr>
      <td>Dining</td>
      <td>Camelot</td>
      <td>Cost of ham, jam, and spam<sup><a href="#fn4">4</a></sup></td>
    </tr>
  </table>
  <p id="fn1">1. Assumed.</p>
  <p id="fn2">2. Footwork impeccable.</p>
  <p id="fn3">3. Quality described as "well".</p>
  <p id="fn4">4. A lot.</p>
</figure>

### 4.15 Disabled elements

An element is said to be *actually disabled* if it is one of the following:

- a `<button>` element that is disabled
- an `<input>` element that is disabled
- a `<select>` element that is disabled
- a `<textarea>` element that is disabled
- an `<optgroup>` element that has a `disabled` attribute
- an `<option>` element that is disabled
- a `<fieldset>` element that is a disabled fieldset
- a form-associated custom element that is disabled

This definition is used to determine what elements are focusable and which elements match the `< :enabled >` and `< :disabled >` pseudo classes.
4.16 Matching HTML elements using selectors and CSS

4.16.1 Case-sensitivity of the CSS ‘attr()’ function

**CSS Values and Units** leaves the case-sensitivity of attribute names for the purpose of the ‘attr()’ function to be defined by the host language. [CSSVALUES]

When comparing the attribute name part of a CSS ‘attr()’ function to the names of namespace-less attributes on **HTML elements** in **HTML documents**, the name part of the CSS ‘attr()’ function must first be converted to ASCII lowercase. The same function when compared to other attributes must be compared according to its original case. In both cases, to match the values must be identical to each other (and therefore the comparison is case sensitive).

This is the same as comparing the name part of a CSS **attribute selector**, specified in the next section.

4.16.2 Case-sensitivity of selectors

**Selectors** leaves the case-sensitivity of element names, attribute names, and attribute values to be defined by the host language. [SELECTORS]

When comparing a CSS element **type selector** to the names of **HTML elements** in **HTML documents**, the CSS element **type selector** must first be converted to ASCII lowercase. The same selector when compared to other elements must be compared according to its original case. In both cases, to match the values must be identical to each other (and therefore the comparison is case sensitive).

When comparing the name part of a CSS **attribute selector** to the names of attributes on **HTML elements** in **HTML documents**, the name part of the CSS **attribute selector** must first be converted to ASCII lowercase. The same selector when compared to other attributes must be compared according to its original case. In both cases, the comparison is case-sensitive.

**Attribute selectors** on an **HTML element** in an **HTML document** must treat the values of attributes with the following names as **ASCII case-insensitive**:

- accept
- accept-charset
- align
- alink
- axis
- bgcolor
- charset
- checked
- clear
- codetype
- color
• compact
• declare
• defer
• dir
• direction
• disabled
• enctype
• face
• frame
• hreflang
• http-equiv
• lang
• language
• link
• media
• method
• multiple
• nohref
• noresize
• noshade
• nowrap
• readonly
• rel
• rev
• rules
• scope
• scrolling
• selected
• shape
• target
• text
• type
• valign
• valuetype
• vlink

For example, the selector [bgcolor="#ffffff"] will match any HTML element with a \texttt{bgcolor} attribute with values including \#ffffff, \#FFFFFF and \#fffFFF. This happens even if \texttt{bgcolor} has no effect for a given element (e.g., \texttt{div}).

The selector [\texttt{type=a s}] will match any HTML element with a \texttt{type} attribute whose value is \texttt{a}, but not whose value is \texttt{A}, due to the \texttt{s} flag.

All other attribute values and everything else must be treated as entirely \texttt{identical to} each other for the purposes of selector matching. This includes:
- IDs and classes in no-quirks mode and limited-quirks mode
- the names of elements not in the HTML namespace
- the names of HTML elements in XML documents
- the names of attributes of elements not in the HTML namespace
- the names of attributes of HTML elements in XML documents
- the names of attributes that themselves have namespaces

Selectors defines that ID and class selectors (such as \#foo and .bar), when matched against elements in documents that are in quirks mode, will be matched in an ASCII case-insensitive manner. However, this does not apply for attribute selectors with "id" or "class" as the name part. The selector `[class="foobar"]` will treat its value as case-sensitive even in quirks mode.

4.16.3 Pseudo-classes

**Pseudo-classes**

There are a number of dynamic selectors that can be used with HTML. This section defines when these selectors match HTML elements. [SELECTORS] [CSSUI]

:`defined`

Support in all current engines.

Firefox63+Safari10+Chrome54+
Opera41+Edge79+
Edge (Legacy)NoInternet ExplorerNo
Firefox Android63+Safari iOS10+Chrome Android54+WebView Android54+Samsung Internet6.0+Opera Android41+

The :defined pseudo-class must match any element that is defined.

:`link`

Support in all current engines.

Firefox1+Safari1+Chrome1+
Support in all current engines.

All a elements that have an href attribute, and all area elements that have an href attribute, must match one of :link and :visited.

Other specifications might apply more specific rules regarding how these elements are to match these pseudo-classes, to mitigate some privacy concerns that apply with straightforward implementations of this requirement.

The :active pseudo-class is defined to match an element “while an element is being activated by the user”.

To determine whether a particular element is being activated for the purposes of defining the :active pseudo-class only, an HTML user agent must use the first relevant entry in the following list.
If the element has a descendant that is currently matching the `:active` pseudo-class

The element is **being activated**.

If the element is the labeled control of a `label` element that is currently matching `:active`

The element is **being activated**.

If the element is a `button` element
If the element is an `input` element whose `type` attribute is in the Submit Button, Image Button, Reset Button, or Button state

The element is **being activated** if it is in a formal activation state and it is not disabled.

For example, if the user is using a keyboard to push a `button` element by pressing the space bar, the element would match this pseudo-class in between the time that the element received the `keydown` event and the time the element received the `keyup` event.

If the element is an a element that has an `href` attribute
If the element is an area element that has an `href` attribute
If the element is a `link` element that has an `href` attribute
If the element is focusable

The element is **being activated** if it is in a formal activation state.

If the element is **being actively pointed at**

The element is **being activated**.

An element is said to be **in a formal activation state** between the time the user begins to indicate an intent to trigger the element’s activation behavior and either the time the user stops indicating an intent to trigger the element’s activation behavior, or the time the element’s activation behavior has finished running, which ever comes first.

An element is said to be **being actively pointed at** while the user indicates the element using a pointing device while that pointing device is in the “down” state (e.g. for a mouse, between the time the mouse button is pressed and the time it is depressed; for a finger in a multitouch environment, while the finger is touching the display surface).

`:hover`

Support in all current engines.
The :hover pseudo-class is defined to match an element “while the user designates an element with a pointing device”. For the purposes of defining the :hover pseudo-class only, an HTML user agent must consider an element as being one that the user designates if it is:

- An element that the user indicates using a pointing device.
- An element that has a descendant that the user indicates using a pointing device.
- An element that is the labeled control of a label element that is currently matching :hover.

Consider in particular a fragment such as:

```html
<p> <label for=c> <input id=a> </label> <span id=b> <input id=c> </span> </p>
```

If the user designates the element with ID "a" with their pointing device, then the p element (and all its ancestors not shown in the snippet above), the label element, the element with ID "a", and the element with ID "c" will match the :hover pseudo-class. The element with ID "a" matches it from condition 1, the label and p elements match it because of condition 2 (one of their descendants is designated), and the element with ID "c" matches it through condition 3 (its Label element matches :hover). However, the element with ID "b" does not match :hover: its descendant is not designated, even though it matches :hover.

:focus

Support in all current engines.

For the purposes of the CSS :focus pseudo-class, an element has the focus when:
- it is not itself a browsing context container; and

- at least one of the following is true:
  - it is one of the elements listed in the current focus chain of the top-level browsing context, or
  - its shadow root shadowRoot is not null and shadowRoot is the root of at least one element that has the focus.

:target

Support in all current engines.

Firefox1+Safari1.3+Chrome1+
Opera9.5+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS2+Chrome Android18+WebView Android2+Samsung Internet1.0+Opera Android10.1+

For the purposes of the CSS :target pseudo-class, the Document’s target elements are a list containing the Document’s target element, if it is not null, or containing no elements, if it is. [SELECTORS]

:enabled

Support in all current engines.

Firefox1+Safari3.1+Chrome1+
Opera9+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS2+Chrome Android18+WebView Android2+Samsung Internet1.0+Opera Android10.1+

The :enabled pseudo-class must match any button, input, select, textarea, optgroup, option, fieldset element, or form-associated custom element that is not actually disabled.

:disabled
The `:disabled` pseudo-class must match any element that is **actually disabled**.

The `:checked` pseudo-class must match any element falling into one of the following categories:

- `input` elements whose `type` attribute is in the Checkbox state and whose checkedness state is true
- `input` elements whose `type` attribute is in the Radio Button state and whose checkedness state is true
- `option` elements whose selectedness is true

The `:indeterminate` pseudo-class must match any element falling in one of the following categories.

Firefox2+Safari3+Chrome1+
Opera9+Edge79+
The `.indeterminate` pseudo-class must match any element falling into one of the following categories:

- `input` elements whose `type` attribute is in the `Checkbox` state and whose `indeterminate` IDL attribute is set to true
- `input` elements whose `type` attribute is in the `Radio Button` state and whose `radio button group` contains no `input` elements whose `checkedness` state is true.
- `progress` elements with no `value` content attribute

`:default
✔✔ MDN

`:default

Support in all current engines.

Firefox 4+Safari 5+Chrome 10+
Opera 10+Edge 79+
Edge (Legacy) No Internet Explorer No

Firefox 4+Safari 5+Chrome 18+WebView Android 37+Samsung
Internet 1.0+Opera Android 10.1+

The `.default` pseudo-class must match any element falling into one of the following categories:

- Submit buttons that are default buttons of their form owner.
- `input` elements to which the `checked` attribute applies and that have a `checked` attribute
- `option` elements that have a `selected` attribute

`:placeholder-shown

The `.placeholder-shown` pseudo-class must match any element falling into one of the following categories:

- `input` elements that have a `placeholder` attribute whose value is currently being presented to the user.
- `textarea` elements that have a `placeholder` attribute whose value is currently being presented to the user.

`:valid
✔✔ MDN
:valid

Support in all current engines.

Firefox 4+ Safari 5+ Chrome 10+
Opera 10+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 10.1+

The :valid pseudo-class must match any element falling into one of the following categories:

- elements that are candidates for constraint validation and that satisfy their constraints
- form elements that are not the form owner of any elements that themselves are candidates for constraint validation but do not satisfy their constraints
- fieldset elements that have no descendant elements that themselves are candidates for constraint validation but do not satisfy their constraints

:invalid

Support in all current engines.

Firefox 4+ Safari 5+ Chrome 10+
 Opera 10+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 10.1+

The :invalid pseudo-class must match any element falling into one of the following categories:

- elements that are candidates for constraint validation but that do not satisfy their constraints
- form elements that are the form owner of one or more elements that themselves are candidates for constraint validation but do not satisfy their constraints
- fieldset elements that have of one or more descendant elements that themselves are candidates for constraint validation but do not satisfy their constraints

:in-range

Support in all current engines.

Firefox 4+ Safari 5+ Chrome 10+
Opera 10+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 10.1+

The :in-range pseudo-class must match any element falling into one of the following categories:

- elements that are candidates for constraint validation but that do not satisfy their constraints
- form elements that are the form owner of one or more elements that themselves are candidates for constraint validation but do not satisfy their constraints
- fieldset elements that have of one or more descendant elements that themselves are candidates for constraint validation but do not satisfy their constraints
The **:in-range** pseudo-class must match all elements that are candidates for constraint validation, have range limitations, and that are neither suffering from an underflow nor suffering from an overflow.

**:out-of-range**

Support in all current engines.

<table>
<thead>
<tr>

</tbody>
</table>

The **:required** pseudo-class must match any element falling into one of the following categories:
• `input` elements that are `required`
• `select` elements that have a `required` attribute
• `textarea` elements that have a `required` attribute

`:optional`

Support in all current engines.

Firefox 4+ Safari 5+ Chrome 10+
Opera 10+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 10.1+

The `:optional` pseudo-class must match any element falling into one of the following categories:

• `input` elements to which the `required` attribute applies that are not `required`
• `select` elements that do not have a `required` attribute
• `textarea` elements that do not have a `required` attribute

`:autofill`

Support in all current engines.

Firefox 86+ Safari preview+ Chrome 96+
Opera 82+ Edge 96+
Edge (Legacy) No Internet Explorer No
Firefox Android 86+ Safari iOS ▶ 1+ Chrome Android 96+ WebView Android 96+ Samsung Internet ▶ 1.0+ Opera Android ▶ 14+
`:-webkit-autofill`

The `:autofill` and `:-webkit-autofill` pseudo-classes must match `input` elements which have been autofilled by user agent. These pseudo-classes must stop matching if the user edits the autofilled field.

One way such autofilling might happen is via the `autocomplete` attribute, but user agents could autofill even without that attribute being involved.

`:read-only`
:read-only

Support in all current engines.

</tbody>
</table>

The :read-write pseudo-class must match any element falling into one of the following categories, which for the purposes of Selectors are thus considered user-alterable:

- input elements to which the readonly attribute applies, and that are mutable (i.e. that do not have the readonly attribute specified and that are not disabled)
- textarea elements that do not have a readonly attribute, and that are not disabled
- elements that are editing hosts or editable and are neither input elements nor textarea elements

The :read-only pseudo-class must match all other HTML elements.

:dir(ltr)

:dir

Support in one engine only.

Firefox 49+ Safari No Chrome No
The :dir(ltr) pseudo-class must match all elements whose directionality is 'ltr'.

:dir(rtl)

The :dir(rtl) pseudo-class must match all elements whose directionality is 'rtl'.

This specification does not define when an element matches the :lang() dynamic pseudo-class, as it is defined in sufficient detail in a language-agnostic fashion in Selectors. [SELECTORS]

5 Microdata

5.1 Introduction

5.1.1 Overview

This section is non-normative.

Sometimes, it is desirable to annotate content with specific machine-readable labels, e.g. to allow generic scripts to provide services that are customized to the page, or to enable content from a variety of cooperating authors to be processed by a single script in a consistent manner.

For this purpose, authors can use the microdata features described in this section. Microdata allows nested groups of name-value pairs to be added to documents, in parallel with the existing content.

5.1.2 The basic syntax

This section is non-normative.

At a high level, microdata consists of a group of name-value pairs. The groups are called items, and each name-value pair is a property. Items and properties are represented by regular elements.

To create an item, the itemscope attribute is used.

To add a property to an item, the itemprop attribute is used on one of the item's descendants.

Here there are two items, each of which has the property "name":

<div itemscope>
<p>My name is <span itemprop="name">Elizabeth</span>.</p>

<aside>
<p>My name is <span itemprop="name">Daniel</span>.</p>
</aside>

Markup without the microdata-related attributes does not have any effect on the microdata model.

These two examples are exactly equivalent, at a microdata level, as the previous two examples respectively:

<aside>
<p>My <em>name</em> is <span itemprop="name">E<strong>liz</strong>abeth</span>.</p>
</aside>

<aside>
<p>My name is <span itemprop="name">Daniel</span>.</p>
</aside>

Properties generally have values that are strings.

Here the item has three properties:

<aside>
<p>My name is <span itemprop="name">Neil</span>.</p>
<p>My band is called <span itemprop="band">Four Parts Water</span>.</p>
<p>I am <span itemprop="nationality">British</span>.</p>
</aside>

When a string value is a URL, it is expressed using the <a>element and its href attribute, the <img> element and its src attribute, or other elements that link to or embed external resources.</p>

In this example, the item has one property, “image”, whose value is a URL:

<aside>
<img itemprop="image" src="google-logo.png" alt="Google">
</aside>

When a string value is in some machine-readable format unsuitable for human consumption, it is expressed using the value attribute of the data element, with the human-readable version given in the element’s contents.
Here, there is an item with a property whose value is a product ID. The ID is not human-friendly, so the product’s name is used the human-visible text instead of the ID.

```html
<h1 itemscope>
  <data itemprop="product-id" value="9678AOU879">The Instigator 2000</data>
</h1>
```

For numeric data, the `meter` element and its `value` attribute can be used instead.

Here a rating is given using a `meter` element.

```html
<div itemscope itemtype="http://schema.org/Product">
  <span itemprop="name">Panasonic White 60L Refrigerator</span>
  <img src="panasonic-fridge-60l-white.jpg" alt="">
  <div itemprop="aggregateRating" itemscope itemtype="http://schema.org/AggregateRating">
    <meter itemprop="ratingValue" min=0 value=3.5 max=5>Rated 3.5/5</meter>
    (based on <span itemprop="reviewCount">11</span> customer reviews)
  </div>
</div>
```

Similarly, for date- and time-related data, the `time` element and its `datetime` attribute can be used instead.

In this example, the item has one property, “birthday”, whose value is a date:

```html
<div itemscope>
  I was born on <time itemprop="birthday" datetime="2009-05-10">May 10th 2009</time>
</div>
```

Properties can also themselves be groups of name-value pairs, by putting the `itemscope` attribute on the element that declares the property.

Items that are not part of others are called top-level microdata items.

In this example, the outer item represents a person, and the inner one represents a band:

```html
<div itemscope>
  <p>Name: <span itemprop="name">Amanda</span></p>
  <p>Band: <span itemprop="band" itemscope> <span itemprop="name">Jazz Band</span> </span></p>
</div>
```

The outer item here has two properties, “name” and “band”. The “name” is “Amanda”, and the “band” is an item in its own right, with two properties, “name” and “size”. The “name” of the band is “Jazz Band”, and the “size” is “12”.

The outer item in this example is a top-level microdata item.
Properties that are not descendants of the element with the `itemscope` attribute can be associated with the `item` using the `itemref` attribute. This attribute takes a list of IDs of elements to crawl in addition to crawling the children of the element with the `itemscope` attribute.

This example is the same as the previous one, but all the properties are separated from their `items`:

```html
<div itemscope id="amanda" itemref="a b"></div>
<p id="a">Name: <span itemprop="name">Amanda</span></p>
<div id="b" itemprop="band" itemscope itemref="c"></div>
<div id="c">
  <p>Band: <span itemprop="name">Jazz Band</span></p>
  <p>Size: <span itemprop="size">12</span> players</p>
</div>
```

This gives the same result as the previous example. The first item has two properties, “name”, set to “Amanda”, and “band”, set to another item. That second item has two further properties, “name”, set to “Jazz Band”, and “size”, set to “12”.

An `item` can have multiple properties with the same name and different values.

This example describes an ice cream, with two flavors:

```html
<div itemscope>
  <p>Flavors in my favorite ice cream:</p>
  <ul>
    <li itemprop="flavor">Lemon sorbet</li>
    <li itemprop="flavor">Apricot sorbet</li>
  </ul>
</div>
```

This thus results in an item with two properties, both “flavor”, having the values “Lemon sorbet” and “Apricot sorbet”.

An element introducing a property can also introduce multiple properties at once, to avoid duplication when some of the properties have the same value.

Here we see an item with two properties, “favorite-color” and “favorite-fruit”, both set to the value “orange”:

```html
<div itemscope>
  <span itemprop="favorite-color favorite-fruit">orange</span>
</div>
```

It’s important to note that there is no relationship between the microdata and the content of the document where the microdata is marked up.
There is no semantic difference, for instance, between the following two examples:

```html
<figure>
  <img src="castle.jpeg">
  <figcaption><span itemscope><span itemprop="name">The Castle</span></span> (1986)</figcaption>
</figure>

<figure>
  <img src="castle.jpeg">
  <figcaption>The Castle (1986)</figcaption>
</figure>
```

Both have a figure with a caption, and both, completely unrelated to the figure, have an item with a name-value pair with the name "name" and the value "The Castle". The only difference is that if the user drags the caption out of the document, in the former case, the item will be included in the drag-and-drop data. In neither case is the image in any way associated with the item.

### 5.1.3 Typed items

*This section is non-normative.*

The examples in the previous section show how information could be marked up on a page that doesn’t expect its microdata to be re-used. Microdata is most useful, though, when it is used in contexts where other authors and readers are able to cooperate to make new uses of the markup.

For this purpose, it is necessary to give each *item* a type, such as "https://example.com/person", or "https://example.org/cat", or "https://band.example.net/". Types are identified as [URLs](https://example.com/). The type for an *item* is given as the value of an *itemtype* attribute on the same element as the *itemscope* attribute.

Here, the item’s type is "https://example.org/animals#cat":

```html
<section itemscope itemtype="https://example.org/animals#cat">
  <h1 itemprop="name">Hedral</h1>
  <p itemprop="desc">Hedral is a male american domestic shorthair, with a fluffy black fur with white paws and belly.</p>
  <img itemprop="img" src="hedral.jpeg" alt="" title="Hedral, age 18 months">
</section>
```

In this example the "https://example.org/animals#cat" item has three properties, a "name" ("Hedral"), a "desc" ("Hedral is..."), and an "img" ("hedral.jpeg").

The type gives the context for the properties, thus selecting a vocabulary: a property named...
“class” given for an item with the type “https://census.example/person” might refer to the economic class of an individual, while a property named “class” given for an item with the type “https://example.com/school/teacher” might refer to the classroom a teacher has been assigned. Several types can share a vocabulary. For example, the types “https://example.org/people/teacher” and “https://example.org/people/engineer” could be defined to use the same vocabulary (though maybe some properties would not be especially useful in both cases, e.g. maybe the “https://example.org/people/engineer” type might not typically be used with the “classroom” property). Multiple types defined to use the same vocabulary can be given for a single item by listing the URLs as a space-separated list in the attribute’s value. An item cannot be given two types if they do not use the same vocabulary, however.

5.1.4 Global identifiers for items

This section is non-normative.

Sometimes, an item gives information about a topic that has a global identifier. For example, books can be identified by their ISBN number.

Vocabularies (as identified by the itemtype attribute) can be designed such that items get associated with their global identifier in an unambiguous way by expressing the global identifiers as URLs given in an itemid attribute.

The exact meaning of the URLs given in itemid attributes depends on the vocabulary used.

Here, an item is talking about a particular book:

```html
<dl itemscope
     itemtype="https://vocab.example.net/book"
     itemid="urn:isbn:0-330-34032-8">
 <dt>Title
 <dd itemprop="title">The Reality Dysfunction
 <dt>Author
 <dd itemprop="author">Peter F. Hamilton
 <dt>Publication date
 <dd><time itemprop="pubdate" datetime="1996-01-26">26 January 1996</time>
</dl>
```

The “https://vocab.example.net/book” vocabulary in this example would define that the itemid attribute takes a urn: URL pointing to the ISBN of the book.

5.1.5 Selecting names when defining vocabularies

This section is non-normative.

Using microdata means using a vocabulary. For some purposes, an ad-hoc vocabulary is adequate. For others, a vocabulary will need to be designed. Where possible, authors are
encouraged to re-use existing vocabularies, as this makes content re-use easier.

When designing new vocabularies, identifiers can be created either using URLs, or, for properties, as plain words (with no dots or colons). For URLs, conflicts with other vocabularies can be avoided by only using identifiers that correspond to pages that the author has control over.

For instance, if Jon and Adam both write content at example.com, at https://example.com/~jon/... and https://example.com/~adam/... respectively, then they could select identifiers of the form "https://example.com/~jon/name" and "https://example.com/~adam/name" respectively.

Properties whose names are just plain words can only be used within the context of the types for which they are intended; properties named using URLs can be reused in items of any type. If an item has no type, and is not part of another item, then if its properties have names that are just plain words, they are not intended to be globally unique, and are instead only intended for limited use. Generally speaking, authors are encouraged to use either properties with globally unique names (URLs) or ensure that their items are typed.

Here, an item is an "https://example.org/animals#cat", and most of the properties have names that are words defined in the context of that type. There are also a few additional properties whose names come from other vocabularies.

This example has one item with the type "https://example.org/animals#cat" and the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Hedral</td>
</tr>
<tr>
<td><a href="https://example.com/fn">https://example.com/fn</a></td>
<td>Hedral</td>
</tr>
<tr>
<td>desc</td>
<td>Hedral is a male American domestic shorthair, with a fluffy black fur with white paws and belly.</td>
</tr>
<tr>
<td><a href="https://example.com/color">https://example.com/color</a></td>
<td>black</td>
</tr>
<tr>
<td><a href="https://example.com/color">https://example.com/color</a></td>
<td>white</td>
</tr>
<tr>
<td>img</td>
<td>.../hedral.jpeg</td>
</tr>
</tbody>
</table>
5.2 Encoding microdata

5.2.1 The microdata model

The microdata model consists of groups of name-value pairs known as items.

Each group is known as an item. Each item can have item types, a global identifier (if the vocabulary specified by the item types support global identifiers for items), and a list of name-value pairs. Each name in the name-value pair is known as a property, and each property has one or more values. Each value is either a string or itself a group of name-value pairs (an item). The names are unordered relative to each other, but if a particular name has multiple values, they do have a relative order.

5.2.2 Items

Global_attributes/itemscope

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes Opera Yes Edge Yes
Edge (Legacy) 12+ Internet Explorer Yes
Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

Every HTML element may have an itemscope attribute specified. The itemscope attribute is a boolean attribute.

An element with the itemscope attribute specified creates a new item, a group of name-value pairs.

Global_attributes/itemtype

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes Opera Yes Edge Yes
Edge (Legacy) 12+ Internet Explorer Yes
Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes
Elements with an `itemscope` attribute may have an `itemtype` attribute specified, to give the item types of the item.

The `itemtype` attribute, if specified, must have a value that is an unordered set of unique space-separated tokens, none of which are identical to another token and each of which is a valid URL string that is an absolute URL, and all of which are defined to use the same vocabulary. The attribute’s value must have at least one token.

The item types of an item are the tokens obtained by splitting the element’s `itemtype` attribute’s value on ASCII whitespace. If the `itemtype` attribute is missing or parsing it in this way finds no tokens, the item is said to have no item types.

The item types must all be types defined in applicable specifications and must all be defined to use the same vocabulary.

Except if otherwise specified by that specification, the URLs given as the item types should not be automatically dereferenced.

A specification could define that its item type can be dereferenced to provide the user with help information, for example. In fact, vocabulary authors are encouraged to provide useful information at the given URL.

Item types are opaque identifiers, and user agents must not dereference unknown item types, or otherwise deconstruct them, in order to determine how to process items that use them.

The `itemtype` attribute must not be specified on elements that do not have an `itemscope` attribute specified.

---

An item is said to be a typed item when either it has an item type, or it is the value of a property of a typed item. The relevant types for a typed item is the item’s item types, if it has any, or else is the relevant types of the item for which it is a property’s value.
vocabulary that is defined to support global identifiers for items may also have an `itemid` attribute specified, to give a global identifier for the `item`, so that it can be related to other `items` on pages elsewhere on the web.

The `itemid` attribute, if specified, must have a value that is a valid URL potentially surrounded by spaces.

The global identifier of an `item` is the value of its element’s `itemid` attribute, if it has one, parsed relative to the node document of the element on which the attribute is specified. If the `itemid` attribute is missing or if resolving it fails, it is said to have no global identifier.

The `itemid` attribute must not be specified on elements that do not have both an `itemscope` attribute and an `itemtype` attribute specified, and must not be specified on elements with an `itemscope` attribute whose `itemtype` attribute specifies a vocabulary that does not support global identifiers for items, as defined by that vocabulary’s specification.

The exact meaning of a global identifier is determined by the vocabulary’s specification. It is up to such specifications to define whether multiple items with the same global identifier (whether on the same page or on different pages) are allowed to exist, and what the processing rules for that vocabulary are with respect to handling the case of multiple items with the same ID.

---

Global attributes/itemref

Support in all current engines.

<table>

</tr>
</tbody>
</table>

Elements with an `itemscope` attribute may have an `itemref` attribute specified, to give a list of additional elements to crawl to find the name-value pairs of the `item`.

The `itemref` attribute, if specified, must have a value that is an unordered set of unique space-separated tokens none of which are identical to another token and consisting of IDs of elements in the same tree.

The `itemref` attribute must not be specified on elements that do not have an `itemscope` attribute specified.

The `itemref` attribute is not part of the microdata data model. It is merely a syntactic construct to aid authors in adding annotations to pages where the data to be annotated does not follow a convenient tree structure. For example, it allows authors to mark up data in a
table so that each column defines a separate item, while keeping the properties in the cells.

This example shows a simple vocabulary used to describe the products of a model railway manufacturer. The vocabulary has just five property names:

**product-code**
An integer that names the product in the manufacturer’s catalog.

**name**
A brief description of the product.

**scale**
One of “HO”, “1”, or “Z” (potentially with leading or trailing whitespace), indicating the scale of the product.

**digital**
If present, one of “Digital”, “Delta”, or “Systems” (potentially with leading or trailing whitespace) indicating that the product has a digital decoder of the given type.

**track-type**
For track-specific products, one of “K”, “M”, “C” (potentially with leading or trailing whitespace) indicating the type of track for which the product is intended.

This vocabulary has four defined item types:

https://md.example.com/loco
Rolling stock with an engine

https://md.example.com/passengers
Passenger rolling stock

https://md.example.com/track
Track pieces

https://md.example.com/lighting
Equipment with lighting

Each item that uses this vocabulary can be given one or more of these types, depending on what the product is.

Thus, a locomotive might be marked up as:

```xml
<dl itemscope itemtype="https://md.example.com/loco
     https://md.example.com/lighting">
  <dt>Name:
  <dd itemprop="name">Tank Locomotive (DB 80)
  <dt>Product code:
  <dd itemprop="product-code">33041
  <dt>Scale:
```

A turnout lantern retrofit kit might be marked up as:

```html
dl itemscope itemtype="https://md.example.com/track https://md.example.com/lighting"
  dt Name:
  dd itemprop="name">Turnout Lantern Kit
  dt Product code:
  dd itemprop="product-code">74470
  dt Purpose:
  dd for retrofitting 2 <span itemprop="track-type">C</span> Track turnouts. <meta itemprop="scale" content="HO">
</dl>
```

A passenger car with no lighting might be marked up as:

```html
dl itemscope itemtype="https://md.example.com/passengers"
  dt Name:
  dd itemprop="name">Express Train Passenger Car (DB Am 203)
  dt Product code:
  dd itemprop="product-code">8710
  dt Scale:
  dd itemprop="scale">Z
</dl>
```

Great care is necessary when creating new vocabularies. Often, a hierarchical approach to types can be taken that results in a vocabulary where each item only ever has a single type, which is generally much simpler to manage.

5.2.3 Names: the `itemprop` attribute

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>Yes</td>

<td>Yes</td>
</tr>
</tbody>
</table>
Every HTML element may have an `itemprop` attribute specified, if doing so adds one or more properties to one or more items (as defined below).

The `itemprop` attribute, if specified, must have a value that is an unordered set of unique space-separated tokens none of which are identical to another token, representing the names of the name-value pairs that it adds. The attribute’s value must have at least one token.

Each token must be either:

- If the item is a typed item: a defined property name allowed in this situation according to the specification that defines the relevant types for the item, or
- A valid URL string that is an absolute URL defined as an item property name allowed in this situation by a vocabulary specification, or
- A valid URL string that is an absolute URL, used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification), or
- If the item is not a typed item: a string that contains no U+002E FULL STOP characters (.) and no U+003A COLON characters (:) used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification).

Specifications that introduce defined property names must ensure all such property names contain no U+002E FULL STOP characters (.), no U+003A COLON characters (:], and no ASCII whitespace.

The rules above disallow U+003A COLON characters (:) in non-URL values because otherwise they could not be distinguished from URLs. Values with U+002E FULL STOP characters (.) are reserved for future extensions. ASCII whitespace are disallowed because otherwise the values would be parsed as multiple tokens.

When an element with an `itemprop` attribute adds a property to multiple items, the requirement above regarding the tokens applies for each item individually.

The property names of an element are the tokens that the element’s `itemprop` attribute is found to contain when its value is split on ASCII whitespace, with the order preserved but with duplicates removed (leaving only the first occurrence of each name).

Within an item, the properties are unordered with respect to each other, except for properties with the same name, which are ordered in the order they are given by the algorithm that defines the properties of an item.

In the following example, the "a" property has the values "1" and "2", in that order, but whether the "a" property comes before the "b" property or not is not important:

```html
<div itemscope>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
  <p itemprop="b">test</p>
</div>
```
Thus, the following is equivalent:

```
<div itemscope>
  <p itemprop="b">test</p>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
</div>
```

As is the following:

```
<div itemscope>
  <p itemprop="a">1</p>
  <p itemprop="b">test</p>
  <p itemprop="a">2</p>
</div>
```

And the following:

```
<div id="x">
  <p itemprop="a">1</p>
</div>
```

```
<div itemscope itemref="x">
  <p itemprop="b">test</p>
  <p itemprop="a">2</p>
</div>
```

5.2.4 Values

The *property value* of a name-value pair added by an element with an `itemprop` attribute is as given for the first matching case in the following list:

**If the element also has an `itemscope` attribute**

The value is the *item* created by the element.

**If the element is a `meta` element**

The value is the value of the element’s `content` attribute, if any, or the empty string if there is no such attribute.

**If the element is an `audio`, `embed`, `iframe`, `img`, `source`, `track`, or `video` element**

The value is the *resulting URL string* that results from parsing the value of the element’s `src` attribute relative to the *node document* of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing it results in an error.
If the element is an **a**, **area**, or **link** element

The value is the **resulting URL string** that results from parsing the value of the element’s **href** attribute relative to the **node document** of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing it results in an error.

If the element is an **object** element

The value is the **resulting URL string** that results from parsing the value of the element’s **data** attribute relative to the **node document** of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing it results in an error.

If the element is a **data** element

The value is the value of the element’s **value** attribute, if it has one, or the empty string otherwise.

If the element is a **meter** element

The value is the value of the element’s **value** attribute, if it has one, or the empty string otherwise.

If the element is a **time** element

The value is the element’s **datetime value**.

Otherwise

The value is the element’s **descendant text content**.

The **URL property elements** are the **a**, **area**, **audio**, **embed**, **iframe**, **img**, **link**, **object**, **source**, **track**, and **video** elements.

If a property’s **value**, as defined by the property’s definition, is an **absolute URL**, the property must be specified using a **URL property element**.

These requirements do not apply just because a property value happens to match the syntax for a URL. They only apply if the property is explicitly defined as taking such a value.

For example, a book about the first moon landing could be called “mission:moon”. A "title" property from a vocabulary that defines a title as being a string would not expect the title to be given in an **a** element, even though it looks like a **URL**. On the other hand, if there was a (rather narrowly scoped!) vocabulary for "books whose titles look like URLs" which had a "title" property defined to take a URL, then the property **would** expect the title to be given in an **a** element (or one of the other **URL property elements**), because of the requirement above.
5.2.5 Associating names with items

To find the properties of an item defined by the element root, the user agent must run the following steps. These steps are also used to flag microdata errors.

1. Let results, memory, and pending be empty lists of elements.
2. Add the element root to memory.
3. Add the child elements of root, if any, to pending.
4. If root has an itemref attribute, split the value of that itemref attribute on ASCII whitespace. For each resulting token ID, if there is an element in the tree of root with the ID ID, then add the first such element to pending.
5. While pending is not empty:
   1. Remove an element from pending and let current be that element.
   2. If current is already in memory, there is a microdata error; continue.
   3. Add current to memory.
   4. If current does not have an itemscope attribute, then: add all the child elements of current to pending.
   5. If current has an itemprop attribute specified and has one or more property names, then add current to results.
6. Sort results in tree order.
7. Return results.

A document must not contain any items for which the algorithm to find the properties of an item finds any microdata errors.

An item is a top-level microdata item if its element does not have an itemprop attribute.

All itemref attributes in a Document must be such that there are no cycles in the graph formed from representing each item in the Document as a node in the graph and each property of an item whose value is another item as an edge in the graph connecting those two items.

A document must not contain any elements that have an itemprop attribute that would not be found to be a property of any of the items in that document were their properties all to be determined.

In this example, a single license statement is applied to two works, using itemref from the items representing the works:
<h1>My photos</h1>
<figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
  <img itemprop="work" src="images/house.jpeg" alt="A white house, boarded up, sits in a forest."/>
  <figcaption itemprop="title">The house I found.</figcaption>
</figure>
<figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
  <img itemprop="work" src="images/mailbox.jpeg" alt="Outside the house is a mailbox. It has a leaflet inside."/>
  <figcaption itemprop="title">The mailbox.</figcaption>
</figure>
<footer>
  <p id="licenses">All images licensed under the <a itemprop="license" href="http://www.opensource.org/licenses/mit-license.php">MIT license</a>.</p>
</footer>
5.2.6 Microdata and other namespaces

Currently, the `itemscope`, `itemprop`, and other microdata attributes are only defined for HTML elements. This means that attributes with the literal names “`itemscope`”, “`itemprop`”, etc, do not cause microdata processing to occur on elements in other namespaces, such as SVG.

Thus, in the following example there is only one item, not two.

```html
<p itemscope></p> <!-- this is an item (with no properties and no type) -->
<svg itemscope></svg> <!-- this is not, it's just an SVG <svg> element with an invalid unknown attribute -->
```

5.3 Sample microdata vocabularies

The vocabularies in this section are primarily intended to demonstrate how a vocabulary is specified, though they are also usable in their own right.

5.3.1 vCard

An item with the `item type` `http://microformats.org/profile/hcard` represents a person’s or organization’s contact information.

This vocabulary does not support global identifiers for items.

The following are the type’s defined property names. They are based on the vocabulary defined in vCard Format Specification (vCard) and its extensions, where more information on how to interpret the values can be found. [RFC6350]

`kind`

Describes what kind of contact the item represents.

The value must be text that is identical to one of the kind strings.

A single property with the name `kind` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

`fn`

Gives the formatted text corresponding to the name of the person or organization.

The value must be text.

Exactly one property with the name `fn` must be present within each `item` with the type `http://microformats.org/profile/hcard`. 

$n$

Gives the structured name of the person or organization.

The value must be an item with zero or more of each of the family-name, given-name, additional-name, honorific-prefix, and honorific-suffix properties.

Exactly one property with the name $n$ must be present within each item with the type http://microformats.org/profile/hcard.

family-name (inside $n$)

Gives the family name of the person, or the full name of the organization.

The value must be text.

Any number of properties with the name family-name may be present within the item that forms the value of the $n$ property of an item with the type http://microformats.org/profile/hcard.

given-name (inside $n$)

Gives the given-name of the person.

The value must be text.

Any number of properties with the name given-name may be present within the item that forms the value of the $n$ property of an item with the type http://microformats.org/profile/hcard.

additional-name (inside $n$)

Gives the any additional names of the person.

The value must be text.

Any number of properties with the name additional-name may be present within the item that forms the value of the $n$ property of an item with the type http://microformats.org/profile/hcard.

honorific-prefix (inside $n$)

Gives the honorific prefix of the person.

The value must be text.

Any number of properties with the name honorific-prefix may be present within the
item that forms the value of the n property of an item with the type http://microformats.org/profile/hcard.

**honorific-suffix** (inside n)

Gives the honorific suffix of the person.

The value must be text.

Any number of properties with the name honorific-suffix may be present within the item that forms the value of the n property of an item with the type http://microformats.org/profile/hcard.

**nickname**

Gives the nickname of the person or organization.

The nickname is the descriptive name given instead of or in addition to the one belonging to a person, place, or thing. It can also be used to specify a familiar form of a proper name specified by the fn or n properties.

The value must be text.

Any number of properties with the name nickname may be present within each item with the type http://microformats.org/profile/hcard.

**photo**

Gives a photograph of the person or organization.

The value must be an absolute URL.

Any number of properties with the name photo may be present within each item with the type http://microformats.org/profile/hcard.

**bday**

Gives the birth date of the person or organization.

The value must be a valid date string.

A single property with the name bday may be present within each item with the type http://microformats.org/profile/hcard.

**anniversary**

Gives the birth date of the person or organization.
The **value** must be a **valid date string**.

A single property with the name **anniversary** may be present within each **item** with the type **http://microformats.org/profile/hcard**.

**sex**

 Gives the biological sex of the person.

The **value** must be one of **F**, meaning “female”, **M**, meaning “male”, **N**, meaning “none or not applicable”, **O**, meaning “other”, or **U**, meaning “unknown”.

A single property with the name **sex** may be present within each **item** with the type **http://microformats.org/profile/hcard**.

**gender-identity**

 Gives the gender identity of the person.

The **value** must be text.

A single property with the name **gender-identity** may be present within each **item** with the type **http://microformats.org/profile/hcard**.

**adr**

 Gives the delivery address of the person or organization.

The **value** must be an **item** with zero or more **type, post-office-box, extended-address, street-address** properties, and optionally a **locality** property, optionally a **region** property, optionally a **postal-code** property, and optionally a **country-name** property.

If no **type** properties are present within an **item** that forms the **value** of an **adr** property of an **item** with the type **http://microformats.org/profile/hcard**, then the **address type string work** is implied.

Any number of properties with the name **adr** may be present within each **item** with the type **http://microformats.org/profile/hcard**.

**type (inside adr)**

 Gives the type of delivery address.

The **value** must be text that is **identical to** one of the **address type strings**.

Any number of properties with the name **type** may be present within the **item** that forms
the value of an adr property of an item with the type http://microformats.org/profile/hcard, but within each such adr property item there must only be one type property per distinct value.

**post-office-box** (inside adr)

Gives the post office box component of the delivery address of the person or organization.

The value must be text.

Any number of properties with the name post-office-box may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard.

vCard urges authors not to use this field.

**extended-address** (inside adr)

Gives an additional component of the delivery address of the person or organization.

The value must be text.

Any number of properties with the name extended-address may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard.

vCard urges authors not to use this field.

**street-address** (inside adr)

Gives the street address component of the delivery address of the person or organization.

The value must be text.

Any number of properties with the name street-address may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard.

**locality** (inside adr)

Gives the locality component (e.g. city) of the delivery address of the person or organization.

The value must be text.

A single property with the name locality may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/
Region (inside adr)

Gives the region component (e.g. state or province) of the delivery address of the person or organization.

The value must be text.

A single property with the name region may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard.

Postal-code (inside adr)

Gives the postal code component of the delivery address of the person or organization.

The value must be text.

A single property with the name postal-code may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard.

country-name (inside adr)

Gives the country name component of the delivery address of the person or organization.

The value must be text.

A single property with the name country-name may be present within the item that forms the value of an adr property of an item with the type http://microformats.org/profile/hcard.

tel

Gives the telephone number of the person or organization.

The value must be either text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121, or an item with zero or more type properties and exactly one value property. [E163] [X121]

If no type properties are present within an item that forms the value of a tel property of an item with the type http://microformats.org/profile/hcard, or if the value of such a tel property is text, then the telephone type string voice is implied.

Any number of properties with the name tel may be present within each item with the type http://microformats.org/profile/hcard.
**type (inside tel)**

Gives the type of telephone number.

The value must be text that is identical to one of the telephone type strings.

Any number of properties with the name type may be present within the item that forms the value of a tel property of an item with the type http://microformats.org/profile/hcard, but within each such tel property item there must only be one type property per distinct value.

**value (inside tel)**

Gives the actual telephone number of the person or organization.

The value must be text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121. [E163] [X121]

Exactly one property with the name value must be present within the item that forms the value of a tel property of an item with the type http://microformats.org/profile/hcard.

**email**

Gives the email address of the person or organization.

The value must be text.

Any number of properties with the name email may be present within each item with the type http://microformats.org/profile/hcard.

**impp**

Gives a URL for instant messaging and presence protocol communications with the person or organization.

The value must be an absolute URL.

Any number of properties with the name impp may be present within each item with the type http://microformats.org/profile/hcard.

**lang**

Gives a language understood by the person or organization.

The value must be a valid BCP 47 language tag. [BCP47].

Any number of properties with the name lang may be present within each item with the

tz

Gives the time zone of the person or organization.

The **value** must be text and must match the following syntax:

1. Either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. A [valid non-negative integer](http://microformats.org/profile/hcard) that is exactly two digits long and that represents a number in the range 00..23.
3. A U+003A COLON character (:).
4. A [valid non-negative integer](http://microformats.org/profile/hcard) that is exactly two digits long and that represents a number in the range 00..59.

Any number of properties with the name **tz** may be present within each **item** with the type [http://microformats.org/profile/hcard](http://microformats.org/profile/hcard).

geo

Gives the geographical position of the person or organization.

The **value** must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

The value specifies latitude and longitude, in that order (i.e., “LAT LON” ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

Any number of properties with the name **geo** may be present within each **item** with the type [http://microformats.org/profile/hcard](http://microformats.org/profile/hcard).
title

Gives the job title, functional position or function of the person or organization.

The value must be text.

Any number of properties with the name title may be present within each item with the type http://microformats.org/profile/hcard.

role

Gives the role, occupation, or business category of the person or organization.

The value must be text.

Any number of properties with the name role may be present within each item with the type http://microformats.org/profile/hcard.

logo

Gives the logo of the person or organization.

The value must be an absolute URL.

Any number of properties with the name logo may be present within each item with the type http://microformats.org/profile/hcard.

agent

Gives the contact information of another person who will act on behalf of the person or organization.

The value must be either an item with the type http://microformats.org/profile/hcard, or an absolute URL, or text.

Any number of properties with the name agent may be present within each item with the type http://microformats.org/profile/hcard.

org

Gives the name and units of the organization.

The value must be either text or an item with one organization-name property and zero or more organization-unit properties.

Any number of properties with the name org may be present within each item with the type http://microformats.org/profile/hcard.
**organization-name** (inside **org**)

Gives the name of the organization.

The value must be text.

Exactly one property with the name **organization-name** must be present within the item that forms the value of an **org** property of an item with the type [http://microformats.org/profile/hcard](http://microformats.org/profile/hcard).

**organization-unit** (inside **org**)

Gives the name of the organization unit.

The value must be text.

Any number of properties with the name **organization-unit** may be present within the item that forms the value of the **org** property of an item with the type [http://microformats.org/profile/hcard](http://microformats.org/profile/hcard).

**member**

Gives a URL that represents a member of the group.

The value must be an absolute URL.

Any number of properties with the name **member** may be present within each item with the type [http://microformats.org/profile/hcard](http://microformats.org/profile/hcard) if the item also has a property with the name **kind** whose value is “group”.

**related**

Gives a relationship to another entity.

The value must be an item with one **url** property and one **rel** properties.

Any number of properties with the name **related** may be present within each item with the type [http://microformats.org/profile/hcard](http://microformats.org/profile/hcard).

**url** (inside **related**)

Gives the URL for the related entity.

The value must be an absolute URL.

Exactly one property with the name **url** must be present within the item that forms the value of a **related** property of an item with the type [http://microformats.org/profile/hcard](http://microformats.org/profile/hcard).
profile/hcard.

rel (inside related)

Gives the relationship between the entity and the related entity.

The value must be text that is identical to one of the relationship strings.

Exactly one property with the name rel must be present within the item that forms the value of a related property of an item with the type http://microformats.org/profile/hcard.

categories

Gives the name of a category or tag that the person or organization could be classified as.

The value must be text.

Any number of properties with the name categories may be present within each item with the type http://microformats.org/profile/hcard.

note

Gives supplemental information or a comment about the person or organization.

The value must be text.

Any number of properties with the name note may be present within each item with the type http://microformats.org/profile/hcard.

rev

Gives the revision date and time of the contact information.

The value must be text that is a valid global date and time string.

The value distinguishes the current revision of the information for other renditions of the information.

Any number of properties with the name rev may be present within each item with the type http://microformats.org/profile/hcard.

sound

Gives a sound file relating to the person or organization.

The value must be an absolute URL.
Any number of properties with the name `sound` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**uid**

Gives a globally unique identifier corresponding to the person or organization.

The `value` must be text.

A single property with the name `uid` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

**url**

Gives a [URL](http://www.w3.org/1999/xhtml) relating to the person or organization.

The `value` must be an [absolute URL](http://www.w3.org/1999/xhtml).

Any number of properties with the name `url` may be present within each `item` with the type `http://microformats.org/profile/hcard`.

The *kind strings* are:

**individual**

Indicates a single entity (e.g. a person).

**group**

Indicates multiple entities (e.g. a mailing list).

**org**

Indicates a single entity that is not a person (e.g. a company).

**location**

Indicates a geographical place (e.g. an office building).

The *address type strings* are:

**home**

Indicates a delivery address for a residence.

**work**

Indicates a delivery address for a place of work.
The *telephone type strings* are:

**home**

Indicates a residential number.

**work**

Indicates a telephone number for a place of work.

**text**

Indicates that the telephone number supports text messages (SMS).

**voice**

Indicates a voice telephone number.

**fax**

Indicates a facsimile telephone number.

**cell**

Indicates a cellular telephone number.

**video**

Indicates a video conferencing telephone number.

**pager**

Indicates a paging device telephone number.

**textphone**

Indicates a telecommunication device for people with hearing or speech difficulties.

The *relationship strings* are:

**emergency**

An emergency contact.

**agent**

Another entity that acts on behalf of this entity.
Has the meaning defined in XFN. [XFN]

5.3.1.1 Conversion to vCard

Given a list of nodes nodes in a Document, a user agent must run the following algorithm to extract any vCard data represented by those nodes (only the first vCard is returned):

1. If none of the nodes in nodes are items with the item type http://microformats.org/profile/hcard, then there is no vCard. Abort the algorithm, returning nothing.

2. Let node be the first node in nodes that is an item with the item type http://microformats.org/profile/hcard.

3. Let output be an empty string.

4. Add a vCard line with the type "BEGIN" and the value "VCARD" to output.

5. Add a vCard line with the type "PROFILE" and the value "VCARD" to output.

6. Add a vCard line with the type "VERSION" and the value "4.0" to output.

7. Add a vCard line with the type "SOURCE" and the result of escaping the vCard text string that is the document’s URL as the value to output.

8. If the title element is not null, add a vCard line with the type "NAME" and with the result of escaping the vCard text string obtained from the title element’s descendant text content as the value to output.
9. Let sex be the empty string.

10. Let gender-identity be the empty string.

11. For each element element that is a property of the item node: for each name name in element’s property names, run the following substeps:
   1. Let parameters be an empty set of name-value pairs.
   2. Run the appropriate set of substeps from the following list. The steps will set a variable value, which is used in the next step.

   If the property’s value is an item subitem and name is n
   1. Let value be the empty string.
   2. Append to value the result of collecting the first vCard subproperty named family-name in subitem.
   3. Append a U+003B SEMICOLON character (;) to value.
   4. Append to value the result of collecting the first vCard subproperty named given-name in subitem.
   5. Append a U+003B SEMICOLON character (;) to value.
   6. Append to value the result of collecting the first vCard subproperty named additional-name in subitem.
   7. Append a U+003B SEMICOLON character (;) to value.
   8. Append to value the result of collecting the first vCard subproperty named honorific-prefix in subitem.
   9. Append a U+003B SEMICOLON character (;) to value.
  10. Append to value the result of collecting the first vCard subproperty named honorific-suffix in subitem.

   If the property’s value is an item subitem and name is adr
   1. Let value be the empty string.
   2. Append to value the result of collecting vCard subproperties named post-office-box in subitem.
   3. Append a U+003B SEMICOLON character (;) to value.
4. Append to value the result of collecting vCard subproperties named \texttt{extended-address} in subitem.

5. Append a U+003B SEMICOLON character (;) to value.

6. Append to value the result of collecting vCard subproperties named \texttt{street-address} in subitem.

7. Append a U+003B SEMICOLON character (;) to value.

8. Append to value the result of collecting the first vCard subproperty named \texttt{locality} in subitem.

9. Append a U+003B SEMICOLON character (;) to value.

10. Append to value the result of collecting the first vCard subproperty named \texttt{region} in subitem.

11. Append a U+003B SEMICOLON character (;) to value.

12. Append to value the result of collecting the first vCard subproperty named \texttt{postal-code} in subitem.

13. Append a U+003B SEMICOLON character (;) to value.

14. Append to value the result of collecting the first vCard subproperty named \texttt{country-name} in subitem.

15. If there is a property named \texttt{type} in subitem, and the first such property has a value that is not an item and whose value consists only of ASCII alphanumerics, then add a parameter named “\texttt{TYPE}” whose value is the value of that property to parameters.

If the property’s \texttt{value} is an \texttt{item subitem} and \texttt{name} is \texttt{org}

1. Let value be the empty string.

2. Append to value the result of collecting the first vCard subproperty named \texttt{organization-name} in subitem.

3. For each property named \texttt{organization-unit} in subitem, run the following steps:
   
   1. If the value of the property is an item, then skip this property.
   
   2. Append a U+003B SEMICOLON character (;) to value.
Append the result of **escaping the vCard text string** given by the **value** of the property to **value**.

If the property’s **value** is an **item subitem** with the **item type** `http://microformats.org/profile/hcard` and **name** is **related**

1. Let **value** be the empty string.

2. If there is a property named **url** in **subitem**, and its element is a **URL property element**, then append the result of **escaping the vCard text string** given by the **value** of the first such property to **value**, and add a parameter with the name “**VALUE**” and the value “**URI**” to **parameters**.

3. If there is a property named **rel** in **subitem**, and the first such property has a **value** that is not an **item** and whose value consists only of **ASCII alphanumerics**, then add a parameter named “**RELATION**” whose value is the **value** of that property to **parameters**.

If the property’s **value** is an **item** and **name** is none of the above

1. Let **value** be the result of **collecting the first vCard subproperty** named **value** in **subitem**.

2. If there is a property named **type** in **subitem**, and the first such property has a **value** that is not an **item** and whose value consists only of **ASCII alphanumeric**, then add a parameter named “**TYPE**” whose value is the **value** of that property to **parameters**.

If the property’s **value** is not an **item** and its **name** is **sex**

If this is the first such property to be found, set **sex** to the property’s **value**.

If the property’s **value** is not an **item** and its **name** is **gender-identity**

If this is the first such property to be found, set **gender-identity** to the property’s **value**.

Otherwise (the property’s **value** is not an **item**)

1. Let **value** be the property’s **value**.

2. If **element** is one of the **URL property elements**, add a parameter with the name “**VALUE**” and the value “**URI**” to **parameters**.

3. Otherwise, if **name** is **bday** or **anniversary** and the **value** is a
valid date string, add a parameter with the name "VALUE" and the value "DATE" to parameters.

4. Otherwise, if name is rev and the value is a valid global date and time string, add a parameter with the name "VALUE" and the value "DATE-TIME" to parameters.

5. Prefix every U+005C REVERSE SOLIDUS character (\) in value with another U+005C REVERSE SOLIDUS character (\).

6. Prefix every U+002C COMMA character (,) in value with a U+005C REVERSE SOLIDUS character (\).

7. Unless name is geo, prefix every U+003B SEMICOLON character (;) in value with a U+005C REVERSE SOLIDUS character (\).

8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in value with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in value with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

3. Add a vCard line with the type name, the parameters parameters, and the value value to output.

12. If either sex or gender-identity has a value that is not the empty string, add a vCard line with the type "GENDER" and the value consisting of the concatenation of sex, a U+003B SEMICOLON character (;), and gender-identity to output.

13. Add a vCard line with the type "END" and the value "VCARD" to output.

When the above algorithm says that the user agent is to add a vCard line consisting of a type type, optionally some parameters, and a value value to a string output, it must run the following steps:

1. Let line be an empty string.

2. Append type, converted to ASCII uppercase, to line.

3. If there are any parameters, then for each parameter, in the order that they were added, run these substeps:

   1. Append a U+003B SEMICOLON character (;) to line.
2. Append the parameter’s name to line.

3. Append a U+003D EQUALS SIGN character (=) to line.

4. Append the parameter’s value to line.

5. Append value to line.

6. Let maximum length be 75.

7. While line’s code point length is greater than maximum length:
   1. Append the first maximum length code points of line to output.
   2. Remove the first maximum length code points from line.
   3. Append a U+000D CARRIAGE RETURN character (CR) to output.
   4. Append a U+000A LINE FEED character (LF) to output.
   5. Append a U+0020 SPACE character to output.
   6. Let maximum length be 74.

8. Append (what remains of) line to output.

9. Append a U+000D CARRIAGE RETURN character (CR) to output.

10. Append a U+000A LINE FEED character (LF) to output.

When the steps above require the user agent to obtain the result of collecting vCard subproperties named subname in subitem, the user agent must run the following steps:

1. Let value be the empty string.

2. For each property named subname in the item subitem, run the following substeps:

   1. If the value of the property is itself an item, then skip this property.

   2. If this is not the first property named subname in subitem (ignoring any that were skipped by the previous step), then append a U+002C COMMA character (,) to value.

   3. Append the result of escaping the vCard text string given by the value of the property to value.
3. Return value.

When the steps above require the user agent to obtain the result of collecting the first vCard subproperty named subname in subitem, the user agent must run the following steps:

1. If there are no properties named subname in subitem, then return the empty string.

2. If the value of the first property named subname in subitem is an item, then return the empty string.

3. Return the result of escaping the vCard text string given by the value of the first property named subname in subitem.

When the above algorithms say the user agent is to escape the vCard text string value, the user agent must use the following steps:

1. Prefix every U+005C REVERSE SOLIDUS character (\) in value with another U+005C REVERSE SOLIDUS character (\).

2. Prefix every U+002C COMMA character (,) in value with a U+005C REVERSE SOLIDUS character (\).

3. Prefix every U+003B SEMICOLON character (;) in value with a U+005C REVERSE SOLIDUS character (\).

4. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in value with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

5. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in value with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

6. Return the mutated value.

This algorithm can generate invalid vCard output, if the input does not conform to the rules described for the http://microformats.org/profile/hcard item type and defined property names.

5.3.1.2 Examples

This section is non-normative.

Here is a long example vCard for a fictional character called “Jack Bauer”:

```html
<section id="jack" itemscope itemtype="http://microformats.org/profile/hcard">
  <h1 itemprop="fn">
    <span itemprop="n">
```
<span itemprop="given-name">Jack</span> <span itemprop="family-name">Bauer</span>  

<p itemprop="organization-name">Counter-Terrorist Unit</p>  
(Los Angeles Division) 

<p itemprop="adr">10201 W. Pico Blvd.<br>Los Angeles, CA<br>90064<br>United States</p>  

<p itemprop="geo">34.052339;-118.410623</p>  

<h2>Assorted Contact Methods</h2>  

<ul>  
<li itemprop="tel">+1 (310) 597 3781 <span itemprop="type" content="voice">work</span></li>  
<li><a itemprop="url" href="https://en.wikipedia.org/wiki/Jack_Bauer">I'm on Wikipedia so you can leave a message on my user talk page.</a></li>  
<li itemprop="email"><a href="mailto:j.bauer@la.ctu.gov.invalid">j.bauer@la.ctu.gov.invalid</a></li>  
<li itemprop="tel">+1 (310) 555 3781 <span itemprop="type" content="cell">mobile phone</span></li>
</ul>  

<ins datetime="2008-07-20 21:00:00+01:00">  
<p itemprop="tel"><strong>Update!</strong> My new <span itemprop="type">home</span> phone number is 01632 960 123.</p>
</ins>  

The odd line wrapping is needed because newlines are meaningful in microdata: newlines would be preserved in a conversion to, for example, the vCard format.

This example shows a site's contact details (using the address element) containing an address with two street components:
The vCard vocabulary can be used to just mark up people's names:

```
BEGIN:VCARD
PROFILE:VCARD
VERSION:4.0
SOURCE: document's address
FN: George Washington
N: Washington; George; ;
END:VCARD
```

This creates a single item with a two name-value pairs, one with the name “fn” and the value “George Washington”, and the other with the name “n” and a second item as its value, the second item having the two name-value pairs “given-name” and “family-name” with the values “George” and “Washington” respectively. This is defined to map to the following vCard:

5.3.25.3.2

vEvent

An item with the item type `http://microformats.org/profile/hcalendar#vevent` represents an event.

This vocabulary does not support global identifiers for items.

The following are the type's defined property names. They are based on the vocabulary defined in Internet Calendaring and Scheduling Core Object Specification (iCalendar), where more information on how to interpret the values can be found. [RFC5545]

Only the parts of the iCalendar vocabulary relating to events are used here; this vocabulary cannot express a complete iCalendar instance.
**attach**

Gives the address of an associated document for the event.

The value must be an absolute URL.

Any number of properties with the name attach may be present within each item with the type [http://microformats.org/profile/hcalendar#vevent](http://microformats.org/profile/hcalendar#vevent).

**categories**

Gives the name of a category or tag that the event could be classified as.

The value must be text.

Any number of properties with the name categories may be present within each item with the type [http://microformats.org/profile/hcalendar#vevent](http://microformats.org/profile/hcalendar#vevent).

**class**

Gives the access classification of the information regarding the event.

The value must be text with one of the following values:

- public
- private
- confidential

This is merely advisory and cannot be considered a confidentiality measure.

A single property with the name class may be present within each item with the type [http://microformats.org/profile/hcalendar#vevent](http://microformats.org/profile/hcalendar#vevent).

**comment**

Gives a comment regarding the event.

The value must be text.

Any number of properties with the name comment may be present within each item with the type [http://microformats.org/profile/hcalendar#vevent](http://microformats.org/profile/hcalendar#vevent).

**description**

Gives a detailed description of the event.

The value must be text.
A single property with the name **description** may be present within each **item** with the type `http://microformats.org/profile/hcalendar#vevent`.

**geo**

Gives the geographical position of the event.

The **value** must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more **ASCII** digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more **ASCII** digits.
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more **ASCII** digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more **ASCII** digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

The value specifies latitude and longitude, in that order (i.e., “LAT LON” ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

A single property with the name **geo** may be present within each **item** with the type `http://microformats.org/profile/hcalendar#vevent`.

**location**

Gives the location of the event.

The **value** must be text.

A single property with the name **location** may be present within each **item** with the type `http://microformats.org/profile/hcalendar#vevent`.

**resources**

Gives a resource that will be needed for the event.

The **value** must be text.

Any number of properties with the name **resources** may be present within each **item**.
with the type http://microformats.org/profile/hcalendar#vevent.

**status**

Gives the confirmation status of the event.

The **value** must be text with one of the following values:

- tentative
- confirmed
- cancelled

A single property with the name **status** may be present within each **item** with the type http://microformats.org/profile/hcalendar#vevent.

**summary**

Gives a short summary of the event.

The **value** must be text.

User agents should replace U+000A LINE FEED (LF) characters in the **value** by U+0020 SPACE characters when using the value.

A single property with the name **summary** may be present within each **item** with the type http://microformats.org/profile/hcalendar#vevent.

**dtend**

Gives the date and time by which the event ends.

If the property with the name **dtend** is present within an **item** with the type http://microformats.org/profile/hcalendar#vevent that has a property with the name **dtstart** whose value is a valid date string, then the **value** of the property with the name **dtend** must be text that is a valid date string also. Otherwise, the **value** of the property must be text that is a valid global date and time string.

In either case, the **value** be later in time than the value of the **dtstart** property of the same **item**.

The time given by the **dtend** property is not inclusive. For day-long events, therefore, the **dtend** property’s **value** will be the day after the end of the event.

A single property with the name **dtend** may be present within each **item** with the type http://microformats.org/profile/hcalendar#vevent, so long as that http://microformats.org/profile/hcalendar#vevent does not have a property with the name **duration**.
**dtstart**

Gives the date and time at which the event starts.

The *value* must be text that is either a *valid date string* or a *valid global date and time string*.

Exactly one property with the name **dtstart** must be present within each *item* with the type **http://microformats.org/profile/hcalendar#vevent**.

**duration**

Gives the duration of the event.

The *value* must be text that is a *valid vevent duration string*.

The duration represented is the sum of all the durations represented by integers in the value.

A single property with the name **duration** may be present within each *item* with the type **http://microformats.org/profile/hcalendar#vevent**, so long as that **http://microformats.org/profile/hcalendar#vevent** does not have a property with the name **dtend**.

**transp**

Gives whether the event is to be considered as consuming time on a calendar, for the purpose of free-busy time searches.

The *value* must be text with one of the following values:

- opaque
- transparent

A single property with the name **transp** may be present within each *item* with the type **http://microformats.org/profile/hcalendar#vevent**.

**contact**

Gives the contact information for the event.

The *value* must be text.

Any number of properties with the name **contact** may be present within each *item* with the type **http://microformats.org/profile/hcalendar#vevent**.
url

Gives a [URL](http://microformats.org/profile/hcalendar#vevent) for the event.

The value must be an absolute URL.

A single property with the name `url` may be present within each item with the type `http://microformats.org/profile/hcalendar#vevent`.

uid

Gives a globally unique identifier corresponding to the event.

The value must be text.

A single property with the name `uid` may be present within each item with the type `http://microformats.org/profile/hcalendar#vevent`.

exdate

Gives a date and time at which the event does not occur despite the recurrence rules.

The value must be text that is either a valid date string or a valid global date and time string.

Any number of properties with the name `exdate` may be present within each item with the type `http://microformats.org/profile/hcalendar#vevent`.

rdate

Gives a date and time at which the event recurs.

The value must be text that is one of the following:

- A valid date string.
- A valid global date and time string.
- A valid global date and time string followed by a U+002F SOLIDUS character (/) followed by a second valid global date and time string representing a later time.
- A valid global date and time string followed by a U+002F SOLIDUS character (/) followed by a valid vevent duration string.

Any number of properties with the name `rdate` may be present within each item with the type `http://microformats.org/profile/hcalendar#vevent`.

rrule

Gives a rule for finding dates and times at which the event occurs.
The value must be text that matches the RECUR value type defined in iCalendar. [RFC5545]

A single property with the name rrule may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

**created**

Gives the date and time at which the event information was first created in a calendaring system.

The value must be text that is a valid global date and time string.

A single property with the name created may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

**last-modified**

Gives the date and time at which the event information was last modified in a calendaring system.

The value must be text that is a valid global date and time string.

A single property with the name last-modified may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

**sequence**

Gives a revision number for the event information.

The value must be text that is a valid non-negative integer.

A single property with the name sequence may be present within each item with the type http://microformats.org/profile/hcalendar#vevent.

A string is a valid vevent duration string if it matches the following pattern:

1. A U+0050 LATIN CAPITAL LETTER P character (P).
2. One of the following:
   - A valid non-negative integer followed by a U+0057 LATIN CAPITAL LETTER W character (W). The integer represents a duration of that number of weeks.
   - At least one, and possible both in this order, of the following:
     1. A valid non-negative integer followed by a U+0044 LATIN CAPITAL LETTER D character (D). The integer represents a duration of that number of days.
     2. A U+0054 LATIN CAPITAL LETTER T character (T) followed by any one of the following, or the first and second of the following in that order, or the second and third of the following in that order, or all three
of the following in this order:

1. A valid non-negative integer followed by a U+0048 LATIN CAPITAL LETTER H character (H). The integer represents a duration of that number of hours.
2. A valid non-negative integer followed by a U+004D LATIN CAPITAL LETTER M character (M). The integer represents a duration of that number of minutes.
3. A valid non-negative integer followed by a U+0053 LATIN CAPITAL LETTER S character (S). The integer represents a duration of that number of seconds.

5.3.2.1 Conversion to iCalendar

Given a list of nodes nodes in a Document, a user agent must run the following algorithm to extract any vEvent data represented by those nodes:

1. If none of the nodes in nodes are items with the type http://microformats.org/profile/hcalendar#vevent, then there is no vEvent data. Abort the algorithm, returning nothing.
2. Let output be an empty string.
3. Add an iCalendar line with the type “BEGIN” and the value “VCALENDAR” to output.
4. Add an iCalendar line with the type “PRODID” and the value equal to a user-agent-specific string representing the user agent to output.
5. Add an iCalendar line with the type “VERSION” and the value “2.0” to output.
6. For each node node in nodes that is an item with the type http://microformats.org/profile/hcalendar#vevent, run the following steps:
   1. Add an iCalendar line with the type “BEGIN” and the value “VEVENT” to output.
   2. Add an iCalendar line with the type “DTSTAMP” and a value consisting of an iCalendar DATE-TIME string representing the current date and time, with the annotation “VALUE=DATE-TIME”, to output. [RFC5545]
   3. For each element element that is a property of the item node: for each name name in element’s property names, run the appropriate set of substeps from the following list:

      If the property’s value is an item

      Skip the property.
If the property is \texttt{dtend}
If the property is \texttt{dtstart}
If the property is \texttt{exdate}
If the property is \texttt{rdate}
If the property is \texttt{created}
If the property is \texttt{last-modified}

Let \textit{value} be the result of stripping all U+002D HYPHEN-MINUS (-) and U+003A COLON (: characters from the property’s \textit{value}.

If the property’s \textit{value} is a valid date string then \textbf{add an iCalendar line} with the type \textit{name} and the value \textit{value} to \textit{output}, with the annotation “VALUE=DATE”.

Otherwise, if the property’s \textit{value} is a valid global date and time string then \textbf{add an iCalendar line} with the type \textit{name} and the value \textit{value} to \textit{output}, with the annotation “VALUE=DATE-TIME”.

Otherwise skip the property.

Otherwise

\textbf{Add an iCalendar line} with the type \textit{name} and the property’s \textit{value} to \textit{output}.

4. \textbf{Add an iCalendar line} with the type “END” and the value “VEVENT” to \textit{output}.

7. \textbf{Add an iCalendar line} with the type “END” and the value “VCALENDAR” to \textit{output}.

When the above algorithm says that the user agent is to \textbf{add an iCalendar line} consisting of a type \textit{type}, a value \textit{value}, and optionally an annotation, to a string \textit{output}, it must run the following steps:

1. Let \textit{line} be an empty string.

2. Append \textit{type}, converted to ASCII uppercase, to \textit{line}.

3. If there is an annotation:

   1. Append a U+003B SEMICOLON character (;) to \textit{line}.

   2. Append the annotation to \textit{line}.

4. Append a U+003A COLON character (:) to \textit{line}.

5. Prefix every U+005C REVERSE SOLIDUS character (\) in \textit{value} with another U+005C REVERSE SOLIDUS character (\).
6. Prefix every U+002C COMMA character (,) in value with a U+005C REVERSE SOLIDUS character (\).

7. Prefix every U+003B SEMICOLON character (;) in value with a U+005C REVERSE SOLIDUS character (\).

8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in value with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in value with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

10. Append value to line.

11. Let maximum length be 75.

12. While line's code point length is greater than maximum length:
   1. Append the first maximum length code points of line to output.
   2. Remove the first maximum length code points from line.
   3. Append a U+000D CARRIAGE RETURN character (CR) to output.
   4. Append a U+000A LINE FEED character (LF) to output.
   5. Append a U+0020 SPACE character to output.
   6. Let maximum length be 74.

13. Append (what remains of) line to output.

14. Append a U+000D CARRIAGE RETURN character (CR) to output.

15. Append a U+000A LINE FEED character (LF) to output.

This algorithm can generate invalid iCalendar output, if the input does not conform to the rules described for the [http://microformats.org/profile/hcalendar#vevent item type](http://microformats.org/profile/hcalendar#vevent) and defined property names.

5.3.2.2 Examples

This section is non-normative.

Here is an example of a page that uses the vEvent vocabulary to mark up an event:
Bluesday Tuesday: Money Road

May 5th @ 7pm (until 9pm)

Location: The RoadHouse

See this event on livebrum.co.uk

5.3.3 Licensing works

An item with the item type `http://n.whatwg.org/work` represents a work (e.g. an article, an image, a video, a song, etc.). This type is primarily intended to allow authors to include licensing information for works.

The following are the type’s defined property names.

work

Identifies the work being described.

The value must be an absolute URL.
Exactly one property with the name work must be present within each item with the type http://n.whatwg.org/work.

**title**

Gives the name of the work.

A single property with the name title may be present within each item with the type http://n.whatwg.org/work.

**author**

Gives the name or contact information of one of the authors or creators of the work.

The value must be either an item with the type http://microformats.org/profile/hcard, or text.

Any number of properties with the name author may be present within each item with the type http://n.whatwg.org/work.

**license**

Identifies one of the licenses under which the work is available.

The value must be an absolute URL.

Any number of properties with the name license may be present within each item with the type http://n.whatwg.org/work.

5.3.3.1 Examples

This section is non-normative.

This example shows an embedded image entitled My Pond, licensed under the Creative Commons Attribution-Share Alike 4.0 International License and the MIT license simultaneously.

```html
<figure itemscope itemtype="http://n.whatwg.org/work">
  <img itemprop="work" src="mypond.jpeg">
  <figcaption>
    <p><cite itemprop="title">My Pond</cite></p>
    <p><small>Licensed under the <a itemprop="license" href="https://creativecommons.org/licenses/by-sa/4.0/">Creative Commons Attribution-Share Alike 4.0 International License</a> and the <a itemprop="license" href="http://www.opensource.org/licenses/mit-license.php">MIT license</a>.</small>
  </figcaption>
</figure>
```
5.4 Converting HTML to other formats

5.4.1 JSON

Given a list of nodes nodes in a Document, a user agent must run the following algorithm to extract the microdata from those nodes into a JSON form:

1. Let result be an empty object.
2. Let items be an empty array.
3. For each node in nodes, check if the element is a top-level microdata item, and if it is then get the object for that element and add it to items.
4. Add an entry to result called "items" whose value is the array items.
5. Return the result of serializing result to JSON in the shortest possible way (meaning no whitespace between tokens, no unnecessary zero digits in numbers, and only using Unicode escapes in strings for characters that do not have a dedicated escape sequence), and with a lowercase "e" used, when appropriate, in the representation of any numbers. [JSON]

This algorithm returns an object with a single property that is an array, instead of just returning an array, so that it is possible to extend the algorithm in the future if necessary.

When the user agent is to get the object for an item item, optionally with a list of elements memory, it must run the following substeps:

1. Let result be an empty object.
2. If no memory was passed to the algorithm, let memory be an empty list.
3. Add item to memory.
4. If the item has any item types, add an entry to result called "type" whose value is an array listing the item types of item, in the order they were specified on the itemType attribute.
5. If the item has a global identifier, add an entry to result called "id" whose value is the global identifier of item.
6. Let properties be an empty object.
7. For each element element that has one or more property names and is one of the
properties of the item item, in the order those elements are given by the algorithm that returns the properties of an item, run the following substeps:

1. Let value be the property value of element.

2. If value is an item, then: If value is in memory, then let value be the string “ERROR”. Otherwise, get the object for value, passing a copy of memory, and then replace value with the object returned from those steps.

3. For each name name in element’s property names, run the following substeps:
   1. If there is no entry named name in properties, then add an entry named name to properties whose value is an empty array.
   2. Append value to the entry named name in properties.

8. Add an entry to result called "properties" whose value is the object properties.

9. Return result.

For example, take this markup:

```html
<!DOCTYPE HTML>
<html lang="en">
<title>My Blog</title>
<article itemscope itemtype="http://schema.org/BlogPosting">
  <header>
    <h1 itemprop="headline">Progress report</h1>
    <p><time itemprop="datePublished" datetime="2013-08-29">today</time></p>
    <link itemprop="url" href="/comments=0" />
  </header>
  <p>All in all, he's doing well with his swim lessons. The biggest thing was he had trouble putting his head in, but we got it down.</p>
</article>
<article itemscope itemtype="http://schema.org/UserComments">
  <footer>
    <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
        <span itemprop="name">Greg</span>
      </span>
  </footer>
  <p>Ha!</p>
</article>
<article itemscope itemtype="http://schema.org/UserComments">
  <footer>
    <p>15 minutes ago</p>
    <p>Ha!</p>
  </footer>
</article>
```

When you say "we got it down"...

It would be turned into the following JSON by the algorithm above (supposing that the page’s URL was https://blog.example.com/progress-report):

```json
{
  "items": [
    {
      "type": [ "http://schema.org/BlogPosting" ],
      "properties": {
        "headline": [ "Progress report" ],
        "datePublished": [ "2013-08-29" ],
        "url": [ "https://blog.example.com/progress-report?comments=0" ],
        "comment": [ {
          "type": [ "http://schema.org/UserComments" ],
          "properties": {
            "url": [ "https://blog.example.com/progress-report#c1" ],
            "creator": [
              {
                "type": [ "http://schema.org/Person" ],
                "properties": {
                  "name": [ "Greg" ]
                }
              }
            ],
            "commentTime": [ "2013-08-29" ]
          }
        } ],
      }
    },
    {
      "type": [ "http://schema.org/UserComments" ],
      "properties": {
        "url": [ "https://blog.example.com/progress-report#c2" ],
        "creator": [
          {
            "type": [ "http://schema.org/Person" ],
            "properties": {
              "name": [ "Charlotte" ]
            }
          }
        ]
      }
    }
  ]
}
```
6 User interaction

6.1 The `hidden` attribute

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>Yes</td>

</tr>
</tbody>
</table>

All HTML elements may have the `hidden` content attribute set. The `hidden` attribute is a boolean attribute. When specified on an element, it indicates that the element is not yet, or is no longer, directly relevant to the page’s current state, or that it is being used to declare content to be reused by other parts of the page as opposed to being directly accessed by the user. User agents should not render elements that have the `hidden` attribute specified. This requirement may be implemented indirectly through the style layer. For example, an HTML+CSS user agent could implement these requirements using the rules suggested in the Rendering section.

Because this attribute is typically implemented using CSS, it’s also possible to override it using CSS. For instance, a rule that applies ‘display: block’ to all elements will cancel the effects of the `hidden` attribute. Authors therefore have to take care when writing their style sheets to make sure that the attribute is still styled as expected.

In the following skeletal example, the attribute is used to hide the web game’s main screen until the user logs in:

```html
<h1>The Example Game</h1>
<section id="login">
  <h2>Login</h2>
```
The `hidden` attribute must not be used to hide content that could legitimately be shown in another presentation. For example, it is incorrect to use `hidden` to hide panels in a tabbed dialog, because the tabbed interface is merely a kind of overflow presentation — one could equally well just show all the form controls in one big page with a scrollbar. It is similarly incorrect to use this attribute to hide content just from one presentation — if something is marked `hidden`, it is hidden from all presentations, including, for instance, screen readers.

Elements that are not themselves `hidden` must not hyperlink to elements that are `hidden`. The `for` attributes of `label` and `output` elements that are not themselves `hidden` must similarly not refer to elements that are `hidden`. In both cases, such references would cause user confusion.

Elements and scripts may, however, refer to elements that are `hidden` in other contexts.

For example, it would be incorrect to use the `href` attribute to link to a section marked with the `hidden` attribute. If the content is not applicable or relevant, then there is no reason to link to it.

It would be fine, however, to use the ARIA `aria-describedby` attribute to refer to descriptions that are themselves `hidden`. While hiding the descriptions implies that they are not useful alone, they could be written in such a way that they are useful in the specific context of being referenced from the elements that they describe.

Similarly, a `canvas` element with the `hidden` attribute could be used by a scripted graphics engine as an off-screen buffer, and a form control could refer to a hidden `form` element using its `form` attribute.

Elements in a section hidden by the `hidden` attribute are still active, e.g. scripts and form controls in such sections still execute and submit respectively. Only their presentation to the user changes.
**hidden** IDL attribute must reflect the content attribute of the same name.

### 6.2 Page visibility

A top-level browsing context has a system visibility state, which is either "hidden" or "visible".

The system visibility state is determined by the user-agent, and represents, for example, whether the browser window is minimized, a browser tab is currently in the background, or a system element such as a task switcher obscures the page.

When a user-agent determines that the system visibility state for top-level browsing context context has changed to newState, it must queue a task on the user interaction task source to update the visibility state of all the Document objects in the top-level browsing context’s document family with newState.

A Document has a visibility state, which is either "hidden" or "visible", initially set to "hidden".

The visibilityState getter steps are to return this’s visibility state.

The hidden getter steps are to return true if this’s visibility state is “hidden”, otherwise false.

To update the visibility state of Document document to visibilityState:

1. If document’s visibility state equals visibilityState, then return.
2. Set document’s visibility state to visibilityState.
3. Run any page visibility change steps which may be defined in other specificactions, with visibility state and document.

It would be better if specification authors sent a pull request to add calls from here into their specifications directly, instead of using the page visibility change steps hook, to ensure well-defined cross-specification call order. As of the time of this writing the
following specifications are known to have page visibility change steps, which will be run in an unspecified order: Device Posture API, Screen Orientation API, and Web NFC. [DEVICEPOSTURE] [SCREENORIENTATION] [WEBNFC]

4. Fire an event named visibilitychange at document, with its bubbles attribute initialized to true.

6.3 Inert subtrees

This section does not define or create any content attribute named “inert”. This section merely defines an abstract concept of inertness.

A node (in particular elements and text nodes) can be marked as inert. When a node is inert, then the user agent must act as if the node was absent for the purposes of targeting user interaction events, may ignore the node for the purposes of find-in-page, and may prevent the user from selecting text in that node. User agents should allow the user to override the restrictions on search and text selection, however.

For example, consider a page that consists of just a single inert paragraph positioned in the middle of a body. If a user moves their pointing device from the body over to the inert paragraph and clicks on the paragraph, no mouseover event would be fired, and the mousemove and click events would be fired on the body element rather than the paragraph.

When a node is inert, it generally cannot be focused. Inert nodes that are commands will also get disabled.

While a browsing context container is marked as inert, its nested browsing context’s active document, and all nodes in that Document, must be marked as inert.

An element is expressly inert if it is inert and its node document is not inert.

A Document document is blocked by a modal dialog subject if subject is the topmost dialog element in document’s top layer. While document is so blocked, every node that is connected to document, with the exception of the subject element and its shadow-including descendants, must be marked inert. (The elements excepted by this paragraph can additionally be marked inert through other means; being part of a modal dialog does not “protect” a node from being marked inert.)

The dialog element’s showModal() method causes this mechanism to trigger, by adding the dialog element to its node document’s top layer.

6.4 Tracking user activation

To prevent abuse of certain APIs that could be annoying to users (e.g., opening popups or vibrating phones), user agents allow these APIs only when the user is actively interacting with the web page or has interacted with the page at least once. This “active interaction” state is maintained through the mechanisms defined in this section.
6.4.1 Data model

For the purpose of tracking user activation, each Window W has a last activation timestamp. This is a number indicating the last time W got an activation notification. It corresponds to a DOMHighResTimeStamp value except for two cases: positive infinity indicates that W has never been activated, while negative infinity indicates that a user activation-gated API has consumed the last user activation of W. The initial value is positive infinity.

A user agent also defines a transient activation duration, which is a constant number indicating how long a user activation is available for certain user activation-gated APIs (e.g., for opening popups).

The transient activation duration is expected be at most a few seconds, so that the user can possibly perceive the link between an interaction with the page and the page calling the activation-gated API.

These two values imply two boolean user activation states for W:

**Sticky activation**

When the current high resolution time is greater than or equal to the last activation timestamp in W, W is said to have sticky activation.

This is W's historical activation state, indicating whether the user has ever interacted in W. It starts false, then changes to true (and never changes back to false) when W gets the very first activation notification.

**Transient activation**

When the current high resolution time is greater than or equal to the last activation timestamp in W, and less than the last activation timestamp in W plus the transient activation duration, then W is said to have transient activation.

This is W's current activation state, indicating whether the user has interacted in W recently. This starts with a false value, and remains true for a limited time after every activation notification W gets.

The transient activation state is considered expired if it becomes false because the transient activation duration time has elapsed since the last user activation. Note that it can become false even before the expiry time through an activation consumption.

6.4.2 Processing model

When a user interaction in a browsing context B causes firing of an activation triggering input event in B's active document D, the user agent must perform the following activation notification steps before dispatching the event:
1. Let \( \text{browsingContexts} \) be a list consisting of:
   - \( B \),
   - all \textit{ancestor browsing contexts} of \( B \), and
   - all the \textit{descendant browsing contexts} of \( D \) that have \textit{active documents} from the \textit{same origin} as that of \( D \).

2. Let \( \text{windows} \) be the list of \textit{Window} objects constructed by taking the \textit{active window} of each item in \textit{browsingContexts}.

3. For each \textit{window} in \textit{windows}, set \textit{window}'s \textit{last activation timestamp} to the \textit{current high resolution time}.

An activation \textit{triggering input event} is any event whose \textit{isTrusted} attribute is true and whose \textit{type} is one of:

- \textit{keydown}, provided the key is neither the Esc key nor a shortcut key reserved by the user agent.
- \textit{mousedown}.
- \textit{pointerdown}, provided the event’s \textit{PointerType} is “mouse”.
- \textit{pointerup}, provided the event’s \textit{PointerType} is not “mouse”.
- \textit{touchend}.

Activation consuming APIs defined in this and other specifications can \textit{consume user activation} by performing the following steps, given a \textit{Window} \( W \):

1. If \( W \)'s \textit{browsing context} is null, then return.

2. Let \( \text{top} \) be \( W \)'s \textit{browsing context}'s top-level \textit{browsing context}.

3. Let \textit{browsingContexts} be the list of the \textit{descendant browsing contexts} of \textit{top}'s \textit{active document}.

4. Append \( \text{top} \) to \textit{browsingContexts}.

5. Let \textit{windows} be the list of \textit{Window} objects constructed by taking the \textit{active window} of each item in \textit{browsingContexts}.

6. For each \textit{window} in \textit{windows}, if \textit{window}'s \textit{last activation timestamp} is not positive infinity, then set \textit{window}'s \textit{last activation timestamp} to negative infinity.

The spec is not clear about how to traverse a tree of documents. See \textit{issue #5020}.

Note the asymmetry in the sets of \textit{browsing contexts} in the page that are affected by an activation notification \textit{vs} an activation consumption: an activation consumption changes (to false) the \textit{transient activation} states for all browsing contexts in the page, but an activation
notification changes (to true) the states for a subset of those browsing contexts. The exhaustive nature of consumption here is deliberate: it prevents malicious sites from making multiple calls to an activation consuming API from a single user activation (possibly by exploiting a deep hierarchy of iframes).

6.4.3 APIs gated by user activation

APIs that are dependent on user activation are classified into three different levels. The levels are as follows, sorted by their “strength of dependence” on user activation (from weakest to strongest):

*Sticky activation-gated APIs*

These APIs require the sticky activation state to be true, so they are blocked until the very first user activation.

*Transient activation-gated APIs*

These APIs require the transient activation state to be true, but they don’t consume it, so multiple calls are allowed per user activation until the transient state expires.

*Transient activation-consuming APIs*

These APIs require the transient activation state to be true, and they consume user activation in each call to prevent multiple calls per user activation.

6.5 Activation behavior of elements

Certain elements in HTML have an activation behavior, which means that the user can activate them. This is always caused by a click event.

The user agent should allow the user to manually trigger elements that have an activation behavior, for instance using keyboard or voice input, or through mouse clicks. When the user triggers an element with a defined activation behavior in a manner other than clicking it, the default action of the interaction event must be to fire a click event at the element.

element.click()

Support in all current engines.

Acts as if the element was clicked.

Each element has an associated `click in progress flag`, which is initially unset.

The `click()` method must run the following steps:

1. If this element is a form control that is `disabled`, then return.
2. If this element’s `click in progress flag` is set, then return.
3. Set this element’s `click in progress flag`.
4. Fire a synthetic pointer event named `click` at this element, with the `not trusted flag` set.
5. Unset this element’s `click in progress flag`.

6.6 Focus

6.6.1 Introduction

This section is non-normative.

An HTML user interface typically consists of multiple interactive widgets, such as form controls, scrollable regions, links, dialog boxes, browser tabs, and so forth. These widgets form a hierarchy, with some (e.g. browser tabs, dialog boxes) containing others (e.g. links, form controls).

When interacting with an interface using a keyboard, key input is channeled from the system, through the hierarchy of interactive widgets, to an active widget, which is said to be `focused`.

Consider an HTML application running in a browser tab running in a graphical environment. Suppose this application had a page with some text controls and links, and was currently showing a modal dialog, which itself had a text control and a button.

The hierarchy of focusable widgets, in this scenario, would include the browser window, which would have, amongst its children, the browser tab containing the HTML application. The tab itself would have as its children the various links and text controls, as well as the dialog. The dialog itself would have as its children the text control and the button.
If the widget with focus in this example was the text control in the dialog box, then key input would be channeled from the graphical system to ① the web browser, then to ② the tab, then to ③ the dialog, and finally to ④ the text control.

Keyboard events are always targeted at this focused element.

6.6.2 Data model

A top-level browsing context has system focus when it can receive keyboard input channeled from the operating system.

System focus is lost when a browser window loses focus, but might also be lost to other system widgets in the browser window such as a URL bar.

The term focusable area is used to refer to regions of the interface that can further become the target of such keyboard input. Focusable areas can be elements, parts of elements, or other regions managed by the user agent.

Each focusable area has a DOM anchor, which is a Node object that represents the position of the focusable area in the DOM. (When the focusable area is itself a Node, it is its own DOM anchor.) The DOM anchor is used in some APIs as a substitute for the focusable area when there is no other DOM object to represent the focusable area.
The following table describes what objects can be *focusable areas*. The cells in the left column describe objects that can be *focusable areas*; the cells in the right column describe the **DOM anchors** for those elements. (The cells that span both columns are non-normative examples.)

<table>
<thead>
<tr>
<th>Focusable area</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Elements that meet all the following criteria:</td>
<td></td>
</tr>
<tr>
<td>• the element’s <strong>tabindex value</strong> is non-null, or the element is determined by the user agent to be focusable;</td>
<td></td>
</tr>
<tr>
<td>• the element is either not a <strong>shadow host</strong>, or has a <strong>shadow root</strong> whose <strong>delegates focus</strong> is false;</td>
<td></td>
</tr>
<tr>
<td>• the element is not <strong>actually disabled</strong>;</td>
<td></td>
</tr>
<tr>
<td>• the element is not <strong>expressly inert</strong>;</td>
<td></td>
</tr>
<tr>
<td>• the element is either <strong>being rendered</strong> or <strong>being used as relevant canvas fallback content</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

*iframe, <input type=text>*, sometimes `<a href=""` (depending on platform conventions).

The shapes of **area** elements in an **image map** associated with an **img** element that is **being rendered** and is not **expressly inert**. The **img** element.

In the following example, the **area** element creates two shapes, one on each image. The **DOM anchor** of the first shape is the first **img** element, and the **DOM anchor** of the second shape is the second **img** element.

```html
<map id=wallmap>
  <area alt="Enter Door" coords="10,10,100,200" href="door.html"...
  <img src="images/innerwall.jpeg" alt="There is a white wall here, with a door."
    ...
  <img src="images/outerwall.jpeg" alt="There is a red wall here, with a door."
  ...
</map>
```

The user-agent provided subwidgets of elements that are **being rendered** and are not **actually disabled** or **expressly inert**. The element is a subwidget.

The **controls in the user interface** for a **video** element, the up and down buttons in a spin-control version...
Focusable area

**Examples**

- `type=number>`, the part of a `details` element’s rendering that enables the element to be opened or closed using keyboard input.

The scrollable regions of elements that are being rendered and are not expressly inert.

The CSS ‘overflow’ property’s ‘scroll’ value typically creates a scrollable region.

The viewport of a `Document` that has a non-null `browsing context` and is not inert.

The contents of an `iframe`.

Any other element or part of an element determined by the user agent to be a focusable area, especially to aid with accessibility or to better match platform conventions.

A user agent could make all list item bullets sequentially focusable, so that a user can more easily navigate lists.

Similarly, a user agent could make all elements with `title` attributes sequentially focusable, so that the advisory information can be accessed.

A `browsing context container` (e.g. an `iframe`) is a focusable area, but key events routed to a `browsing context container` get immediately routed to its nested `browsing context`’s active document. Similarly, in sequential focus navigation a `browsing context container` essentially acts merely as a placeholder for its nested `browsing context`’s active document.

One focusable area in each `Document` is designated the **focused area of the document**. Which control is so designated changes over time, based on algorithms in this specification.
Even if a document is not **fully active** and not shown to the user, it can still have a **focused area of the document**. If a document’s **fully active** state changes, its **focused area of the document** will stay the same.

The **currently focused area of a top-level browsing context** `topLevelBC` at any particular time is the **focusable area** or-null returned by this algorithm:

1. If `topLevelBC` does not have **system focus**, then return null.
2. Let `candidate` be `topLevelBC`’s **active document**.
3. While `candidate`’s **focused area** is a browsing context container with a non-null nested browsing context: set `candidate` to the **active document** of that browsing context container’s nested browsing context.
4. If `candidate`’s **focused area** is non-null, set `candidate` to `candidate`’s **focused area**.
5. Return `candidate`.

The **current focus chain of a top-level browsing context** `topLevelBC` at any particular time is the **focus chain** of the **currently focused area** of `topLevelBC`, if `topLevelBC` is non-null, or an empty list otherwise.

An element that is the DOM anchor of a **focusable area** is said to **gain focus** when that **focusable area** becomes the **currently focused area** of a top-level browsing context. When an element is the **DOM anchor** of a **focusable area** of the **currently focused area** of a top-level browsing context, it is **focused**.

The **focus chain** of a **focusable area** **subject** is the ordered list constructed as follows:

1. Let `output` be an empty list.
2. Let `currentObject` be `subject`.
3. While true:
   1. **Append** `currentObject` to `output`.
   2. If `currentObject` is an **area** element’s shape, then **append** that **area** element to `output`.

      Otherwise, if `currentObject`’s **DOM anchor** is an element that is not `currentObject` itself, then **append** `currentObject`’s **DOM anchor** to `output`.

   3. If `currentObject` is a **focusable area**, then set `currentObject` to `currentObject`’s **DOM anchor**’s node document.

      Otherwise, if `currentObject` is a **Document** whose **browsing context** is a **child**
browsing context, then set `currentObject` to `currentObject`’s browsing context’s container.

Otherwise, `break`.

4. Return `output`.

The chain starts with `subject` and (if `subject` is or can be the currently focused area of a top-level browsing context) continues up the focus hierarchy up to the `Document` of the top-level browsing context.

All elements that are `focusable areas` are said to be `focusable`.

There are two special types of focusability for `focusable areas`:

- A `focusable area` is said to be `sequentially focusable` if it is included in its `Document`’s sequential focus navigation order and the user agent determines that it is sequentially focusable.

- A `focusable area` is said to be `click focusable` if the user agent determines that it is click focusable. User agents should consider focusable areas with non-null `tabindex values` to be click focusable.

Elements which are not `focusable` are not `focusable areas`, and thus not `sequentially focusable` and not `click focusable`.

Being `focusable` is a statement about whether an element can be focused programmatically, e.g. via the `focus()` method or `autofocus` attribute. In contrast, `sequentially focusable` and `click focusable` govern how the user agent responds to user interaction: respectively, to `sequential focus navigation` and as `activation behavior`.

The user agent might determine that an element is not `sequentially focusable` even if it is `focusable` and is included in its `Document`’s sequential focus navigation order, according to user preferences. For example, macOS users can set the user agent to skip non-form control elements, or can skip links when doing `sequential focus navigation` with just the Tab key (as opposed to using both the Option and Tab keys).

Similarly, the user agent might determine that an element is not `click focusable` even if it is `focusable`. For example, in some user agents, clicking on a non-editable form control does not focus it, i.e. the user agent has determined that such controls are not click focusable.

Thus, an element can be `focusable`, but neither `sequentially focusable` nor `click focusable`. For example, in some user agents, a non-editable form-control with a negative-integer `tabindex value` would not be focusable via user interaction, only via programmatic APIs.

When a user activates a `click focusable focusable area`, the user agent must run the `focusing steps` on the `focusable area` with focus trigger set to "click".
Note that focusing is not an activation behavior, i.e. calling the `click()` method on an element or dispatching a synthetic `click` event on it won’t cause the element to get focused.

A node is a focus navigation scope owner if it is a document, a shadow host or a slot.

Each focus navigation scope owner has a focus navigation scope, which is a list of elements. Its contents are determined as follows:

Every element element has an associated focus navigation owner, which is either null or a focus navigation scope owner. It is determined by the following algorithm:

1. If element’s parent is null, then return null.
2. If element’s parent is a shadow host, then return element’s assigned slot.
3. If element’s parent is a shadow root, then return the parent’s host.
4. If element’s parent is the document element, then return the parent’s node document.
5. Return element’s parent’s associated focus navigation owner.

Then, the contents of a given focus navigation scope owner owner’s focus navigation scope are all elements whose associated focus navigation owner is owner.

The order of elements within a focus navigation scope does not impact any of the algorithms in this specification. Ordering only becomes important for the tabindex-ordered focus navigation scope and flattened tabindex-ordered focus navigation scope concepts defined below.

A tabindex-ordered focus navigation scope is a list of focusable areas and focus navigation scope owners. Every focus navigation scope owner owner has a tabindex-ordered focus navigation scope, whose contents are determined as follows:

- It contains all elements in owner’s focus navigation scope that are themselves focus navigation scope owners, except the elements whose tabindex value is a negative integer.
- It contains all of the focusable areas whose DOM anchor is an element in owner’s focus navigation scope, except the focusable areas whose tabindex value is a negative integer.

The order within a tabindex-ordered focus navigation scope is determined by each element’s tabindex value, as described in the section below.

The rules there do not give a precise ordering, as they are composed mostly of "should" statements and relative orderings.

A flattened tabindex-ordered focus navigation scope is a list of focusable areas. Every focus navigation scope owner owner owns a distinct flattened tabindex-ordered focus navigation
scope, whose contents are determined by the following algorithm:

1. Let result be a clone of owner’s tabindex-ordered focus navigation scope.

2. For each item of result:
   
   1. If item is not a focus navigation scope owner, then continue.
   
   2. If item is not a focusable area, then replace item with all of the items in item’s flattened tabindex-ordered focus navigation scope.

   3. Otherwise, insert the contents of item’s flattened tabindex-ordered focus navigation scope after item.

6.6.3 The **tabindex** attribute

![MDN](https://developer.mozilla.org/en-US/docs/Web/HTML/Global_attributes/tabindex)

**Global attributes/tabindex**

The **tabindex** content attribute allows authors to make an element and regions that have the element as its DOM anchor be focusable areas, allow or prevent them from being sequentially focusable, and determine their relative ordering for sequential focus navigation.

The name “tab index” comes from the common use of the **Tab** key to navigate through the focusable elements. The term “tabbing” refers to moving forward through sequentially focusable focusable areas.

The **tabindex** attribute, if specified, must have a value that is a valid integer. Positive numbers specify the relative position of the element’s focusable areas in the sequential focus navigation order, and negative numbers indicate that the control is not sequentially focusable.

Developers should use caution when using values other than 0 or −1 for their **tabindex** attributes as this is complicated to do correctly.

The following provides a non-normative summary of the behaviors of the possible **tabindex** attribute values. The below processing model gives the more precise rules.
The user agent will decide whether the element is **focusable**, and if it is, whether it is **sequentially focusable** or **click focusable** (or both).

### −1 (or other negative integer values)
Causes the element to be **focusable**, and indicates that the author would prefer the element to be **click focusable** but not **sequentially focusable**. The user agent might ignore this preference for click and sequential focusability, e.g., for specific element types according to platform conventions, or for keyboard-only users.

0
Causes the element to be **focusable**, and indicates that the author would prefer the element to be both **click focusable** and **sequentially focusable**. The user agent might ignore this preference for click and sequential focusability.

### positive integer values
Behaves the same as 0, but in addition creates a relative ordering within a **tabindex-ordered focus navigation scope**, so that elements with higher **tabindex** attribute value come later.

Note that the **tabindex** attribute cannot be used to make an element non-focusable. The only way a page author can do that is by **disabling** the element, or making it **inert**.

The **tabindex value** of an element is the value of its **tabindex** attribute, parsed using the **rules for parsing integers**. If parsing fails or the attribute is not specified, then the **tabindex value** is null.

The **tabindex value** of a **focusable area** is the **tabindex value** of its **DOM anchor**.

The **tabindex value** of an element must be interpreted as follows:

**If the value is null**

The user agent should follow platform conventions to determine if the element should be considered as a **focusable area** and if so, whether the element and any **focusable areas** that have the element as their **DOM anchor** are **sequentially focusable**, and if so, what their relative position in their **tabindex-ordered focus navigation scope** is to be. If the element is a **focus navigation scope owner**, it must be included in its **tabindex-ordered focus navigation scope** even if it is not a **focusable area**.

The relative ordering within a **tabindex-ordered focus navigation scope** for elements and **focusable areas** that belong to the same **focus navigation scope** and whose **tabindex value** is null should be in **shadow-including tree order**.

Modulo platform conventions, it is suggested that the following elements should be considered as **focusable areas** and be **sequentially focusable**:
- `a` elements that have an `href` attribute
- `button` elements
- `input` elements whose `type` attribute are not in the `Hidden` state
- `select` elements
- `textarea` elements
- `summary` elements that are the first `summary` element child of a `details` element
- Elements with a `draggable` attribute set, if that would enable the user agent to allow the user to begin drag operations for those elements without the use of a pointing device
- Editing hosts
- Browsing context containers

If the value is a negative integer

The user agent must consider the element as a focusable area, but should omit the element from any `tabindex-ordered focus navigation scope`.

One valid reason to ignore the requirement that sequential focus navigation not allow the author to lead to the element would be if the user’s only mechanism for moving the focus is sequential focus navigation. For instance, a keyboard-only user would be unable to click on a text control with a negative `tabindex`, so that user’s user agent would be well justified in allowing the user to tab to the control regardless.

If the value is a zero

The user agent must allow the element to be considered as a focusable area and should allow the element and any focusable areas that have the element as their DOM anchor to be sequentially focusable.

The relative ordering within a `tabindex-ordered focus navigation scope` for elements and focusable areas that belong to the same focus navigation scope and whose `tabindex value` is zero should be in shadow-including tree order.

If the value is greater than zero

The user agent must allow the element to be considered as a focusable area and should allow the element and any focusable areas that have the element as their DOM anchor to be sequentially focusable, and should place the element — referenced as candidate below — and the aforementioned focusable areas in the `tabindex-ordered focus navigation scope` where the element is a part of so that, relative to other elements and focusable areas that belong to the same focus navigation scope, they are:

- before any focusable area whose DOM anchor is an element whose `tabindex` attribute has been omitted or whose value, when parsed, returns an error,
- before any focusable area whose DOM anchor is an element whose `tabindex` attribute has a value equal to or less than zero,
- after any focusable area whose DOM anchor is an element whose `tabindex`
attribute has a value greater than zero but less than the value of the `tabindex` attribute on `candidate`,

- after any focusable area whose DOM anchor is an element whose `tabindex` attribute has a value equal to the value of the `tabindex` attribute on `candidate` but that is located earlier than `candidate` in shadow-including tree order,
- before any focusable area whose DOM anchor is an element whose `tabindex` attribute has a value equal to the value of the `tabindex` attribute on `candidate` but that is located later than `candidate` in shadow-including tree order, and
- before any focusable area whose DOM anchor is an element whose `tabindex` attribute has a value greater than the value of the `tabindex` attribute on `candidate`.

The `tabIndex` IDL attribute must reflect the value of the `tabindex` content attribute. The default value is 0 if the element is an `a`, `area`, `button`, `frame`, `iframe`, `input`, `object`, `select`, `textarea`, or SVG `a` element, or is a `summary` element that is a summary for its parent details. The default value is −1 otherwise.

The varying default value based on element type is a historical artifact.

### 6.6.4 Processing model

To get the focusable area for a focus target that is either an element that is not a focusable area, or is a browsing context, given an optional string focus trigger (default "other"), run the first matching set of steps from the following list:

If focus target is an area element with one or more shapes that are focusable areas

Return the shape corresponding to the first `img` element in tree order that uses the image map to which the area element belongs.

If focus target is an element with one or more scrollable regions that are focusable areas

Return the element’s first scrollable region, according to a pre-order, depth-first traversal of the flat tree. [CSSSCOPING]
If `focus target` is the **document element** of its **Document**

Return the **Document**’s viewport.

If `focus target` is a **browsing context**

Return the **browsing context**’s active document.

If `focus target` is a **browsing context container** with a non-null nested **browsing context**

Return the **browsing context container**’s nested browsing context’s active document.

If `focus target` is a **shadow host** whose **shadow root**’s **delegates focus** is true

1. Let `root` be `focus target`’s **shadow root**.
2. If `root` is a shadow-including inclusive ancestor of the currently focused area of a top-level **browsing context**’s **DOM anchor**, then return null.
3. Return the **focus delegate** for `root` given `focus trigger`.

For **sequential focusability**, the handling of **shadow hosts** and **delegates focus** is done when constructing the **sequential focus navigation order**. That is, the **focusing steps** will never be called on such **shadow hosts** as part of sequential focus navigation.

Otherwise

Return null.

The **focus delegate** for a **focus target**, given an optional string `focus trigger` (default "other"), is given by the following steps:

1. Let `autofocus delegate` be the **autofocus delegate** for `focus target` given `focus trigger`.
2. If `autofocus delegate` is not null, then return `autofocus delegate`.
3. If `focus trigger` is "click", then let **possible focus delegates** be the list of all **click focusable** focusable areas whose **DOM anchor** is a shadow-including descendant of `focus target`.
4. Otherwise, let **possible focus delegates** be the list of all **focusable areas** whose **DOM anchor** is a shadow-including descendant of `focus target`.
5. If **possible focus delegates** is empty, then return null.
6. Sort **possible focus delegates** by shadow-including tree order of their **DOM anchors**.
7. Return **possible focus delegates**[0].
The autofocus delegate for a focus target given a focus trigger is given by the following steps:

1. For each descendant descendant of focus target, in tree order:
   1. If descendant does not have an autofocus content attribute, then continue.
   2. Let focusable area be descendant, if descendant is a focusable area; otherwise let focusable area be the result of getting the focusable area for descendant given focus trigger.
   3. If focusable area is null, then continue.
   4. If focusable area is not click focusable and focus trigger is "click", then continue.
   5. Return focusable area.

2. Return null.

The focusing steps for an object new focus target that is either a focusable area, or an element that is not a focusable area, or a browsing context, are as follows. They can optionally be run with a fallback target and a string focus trigger.

1. If new focus target is not a focusable area, then set new focus target to the result of getting the focusable area for new focus target, given focus trigger if it was passed.

2. If new focus target is null, then:
   1. If no fallback target was specified, then return.
   2. Otherwise, set new focus target to the fallback target.

3. If new focus target is a browsing context container with non-null nested browsing context, then set new focus target to the nested browsing context’s active document.

4. If new focus target is a focusable area and its DOM anchor is inert, then return.

5. If new focus target is the currently focused area of a top-level browsing context, then return.

6. Let old chain be the current focus chain of the top-level browsing context in which new focus target finds itself.

7. Let new chain be the focus chain of new focus target.

8. Run the focus update steps with old chain, new chain, and new focus target respectively.
User agents must immediately run the focusing steps for a focusable area or browsing context candidate whenever the user attempts to move the focus to candidate.

The unfocusing steps for an object old focus target that is either a focusable area or an element that is not a focusable area are as follows:

1. If old focus target is a shadow host whose shadow root’s delegates focus is true, and old focus target’s shadow root is a shadow-including inclusive ancestor of the currently focused area of a top-level browsing context’s DOM anchor, then set old focus target to that currently focused area of a top-level browsing context.

2. If old focus target is inert, then return.

3. If old focus target is an area element and one of its shapes is the currently focused area of a top-level browsing context, or, if old focus target is an element with one or more scrollable regions, and one of them is the currently focused area of a top-level browsing context, then let old focus target be that currently focused area of a top-level browsing context.

4. Let old chain be the current focus chain of the top-level browsing context in which old focus target finds itself.

5. If old focus target is not one of the entries in old chain, then return.

6. If old focus target is not a focusable area, then return.

7. Let topDocument be old chain’s last entry.

8. If topDocument’s browsing context has system focus, then run the focusing steps for topDocument’s viewport.

   Otherwise, apply any relevant platform-specific conventions for removing system focus from topDocument’s browsing context, and run the focus update steps with old chain, an empty list, and null respectively.

When the currently focused area of a top-level browsing context is somehow unfocused without another element being explicitly focused in its stead, the user agent must immediately run the unfocusing steps for that object.

The unfocusing steps do not always result in the focus changing, even when applied to the currently focused area of a top-level browsing context. For example, if the currently focused area of a top-level browsing context is a viewport, then it will usually keep its focus regardless until another focusable area is explicitly focused with the focusing steps.

Focus fixup rule: When the designated focused area of the document is removed from that Document in some way (e.g. it stops being a focusable area, it is removed from the DOM, it becomes expressly inert, etc.), designate the Document’s viewport to be the new focused area of
the document.

For example, this might happen because an element is removed from its Document, or has a hidden attribute added. It might also happen to an input element when the element gets disabled.

In a Document whose focused area is a button element, removing, disabling, or hiding that button would cause the page’s new focused area to be the viewport of the Document. This would, in turn, be reflected through the activeElement API as the body element.

The focus update steps, given an old chain, a new chain, and a new focus target respectively, are as follows:

1. If the last entry in old chain and the last entry in new chain are the same, pop the last entry from old chain and the last entry from new chain and redo this step.

2. For each entry entry in old chain, in order, run these substeps:

   1. If entry is an input element, and the change event applies to the element, and the element does not have a defined activation behavior, and the user has changed the element’s value or its list of selected files while the control was focused without committing that change (such that it is different to what it was when the control was first focused), then fire an event named change at the element, with the bubbles attribute initialized to true.

   2. If entry is an element, let blur event target be entry.

      If entry is a Document object, let blur event target be that Document object’s relevant global object.

      Otherwise, let blur event target be null.

   3. If entry is the last entry in old chain, and entry is an Element, and the last entry in new chain is also an Element, then let related blur target be the last entry in new chain. Otherwise, let related blur target be null.

   4. If blur event target is not null, fire a focus event named blur at blur event target, with related blur target as the related target.

      In some cases, e.g. if entry is an area element’s shape, a scrollable region, or a viewport, no event is fired.

3. Apply any relevant platform-specific conventions for focusing new focus target. (For example, some platforms select the contents of a text control when that control is focused.)
4. For each entry \textit{entry} in new chain, in reverse order, run these substeps:

1. If \textit{entry} is a \textit{focusable area}: designate \textit{entry} as the \textit{focused area of the document}.

2. If \textit{entry} is an element, let \textit{focus event target} be \textit{entry}.

   If \textit{entry} is a \texttt{Document} object, let \textit{focus event target} be that \texttt{Document} object’s relevant global object.

   Otherwise, let \textit{focus event target} be null.

3. If \textit{entry} is the last entry in new chain, and \textit{entry} is an \texttt{Element}, and the last entry in old chain is also an \texttt{Element}, then let \textit{related focus target} be the last entry in old chain. Otherwise, let \textit{related focus target} be null.

4. If \textit{focus event target} is not null, fire a focus event named \textit{focus} at \textit{focus event target}, with \textit{related focus target} as the related target.

   In some cases, e.g. if \textit{entry} is an \textit{area} element’s shape, a scrollable region, or a \textit{viewport}, no event is fired.

To fire a focus event named \textit{e} at an element \textit{t} with a given related target \textit{r}, fire an event named \textit{e} at \textit{t}, using \texttt{FocusEvent}, with the \texttt{relatedTarget} attribute initialized to \textit{r}, the \texttt{view} attribute initialized to \textit{t}’s node document’s relevant global object, and the \texttt{composed} flag set.

---

When a key event is to be routed in a \textit{top-level browsing context}, the user agent must run the following steps:

1. Let \textit{target area} be the \textit{currently focused area of the top-level browsing context}.

2. Assert: \textit{target area} is not null, since key events are only routed to top-level browsing contexts that have system focus.

3. If \textit{target area} is a \textit{focusable area}, let \textit{target node} be target area’s DOM anchor. Otherwise, \textit{target area} is a \textit{dialog}; let \textit{target node} be \textit{target area}.

4. If \textit{target node} is a \texttt{Document} that has a \textit{body element}, then let \textit{target node} be the \textit{body element} of that \texttt{Document}.

   Otherwise, if \textit{target node} is a \texttt{Document} object that has a non-null \textit{document element}, then let \textit{target node} be that \textit{document element}.

5. If \textit{target node} is not \texttt{inert}, then:

   It is possible for the currently focused area of a top-level browsing context to be \texttt{inert}, for example if a \texttt{modal dialog is shown}, and then that \texttt{dialog} element is made \texttt{inert}. It
is likely to be the result of a logic error in the application, though.

1. Let $canHandle$ be the result of dispatching the key event at $target$ node.

2. If $canHandle$ is true, then let $target$ area handle the key event. This might include firing a click event at $target$ node.

The has focus steps, given a Document object $target$, are as follows:

1. If $target$’s browsing context’s top-level browsing context does not have system focus, then return false.

2. Let $candidate$ be $target$’s browsing context’s top-level browsing context’s active document.

3. While true:
   
   1. If $candidate$ is $target$, then return true.

   2. If the focused area of $candidate$ is a browsing context container with a non-null nested browsing context, then set $candidate$ to the active document of that browsing context container’s nested browsing context.

   3. Otherwise, return false.

6.6.5 Sequential focus navigation

Each Document has a sequential focus navigation order, which orders some or all of the focusable areas in the Document relative to each other. Its contents and ordering are given by the flattened tabindex-ordered focus navigation scope of the Document.

Per the rules defining the flattened tabindex-ordered focus navigation scope, the ordering is not necessarily related to the tree order of the Document.

If a focusable area is omitted from the sequential focus navigation order of its Document, then it is unreachable via sequential focus navigation.

There can also be a sequential focus navigation starting point. It is initially unset. The user agent may set it when the user indicates that it should be moved.

For example, the user agent could set it to the position of the user’s click if the user clicks on the document contents.

User agents are required to set the sequential focus navigation starting point to the target element when navigating to a fragment.
When the user requests that focus move from the currently focused area of a top-level browsing context to the next or previous focusable area (e.g. as the default action of pressing the **tab** key), or when the user requests that focus sequentially move to a top-level browsing context in the first place (e.g. from the browser’s location bar), the user agent must use the following algorithm:

1. Let *starting point* be the currently focused area of a top-level browsing context, if the user requested to move focus sequentially from there, or else the top-level browsing context itself, if the user instead requested to move focus from outside the top-level browsing context.

2. If there is a sequential focus navigation starting point defined and it is inside *starting point*, then let *starting point* be the sequential focus navigation starting point instead.

3. Let *direction* be *forward* if the user requested the next control, and *backward* if the user requested the previous control.

   Typically, pressing **tab** requests the next control, and pressing **shift+tab** requests the previous control.

4. **Loop:** Let *selection mechanism* be *sequential* if the *starting point* is a browsing context or if *starting point* is in its Document’s sequential focus navigation order.

   Otherwise, *starting point* is not in its Document’s sequential focus navigation order; let *selection mechanism* be DOM.

5. Let *candidate* be the result of running the sequential navigation search algorithm with *starting point*, *direction*, and *selection mechanism* as the arguments.

6. If *candidate* is not null, then run the focusing steps for *candidate* and return.

7. Otherwise, unset the sequential focus navigation starting point.

8. If *starting point* is the top-level browsing context, or a focusable area in the top-level browsing context, the user agent should transfer focus to its own controls appropriately (if any), honouring *direction*, and then return.

   For example, if *direction* is *backward*, then the last sequentially focusable control before the browser’s rendering area would be the control to focus.

   If the user agent has no sequentially focusable controls — a kiosk-mode browser, for instance — then the user agent may instead restart these steps with the *starting point* being the top-level browsing context itself.

9. Otherwise, *starting point* is a focusable area in a child browsing context. Set *starting point* to that child browsing context’s container and return to the step labeled *loop*.

The sequential navigation search algorithm consists of the following steps. This algorithm takes
three arguments: starting point, direction, and selection mechanism.

1. Pick the appropriate cell from the following table, and follow the instructions in that cell.

The appropriate cell is the one that is from the column whose header describes direction and from the first row whose header describes starting point and selection mechanism.

<table>
<thead>
<tr>
<th>starting point is a browsing context</th>
<th>direction is forward</th>
<th>direction is backward</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Let candidate be the first suitable sequentially focusable area in starting point’s active document, if any; or else null</td>
<td>Let candidate be the last suitable sequentially focusable area in starting point’s active document, if any; or else null</td>
</tr>
<tr>
<td>selection mechanism is DOM</td>
<td>Let candidate be the first suitable sequentially focusable area in the home document following starting point, if any; or else null</td>
<td>Let candidate be the last suitable sequentially focusable area in the home document preceding starting point, if any; or else null</td>
</tr>
<tr>
<td>selection mechanism is sequential</td>
<td>Let candidate be the first suitable sequentially focusable area in the home sequential focus navigation order following starting point, if any; or else null</td>
<td>Let candidate be the last suitable sequentially focusable area in the home sequential focus navigation order preceding starting point, if any; or else null</td>
</tr>
</tbody>
</table>

A suitable sequentially focusable area is a focusable area whose DOM anchor is not inert and is sequentially focusable.

The home document is the Document to which starting point belongs.

The home sequential focus navigation order is the sequential focus navigation order to which starting point belongs.

The home sequential focus navigation order is the home document’s sequential focus navigation order, but is only used when the starting point is in that sequential focus navigation order (when it’s not, selection mechanism will be DOM).

2. If candidate is a browsing context container with a non-null nested browsing context, then let new candidate be the result of running the sequential navigation search algorithm with candidate’s nested browsing context as the first argument, direction as the second, and sequential as the third.

If new candidate is null, then let starting point be candidate, and return to the top of this algorithm. Otherwise, let candidate be new candidate.

3. Return candidate.
6.6.6 Focus management APIs

```javascript
dictionary FocusOptions {
  boolean preventScroll = false;
};
```

`documentOrShadowRoot.activeElement`

MDN Document/activeElement

Support in all current engines.

Firefox3+ Safari4+ Chrome1+
Opera12.1+ Edge79+
Edge (Legacy)12+ Internet Explorer6+
Firefox Android4+Safari iOS3.2+ Chrome Android18+ WebView Android37+Samsung Internet1.0+ Opera Android12.1+

ShadowRoot/activeElement

Support in all current engines.

Firefox63+Safari10.1+Chrome53+
Opera40+Edge79+
Edge (Legacy)No Internet ExplorerNo
Firefox Android63+Safari iOS10.3+ Chrome Android53+ WebView Android53+Samsung Internet6.0+ Opera Android41+

Returns the deepest element in the document through which or to which key events are being routed. This is, roughly speaking, the focused element in the document.

For the purposes of this API, when a **child browsing context** is focused, its **container** is **focused** in the **parent browsing context**. For example, if the user moves the focus to a text control in an **iframe**, the **iframe** is the element returned by the **activeElement** API in the **iframe**’s node document.

Similarly, when the focused element is in a different **node tree** than **documentOrShadowRoot**, the element returned will be the **host** that’s located in the same **node tree** as **documentOrShadowRoot** if **documentOrShadowRoot** is a **shadow-including inclusive ancestor** of the focused element, and null if not.

`document.hasFocus()`

MDN Document/hasFocus
Support in all current engines.

Firefox 3+ Safari 4+ Chrome 1+
Opera 15+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 5.5+
Firefox Android 4+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+
Samsung Internet 1.0+ Opera Android 14+

Returns true if key events are being routed through or to the document; otherwise, returns false. Roughly speaking, this corresponds to the document, or a document nested inside this one, being focused.

`window.focus()`

✔️ MDN

Window/focus

Support in all current engines.

Firefox 1+ Safari 1+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 4+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

Moves the focus to the window’s browsing context, if any.

`element.focus([ { preventScroll: true } ])`

✔️ MDN

HTMLElement/focus

Support in all current engines.

Firefox 1.5+ Safari 3+ Chrome 1+
Opera 8+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 5.5+
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 4.4+ Samsung Internet 1.0+ Opera Android 10.1+

Moves the focus to the element.

If the element is a browsing context container, moves the focus to its nested browsing context instead.

By default, this method also scrolls the element into view. Providing the preventScroll
option and setting it to true prevents this behavior.

```javascript
element.blur()
```

** HTMLElement/blur**

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>1.5+</td>
</tr>
<tr>
<td>Safari</td>
<td>3+</td>
</tr>
<tr>
<td>Chrome</td>
<td>1+</td>
</tr>
<tr>
<td>Opera</td>
<td>8+</td>
</tr>
<tr>
<td>Edge (Legacy)</td>
<td>12+</td>
</tr>
<tr>
<td>Internet Explorer</td>
<td>5.5+</td>
</tr>
<tr>
<td>Firefox Android</td>
<td>4+</td>
</tr>
<tr>
<td>Safari iOS</td>
<td>1+</td>
</tr>
<tr>
<td>Chrome Android</td>
<td>18+</td>
</tr>
<tr>
<td>WebView Android</td>
<td>4.4+</td>
</tr>
<tr>
<td>Samsung</td>
<td></td>
</tr>
<tr>
<td>Internet</td>
<td>1.0+</td>
</tr>
<tr>
<td>Opera Android</td>
<td>10.1+</td>
</tr>
</tbody>
</table>

Moves the focus to the **viewport**. Use of this method is discouraged; if you want to focus the **viewport**, call the **focus()** method on the **Document**’s **document element**.

Do not use this method to hide the focus ring if you find the focus ring unsightly. Instead, use the **:focus-visible** pseudo-class to override the **outline** property, and provide a different way to show what element is focused. Be aware that if an alternative focusing style isn’t made available, the page will be significantly less usable for people who primarily navigate pages using a keyboard, or those with reduced vision who use focus outlines to help them navigate the page.

For example, to hide the outline from **textarea** elements and instead use a yellow background to indicate focus, you could use:

```css
textarea:focus-visible { outline: none; background: yellow; color: black; }
```

The **activeElement** attribute’s getter must run these steps:

1. Let `candidate` be the **DOM anchor** of the **focused area** of this **DocumentOrShadowRoot**’s **node document**.
2. Set `candidate` to the result of **retargeting** `candidate` against this **DocumentOrShadowRoot**.
3. If `candidate`’s **root** is not this **DocumentOrShadowRoot**, then return null.
4. If `candidate` is not a **Document** object, then return `candidate`.
5. If `candidate` has a **body element**, then return that **body element**.
6. If `candidate`’s **document element** is non-null, then return that **document element**.
7. Return null.
The `hasFocus()` method on the `Document` object, when invoked, must return the result of running the `has focus steps` with the `Document` object as the argument.

The `focus()` method, when invoked, must run these steps:

1. Let `current` be this `Window` object’s `browsing context`.
2. If `current` is null, then return.
3. Run the focusing steps with `current`.
4. If `current` is a top-level `browsing context`, user agents are encouraged to trigger some sort of notification to indicate to the user that the page is attempting to gain focus.

MDN

Window/blur

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>

<td></td>
</tr>
<tr>
<td>Opera Android12.1+</td>
<td></td>
</tr>
</tbody>
</table>

The `blur()` method, when invoked, provides a hint to the user agent that the script believes the user probably is not currently interested in the contents of this `Window` object’s `browsing context`, if non-null, but that the contents might become interesting again in the future.

User agents are encouraged to ignore calls to this `blur()` method entirely.

Historically, the `focus()` and `blur()` methods actually affected the system-level focus of the system widget (e.g., tab or window) that contained the `browsing context`, but hostile sites widely abuse this behavior to the user’s detriment.

The `focus(options)` method on elements, when invoked, must run the following steps:

1. If the element is marked as `locked for focus`, then return.
2. Mark the element as `locked for focus`.
3. Run the focusing steps for the element.
4. If the value of the `preventScroll` dictionary member of `options` is false, then scroll the element into view with scroll behavior "auto", block flow direction position set to an implementation-defined value, and inline base direction position set to an...
5. Unmark the element as **locked for focus**.

The `blur()` method, when invoked, should run the unfocusing steps for the element on which the method was called. User agents may selectively or uniformly ignore calls to this method for usability reasons.

For example, if the `blur()` method is unwisely being used to remove the focus ring for aesthetics reasons, the page would become unusable by keyboard users. Ignoring calls to this method would thus allow keyboard users to interact with the page.

### 6.6.7 The autofocus attribute

The `autofocus` content attribute allows the author to indicate that an element is to be focused as soon as the page is loaded or as soon as the `dialog` within which it finds itself is shown, allowing the user to just start typing without having to manually focus the main element.

The `autofocus` attribute is a **boolean attribute**.

An element’s **nearest ancestor autofocus scoping root element** is the element itself if the element is a `dialog` element, or else is the element’s nearest ancestor `dialog` element, if any, or else is the element’s last **inclusive ancestor** element.

There must not be two elements with the same **nearest ancestor autofocus scoping root element** that both have the `autofocus` attribute specified.

Each `Document` has an **autofocus candidates list**, initially empty.

Each `Document` has an **autofocus processed flag** boolean, initially false.

When an element with the `autofocus` attribute specified is **inserted into a document**, run the following steps:

1. If the user has indicated (for example, by starting to type in a form control) that they do not wish focus to be changed, then optionally return.

2. Let `target` be the element’s **node document**.

3. If `target`’s **browsing context** is null, then return.

4. If `target`’s **active sandboxing flag set** has the **sandboxed automatic features browsing context flag**, then return.

5. For each `ancestorBC` of `target`’s **browsing context**’s ancestor browsing contexts: if `ancestorBC`’s **active document**’s **origin** is not **same origin** with `target`’s **origin**, then
Let `topDocument` be the active document of target's browsing context's top-level browsing context.

If `topDocument`'s autofocus processed flag is false, then remove the element from `topDocument`'s autofocus candidates, and append the element to `topDocument`'s autofocus candidates.

We do not check if an element is a focusable area before storing it in the autofocus candidates list, because even if it is not a focusable area when it is inserted, it could become one by the time `flush autofocus candidates` sees it.

To `flush autofocus candidates` for a document `topDocument`, run these steps:

1. If `topDocument`'s autofocus processed flag is true, then return.

2. Let `candidates` be `topDocument`'s autofocus candidates.

3. If `candidates` is empty, then return.

4. If `topDocument`'s focused area is not `topDocument` itself, or `topDocument` has non-null target element, then:
   1. Empty `candidates`.
   2. Set `topDocument`'s autofocus processed flag to true.
   3. Return.

5. While `candidates` is not empty:
   1. Let `element` be `candidates`[0].
   2. Let `doc` be `element`'s node document.
   3. If `doc` is not fully active, then remove `element` from `candidates`, and continue.
   4. If `doc`'s browsing context's top-level browsing context is not same as `topDocument`'s browsing context, then remove `element` from `candidates`, and continue.
   5. If `doc`'s script-blocking style sheet counter is greater than 0, then return.

   In this case, `element` is the currently-best candidate, but `doc` is not ready for autofocusing. We'll try again next time `flush autofocus candidates` is called.

6. Remove `element` from `candidates`. 

return.
7. Let inclusiveAncestorDocuments be a list consisting of doc, plus the active documents of each of doc’s browsing context’s ancestor browsing contexts.

8. If any Document in inclusiveAncestorDocuments has non-null target element, then continue.

9. Let target be element.

10. If target is not a focusable area, then set target to the result of getting the focusable area for target.

    Autofocus candidates can contain elements which are not focusable areas. In addition to the special cases handled in the get the focusable area algorithm, this can happen because a non-focusable area element with an autofocus attribute was inserted into a document and it never became focusable, or because the element was focusable but its status changed while it was stored in autofocus candidates.

11. If target is not null, then:

    1. Empty candidates.
    2. Set topDocument’s autofocus processed flag to true.
    3. Run the focusing steps for target.

This handles the automatic focusing during document load. The show() and showModal() methods of dialog elements also processes the autofocus attribute.

Focusing the element does not imply that the user agent has to focus the browser window if it has lost focus.

The autofocus IDL attribute must reflect the content attribute of the same name.

In the following snippet, the text control would be focused when the document was loaded.
The `autofocus` attribute applies to all elements, not just to form controls. This allows examples such as the following:

```html
<div contenteditable autofocus> Edit <strong>me!</strong></div>
```

6.7 Assigning keyboard shortcuts

6.7.1 Introduction

This section is non-normative.

Each element that can be activated or focused can be assigned a single key combination to activate it, using the `accesskey` attribute.

The exact shortcut is determined by the user agent, based on information about the user’s keyboard, what keyboard shortcuts already exist on the platform, and what other shortcuts have been specified on the page, using the information provided in the `accesskey` attribute as a guide.

In order to ensure that a relevant keyboard shortcut is available on a wide variety of input devices, the author can provide a number of alternatives in the `accesskey` attribute.

Each alternative consists of a single character, such as a letter or digit.

User agents can provide users with a list of the keyboard shortcuts, but authors are encouraged to do so also. The `accessKeyLabel` IDL attribute returns a string representing the actual key combination assigned by the user agent.

In this example, an author has provided a button that can be invoked using a shortcut key. To support full keyboards, the author has provided "C" as a possible key. To support devices equipped only with numeric keypads, the author has provided "1" as another possible key.

```html
<input type=button value=Collect onclick="collect()"
    accesskey="C 1" id=c>
```

To tell the user what the shortcut key is, the author has this script here opted to explicitly add the key combination to the button’s label:

```javascript
function addShortcutKeyLabel(button) {
    if (button.accessKeyLabel != '')
        button.value += ' (' + button.accessKeyLabel + ')';
}
addShortcutKeyLabel(document.getElementById('c'));
```
Browsers on different platforms will show different labels, even for the same key combination, based on the convention prevalent on that platform. For example, if the key combination is the Control key, the Shift key, and the letter C, a Windows browser might display “Ctrl+Shift+C”, whereas a Mac browser might display “^⇧C”, while an Emacs browser might just display “C-C”. Similarly, if the key combination is the Alt key and the Escape key, Windows might use “Alt+Esc”, Mac might use “⌥⎋”, and an Emacs browser might use “M-ESC” or “ESC ESC”.

In general, therefore, it is unwise to attempt to parse the value returned from the accessKeyLabel IDL attribute.

6.7.2 The accesskey attribute

Global_attributes/accesskey

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes
Opera Yes Edge Yes
Edge (Legacy) 12+ Internet Explorer Yes
Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

All HTML elements may have the accesskey content attribute set. The accesskey attribute’s value is used by the user agent as a guide for creating a keyboard shortcut that activates or focuses the element.

If specified, the value must be an ordered set of unique space-separated tokens none of which are identical to another token and each of which must be exactly one code point in length.

In the following example, a variety of links are given with access keys so that keyboard users familiar with the site can more quickly navigate to the relevant pages:

```
<nav>
 <p>
 <a title="Consortium Activities" accesskey="A" href="/Consortium/activities/">
     Consortium Activities
 </a>
 <a title="Technical Reports and Recommendations" accesskey="T" href="/TR/">
     Technical Reports
 </a>
 <a title="Alphabetical Site Index" accesskey="S" href="/Consortium/siteindex/">
     Site Index
 </a>
 <a title="About This Site" accesskey="B" href="/Consortium/">
     About Consortium
 </a>
 <a title="Contact Consortium" accesskey="C" href="/Consortium/contact/">
     Contact
 </a>
 </p>
</nav>
```

In the following example, the search field is given two possible access keys, "s" and "0" (in that
order). A user agent on a device with a full keyboard might pick Ctrl+Alt+S as the shortcut key, while a user agent on a small device with just a numeric keypad might pick just the plain unadorned key 0:

```html
<form action="/search">
  <label>Search: <input type="search" name="q" accesskey="s 0"></label>
  <input type="submit">
</form>
```

In the following example, a button has possible access keys described. A script then tries to update the button’s label to advertise the key combination the user agent selected.

```html
<input type=submit accesskey="N @ 1" value="Compose">
...<script>
  function labelButton(button) {
    if (button.accessKeyLabel)
      button.value += ' (' + button.accessKeyLabel + ')';
  }
  var inputs = document.getElementsByTagName('input');
  for (var i = 0; i < inputs.length; i += 1) {
    if (inputs[i].type == "submit")
      labelButton(inputs[i]);
  }
</script>
```

On one user agent, the button’s label might become “Compose (⌘N)”. On another, it might become “Compose (Alt+⇧+1)”. If the user agent doesn’t assign a key, it will be just “Compose”. The exact string depends on what the assigned access key is, and on how the user agent represents that key combination.

### 6.7.3 Processing model

An element’s assigned access key is a key combination derived from the element’s accesskey content attribute. Initially, an element must not have an assigned access key.

Whenever an element’s accesskey attribute is set, changed, or removed, the user agent must update the element’s assigned access key by running the following steps:

1. If the element has no accesskey attribute, then skip to the fallback step below.

2. Otherwise, split the attribute’s value on ASCII whitespace, and let keys be the resulting tokens.

3. For each value in keys in turn, in the order the tokens appeared in the attribute’s value, run the following substeps:
1. If the value is not a string exactly one code point in length, then skip the remainder of these steps for this value.

2. If the value does not correspond to a key on the system’s keyboard, then skip the remainder of these steps for this value.

3. (This is a tracking vector.) If the user agent can find a mix of zero or more modifier keys that, combined with the key that corresponds to the value given in the attribute, can be used as the access key, then the user agent may assign that combination of keys as the element’s **assigned access key** and return.

4. **Fallback:** Optionally, the user agent may assign a key combination of its choosing as the element’s **assigned access key** and then return.

5. If this step is reached, the element has no **assigned access key**.

Once a user agent has selected and assigned an access key for an element, the user agent should not change the element’s **assigned access key** unless the **accesskey** content attribute is changed or the element is moved to another **Document**.

When the user presses the key combination corresponding to the **assigned access key** for an element, if the element **defines a command**, the command’s **Hidden State** facet is false (visible), the command’s **Disabled State** facet is also false (enabled), the element is **in a document** that has a non-null **browsing context**, and neither the element nor any of its ancestors has a **hidden** attribute specified, then the user agent must trigger the **Action** of the command.

User agents **might expose** elements that have an **accesskey** attribute in other ways as well, e.g. in a menu displayed in response to a specific key combination.

---

**MDN**

**HTMLElement/accessKey**

Support in all current engines.

Firefox5+Safari6+Chrome17+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer5.5+
Firefox Android5+Safari iOS6+Chrome Android18+WebView Android4.4+Samsung Internet1.0+Opera Android12.1+

The **accessKey** IDL attribute must **reflect** the **accesskey** content attribute.
The `accessKeyLabel` IDL attribute must return a string that represents the element’s assigned access key, if any. If the element does not have one, then the IDL attribute must return the empty string.

6.8 Editing

6.8.1 Making document regions editable: The `contentEditable` content attribute

```javascript
interface mixin ElementContentEditable {
  [CEReactions] attribute DOMString contentEditable;
  [CEReactions] attribute DOMString enterKeyHint;
  readonly attribute boolean isContentEditable;
  [CEReactions] attribute DOMString inputMode;
};
```

Global_attributes/contenteditable

Support in all current engines.

Firefox3+Safari3+Chrome1+
Opera9+Edge79+
Edge (Legacy)12+Internet Explorer5.5+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android4.4+Samsung Internet1.0+Opera Android10.1+
The **contenteditable** content attribute is an enumerated attribute whose keywords are the empty string, `true`, and `false`. The empty string and the `true` keyword map to the `true` state. The `false` keyword maps to the `false` state. In addition, there is a third state, the `inherit` state, which is the missing value default and the invalid value default.

The `true` state indicates that the element is editable. The `inherit` state indicates that the element is editable if its parent is. The `false` state indicates that the element is not editable.

For example, consider a page that has a form and a textarea to publish a new article, where the user is expected to write the article using HTML:

```html
<form method=POST>
  <fieldset>
    <legend>New article</legend>
    <textarea name=article>&lt;p&gt;Hello world.&lt;/p&gt;</textarea>
  </fieldset>
  &lt;p&gt;&lt;button&gt;Publish&lt;/button&gt;&lt;/p&gt;
</form>
```

When scripting is enabled, the textarea element could be replaced with a rich text control instead, using the contenteditable attribute:

```html
<form method=POST>
  <fieldset>
    <legend>New article</legend>
    <textarea id=textarea name=article>&lt;p&gt;Hello world.&lt;/p&gt;</textarea>
    <div id=div style=white-space: pre-wrap hidden>&lt;p&gt;Hello world.&lt;/p&gt;</div>
  </fieldset>
  &lt;p&gt;&lt;button&gt;Publish&lt;/button&gt;&lt;/p&gt;
</form>
```

Features to enable, e.g., inserting links, can be implemented using the `document.execCommand()` API, or using Selection APIs and other DOM APIs.

[document.execCommand()] [Selection] [DOM]
The `contenteditable` attribute can also be used to great effect:

```html
<!doctype html>
<html lang=en>
<title>Live CSS editing!</title>
<style style=white-space:pre contenteditable>
html { margin:.2em; font-size:2em; color:lime; background:purple }
head, title, style { display:block }
body { display: none }
</style>

``element.contentEditable`` [ = value ]

Returns "true", "false", or "inherit", based on the state of the `contenteditable` attribute.

Can be set, to change that state.

Throws a “`SyntaxError`” `DOMException` if the new value isn’t one of those strings.

``element.isContentEditable``

[MDN](https://developer.mozilla.org)

`HTMLElement/isContentEditable`

Support in all current engines.

Firefox4+Safari3+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer5.5+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android4.4+Samsung
Internet1.0+Opera Android12.1+

Returns true if the element is editable; otherwise, returns false.

The `contentEditable` IDL attribute, on getting, must return the string "true" if the content attribute is set to the true state, "false" if the content attribute is set to the false state, and "inherit" otherwise. On setting, if the new value is an ASCII case-insensitive match for the string "inherit" then the content attribute must be removed, if the new value is an ASCII case-insensitive match for the string "true" then the content attribute must be set to the string "true", if the new value is an ASCII case-insensitive match for the string "false" then the content attribute must be set to the string "false", and otherwise the attribute setter must throw a “`SyntaxError`” `DOMException`.

The `isContentEditable` IDL attribute, on getting, must return true if the element is either an editing host or editable, and false otherwise.
6.8.2 Making entire documents editable: the `designMode` getter and setter

document.designMode [ = value ]

✔️MDN

Document/designMode

Support in all current engines.

Firefox1+Safari1.2+Chrome1+
Opera9+Edge79+
Edge (Legacy)12+Internet Explorer4+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android10.1+

Returns “on” if the document is editable, and “off” if it isn’t.

Can be set, to change the document’s current state. This focuses the document and resets
the selection in that document.

Document objects have an associated design mode enabled, which is a boolean. It is initially
false.

The `designMode` getter steps are to return “on” if this’s design mode enabled is true; otherwise
“off”.

The `designMode` setter steps are:

1. Let value be the given value, converted to ASCII lowercase.

2. If value is “on” and this’s design mode enabled is false, then:
   1. Set this’s design mode enabled to true.
   2. Reset this’s active range’s start and end boundary points to be at the start of
      this.
   3. Run the focusing steps for this’s document element, if non-null.

3. If value is “off”, then set this’s design mode enabled to false.

6.8.3 Best practices for in-page editors

Authors are encouraged to set the ‘white-space’ property on editing hosts and on markup that
was originally created through these editing mechanisms to the value ‘pre-wrap’. Default
HTML whitespace handling is not well suited to WYSIWYG editing, and line wrapping will not
work correctly in some corner cases if ‘white-space’ is left at its default value.

As an example of problems that occur if the default ‘normal’ value is used instead, consider the case of the user typing “yellow␣␣ball”, with two spaces (here represented by “␣”) between the words. With the editing rules in place for the default value of ‘white-space’ (‘normal’), the resulting markup will either consist of “yellow&nbsp; ball” or “yellow &nbsp;ball”; i.e., there will be a non-breaking space between the two words in addition to the regular space. This is necessary because the ‘normal’ value for ‘white-space’ requires adjacent regular spaces to be collapsed together.

In the former case, “yellow␣” might wrap to the next line (“␣” being used here to represent a non-breaking space) even though “yellow” alone might fit at the end of the line; in the latter case, “␣ball”, if wrapped to the start of the line, would have visible indentation from the non-breaking space.

When ‘white-space’ is set to ‘pre-wrap’, however, the editing rules will instead simply put two regular spaces between the words, and should the two words be split at the end of a line, the spaces would be neatly removed from the rendering.

6.8.4 Editing APIs

An editing host is either an HTML element with its contenteditable attribute in the true state, or a child HTML element of a Document whose design mode enabled is true.

The definition of the terms active range, editing host of, and editable, the user interface requirements of elements that are editing hosts or editable, the execCommand(), queryCommandEnabled(), queryCommandIndeterm(), queryCommandState(), queryCommandSupported(), and queryCommandValue() methods, text selections, and the delete the selection algorithm are defined in execCommand.[EXECCOMMAND]

6.8.5 Spelling and grammar checking

User agents can support the checking of spelling and grammar of editable text, either in form controls (such as the value of textarea elements), or in elements in an editing host (e.g. using contenteditable).

For each element, user agents must establish a default behavior, either through defaults or through preferences expressed by the user. There are three possible default behaviors for each element:

true-by-default
The element will be checked for spelling and grammar if its contents are editable and spellchecking is not explicitly disabled through the spellcheck attribute.

false-by-default
The element will never be checked for spelling and grammar unless spellchecking is
explicitly enabled through the `spellcheck` attribute.

**inherit-by-default**

The element’s default behavior is the same as its parent element’s. Elements that have no parent element cannot have this as their default behavior.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>Yes</td>
</tr>
<tr>
<td>Safari</td>
<td>Yes</td>
</tr>
<tr>
<td>Chrome</td>
<td>9+</td>
</tr>
<tr>
<td>Opera</td>
<td>Yes</td>
</tr>
<tr>
<td>Edge</td>
<td>79+</td>
</tr>
<tr>
<td>Edge (Legacy)</td>
<td>12+</td>
</tr>
<tr>
<td>Internet Explorer</td>

<td>WebView Android</td>
<td>47+</td>
</tr>
<tr>
<td>Samsung Internet</td>
<td>5.0+</td>
</tr>
<tr>
<td>Opera Android</td>
<td>37+</td>
</tr>
</tbody>
</table>

The `spellcheck` attribute is an enumerated attribute whose keywords are the empty string, `true` and `false`. The empty string and the `true` keyword map to the `true` state. The `false` keyword maps to the `false` state. In addition, there is a third state, the `default` state, which is the missing value default and the invalid value default.

The `true` state indicates that the element is to have its spelling and grammar checked. The `default` state indicates that the element is to act according to a default behavior, possibly based on the parent element’s own `spellcheck` state, as defined below. The `false` state indicates that the element is not to be checked.

**element.spellcheck [ = value ]**

Returns true if the element is to have its spelling and grammar checked; otherwise, returns false.

Can be set, to override the default and set the `spellcheck` content attribute.

The `spellcheck` IDL attribute, on getting, must return true if the element’s `spellcheck` content attribute is in the `true` state, or if the element’s `spellcheck` content attribute is in the `default` state and the element’s `default behavior` is `true-by-default`, or if the element’s `spellcheck` content attribute is in the `default` state and the element’s `default behavior` is `inherit-by-default` and the element’s parent element’s `spellcheck` IDL attribute would return true; otherwise, if none of those conditions applies, then the attribute must instead return false.

The `spellcheck` IDL attribute is not affected by user preferences that override the `spellcheck` content attribute, and therefore might not reflect the actual spellchecking state.

On setting, if the new value is true, then the element’s `spellcheck` content attribute must be
set to the literal string "true", otherwise it must be set to the literal string "false".

User agents must only consider the following pieces of text as checkable for the purposes of this feature:

- The value of input elements whose type attributes are in the Text, Search, URL, or Email states and that are mutable (i.e. that do not have the readonly attribute specified and that are not disabled).
- The value of textarea elements that do not have a readonly attribute and that are not disabled.
- Text in Text nodes that are children of editing hosts or editable elements.
- Text in attributes of editable elements.

For text that is part of a Text node, the element with which the text is associated is the element that is the immediate parent of the first character of the word, sentence, or other piece of text. For text in attributes, it is the attribute’s element. For the values of input and textarea elements, it is the element itself.

To determine if a word, sentence, or other piece of text in an applicable element (as defined above) is to have spelling- and grammar-checking enabled, the UA must use the following algorithm:

1. If the user has disabled the checking for this text, then the checking is disabled.
2. Otherwise, if the user has forced the checking for this text to always be enabled, then the checking is enabled.
3. Otherwise, if the element with which the text is associated has a spellcheck content attribute, then: if that attribute is in the true state, then checking is enabled; otherwise, if that attribute is in the false state, then checking is disabled.
4. Otherwise, if there is an ancestor element with a spellcheck content attribute that is not in the default state, then: if the nearest such ancestor’s spellcheck content attribute is in the true state, then checking is enabled; otherwise, checking is disabled.
5. Otherwise, if the element’s default behavior is true-by-default, then checking is enabled.
6. Otherwise, if the element’s default behavior is false-by-default, then checking is disabled.
7. Otherwise, if the element’s parent element has its checking enabled, then checking is enabled.
8. Otherwise, checking is disabled.

If the checking is enabled for a word/sentence/text, the user agent should indicate spelling and grammar errors in that text. User agents should take into account the other semantics given in the document when suggesting spelling and grammar corrections. User agents may use the language of the element to determine what spelling and grammar rules to use, or may use the user’s preferred language settings. UAs should use input element attributes such as pattern to ensure that the resulting value is valid, where possible.

If checking is disabled, the user agent should not indicate spelling or grammar errors for that
The element with ID "a" in the following example would be the one used to determine if the word "Hello" is checked for spelling errors. In this example, it would not be.

```html
<div contenteditable="true">
  <span spellcheck="false" id="a">Hell</span><em>o!</em>
</div>
```

The element with ID "b" in the following example would have checking enabled (the leading space character in the attribute's value on the `input` element causes the attribute to be ignored, so the ancestor's value is used instead, regardless of the default).

```html
<p spellcheck="true">
  <label>Name: <input spellcheck="false" id="b"></label>
</p>
```

This specification does not define the user interface for spelling and grammar checkers. A user agent could offer on-demand checking, could perform continuous checking while the checking is enabled, or could use other interfaces.

### 6.8.6 Autocapitalization

Some methods of entering text, for example virtual keyboards on mobile devices, and also voice input, often assist users by automatically capitalizing the first letter of sentences (when composing text in a language with this convention). A virtual keyboard that implements autocapitalization might automatically switch to showing uppercase letters (but allow the user to toggle it back to lowercase) when a letter that should be autocapitalized is about to be typed. Other types of input, for example voice input, may perform autocapitalization in a way that does not give users an option to intervene first. The `autocapitalize` attribute allows authors to control such behavior.

The `autocapitalize` attribute, as typically implemented, does not affect behavior when typing on a physical keyboard. (For this reason, as well as the ability for users to override the autocapitalization behavior in some cases or edit the text after initial input, the attribute must not be relied on for any sort of input validation.)

The `autocapitalize` attribute can be used on an editing host to control autocapitalization behavior for the hosted editable region, on an `input` or `textarea` element to control the behavior for inputting text into that element, or on a `form` element to control the default behavior for all `autocapitalize-inheriting elements` associated with the `form` element.

The `autocapitalize` attribute never causes autocapitalization to be enabled for `input` elements whose `type` attribute is in one of the `URL`, `Email`, or `Password` states. (This behavior is included in the used autocapitalization hint algorithm below.)

The autocapitalization processing model is based on selecting among five `autocapitalization`
hints, defined as follows:

**default**

The user agent and input method should use make their own determination of whether or not to enable autocapitalization.

**none**

No autocapitalization should be applied (all letters should default to lowercase).

**sentences**

The first letter of each sentence should default to a capital letter; all other letters should default to lowercase.

**words**

The first letter of each word should default to a capital letter; all other letters should default to lowercase.

**characters**

All letters should default to uppercase.

The autocapitalize attribute is an enumerated attribute whose states are the possible autocapitalization hints. The autocapitalization hint specified by the attribute’s state combines with other considerations to form the used autocapitalization hint, which informs the behavior of the user agent. The keywords for this attribute and their state mappings are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>none</td>
</tr>
<tr>
<td>none</td>
<td></td>
</tr>
<tr>
<td>on</td>
<td>sentences</td>
</tr>
</tbody>
</table>
The *invalid value default* is the *sentences* state. The *missing value default* is the *default* state.

**element.autocapitalize** [ = value ]

Returns the current autocapitalization state for the element, or an empty string if it hasn’t been set. Note that for **input** and **textarea** elements that inherit their state from a **form** element, this will return the autocapitalization state of the **form** element, but for an element in an editable region, this will not return the autocapitalization state of the editing host (unless this element is, in fact, the *editing host*).

Can be set, to set the **autocapitalize** content attribute (and thereby change the autocapitalization behavior for the element).

To compute the *own autocapitalization hint* of an element *element*, run the following steps:

1. If the **autocapitalize** content attribute is present on *element*, and its value is not the empty string, return the state of the attribute.

2. If *element* is an autocapitalize-inheriting element and has a non-null **form owner**, return the *own autocapitalization hint* of *element*’s **form owner**.

3. Return *default*.

The **autocapitalize** getter steps are to:

1. Let *state* be the *own autocapitalization hint* of *this*.

2. If *state* is *default*, then return the empty string.

3. If *state* is *none*, then return "*none*".

4. If *state* is *sentences*, then return "*sentences*".

5. Return the keyword value corresponding to *state*.

The **autocapitalize** setter steps are to set the **autocapitalize** content attribute to the given value.

User agents that support customizable autocapitalization behavior for a text input method and wish to allow web developers to control this functionality should, during text input into an element, compute the *used autocapitalization hint* for the element. This will be an
autocapitalization hint that describes the recommended autocapitalization behavior for text input into the element.

User agents or input methods may choose to ignore or override the used autocapitalization hint in certain circumstances.

The used autocapitalization hint for an element element is computed using the following algorithm:

1. If element is an input element whose type attribute is in one of the URL, Email, or Password states, then return default.
2. If element is an input element or a textarea element, then return element's own autocapitalization hint.
3. If element is an editing host or an editable element, then return the own autocapitalization hint of the editing host of element.
4. Assert: this step is never reached, since text input only occurs in elements that meet one of the above criteria.

6.8.7 Input modalities: the inputmode attribute

User agents can support the inputmode attribute on form controls (such as the value of textarea elements), or in elements in an editing host (e.g., using contenteditable).

Global_attributes/inputmode

Support in all current engines.

Firefox 23+ Safari No Chrome 66+
Opera 53+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 79+ Safari iOS 12.2+ Chrome Android 66+ WebView Android 66+ Samsung Internet 9.0+ Opera Android 47+

The inputmode content attribute is an enumerated attribute that specifies what kind of input mechanism would be most helpful for users entering content.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>The user agent should not display a virtual keyboard. This keyword is useful for content that renders its own keyboard control.</td>
</tr>
<tr>
<td>text</td>
<td>The user agent should display a virtual keyboard capable of text input in the user's locale.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>tel</td>
<td>The user agent should display a virtual keyboard capable of telephone number input. This should including keys for the digits 0 to 9, the &quot;#&quot; character, and the &quot;*&quot; character. In some locales, this can also include alphabetic mnemonic labels (e.g., in the US, the key labeled &quot;2&quot; is historically also labeled with the letters A, B, and C). The user agent should display a virtual keyboard capable of text input in the user’s locale, with keys for aiding in the input of URLs, such as that for the &quot;/&quot; and &quot;.&quot; characters and for quick input of strings commonly found in domain names such as &quot;www.&quot; or &quot;.com&quot;.</td>
</tr>
<tr>
<td>url</td>
<td>The user agent should display a virtual keyboard capable of text input in the user’s locale, with keys for aiding in the input of email addresses, such as that for the &quot;@&quot; character and the &quot;.&quot; character.</td>
</tr>
<tr>
<td>email</td>
<td>The user agent should display a virtual keyboard capable of text input in the user’s locale, with keys for aiding in the input of email addresses, such as that for the &quot;@&quot; character and the &quot;.&quot; character.</td>
</tr>
<tr>
<td>numeric</td>
<td>The user agent should display a virtual keyboard capable of numeric input. This keyword is useful for PIN entry.</td>
</tr>
<tr>
<td>decimal</td>
<td>The user agent should display a virtual keyboard capable of fractional numeric input. Numeric keys and the format separator for the locale should be shown.</td>
</tr>
<tr>
<td>search</td>
<td>The user agent should display a virtual keyboard optimized for search.</td>
</tr>
</tbody>
</table>

The `inputMode` IDL attribute must reflect the `inputmode` content attribute, limited to only known values.

When `inputmode` is unspecified (or is in a state not supported by the user agent), the user agent should determine the default virtual keyboard to be shown. Contextual information such as the input `type` or `pattern` attributes should be used to determine which type of virtual keyboard should be presented to the user.

### 6.8.8 Input modalities: the `enterkeyhint` attribute

User agents can support the `enterkeyhint` attribute on form controls (such as the value of `textarea` elements), or in elements in an editing host (e.g., using `contenteditable`).

![MDN](Global_attributes/enterkeyhint)

Support in all current engines.

<table>
<thead>
<tr>
<th>Engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox94+Safari13.1+Chrome77+</td>
</tr>
<tr>
<td>Opera66+Edge79+</td>

<tr>
<td>Edge (Legacy)</td>
</tr>
<tr>
<td>Internet ExplorerNo</td>
</tr>
<tr>
<td>Firefox Android94+Safari iOS13.4+Chrome Android77+WebView Android77+WebView Android77+Samsung Internet12.0+Opera Android57+</td>
</tr>
</tbody>
</table>

The `enterkeyhint` content attribute is an enumerated attribute that specifies what action label (or icon) to present for the enter key on virtual keyboards. This allows authors to
customize the presentation of the enter key in order to make it more helpful for users.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enter</td>
<td>The user agent should present a cue for the operation ‘enter’, typically inserting a new line.</td>
</tr>
<tr>
<td>done</td>
<td>The user agent should present a cue for the operation ‘done’, typically meaning there is nothing more to input and the input method editor (IME) will be closed.</td>
</tr>
<tr>
<td>go</td>
<td>The user agent should present a cue for the operation ‘go’, typically meaning to take the user to the target of the text they typed.</td>
</tr>
<tr>
<td>next</td>
<td>The user agent should present a cue for the operation ‘next’, typically taking the user to the next field that will accept text.</td>
</tr>
<tr>
<td>previous</td>
<td>The user agent should present a cue for the operation ‘previous’, typically taking the user to the previous field that will accept text.</td>
</tr>
<tr>
<td>search</td>
<td>The user agent should present a cue for the operation ‘search’, typically taking the user to the results of searching for the text they have typed.</td>
</tr>
<tr>
<td>send</td>
<td>The user agent should present a cue for the operation ‘send’, typically delivering the text to its target.</td>
</tr>
</tbody>
</table>

** HTMLElement/enterKeyHint**

Support in all current engines.

<table>
<thead>
<tr>
<th>Engine</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>94+</td>
</tr>
<tr>
<td>Safari</td>
<td>13.1+</td>
</tr>
<tr>

<tr>
<td>Opera Android</td>
<td>55+</td>
</tr>
</tbody>
</table>

The `enterKeyHint` IDL attribute must reflect the `enterkeyhint` content attribute, limited to only known values.

When `enterkeyhint` is unspecified (or is in a state not supported by the user agent), the user agent should determine the default action label (or icon) to present. Contextual information such as the `inputmode`, `type`, or `pattern` attributes should be used to determine which action label (or icon) to present on the virtual keyboard.

### 6.9 Find-in-page

#### 6.9.1 Introduction

This section defines find-in-page — a common user-agent mechanism which allows users to search through the contents of the page for particular information.

Access to find-in-page feature is provided via a find-in-page interface. This is a user-agent
provided user interface, which allows the user to specify input and the parameters of the search. This interface can appear as a result of a shortcut or a menu selection.

A combination of text input and settings in the find-in-page interface represents the user query. This typically includes the text that the user wants to search for, as well as optional settings (e.g., the ability to restrict the search to whole words only).

The user-agent processes page contents for a given query, and identifies zero or more matches, which are content ranges that satisfy the user query.

One of the matches is identified to the user as the active match. It is highlighted and scrolled into view. The user can navigate through the matches by advancing the active match using the find-in-page interface.

Issue #3539 tracks standardizing how find-in-page underlies the currently-unspecified window.find() API.

6.9.2 Interaction with details

When find-in-page begins searching for matches, all details elements in the page which do not have their open attribute set should have the skipped contents of their second slot become accessible, without modifying the open attribute, in order to make find-in-page able to search through it. After find-in-page finishes searching for matches, those details elements should have their contents become skipped again. This entire process must happen synchronously (and so is not observable to users or to author code). [CSSCONTAIN]

When find-in-page chooses a new active match, perform the following steps:

1. Let node be the first node in the active match.
2. Queue a global task on the user interaction task source given node's relevant global object to run the ancestor details revealing algorithm on node.

(This is a tracking vector.) When find-in-page auto-expands a details element like this, it will fire a toggle event. As with the separate scroll event that find-in-page fires, this event could be used by the page to discover what the user is typing into the find-in-page dialog. If the page creates a tiny scrollable area with the current search term and every possible next character the user could type separated by a gap, and observes which one the browser scrolls to, it can add that character to the search term and update the scrollable area to incrementally build the search term. By wrapping each possible next match in a closed details element, the page could listen to toggle events instead of scroll events. This attack could be addressed for both events by not acting on every character the user types into the find-in-page dialog.
6.9.3 Interaction with selection

The find-in-page process is invoked in the context of a document, and may have an effect on the selection of that document. Specifically, the range that defines the active match can dictate the current selection. These selection updates, however, can happen at different times during the find-in-page process (e.g. upon the find-in-page interface dismissal or upon a change in the active match range).

6.10 Drag and drop

![MDN](https://developer.mozilla.org/en-US/docs/Web/API/Drag_and_Drop_API)

**HTML Drag and Drop API**

Support in all current engines.

This section defines an event-based drag-and-drop mechanism.

This specification does not define exactly what a drag-and-drop operation actually is.

On a visual medium with a pointing device, a drag operation could be the default action of a mousedown event that is followed by a series ofmousemove events, and the drop could be triggered by the mouse being released.

When using an input modality other than a pointing device, users would probably have to explicitly indicate their intention to perform a drag-and-drop operation, stating what they wish to drag and where they wish to drop it, respectively.

However it is implemented, drag-and-drop operations must have a starting point (e.g. where the mouse was clicked, or the start of the selection or element that was selected for the drag), may have any number of intermediate steps (elements that the mouse moves over during a drag, or elements that the user picks as possible drop points as they cycle through possibilities), and must either have an end point (the element above which the mouse button was released, or the element that was finally selected), or be canceled. The end point must be the last element selected as a possible drop point before the drop occurs (so if the operation is not canceled, there must be at least one element in the middle step).

6.10.1 Introduction

*This section is non-normative.*
To make an element draggable, give the element a `draggable` attribute, and set an event listener for `dragstart` that stores the data being dragged.

The event handler typically needs to check that it’s not a text selection that is being dragged, and then needs to store data into the `DataTransfer` object and set the allowed effects (copy, move, link, or some combination).

For example:

```html
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)"
    draggable="true" data-value="fruit-apple">Apples</li>
<li draggable="true" data-value="fruit-orange">Oranges</li>
<li draggable="true" data-value="fruit-pear">Pears</li>
</ol>
<script>
var internalDNDType = 'text/x-example'; // set this to something specific to your site
function dragStartHandler(event) {
    if (event.target instanceof HTMLLIElement) {
        // use the element's data-value= attribute as the value to be moving:
        event.dataTransfer.setData(internalDNDType, event.target.dataset.value);
        event.dataTransfer.effectAllowed = 'move'; // only allow moves
    } else {
        event.preventDefault(); // don't allow selection to be dragged
    }
}
</script>
```

To accept a drop, the drop target has to listen to the following events:

1. The `dragenter` event handler reports whether or not the drop target is potentially willing to accept the drop, by canceling the event.
2. The `dragover` event handler specifies what feedback will be shown to the user, by setting the `dropEffect` attribute of the `DataTransfer` associated with the event. This event also needs to be canceled.
3. The `drop` event handler has a final chance to accept or reject the drop. If the drop is accepted, the event handler must perform the drop operation on the target. This event needs to be canceled, so that the `dropEffect` attribute’s value can be used by the source. Otherwise, the drop operation is rejected.

For example:

```html
<p>Drop your favorite fruits below:</p>
<ol ondragenter="dragEnterHandler(event)" ondragover="dragOverHandler(event)"
dondrop="dropHandler(event)"
</ol>
```
<script>
var internalDNDType = 'text/x-example'; // set this to something specific to your site

function dragEnterHandler(event) {
    var items = event.dataTransfer.items;
    for (var i = 0; i < items.length; ++i) {
        var item = items[i];
        if (item.kind == 'string' && item.type == internalDNDType) {
            event.preventDefault();
            return;
        }
    }
}

function dragOverHandler(event) {
    event.dataTransfer.dropEffect = 'move';
    event.preventDefault();
}

function dropHandler(event) {
    var li = document.createElement('li');
    var data = event.dataTransfer.getData(internalDNDType);
    if (data == 'fruit-apple') {
        li.textContent = 'Apples';
    } else if (data == 'fruit-orange') {
        li.textContent = 'Oranges';
    } else if (data == 'fruit-pear') {
        li.textContent = 'Pears';
    } else {
        li.textContent = 'Unknown Fruit';
    }
    event.target.appendChild(li);
}
</script>

To remove the original element (the one that was dragged) from the display, the dragend event can be used.

For our example here, that means updating the original markup to handle that event:

<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)" ondragend="dragEndHandler(event)">
    ...as before...
</ol>
<script>
    function dragStartHandler(event) {
        // ...as before...
    }
    function dragEndHandler(event) {

```javascript
if (event.dataTransfer.dropEffect == 'move') {
  // remove the dragged element
  event.target.parentNode.removeChild(event.target);
}
</script>

6.10.2 The drag data store

The data that underlies a drag-and-drop operation, known as the drag data store, consists of the following information:

- A drag data store item list, which is a list of items representing the dragged data, each consisting of the following information:

  **The drag data item kind**

  The kind of data:

  *Text*

  Text.

  *File*

  Binary data with a filename.

  **The drag data item type string**

  A Unicode string giving the type or format of the data, generally given by a MIME type. Some values that are not MIME types are special-cased for legacy reasons. The API does not enforce the use of MIME types; other values can be used as well. In all cases, however, the values are all converted to ASCII lowercase by the API.

  There is a limit of one text item per item type string.

  **The actual data**

  A Unicode or binary string, in some cases with a filename (itself a Unicode string), as per the drag data item kind.

  The drag data store item list is ordered in the order that the items were added to the list; most recently added last.

- The following information, used to generate the UI feedback during the drag:

  - User-agent-defined default feedback information, known as the drag data store default feedback.
• Optionally, a bitmap image and the coordinate of a point within that image, known as the drag data store bitmap and drag data store hot spot coordinate.

• A drag data store mode, which is one of the following:

  **Read/write mode**
  
  For the dragstart event. New data can be added to the drag data store.

  **Read-only mode**
  
  For the drop event. The list of items representing dragged data can be read, including the data. No new data can be added.

  **Protected mode**
  
  For all other events. The formats and kinds in the drag data store list of items representing dragged data can be enumerated, but the data itself is unavailable and no new data can be added.

• A drag data store allowed effects state, which is a string.

When a drag data store is created, it must be initialized such that its drag data store item list is empty, it has no drag data store default feedback, it has no drag data store bitmap and drag data store hot spot coordinate, its drag data store mode is protected mode, and its drag data store allowed effects state is the string “uninitialized”.

6.10.3 The DataTransfer interface

[Exposed=Window]
interface DataTransfer {

  constructor();
}
attribute DOMString dropEffect;
attribute DOMString effectAllowed;

[SameObject] readonly attribute DataTransferItemList items;

undefined setDragImage(Element image, long x, long y);

/* old interface */
readonly attribute FrozenArray&lt;DOMString&gt; types;
DOMString getData(DOMString format);
undefined setData(DOMString format, DOMString data);
undefined clearData(optional DOMString format);
[SameObject] readonly attribute FileList files;

};

dataTransfer = new DataTransfer()

DataTransfer/DataTransfer

Support in all current engines.

Firefox62+Safari14.1+Chrome60+
Opera47+Edge79+
Edge (Legacy)17+Internet ExplorerNo
Firefox Android62+Safari iOS14.5+Chrome Android60+WebView Android60+Samsung
Internet8.0+Opera Android44+

Creates a new DataTransfer object with an empty drag data store.

dataTransfer.dropEffect [ = value ]

DataTransfer/dropEffect

Support in all current engines.

Firefox3.5+Safari4+Chrome3+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer8+
Firefox Android4+Safari iOS3+Chrome Android18+WebView Android37+Samsung
Internet1.0+Opera Android12.1+

Returns the kind of operation that is currently selected. If the kind of operation isn’t one of those that is allowed by the effectAllowed attribute, then the operation will fail.
Can be set, to change the selected operation.

The possible values are "none", "copy", "link", and "move".

`dataTransfer.effectAllowed [ = value ]`

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 3+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 8+
Firefox Android 4+ Safari iOS 3+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the kinds of operations that are to be allowed.

Can be set (during the `dragstart` event), to change the allowed operations.

The possible values are "none", "copy", "copyLink", "copyMove", "link", "linkMove", "move", "all", and "uninitialized".

`dataTransfer.items`

Support in all current engines.

Firefox 50+ Safari 11.1+ Chrome 4+
Opera 12+ Edge 79+
Edge (Legacy) 12+ Internet Explorer No
Firefox Android 52+ Safari iOS 11.3+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12+

Returns a `DataTransferItemList` object, with the drag data.

`dataTransfer.setDragImage(element, x, y)`
Uses the given element to update the drag feedback, replacing any previously specified feedback.

**dataTransfer.types**

Support in all current engines.

- Firefox 3.5+ Safari 4+ Chrome 3+
- Opera 12.1+ Edge 79+
- Edge (Legacy) 12+ Internet Explorer 10+
- Firefox Android 4+ Safari iOS 3+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Returns a frozen array listing the formats that were set in the `dataTransfer` event. In addition, if any files are being dragged, then one of the types will be the string “Files”.

**data = dataTransfer.getData(format)**

Support in all current engines.

- Firefox 3.5+ Safari 4+ Chrome 3+
- Opera 12.1+ Edge 79+
- Edge (Legacy) 12+ Internet Explorer 8+
- Firefox Android 4+ Safari iOS 3+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the specified data. If there is no such data, returns the empty string.

**dataTransfer.setData(format, data)**

Support in all current engines.

- Firefox 3.5+ Safari 4+ Chrome 3+
- Opera 12.1+ Edge 79+
- Edge (Legacy) 12+ Internet Explorer 8+
- Firefox Android 4+ Safari iOS 3+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+
Support in all current engines.

Firefox10+Safari5+Chrome3+
Opera12+Edge79+
Edge (Legacy)12+Internet Explorer8+
Firefox Android10+Safari iOS5+Chrome Android18+WebView Android37+Samsung
Internet1.0+Opera Android12+

Adds the specified data.

dataTransfer.\texttt{clearData}([ \texttt{format} ])

Support in all current engines.

Firefox3.5+Safari4+Chrome3+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer8+
Firefox Android4+Safari iOS3+Chrome Android18+WebView Android37+Samsung
Internet1.0+Opera Android12.1+

Removes the data of the specified formats. Removes all data if the argument is omitted.

dataTransfer.\texttt{files}

Support in all current engines.

Firefox3.6+Safari4+Chrome3+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer10+
Firefox Android4+Safari iOS3+Chrome Android18+WebView Android37+Samsung
Internet1.0+Opera Android12.1+

Returns a FileList of the files being dragged, if any.

DataTransfer objects that are created as part of drag-and-drop events are only valid while those events are being fired.

A DataTransfer object is associated with a drag data store while it is valid.

A DataTransfer object has an associated types array, which is a
FrozenArray<DOMString>, initially empty. When the contents of the DataTransfer object’s drag data store item list change, or when the DataTransfer object becomes no longer associated with a drag data store, run the following steps:

1. Let \( L \) be an empty sequence.

2. If the DataTransfer object is still associated with a drag data store, then:
   
   1. For each item in the DataTransfer object’s drag data store item list whose kind is text, add an entry to \( L \) consisting of the item’s type string.
   
   2. If there are any items in the DataTransfer object’s drag data store item list whose kind is File, then add an entry to \( L \) consisting of the string ”Files”. (This value can be distinguished from the other values because it is not lowercase.)

3. Set the DataTransfer object’s types array to the result of creating a frozen array from \( L \).

The DataTransfer() constructor, when invoked, must return a newly created DataTransfer object initialized as follows:

1. Set the drag data store’s item list to be an empty list.

2. Set the drag data store’s mode to read/write mode.

3. Set the dropEffect and effectAllowed to “none”.

The dropEffect attribute controls the drag-and-drop feedback that the user is given during a drag-and-drop operation. When the DataTransfer object is created, the dropEffect attribute is set to a string value. On getting, it must return its current value. On setting, if the new value is one of ”none”, ”copy”, ”link”, or ”move”, then the attribute’s current value must be set to the new value. Other values must be ignored.

The effectAllowed attribute is used in the drag-and-drop processing model to initialize the dropEffect attribute during the dragenter and dragover events. When the DataTransfer object is created, the effectAllowed attribute is set to a string value. On getting, it must return its current value. On setting, if drag data store’s mode is the read/write mode and the new value is one of ”none”, ”copy”, ”copyLink”, ”copyMove”, ”link”, ”linkMove”, ”move”, ”all”, or ”uninitialized”, then the attribute’s current value must be set to the new value. Otherwise it must be left unchanged.

The items attribute must return a DataTransferItemList object associated with the DataTransfer object.

The setDragImage(image, x, y) method must run the following steps:

1. If the DataTransfer object is no longer associated with a drag data store, return.
Nothing happens.

2. If the drag data store's mode is not the read/write mode, return. Nothing happens.

3. If image is an img element, then set the drag data store bitmap to the element's image (at its intrinsic size); otherwise, set the drag data store bitmap to an image generated from the given element (the exact mechanism for doing so is not currently specified).

4. Set the drag data store hot spot coordinate to the given x, y coordinate.

The types attribute must return this DataTransfer object’s types array.

The `getData(format)` method must run the following steps:

1. If the DataTransfer object is no longer associated with a drag data store, then return the empty string.

2. If the drag data store’s mode is the protected mode, then return the empty string.

3. Let format be the first argument, converted to ASCII lowercase.

4. Let convert-to-URL be false.

5. If format equals “text”, change it to “text/plain”.

6. If format equals “url”, change it to “text/uri-list” and set convert-to-URL to true.

7. If there is no item in the drag data store item list whose kind is text and whose type string is equal to format, return the empty string.

8. Let result be the data of the item in the drag data store item list whose kind is Plain Unicode string and whose type string is equal to format.

9. If convert-to-URL is true, then parse result as appropriate for text/uri-list data, and then set result to the first URL from the list, if any, or the empty string otherwise. [RFC2483]

10. Return result.

The `setData(format, data)` method must run the following steps:

1. If the DataTransfer object is no longer associated with a drag data store, return. Nothing happens.

2. If the drag data store’s mode is not the read/write mode, return. Nothing happens.

3. Let format be the first argument, converted to ASCII lowercase.
4. If \textit{format} equals "text", change it to "text/plain".

If \textit{format} equals "url", change it to "text/uri-list".

5. Remove the item in the drag data store item list whose kind is text and whose type string is equal to \textit{format}, if there is one.

6. Add an item to the drag data store item list whose kind is text, whose type string is equal to \textit{format}, and whose data is the string given by the method's second argument.

The \texttt{clearData(\textit{format})} method must run the following steps:

1. If the \texttt{DataTransfer} object is no longer associated with a drag data store, return. Nothing happens.

2. If the drag data store's mode is not the read/write mode, return. Nothing happens.

3. If the method was called with no arguments, remove each item in the drag data store item list whose kind is Plain Unicode string, and return.

4. Set \textit{format} to \textit{format}, converted to ASCII lowercase.

5. If \textit{format} equals "text", change it to "text/plain".

If \textit{format} equals "url", change it to "text/uri-list".

6. Remove the item in the drag data store item list whose kind is text and whose type string is equal to \textit{format}, if there is one.

The \texttt{clearData()} method does not affect whether any files were included in the drag, so the \texttt{types} attribute's list might still not be empty after calling \texttt{clearData()} (it would still contain the "Files" string if any files were included in the drag).

The \texttt{files} attribute must return a live FileList sequence consisting of File objects representing the files found by the following steps. Furthermore, for a given FileList object and a given underlying file, the same File object must be used each time.

1. Start with an empty list \texttt{L}.

2. If the \texttt{DataTransfer} object is no longer associated with a drag data store, the FileList is empty. Return the empty list \texttt{L}.

3. If the drag data store's mode is the protected mode, Return the empty list \texttt{L}.

4. For each item in the drag data store item list whose kind is File, add the item's data (the file, in particular its name and contents, as well as its type) to the list \texttt{L}.

5. The files found by these steps are those in the list \texttt{L}. 
This version of the API does not expose the types of the files during the drag.

6.10.3.1 The `DataTransferItemList` interface

![MDN](https://developer.mozilla.org/en-US/docs/Web/API/DataTransferItemList)

`DataTransferItemList`

Support in all current engines.

<table>
<thead>
<tr>
<th></th>
<th>Firefox</th>
<th>Safari</th>
<th>Chrome</th>
<th>Opera</th>
<th>Edge</th>
<th>Internet Explorer</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>50+</td>
<td>6+</td>
<td>13+</td>
<td>12+</td>
<td>79+</td>
<td>No</td>
</tr>
</tbody>
</table>

Each `DataTransfer` object is associated with a `DataTransferItemList` object.

```javascript
[Exposed=Window]
interface DataTransferItemList {
    readonly attribute unsigned long length;
    getter DataTransferItem (unsigned long index);
    DataTransferItem? add(DOMString data, DOMString type);
    DataTransferItem? add(File data);
    undefined remove(unsigned long index);
    undefined clear();
};
```

`items.length`  ![MDN](https://developer.mozilla.org/en-US/docs/Web/API/DataTransferItemList/length)

`DataTransferItemList/length`

Support in all current engines.

<table>
<thead>
<tr>
<th></th>
<th>Firefox</th>
<th>Safari</th>
<th>Chrome</th>
<th>Opera</th>
<th>Edge</th>
<th>Internet Explorer</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>50+</td>
<td>6+</td>
<td>13+</td>
<td>12+</td>
<td>79+</td>
<td>No</td>
</tr>
</tbody>
</table>

Returns the number of items in the drag data store.

`items[index]`

Returns the `DataTransferItem` object representing the `index`th entry in the drag data.
store.

\texttt{items.remove(index)}

\texttt{DataTransferItemList/remove}

Support in all current engines.

Firefox50+Safari6+Chrome31+
Opera12+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android50+Safari iOS6+Chrome Android31+WebView Android4.4.3+Samsung
Internet2.0+Opera AndroidNo

Removes the \textit{index}th entry in the \textit{drag data store}.

\texttt{items.clear()}

\texttt{DataTransferItemList/clear}

Support in all current engines.

Firefox50+Safari6+Chrome13+
Opera12+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android50+Safari iOS6+Chrome Android18+WebView Android4.4.3+Samsung
Internet1.0+Opera AndroidNo

Removes all the entries in the \textit{drag data store}.
`items.add(data)`

Support in all current engines.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Opera Android</td>
<td>No</td>
</tr>
</tbody>
</table>

`items.add(data, type)`

Adds a new entry for the given data to the drag data store. If the data is plain text then a type string has to be provided also.

While the `DataTransferItemList` object’s `DataTransfer` object is associated with a drag data store, the `DataTransferItemList` object’s mode is the same as the drag data store mode. When the `DataTransferItemList` object’s `DataTransfer` object is not associated with a drag data store, the `DataTransferItemList` object’s mode is the disabled mode. The drag data store referenced in this section (which is used only when the `DataTransferItemList` object is not in the disabled mode) is the drag data store with which the `DataTransferItemList` object’s `DataTransfer` object is associated.

The `length` attribute must return zero if the object is in the disabled mode; otherwise it must return the number of items in the drag data store item list.

When a `DataTransferItemList` object is not in the disabled mode, its supported property indices are the indices of the drag data store item list.

To determine the value of an indexed property `i` of a `DataTransferItemList` object, the user agent must return a `DataTransferItem` object representing the `i`th item in the drag data store. The same object must be returned each time a particular item is obtained from this `DataTransferItemList` object. The `DataTransferItem` object must be associated with the same `DataTransfer` object as the `DataTransferItemList` object when it is first created.

The `add()` method must run the following steps:

1. If the `DataTransferItemList` object is not in the read/write mode, return null.
2. Jump to the appropriate set of steps from the following list:
If the first argument to the method is a string

If there is already an item in the drag data store item list whose kind is text and whose type string is equal to the value of the method’s second argument, converted to ASCII lowercase, then throw a "NotSupportedException" DOMException.

Otherwise, add an item to the drag data store item list whose kind is text, whose type string is equal to the value of the method’s second argument, converted to ASCII lowercase, and whose data is the string given by the method’s first argument.

If the first argument to the method is a File

Add an item to the drag data store item list whose kind is File, whose type string is the type of the File, converted to ASCII lowercase, and whose data is the same as the File’s data.

3. Determine the value of the indexed property corresponding to the newly added item, and return that value (a newly created DataTransferItem object).

The remove(index) method must run these steps:

1. If the DataTransferItemList object is not in the read/write mode, throw an “InvalidStateError” DOMException.

2. Remove the indexth item from the drag data store.

The clear() method, if the DataTransferItemList object is in the read/write mode, must remove all the items from the drag data store. Otherwise, it must do nothing.

6.10.3.2 The DataTransferItem interface

DataTransferItem

Support in all current engines.

Firefox50+Safari5.1+Chrome11+
Opera12+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android50+Safari iOS5+Chrome Android18+WebView Android4+Samsung
Internet1.0+Opera AndroidNo

Each DataTransferItem object is associated with a DataTransfer object.

[Exposed=Window]
interface DataTransferItem {
    readonly attribute DOMString kind;
    readonly attribute DOMString type;
    undefined getAsString(FunctionStringCallback? _callback);
    File? getAsFile();
};

callback FunctionStringCallback = undefined (DOMString data);

**item.kind**

DataTransferItem/kind

Support in all current engines.

Firebox50+Safari5.1+Chrome11+
Opera12+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android50+Safari iOS5+Chrome Android18+WebView Android4+Samsung
Internet1.0+Opera AndroidNo

Returns the drag data item kind, one of: "string", "file".

**item.type**

DataTransferItem/type

Support in all current engines.

Firebox50+Safari5.1+Chrome11+
Opera12+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android50+Safari iOS5+Chrome Android18+WebView Android4+Samsung
Internet1.0+Opera AndroidNo

Returns the drag data item type string.

**item.getAsString(callback)**

DataTransferItem/getAsString

Support in all current engines.
Invokes the callback with the string data as the argument, if the drag data item kind is text.

```javascript
file = item.getAsFile()
```

DataTransferItem/getAsFile

Support in all current engines.

</tbody>
</table>

Returns a File object, if the drag data item kind is File.

While the DataTransferItem object’s DataTransfer object is associated with a drag data store and that drag data store’s drag data store item list still contains the item that the DataTransferItem object represents, the DataTransferItem object’s mode is the same as the drag data store mode. When the DataTransferItem object’s DataTransfer object is not associated with a drag data store, or if the item that the DataTransferItem object represents has been removed from the relevant drag data store item list, the DataTransferItem object’s mode is the disabled mode. The drag data store referenced in this section (which is used only when the DataTransferItem object is not in the disabled mode) is the drag data store with which the DataTransferItem object’s DataTransfer object is associated.

The kind attribute must return the empty string if the DataTransferItem object is in the disabled mode; otherwise it must return the string given in the cell from the second column of the following table from the row whose cell in the first column contains the drag data item kind of the item represented by the DataTransferItem object:

<table>
<thead>
<tr>
<th>Kind</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>&quot;string&quot;</td>
</tr>
<tr>
<td>File</td>
<td>&quot;file&quot;</td>
</tr>
</tbody>
</table>

The type attribute must return the empty string if the DataTransferItem object is in the
disabled mode; otherwise it must return the drag data item type string of the item represented by the `DataTransferItem` object.

The `getAsString(callback)` method must run the following steps:

1. If the `callback` is null, return.

2. If the `DataTransferItem` object is not in the **read/write mode** or the **read-only mode**, return. The callback is never invoked.

3. If the drag data item kind is not **text**, then return. The callback is never invoked.

4. Otherwise, queue a task to invoke `callback`, passing the actual data of the item represented by the `DataTransferItem` object as the argument.

The `getAsFile()` method must run the following steps:

1. If the `DataTransferItem` object is not in the **read/write mode** or the **read-only mode**, then return null.

2. If the drag data item kind is not **File**, then return null.

3. Return a new `File` object representing the actual data of the item represented by the `DataTransferItem` object.

6.10.4 The `DragEvent` interface

</table>
The drag-and-drop processing model involves several events. They all use the DragEvent interface.

```
[Exposed=Window]
interface DragEvent : MouseEvent {
    constructor(DOMString type, optional DragEventInit eventInitDict = {});

    readonly attribute DataTransfer? dataTransfer;
};

dictionary DragEventInit : MouseEventInit {
    DataTransfer? dataTransfer = null;
};
```

The `dataTransfer` attribute of the DragEvent interface must return the value it was initialized to. It represents the context information for the event.

Although, for consistency with other event interfaces, the DragEvent interface has a constructor, it is not particularly useful. In particular, there's no way to create a useful DataTransfer object from script, as DataTransfer objects have a processing and security model that is coordinated by the browser during drag-and-drops.

The `dataTransfer` attribute of the DragEvent interface must return the value it was initialized to. It represents the context information for the event.

When a user agent is required to fire a DND event named `e` at an element, using a particular drag data store, and optionally with a specific related target, the user agent must run the following steps:

1. Let `dataDragStoreWasChanged` be false.
2. If no specific related target was provided, set related target to null.
3. Let window be the relevant global object of the Document object of the specified target element.

4. If e is dragstart, then set the drag data store mode to the read/write mode and set dataDragStoreWasChanged to true.

If e is drop, set the drag data store mode to the read-only mode.

5. Let dataTransfer be a newly created DataTransfer object associated with the given drag data store.

6. Set the effectAllowed attribute to the drag data store’s drag data store allowed effects state.

7. Set the dropEffect attribute to “none” if e is dragstart, drag, or dragleave; to the value corresponding to the current drag operation if e is drop or dragend; and to a value based on the effectAllowed attribute’s value and the drag-and-drop source, as given by the following table, otherwise (i.e. if e is dragenter or dragover):

<table>
<thead>
<tr>
<th>effectAllowed</th>
<th>dropEffect</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;none&quot;</td>
<td>&quot;none&quot;</td>
</tr>
<tr>
<td>&quot;copy&quot;</td>
<td>&quot;copy&quot;</td>
</tr>
<tr>
<td>&quot;copyLink&quot;</td>
<td>&quot;copy&quot;, or, if appropriate, &quot;link&quot;</td>
</tr>
<tr>
<td>&quot;copyMove&quot;</td>
<td>&quot;copy&quot;, or, if appropriate, &quot;move&quot;</td>
</tr>
<tr>
<td>&quot;all&quot;</td>
<td>&quot;copy&quot;, or, if appropriate, either &quot;link&quot; or &quot;move&quot;</td>
</tr>
<tr>
<td>&quot;link&quot;</td>
<td>&quot;link&quot;</td>
</tr>
<tr>
<td>&quot;linkMove&quot;</td>
<td>&quot;link&quot;, or, if appropriate, &quot;move&quot;</td>
</tr>
<tr>
<td>&quot;move&quot;</td>
<td>&quot;move&quot;</td>
</tr>
<tr>
<td>&quot;uninitialized&quot;</td>
<td>&quot;move&quot;, or, if appropriate, either &quot;copy&quot; or &quot;link&quot;</td>
</tr>
<tr>
<td>&quot;uninitialized&quot;</td>
<td>&quot;copy&quot;, or, if appropriate, either &quot;link&quot; or &quot;move&quot;</td>
</tr>
<tr>
<td>&quot;uninitialized&quot;</td>
<td>&quot;copy&quot;, or, if appropriate, either &quot;link&quot; or &quot;move&quot;</td>
</tr>
<tr>
<td>element with an href attribute</td>
<td>&quot;copy&quot;, or, if appropriate, either &quot;link&quot; or &quot;move&quot;</td>
</tr>
<tr>
<td>Any other case</td>
<td>&quot;copy&quot;, or, if appropriate, either &quot;link&quot; or &quot;move&quot;</td>
</tr>
</tbody>
</table>

Where the table above provides possibly appropriate alternatives, user agents may instead use the listed alternative values if platform conventions dictate that the user has requested those alternate effects.
For example, Windows platform conventions are such that dragging while holding the "alt" key indicates a preference for linking the data, rather than moving or copying it. Therefore, on a Windows system, if "link" is an option according to the table above while the "alt" key is depressed, the user agent could select that instead of "copy" or "move".

8. Let event be the result of creating an event using DragEvent.

9. Initialize event's type attribute to e, its bubbles attribute to true, its view attribute to window, its relatedTarget attribute to related target, and its dataTransfer attribute to dataTransfer.

10. If e is not dragleave or dragend, then initialize event's cancelable attribute to true.

11. Initialize event's mouse and key attributes initialized according to the state of the input devices as they would be for user interaction events.

   If there is no relevant pointing device, then initialize event's screenX, screenY, clientX, clientY, and button attributes to 0.

12. Dispatch event at the specified target element.

13. Set the drag data store allowed effects state to the current value of dataTransfer's effectAllowed attribute. (It can only have changed value if e is dragstart.)

14. If dataDragStoreWasChanged is true, then set the drag data store mode back to the protected mode.

15. Break the association between dataTransfer and the drag data store.

6.10.5 Processing model

When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent’s purview.

1. Determine what is being dragged, as follows:

   If the drag operation was invoked on a selection, then it is the selection that is being dragged.

   Otherwise, if the drag operation was invoked on a Document, it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute draggable set to true. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.
Otherwise, the drag operation was invoked outside the user agent’s purview. What is being dragged is defined by the document or application where the drag was started.

**img** elements and **a** elements with an **href** attribute have their **draggable** attribute set to true by default.

2. **Create a drag data store.** All the DND events fired subsequently by the steps in this section must use this **drag data store**.

3. Establish which DOM node is the **source node**, as follows:

   If it is a selection that is being dragged, then the **source node** is the **Text** node that the user started the drag on (typically the **Text** node that the user originally clicked). If the user did not specify a particular node, for example if the user just told the user agent to begin a drag of “the selection”, then the **source node** is the first **Text** node containing a part of the selection.

   Otherwise, if it is an element that is being dragged, then the **source node** is the element that is being dragged.

   Otherwise, the **source node** is part of another document or application. When this specification requires that an event be dispatched at the **source node** in this case, the user agent must instead follow the platform-specific conventions relevant to that situation.

   Multiple events are fired on the **source node** during the course of the drag-and-drop operation.

4. Determine the **list of dragged nodes**, as follows:

   If it is a selection that is being dragged, then the **list of dragged nodes** contains, in **tree order**, every node that is partially or completely included in the selection (including all their ancestors).

   Otherwise, the **list of dragged nodes** contains only the **source node**, if any.

5. If it is a selection that is being dragged, then add an item to the **drag data store item list**, with its properties set as follows:

   **The drag data item type string**
   
   "text/plain"

   **The drag data item kind**
   
   **Text**

   **The actual data**
   
   The text of the selection
Otherwise, if any files are being dragged, then add one item per file to the drag data store item list, with their properties set as follows:

**The drag data item type string**
- The MIME type of the file, if known, or “application/octet-stream” otherwise.

**The drag data item kind**
- File

**The actual data**
- The file’s contents and name.

Dragging files can currently only happen from outside a browsing context, for example from a file system manager application.

If the drag initiated outside of the application, the user agent must add items to the drag data store item list as appropriate for the data being dragged, honoring platform conventions where appropriate; however, if the platform conventions do not use MIME types to label dragged data, the user agent must make a best-effort attempt to map the types to MIME types, and, in any case, all the drag data item type strings must be converted to ASCII lowercase.

User agents may also add one or more items representing the selection or dragged element(s) in other forms, e.g. as HTML.

6. If the list of dragged nodes is not empty, then extract the microdata from those nodes into a JSON form, and add one item to the drag data store item list, with its properties set as follows:

**The drag data item type string**
- application/microdata+json

**The drag data item kind**
- Text

**The actual data**
- The resulting JSON string.

7. Run the following substeps:

   1. Let urls be an empty list of absolute URLs.

   2. For each node in the list of dragged nodes:

      If the node is an a element with an href attribute
      - Add to urls the result of parsing the element’s href content attribute relative to the element’s node document.
If the node is an img element with a src attribute
Add to urls the result of parsing the element’s src content attribute relative to the element’s node document.

3. If urls is still empty, then return.

4. Let url string be the result of concatenating the strings in urls, in the order they were added, separated by a U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF).

5. Add one item to the drag data store item list, with its properties set as follows:

<table>
<thead>
<tr>
<th>The drag data item type string</th>
<th>text/uri-list</th>
</tr>
</thead>
<tbody>
<tr>
<td>The drag data item kind</td>
<td>Text</td>
</tr>
<tr>
<td>The actual data</td>
<td>url string</td>
</tr>
</tbody>
</table>

8. Update the drag data store default feedback as appropriate for the user agent (if the user is dragging the selection, then the selection would likely be the basis for this feedback; if the user is dragging an element, then that element’s rendering would be used; if the drag began outside the user agent, then the platform conventions for determining the drag feedback should be used).

9. Fire a DND event named dragstart at the source node.

If the event is canceled, then the drag-and-drop operation should not occur; return.

Since events with no event listeners registered are, almost by definition, never canceled, drag-and-drop is always available to the user if the author does not specifically prevent it.

10. Fire a pointer event at the source node named pointercancel, and fire any other follow-up events as required by Pointer Events. [POINTEREVENTS]

11. Initiate the drag-and-drop operation in a manner consistent with platform conventions, and as described below.

The drag-and-drop feedback must be generated from the first of the following sources that is available:

1. The drag data store bitmap, if any. In this case, the drag data store hot spot coordinate should be used as hints for where to put the cursor relative to the resulting image. The values are expressed as distances in CSS pixels from the left side and from the top side of the image respectively. [CSS]
2. The **drag data store default feedback**.

From the moment that the user agent is to *initiate the drag-and-drop operation*, until the end of the drag-and-drop operation, device input events (e.g. mouse and keyboard events) must be suppressed.

During the drag operation, the element directly indicated by the user as the drop target is called the *immediate user selection*. (Only elements can be selected by the user; other nodes must not be made available as drop targets.) However, the *immediate user selection* is not necessarily the *current target element*, which is the element currently selected for the drop part of the drag-and-drop operation.

The *immediate user selection* changes as the user selects different elements (either by pointing at them with a pointing device, or by selecting them in some other way). The *current target element* changes when the *immediate user selection* changes, based on the results of event listeners in the document, as described below.

Both the *current target element* and the *immediate user selection* can be null, which means no target element is selected. They can also both be elements in other (DOM-based) documents, or other (non-web) programs altogether. (For example, a user could drag text to a word-processor.) The *current target element* is initially null.

In addition, there is also a *current drag operation*, which can take on the values "*none*", "*copy*", "*link*", and "*move*". Initially, it has the value "*none*". It is updated by the user agent as described in the steps below.

User agents must, as soon as the drag operation is *initiated* and every 350ms (±200ms) thereafter for as long as the drag operation is ongoing, queue a task to perform the following steps in sequence:

1. If the user agent is still performing the previous iteration of the sequence (if any) when the next iteration becomes due, return for this iteration (effectively "skipping missed frames" of the drag-and-drop operation).

2. **Fire a DND event** named **drag** at the **source node**. If this event is canceled, the user agent must set the **current drag operation** to "*none*" (no drag operation).

3. If the **drag** event was not canceled and the user has not ended the drag-and-drop operation, check the state of the drag-and-drop operation, as follows:

   1. If the user is indicating a different *immediate user selection* than during the last iteration (or if this is the first iteration), and if this *immediate user selection* is not the same as the *current target element*, then update the **current target element** as follows:

      **If the new *immediate user selection* is null**

      Set the **current target element** to null also.
If the new **immediate user selection** is in a non-DOM document or application

Set the **current target element** to the **immediate user selection**.

Otherwise

Fire a DND event named **dragenter** at the **immediate user selection**.

If the event is canceled, then set the **current target element** to the **immediate user selection**.

Otherwise, run the appropriate step from the following list:

If the **immediate user selection** is a text control (e.g., **textarea**, or an **input** element whose **type** attribute is in the Text state) or an editing host or editable element, and the drag data store item list has an item with the drag data item type string "text/plain" and the drag data item kind text

Set the **current target element** to the **immediate user selection** anyway.

If the **immediate user selection** is the body element

Leave the **current target element** unchanged.

Otherwise

Fire a DND event named **dragenter** at the body element, if there is one, or at the **Document** object, if not. Then, set the **current target element** to the body element, regardless of whether that event was canceled or not.

2. If the previous step caused the **current target element** to change, and if the previous target element was not null or a part of a non-DOM document, then fire a DND event named **dragleave** at the previous target element, with the new **current target element** as the specific related target.

3. If the **current target element** is a DOM element, then fire a DND event named **dragover** at this **current target element**.

If the **dragover** event is not canceled, run the appropriate step from the following list:
If the current target element is a text control (e.g., textarea, or an input element whose type attribute is in the Text state) or an editing host or editable element, and the drag data store item list has an item with the drag data item type string “text/plain” and the drag data item kind text

Set the current drag operation to either “copy” or “move”, as appropriate given the platform conventions.

Otherwise

Reset the current drag operation to “none”.

Otherwise (if the dragover event is canceled), set the current drag operation based on the values of the effectAllowed and dropEffect attributes of the DragEvent object’s dataTransfer object as they stood after the event dispatch finished, as per the following table:

<table>
<thead>
<tr>
<th>effectAllowed</th>
<th>dropEffect</th>
<th>Drag operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>“uninitialized”, “copy”, “copyLink”, “copyMove”, or “all”</td>
<td>“copy”</td>
<td>“copy”</td>
</tr>
<tr>
<td>“uninitialized”, “link”, “copyLink”, “linkMove”, or “all”</td>
<td>“link”</td>
<td>“link”</td>
</tr>
<tr>
<td>“uninitialized”, “move”, “copyMove”, “linkMove”, or “all”</td>
<td>“move”</td>
<td>“move”</td>
</tr>
<tr>
<td>Any other case</td>
<td></td>
<td>“none”</td>
</tr>
</tbody>
</table>

4. Otherwise, if the current target element is not a DOM element, use platform-specific mechanisms to determine what drag operation is being performed (none, copy, link, or move), and set the current drag operation accordingly.

5. Update the drag feedback (e.g. the mouse cursor) to match the current drag operation, as follows:

<table>
<thead>
<tr>
<th>Drag operation</th>
<th>Feedback</th>
</tr>
</thead>
<tbody>
<tr>
<td>“copy”</td>
<td>Data will be copied if dropped here.</td>
</tr>
<tr>
<td>“link”</td>
<td>Data will be linked if dropped here.</td>
</tr>
<tr>
<td>“move”</td>
<td>Data will be moved if dropped here.</td>
</tr>
<tr>
<td>“none”</td>
<td>No operation allowed, dropping here will cancel the drag-and-drop operation.</td>
</tr>
</tbody>
</table>

4. Otherwise, if the user ended the drag-and-drop operation (e.g. by releasing the mouse button in a mouse-driven drag-and-drop interface), or if the drag event was canceled, then this will be the last iteration. Run the following steps, then stop the drag-and-drop
If the current drag operation is "none" (no drag operation), or, if the user ended
the drag-and-drop operation by canceling it (e.g. by hitting the Escape key), or
if the current target element is null, then the drag operation failed. Run these
substeps:

1. Let dropped be false.
2. If the current target element is a DOM element, fire a DND event named
dragleave at it; otherwise, if it is not null, use platform-specific
conventions for drag cancelation.
3. Set the current drag operation to "none".

Otherwise, the drag operation might be a success; run these substeps:

1. Let dropped be true.
2. If the current target element is a DOM element, fire a DND event named
drop at it; otherwise, use platform-specific conventions for indicating a
drop.
3. If the event is canceled, set the current drag operation to the value of the
dropEffect attribute of the DragEvent object’s dataTransfer
object as it stood after the event dispatch finished.

Otherwise, the event is not canceled; perform the event’s default action,
which depends on the exact target as follows:

If the current target element is a text control (e.g., textarea, or an
input element whose type attribute is in the Text state) or an editing
host or editable element, and the drag data store item list has an item
with the drag data item type string "text/plain" and the drag data
item kind text

Insert the actual data of the first item in the drag data store item list
to have a drag data item type string of "text/plain" and a drag
data item kind that is text into the text control or editing host or
editable element in a manner consistent with platform-specific
conventions (e.g. inserting it at the current mouse cursor position, or
inserting it at the end of the field).

Otherwise

Reset the current drag operation to "none".
2. Fire a DND event named `dragend` at the source node.

3. Run the appropriate steps from the following list as the default action of the `dragend` event:

   If `dropped` is true, the `current target element` is a `text control` (see below), the `current drag operation` is "move", and the source of the drag-and-drop operation is a selection in the DOM that is entirely contained within an editing host

   Delete the selection.

   If `dropped` is true, the `current target element` is a `text control` (see below), the `current drag operation` is "move", and the source of the drag-and-drop operation is a selection in a text control

   The user agent should delete the dragged selection from the relevant text control.

   If `dropped` is false or if the `current drag operation` is "none"

   The drag was canceled. If the platform conventions dictate that this be represented to the user (e.g. by animating the dragged selection going back to the source of the drag-and-drop operation), then do so.

   Otherwise

   The event has no default action.

   For the purposes of this step, a `text control` is a `textarea` element or an `input` element whose `type` attribute is in one of the `Text`, `Search`, `Tel`, `URL`, `Email`, `Password`, or `Number` states.

User agents are encouraged to consider how to react to drags near the edge of scrollable regions. For example, if a user drags a link to the bottom of the viewport on a long page, it might make sense to scroll the page so that the user can drop the link lower on the page.

This model is independent of which `Document` object the nodes involved are from; the events are fired as described above and the rest of the processing model runs as described above, irrespective of how many documents are involved in the operation.

6.10.6 Events summary

*This section is non-normative.*

The following events are involved in the drag-and-drop model.

**Document/dragend_event**

- Firefox 3.5+ Safari 3.1+ Chrome 4+
- Opera 12+ Edge 79+
- Edge (Legacy) 12+ Internet Explorer 10+
- Firefox Android No Safari
- iOS 11+ Chrome
- Android No WebView
- Android No Samsung
- Internet No Opera Android No

All of these events bubble, are composed, and the `effectAllowed` attribute always has the value it had after the `dragstart` event, defaulting to "uninitialized" in the `dragstart` event.

6.10.7 **The draggable attribute**

- ✔ MDN

**Global_attributes/draggable**
Support in all current engines.

Firefox 2+ Safari Yes Chrome Yes
Opera 12+ Edge Yes
Edge (Legacy) 12+ Internet Explorer Yes
Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

All HTML elements may have the draggable content attribute set. The draggable attribute is an enumerated attribute. It has three states. The first state is true and it has the keyword true. The second state is false and it has the keyword false. The third state is auto; it has no keywords but it is the missing value default and the invalid value default.

The true state means the element is draggable; the false state means that it is not. The auto state uses the default behavior of the user agent.

An element with a draggable attribute should also have a title attribute that names the element for the purpose of non-visual interactions.

```javascript
element.draggable [ = value ]
```

Returns true if the element is draggable; otherwise, returns false.

Can be set, to override the default and set the draggable content attribute.

The draggable IDL attribute, whose value depends on the content attribute’s in the way described below, controls whether or not the element is draggable. Generally, only text selections are draggable, but elements whose draggable IDL attribute is true become draggable as well.

If an element’s draggable content attribute has the state true, the draggable IDL attribute must return true.

Otherwise, if the element’s draggable content attribute has the state false, the draggable IDL attribute must return false.

Otherwise, the element’s draggable content attribute has the state auto. If the element is an img element, an object element that represents an image, or an a element with an href content attribute, the draggable IDL attribute must return true; otherwise, the draggable IDL attribute must return false.

If the draggable IDL attribute is set to the value false, the draggable content attribute must be set to the literal value “false”. If the draggable IDL attribute is set to the value true, the draggable content attribute must be set to the literal value “true”.

An element with a draggable attribute should also have a title attribute that names the element for the purpose of non-visual interactions.

```javascript
element.draggable [ = value ]
```

Returns true if the element is draggable; otherwise, returns false.

Can be set, to override the default and set the draggable content attribute.

The draggable IDL attribute, whose value depends on the content attribute’s in the way described below, controls whether or not the element is draggable. Generally, only text selections are draggable, but elements whose draggable IDL attribute is true become draggable as well.

If an element’s draggable content attribute has the state true, the draggable IDL attribute must return true.

Otherwise, if the element’s draggable content attribute has the state false, the draggable IDL attribute must return false.

Otherwise, the element’s draggable content attribute has the state auto. If the element is an img element, an object element that represents an image, or an a element with an href content attribute, the draggable IDL attribute must return true; otherwise, the draggable IDL attribute must return false.

If the draggable IDL attribute is set to the value false, the draggable content attribute must be set to the literal value “false”. If the draggable IDL attribute is set to the value true, the draggable content attribute must be set to the literal value “true”.
6.10.8 Security risks in the drag-and-drop model

User agents must not make the data added to the DataTransfer object during the dragstart event available to scripts until the drop event, because otherwise, if a user were to drag sensitive information from one document to a second document, crossing a hostile third document in the process, the hostile document could intercept the data.

For the same reason, user agents must consider a drop to be successful only if the user specifically ended the drag operation — if any scripts end the drag operation, it must be considered unsuccessful (canceled) and the drop event must not be fired.

User agents should take care to not start drag-and-drop operations in response to script actions. For example, in a mouse-and-window environment, if a script moves a window while the user has their mouse button depressed, the UA would not consider that to start a drag. This is important because otherwise UAs could cause data to be dragged from sensitive sources and dropped into hostile documents without the user’s consent.

User agents should filter potentially active (scripted) content (e.g. HTML) when it is dragged and when it is dropped, using a safelist of known-safe features. Similarly, relative URLs should be turned into absolute URLs to avoid references changing in unexpected ways. This specification does not specify how this is performed.

Consider a hostile page providing some content and getting the user to select and drag and drop (or indeed, copy and paste) that content to a victim page’s contenteditable region. If the browser does not ensure that only safe content is dragged, potentially unsafe content such as scripts and event handlers in the selection, once dropped (or pasted) into the victim site, get the privileges of the victim site. This would thus enable a cross-site scripting attack.

7 Loading web pages

This section describes features that apply most directly to web browsers. Having said that, except where specified otherwise, the requirements defined in this section do apply to all user agents, whether they are web browsers or not.

7.1 Browsing contexts

A browsing context is an environment in which Document objects are presented to the user.

A tab or window in a web browser typically contains a browsing context, as does an iframe or frames in a frameset.

A browsing context has a corresponding WindowProxy object.

A browsing context has an opener browsing context, which is null or a browsing context. It is initially null.
A browsing context has a disowned boolean. It is initially false.

A browsing context has an is closing boolean. It is initially false.

The following example illustrates the various possibilities of a browsing context. It can be disowned, is closing, neither, or both.

```javascript
// Neither disowned nor is closing:
const popup1 = window.open();

// Disowned, but not is closing:
const popup2 = window.open();
popup2.opener = null;

// Not disowned, but is closing:
const popup3 = window.open();
popup3.close();

// Disowned, is closing:
const popup4 = window.open();
popup4.opener = null;
popup4.close();
```

A browsing context has a session history, which lists the Document objects that the browsing context has presented, is presenting, or will present. A Document’s browsing context is the browsing context whose session history contains the Document, if any such browsing context exists and has not been discarded, and null otherwise.

A Document does not necessarily have a non-null browsing context. In particular, data mining tools are likely to never instantiate browsing contexts. A Document created using an API such as `createDocument()` never has a non-null browsing context. And the Document originally created for an iframe element, which has since been removed from the document, has no associated browsing context, since that browsing context was discarded.

A browsing context’s active window is its WindowProxy object’s [[Window]] internal slot value. A browsing context’s active document is its active window’s associated Document.

In general, there is a 1-to-1 mapping from the Window object to the Document object, as long as the Document object has a non-null browsing context. There is one exception. A Window can be reused for the presentation of a second Document in the same browsing context, such that the mapping is then 1-to-2. This occurs when a browsing context is navigated from the initial about:blank Document to another, with historyHandling set to “replace”.

A browsing context has a virtual browsing context group ID integer. It is initially 0. This is used by cross-origin opener policy reporting, to keep track of the browsing context group switches that would have happened if the report-only policy had been enforced.
A **browsing context** has an *initial URL*, which is a **URL** or null. It is initially null.

A **browsing context** has an *opener origin at creation*, which is an **origin** or null. It is initially null.

### 7.1.1 Creating browsing contexts

To *set the active document* of a **browsing context** **browsingContext** to a **Document** object **document**, run these steps:

1. Let **window** be **document**'s **relevant global object**.
2. Set **document**'s **visibility state** to **browsingContext**'s **top-level browsing context**’s **system visibility state**.
3. Set **browsingContext**'s **active window** to **window**.
4. Set **window**'s **associated Document** to **document**.
5. Set **window**'s **relevant settings object**’s **execution ready flag**.

A **browsing context** has an associated **creator origin** (null or returns an **origin**), **creator URL** (null or returns a **URL**), and **creator base URL** (null or returns a **URL**). These are all initially null.

To *determine the origin*, given **browsing context** **browsingContext**, **URL** **url**, sandboxing flag set **sandboxFlags**, and an **origin** **invocationOrigin**:

1. If **sandboxFlags** has its **sandboxed origin browsing context flag** set, then return a new **opaque origin**.
2. If **url** is null, then return a new **opaque origin**.
3. If **invocationOrigin** is non-null and **url** matches **about:blank**, then return **invocationOrigin**.

The result here is that two documents end up with the same underlying **origin**, meaning that **document.domain** affects both.

4. If **url** is **about:srccdoc**, then return the **origin** of **browsingContext**’s **container document**.
5. Return **url**'s **origin**.

To *create a new browsing context*, given null or a **Document** object **creator**, null or an element **embedder**, and a **browsing context group** **group**, run these steps:
1. Let `browsingContext` be a new browsing context.

2. If `creator` is non-null, then set `browsingContext`'s creator origin to return creator's origin, `browsingContext`'s creator URL to return creator's URL, `browsingContext`'s creator base URL to return creator's base URL, and `browsingContext`'s virtual browsing context group ID to creator's top-level browsing context's virtual browsing context group ID.

3. Let `sandboxFlags` be the result of determining the creation sandboxing flags given `browsingContext` and `embedder`.

4. Let `origin` be the result of determining the origin given `browsingContext`, `about:blank`, `sandboxFlags`, and `browsingContext`'s creator origin.

5. Let `permissionsPolicy` be the result of creating a permissions policy given `browsingContext` and `origin`. [PERMISSIONSPOLICY]
   
   This needs to use `embedder`.

6. Let `agent` be the result of obtaining a similar-origin window agent given `origin`, `group`, and false.

7. Let `realm execution context` be the result of creating a new JavaScript realm given `agent` and the following customizations:
   
   ◦ For the global object, create a new Window object.
   
   ◦ For the global this binding, use `browsingContext`'s WindowProxy object.

8. Let `topLevelCreationURL` be `about:blank` if `embedder` is null; otherwise `embedder`'s relevant settings object's top-level creation URL.

9. Let `topLevelOrigin` be `origin` if `embedder` is null; otherwise `embedder`'s relevant settings object's top-level origin.

10. Set up a window environment settings object with `about:blank`, `realm execution context`, null, `topLevelCreationURL`, and `topLevelOrigin`.

11. Let `coop` be a new cross-origin opener policy.

12. If `creator` is non-null and `creator`'s origin is same origin with `creator`'s relevant settings object's top-level origin, then set `coop` to `creator`'s browsing context's top-level browsing context's active document's cross-origin opener policy.

13. Let `document` be a new Document, marked as an HTML document in quirks mode, whose content type is "text/html", origin is `origin`, active sandboxing flag set is `sandboxFlags`, permissions policy is `permissionsPolicy`, cross-origin opener policy is `coop`, navigation id is null, and which is ready for post-load tasks.

15. Set document’s is initial about:blank to true.

16. Ensure that document has a single child html node, which itself has two empty child nodes: a head element, and a body element.

17. Set the active document of browsingContext to document.

18. If browsingContext’s creator URL is non-null, then set document’s referrer to the serialization of it.

19. If creator is non-null, then set document’s policy container to a clone of creator’s policy container.

20. Append a new session history entry to browsingContext’s session history whose URL is about:blank and document is document.

22. Return browsingContext.

To create a new top-level browsing context:

1. Let group be the result of creating a new browsing context group.

2. Return group’s browsing context set[0].

This creates a top-level browsing context.

To create a new auxiliary browsing context, given a browsing context opener:

1. Let group be opener’s top-level browsing context’s group

2. Assert: group is non-null, as navigating invokes this directly.

3. Let browsingContext be the result of creating a new browsing context with opener’s active document, null, and group.

4. Append browsingContext to group.

5. Set browsingContext’s opener browsing context to opener.

6. Set browsingContext’s virtual browsing context group ID to opener’s top-level browsing context’s virtual browsing context group ID.

7. Set browsingContext’s opener origin at creation to opener’s active document’s origin.
8. Legacy-clone a browsing session storage shed with opener's browsing session and browsingContext's browsing session. [STORAGE]

This creates a top-level browsing context that is also an auxiliary browsing context.

To create a new nested browsing context, given an element element:

1. Let group be element's node document's browsing context’s top-level browsing context’s group.

2. Let browsingContext be the result of creating a new browsing context with element's node document, element, and group.

3. Set element's nested browsing context to browsingContext.

4. If element has a name attribute, then set browsingContext's name to the value of this attribute.

7.1.2 Related browsing contexts

Certain elements (for example, iframe elements) can instantiate further browsing contexts. These elements are called browsing context containers.

Each browsing context container has a nested browsing context, which is either a browsing context or null. It is initially null.

The container of a browsing context bc is the browsing context container whose nested browsing context is bc, or null if there is no such element.

Each browsing context bc has a container document, which is the result of running these steps:

1. If bc's container is null, then return null.

2. Return bc's container's node document.

   This is equal to bc's container's shadow-including root as bc's container has to be connected.

A browsing context child is said to be a child browsing context of another browsing context parent, if child's container document is non-null and child's container document's browsing context is parent.

A browsing context child is a document-tree child browsing context of parent if child is a child browsing context and child's container is in a document tree.

A browsing context child may have a parent browsing context. This is the unique browsing
A context that has child as a child browsing context, if any such browsing context exists. Otherwise, the browsing context has no parent browsing context.

A browsing context $A$ is said to be an ancestor of a browsing context $B$ if there exists a browsing context $A'$ that is a child browsing context of $A$ and that is itself an ancestor of $B$, or if the browsing context $A$ is the parent browsing context of $B$.

A browsing context that has no parent browsing context is the top-level browsing context for itself and all of the browsing contexts for which it is an ancestor browsing context.

A top-level browsing context has an associated group (null or a browsing context group). It is initially null.

A top-level browsing context has an is popup boolean. It is initially false.

The only mandatory impact in this specification of is popup is on the visible getter of the relevant BarProp objects. However, user agents might also use it in the following ways:

- Deciding whether or not to provide a minimal web browser user interface for the browsing context.
- Performing the optional steps in set up browsing context features.

In both cases user agents might additionally incorporate user preferences, or present a choice as to whether to go down the popup route.

User agents that provides a minimal web browser user interface for such popups are encouraged to not hide the browser’s location bar.

It is possible to create new browsing contexts that are related to a top-level browsing context while their container is null. Such browsing contexts are called auxiliary browsing contexts. Auxiliary browsing contexts are always top-level browsing contexts.

The transitive closure of parent browsing contexts for a browsing context that is a child browsing context gives the list of ancestor browsing contexts.

The list of the descendant browsing contexts of a Document $d$ is the (ordered) list returned by the following algorithm:

1. Let list be an empty list.
2. For each browsing context container container, whose nested browsing context is non-null and whose shadow-including root is $d$, in shadow-including tree order:
   1. Let nestedBC be container’s nested browsing context.
   2. Append nestedBC to list.
3. Extend list with the list of the descendant browsing contexts of nestedBC's active document.

3. Return list.

A Document d is said to be fully active when d's browsing context is non-null, d's browsing context's active document is d, and either d's browsing context is a top-level browsing context, or d's browsing context's container document is fully active.

Because they are associated with an element, child browsing contexts are always tied to a specific Document in their parent browsing context. User agents must not allow the user to interact with child browsing contexts of elements that are in Documents that are not themselves fully active.

The following example illustrates the differences between active and fully active Document objects. Here a.html is loaded into a browser window, b-1.html starts out loaded into an iframe as shown, and b-2.html and c.html are omitted (they can simply be an empty document).

<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Browsing context A</title>

<iframe src="b-1.html"></iframe>
<button onclick="frames[0].location.href = 'b-2.html'">Click me</button>

<!-- b-1.html -->
<!DOCTYPE html>
<html lang="en">
<title>Browsing context B</title>

<iframe src="c.html"></iframe>

At this point, the documents given by a.html, b-1.html, and c.html are all the active documents of their respective browsing contexts. They are also all fully active.

After clicking on the button, and thus loading a new Document from b-2.html into browsing context B, we have the following results:

- The a.html Document remains both the active document of browsing context A, and fully active.
- The b-1.html Document is now not the active document of browsing context B. As such it is also not fully active.
- The new b-2.html Document is now the active document of browsing context B, and
is also fully active.

- The c.html Document is still the active document of browsing context C. However, since C’s container document is the b-1.html Document, which is itself not fully active, this means the c.html Document is now not fully active (even though it is active).

For more explorations of the complexities involved here, especially as it impacts the session history, see A Model of Navigation History. [NAVMODEL]

A child browsing context can be put into a delaying load events mode. This is used when it is navigated, to delay the load event of its container before the new Document is created.

The document family of a browsing context consists of the union of all the Document objects in that browsing context’s session history and the document families of all those Document objects. The document family of a Document object consists of the union of all the document families of the browsing contexts in the list of the descendant browsing contexts of the Document object.

The content document of a browsing context container container is the result of the following algorithm:

1. If container’s nested browsing context is null, then return null.
2. Let context be container’s nested browsing context.
3. Let document be context’s active document.
4. If document’s origin and container’s node document’s origin are not same origin-domain, then return null.
5. Return document.

7.1.2.17.1.2.1 Navigating related browsing contexts in the DOM

window.top

✔️MDN

Window/top

Support in all current engines.

Firefox1+Safari3+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer4+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Returns the `WindowProxy` for the top-level browsing context.

```javascript
window.opener [ = value ]
```

**Window/opener**

Support in all current engines.

<table>
<thead>
<tr>

<td>1+1+</td>
</tr>
<tr>
<td>Samsung</td>
<td></td>
</tr>
</tbody>
</table>

Returns the `WindowProxy` for the parent browsing context.

```javascript
window.frameElement
```

**Window/frameElement**

Support in all current engines.

<table>
<thead>
<tr>
<th>Engine</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>1+1+</td>
</tr>
<tr>
<td>Safari</td>
<td>3+3+</td>
</tr>
<tr>
<td>Chrome</td>
<td>1+1+</td>
</tr>
</tbody>
</table>
Returns the **Element** for the browsing context container.

Returns null if there isn’t one, and in cross-origin situations.

The **top** attribute’s getter must run these steps:

1. If this **Window** object’s browsing context is null, then return null.
2. Return this **Window** object’s browsing context’s top-level browsing context’s **WindowProxy** object.

The **opener** getter steps are:

1. Let **current** be this’s browsing context.
2. If **current** is null, then return null.
3. If **current’s** disowned is true, then return null.
4. If **current’s** opener browsing context is null, then return null.
5. Return **current’s** opener browsing context’s **WindowProxy** object.

The **opener** setter steps are:

1. If the given value is null and this’s browsing context is non-null, then set this’s browsing context’s disowned to true.
2. If the given value is non-null, then return ? OrdinaryDefineOwnProperty(this, "opener", { [[Value]]: the given value, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true }).

If a browsing context’s disowned is true, its window.opener attribute is null. That prevents scripts in the browsing context from changing any properties of its opener browsing context’s **Window** object (i.e., the **Window** object from which the browsing context was created).

Otherwise, if a browsing context’s disowned is false, then scripts in that browsing context can use window.opener to change properties of its opener browsing context’s **Window** object. For example, a script running in the browsing context can change the value of window.opener.location, causing the opener browsing context to navigate to a completely different document.
The `parent` attribute’s getter must run these steps:

1. Let `current` be this `Window` object’s browsing context.
2. If `current` is null, then return null.
3. If `current` is a child browsing context of another browsing context `parent`, then return `parent`’s `WindowProxy` object.
4. Assert: `current` is a top-level browsing context.
5. Return `current`’s `WindowProxy` object.

The `frameElement` getter steps are:

1. Let `current` be this `Window` object’s browsing context.
2. If `current` is null, then return null.
3. Let `container` be `current`’s container.
4. If `container` is null, then return null.
5. If `container`’s node document’s origin is not same origin-domain with the current settings object’s origin, then return null.
6. Return `container`.

An example of when these IDL attributes can return null is as follows:

```html
<!DOCTYPE html>
<iframe></iframe>
<script>
"use strict";
const element = document.querySelector("iframe");
const iframeWindow = element.contentWindow;
element.remove();

console.assert(iframeWindow.top === null);
console.assert(iframeWindow.parent === null);
console.assert(iframeWindow.frameElement === null);
</script>
```

Here the browsing context corresponding to `iframeWindow` was discarded when `element` was removed from the document.
7.1.3 Security

A **browsing context** \( A \) is *familiar with* a second **browsing context** \( B \) if one of the following conditions is true:

- Either the **origin** of the **active document** of \( A \) is the **same** as the **origin** of the **active document** of \( B \), or
- The browsing context \( A \) is a **child browsing context** and its **top-level browsing context** is \( B \), or
- The browsing context \( B \) is an **auxiliary browsing context** and \( A \) is **familiar with** \( B \)’s **opener browsing context**, or
- The browsing context \( B \) is not a **top-level browsing context**, but there exists an **ancestor browsing context** of \( B \) whose **active document** has the **same origin** as the **active document** of \( A \) (possibly in fact being \( A \) itself).

A **browsing context** \( A \) is **allowed to navigate** a second **browsing context** \( B \) if the following algorithm returns true:

1. If \( A \) is not the same **browsing context** as \( B \), and \( A \) is not one of the **ancestor browsing contexts** of \( B \), and \( B \) is not a **top-level browsing context**, and \( A \)’s **active sandboxing flag set** has its **sandboxed navigation browsing context flag** set, then return false.

2. Otherwise, if \( B \) is a **top-level browsing context**, and is one of the **ancestor browsing contexts** of \( A \), then:
   1. If \( A \)’s **active window** has **transient activation** and \( A \)’s **active document**’s **active sandboxing flag set** has its **sandboxed top-level navigation with user activation browsing context flag** set, then return false.
   2. Otherwise, if \( A \)’s **active window** does not have **transient activation** and \( A \)’s **active document**’s **active sandboxing flag set** has its **sandboxed top-level navigation without user activation browsing context flag** set, then return false.

3. Otherwise, if \( B \) is a **top-level browsing context**, and is neither \( A \) nor one of the **ancestor browsing contexts** of \( A \), and \( A \)’s **Document**’s **active sandboxing flag set** has its **sandboxed navigation browsing context flag** set, and \( A \) is not the **one permitted sandboxed navigator** of \( B \), then return false.

4. Return true.

An element has a **browsing context scope origin** if its **Document**’s **browsing context** is a **top-level browsing context** or if all of its **Document**’s **ancestor browsing contexts** all have **active documents** whose **origins** are the **same origin** as the element’s **node document**’s **origin**. If an element has a **browsing context scope origin**, then its value is the **origin** of the element’s **node**.
7.1.4 Groupings of browsing contexts

A user agent holds a *browsing context group set* (a set of *browsing context groups*).

A *browsing context group* holds a *browsing context set* (a set of *top-level browsing contexts*).

A *top-level browsing context* is added to the *group* when the group is created. All subsequent *top-level browsing contexts* added to the *group* will be *auxiliary browsing contexts*.

A *browsing context group* has an associated *agent cluster map* (a weak map of *agent cluster keys* to *agent clusters*). User agents are responsible for collecting agent clusters when it is deemed that nothing can access them anymore.

A *browsing context group* has an associated *historical agent cluster key map*, which is a map of origins to agent cluster keys. This map is used to ensure the consistency of the *origin-keyed agent clusters* feature by recording what agent cluster keys were previously used for a given origin.

The *historical agent cluster key map* only ever gains entries over the lifetime of the browsing context group.

A *browsing context group* has a *cross-origin isolation mode*, which is a *cross-origin isolation mode*. It is initially "none".

A *cross-origin isolation mode* is one of three possible values: "none", "logical", or "concrete".

"logical" and "concrete" are similar. They are both used for *browsing context groups* where:

- every top-level Document has `Cross-Origin-Opener-Policy: same-origin`;

- every Document has a `Cross-Origin-Embedder-Policy` header whose value is compatible with cross-origin isolation.

On some platforms, it is difficult to provide the security properties required to grant safe access to the APIs gated by the *cross-origin isolated capability*. As a result, only "concrete" can grant access that capability. "logical" is used on platform not supporting this capability, where various restrictions imposed by cross-origin isolation will still apply, but the capability is not granted.

To *create a new browsing context group*, run these steps:

1. Let *group* be a new *browsing context group*. 
2. Append group to the user agent’s browsing context group set.

3. Let browsingContext be the result of creating a new browsing context with null, null, and group.

4. Append browsingContext to group.

5. Return group.

To append a top-level browsing context browsingContext to a browsing context group group, run these steps:

1. Append browsingContext to group’s browsing context set.

2. Set browsingContext’s group to group.

To remove a top-level browsing context browsingContext, run these steps:

1. Assert: browsingContext’s group is non-null, because a browsing context only gets discarded once.

2. Let group be browsingContext’s group.

3. Set browsingContext’s group to null.

4. Remove browsingContext from group’s browsing context set.

5. If group’s browsing context set is empty, then remove group from the user agent’s browsing context group set.

Append and remove are primitive operations that help define the lifetime of a browsing context group. They are called from creating a new browsing context group, creating a new auxiliary browsing context, and discarding a browsing context.

The HTML Standard used to define “unit of related browsing contexts” and “unit of related similar-origin browsing contexts”. These have been removed as they were not adequate.

7.1.5 Browsing context names

Browsing contexts can have a browsing context name. Unless stated otherwise, it is the empty string.

A valid browsing context name is any string with at least one character that does not start with a U+005F LOW LINE character. (Names starting with an underscore are reserved for special keywords.)

A valid browsing context name or keyword is any string that is either a valid browsing context
name or that is an ASCII case-insensitive match for one of: _blank, _self, _parent, or _top.

These values have different meanings based on whether the page is sandboxed or not, as summarized in the following (non-normative) table. In this table, “current” means the browsing context that the link or script is in, “parent” means the parent browsing context of the one the link or script is in, “top” means the top-level browsing context of the one the link or script is in, “new” means a new top-level browsing context or auxiliary browsing context is to be created, subject to various user preferences and user agent policies, “none” means that nothing will happen, and “maybe new” means the same as “new” if the allow-popups keyword is also specified on the sandbox attribute (or if the user overrode the sandboxing), and the same as “none” otherwise.

| Keyword | Ordinary effect | Effect in an iframe with sandbox="" sandbox="allow-top-navigation"

| none specified, for links and form submissions | current | current | current |
| empty string | current | current | current |
| _blank | new | maybe new | maybe new |
| _self | current | current | current |
| _parent if there isn’t a parent | parent/top | none | parent/top |
| _parent if parent is also top | parent | none | none |
| _parent if there is one and it’s not top | current | current | current |
| _top if top is current | top | none | top |
| _top if top is not current | new | maybe new | maybe new |
| name that doesn’t exist | specified | specified | specified |
| name that exists and is a descendant | specified descendant | specified descendant | specified descendant |
| name that exists and is current | current | current | current |
| name that exists and is an ancestor that is top | specified ancestor | none | specified ancestor/top |
| name that exists and is an ancestor that is not top | specified ancestor | none | none |
| other name that exists with common top | specified | none | none |
| name that exists with different top, if familiar and one permitted sandboxed navigator | specified | specified | specified |
| name that exists with different top, if familiar but not one permitted sandboxed navigator | specified | none | none |
| name that exists with different top, not familiar | new | maybe new | maybe new |

Most of the restrictions on sandboxed browsing contexts are applied by other algorithms, e.g. the navigation algorithm, not the rules for choosing a browsing context given below.
The rules for choosing a browsing context, given a browsing context name name, a browsing context current, and a boolean noopener are as follows:

1. Let chosen be null.

2. Let windowType be "existing or none".

3. Let sandboxingFlagSet be current’s active document’s active sandboxing flag set.

4. If name is the empty string or an ASCII case-insensitive match for "_self", then set chosen to current.

5. Otherwise, if name is an ASCII case-insensitive match for "_parent", set chosen to current’s parent browsing context, if any, and current otherwise.

6. Otherwise, if name is an ASCII case-insensitive match for "_top", set chosen to current’s top-level browsing context, if any, and current otherwise.

7. Otherwise, if name is not an ASCII case-insensitive match for "_blank", there exists a browsing context whose name is the same as name, current is familiar with that browsing context, and the user agent determines that the two browsing contexts are related enough that it is ok if they reach each other, set chosen to that browsing context. If there are multiple matching browsing contexts, the user agent should set chosen to one in some arbitrary consistent manner, such as the most recently opened, most recently focused, or more closely related.

This will be made more precise in issue #313.

8. Otherwise, a new browsing context is being requested, and what happens depends on the user agent’s configuration and abilities — it is determined by the rules given for the first applicable option from the following list:

   If current’s active window does not have transient activation and the user agent has been configured to not show popups (i.e., the user agent has a “popup blocker” enabled)

       The user agent may inform the user that a popup has been blocked.

   If sandboxingFlagSet has the sandboxed auxiliary navigation browsing context flag set

       The user agent may report to a developer console that a popup has been blocked.

   If the user agent has been configured such that in this instance it will create a new browsing context

       1. Set windowType to “new and unrestricted”.

       2. If current’s top-level browsing context’s active document’s cross-origin opener policy’s value is “same-origin” or “same-origin-plus-COEP”,

then:

1. Let currentDocument be current’s active document.

2. If currentDocument’s origin is not same origin with currentDocument’s relevant settings object’s top-level origin, then set noopen to true, name to "_blank", and windowType to "new with no opener".

   In the presence of a cross-origin opener policy, nested documents that are cross-origin with their top-level browsing context’s active document always set noopen to true.

3. If noopen is true, then set chosen to the result of creating a new top-level browsing context.

4. Otherwise:

   1. Set chosen to the result of creating a new auxiliary browsing context with current.

   2. If sandboxingFlagSet’s sandboxed navigation browsing context flag is set, then current must be set as chosen’s one permitted sandboxed navigator.

5. If sandboxingFlagSet’s sandbox propagates to auxiliary browsing contexts flag is set, then all the flags that are set in sandboxingFlagSet must be set in chosen’s popup sandboxing flag set.

6. If name is not an ASCII case-insensitive match for "_blank", then set chosen’s name to name.

   If the newly created browsing context is immediately navigated, then the navigation will be done with historyHandling set to "replace".

   If the user agent has been configured such that in this instance it will reuse current

       Set chosen to current.

   If the user agent has been configured such that in this instance it will not find a browsing context

       Do nothing.

   User agents are encouraged to provide a way for users to configure the user agent to always reuse current.

9. Return chosen and windowType.
7.2 Security infrastructure for **Window**, **WindowProxy**, and **Location** objects

Although typically objects cannot be accessed across origins, the web platform would not be true to itself if it did not have some legacy exceptions to that rule that the web depends upon.

7.2.1 Integration with IDL

When perform a security check is invoked, with a platformObject, identifier, and type, run these steps:

1. If platformObject is not a **Window** or **Location** object, then return.

2. For each e of !CrossOriginProperties(platformObject):

   1. If SameValue(e.[[Property]], identifier) is true, then:

      1. If type is "method" and e has neither [[NeedsGet]] nor [[NeedsSet]], then return.

      2. Otherwise, if type is "getter" and e.[[NeedsGet]] is true, then return.

      3. Otherwise, if type is "setter" and e.[[NeedsSet]] is true, then return.

3. If !IsPlatformObjectSameOrigin(platformObject) is false, then throw a "SecurityError" DOMException.

7.2.2 Shared internal slot: [[CrossOriginPropertyDescriptorMap]]

**Window** and **Location** objects both have a [[CrossOriginPropertyDescriptorMap]] internal slot, whose value is initially an empty map.

The [[CrossOriginPropertyDescriptorMap]] internal slot contains a map with entries whose keys are (currentGlobal, objectGlobal, propertyKey)-tuples and values are property descriptors, as a memoization of what is visible to scripts when currentGlobal inspects a **Window** or **Location** object from objectGlobal. It is filled lazily by CrossOriginGetOwnPropertyHelper, which consults it on future lookups.

User agents should allow a value held in the map to be garbage collected along with its corresponding key when nothing holds a reference to any part of the value. That is, as long as garbage collection is not observable.

For example, with const href = Object.getOwnPropertyDescriptor(crossOriginLocation, "href").set the value and its corresponding key in the map cannot be garbage collected as that would be observable.

User agents may have an optimization whereby they remove key-value pairs from the map
when `document.domain` is set. This is not observable as `document.domain` cannot revisit an earlier value.

For example, setting `document.domain` to "example.com" on www.example.com means user agents can remove all key-value pairs from the map where part of the key is www.example.com, as that can never be part of the origin again and therefore the corresponding value could never be retrieved from the map.

7.2.3 Shared abstract operations

7.2.3.1 `CrossOriginProperties( O )`

1. Assert: `O` is a `Location` or `Window` object.

2. If `O` is a `Location` object, then return « { [[Property]]: "href", [[NeedsGet]]: false, [[NeedsSet]]: true }, { [[Property]]: "replace" } ».

Indexed properties do not need to be safelisted in this algorithm, as they are handled directly by the `WindowProxy` object.

A JavaScript property name `P` is a cross-origin accessible window property name if it is "window", "self", "location", "close", "closed", "focus", "blur", "frames", "length", "top", "opener", "parent", "postMessage", or an array index property name.

7.2.3.2 `CrossOriginPropertyFallback( P )`

1. If `P` is "then", @@toStringTag, @@hasInstance, or @@isConcatSpreadable, then return `PropertyDescriptor`{ [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

2. Throw a `SecurityError` DOMException.

7.2.3.3 `IsPlatformObjectSameOrigin( O )`

1. Return true if the current settings object’s origin is same origin-domain with `O`'s relevant settings object’s origin, and false otherwise.
Here the current settings object roughly corresponds to the “caller”, because this check occurs before the execution context for the getter/setter/method in question makes its way onto the JavaScript execution context stack. For example, in the code `w.document`, this step is invoked before the `document` getter is reached as part of the `[[Get]]` algorithm for the WindowProxy `w`.

7.2.3.4 CrossOriginGetOwnPropertyHelper ( O, P )

If this abstract operation returns undefined and there is no custom behavior, the caller needs to throw a “SecurityError” DOMException. In practice this is handled by the caller calling CrossOriginPropertyFallback.

1. Let crossOriginKey be a tuple consisting of the current settings object, O’s relevant settings object, and P.

2. For each e of ! CrossOriginProperties(O):
   1. If SameValue(e.[[Property]], P) is true, then:
      1. If the value of the `[[CrossOriginPropertyDescriptorMap]]` internal slot of O contains an entry whose key is crossOriginKey, then return that entry’s value.
      2. Let originalDesc be OrdinaryGetOwnProperty(O, P).
      3. Let crossOriginDesc be undefined.
      4. If e.[[NeedsGet]] and e.[[NeedsSet]] are absent, then:
         1. Let value be originalDesc.[[Value]].
         2. If ! IsCallable(value) is true, then set value to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the IDL operation P on object O.
         3. Set crossOriginDesc to PropertyDescriptor{ [[Value]]: value, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true }.
      5. Otherwise:
         1. Let crossOriginGet be undefined.
         2. If e.[[NeedsGet]] is true, then set crossOriginGet to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the getter of the IDL attribute P on object O.
      3. Let crossOriginSet be undefined.
4. If `e.[[NeedsSet]]` is true, then set `crossOriginSet` to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the setter of the IDL attribute `P` on object `O`.

5. Set `crossOriginDesc` to `PropertyDescriptor` `{ [[Get]]: `crossOriginGet`, [[Set]]: `crossOriginSet`, [[Enumerable]]: false, [[Configurable]]: true }.

6. Create an entry in the value of the `[[CrossOriginPropertyDescriptorMap]]` internal slot of `O` with key `crossOriginKey` and value `crossOriginDesc`.

7. Return `crossOriginDesc`.

3. Return undefined.

The reason that the property descriptors produced here are configurable is to preserve the invariants of the essential internal methods required by the JavaScript specification. In particular, since the value of the property can change as a consequence of navigation, it is required that the property be configurable. (However, see tc39/ecma262 issue #672 and references to it elsewhere in this specification for cases where we are not able to preserve these invariants, for compatibility with existing web content.) [JAVASCRIPT]

The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See issue #3183 for details.

7.2.3.5 `CrossOriginGet (O, P, Receiver)`

1. Let `desc` be `O.[[GetOwnProperty]](P).

2. Assert: `desc` is not undefined.

3. If `IsDataDescriptor(desc)` is true, then return `desc.[[Value]]`.

4. Assert: `IsAccessorDescriptor(desc)` is true.

5. Let `getter` be `desc.[[Get]]`.

6. If `getter` is undefined, then throw a `"SecurityError"` DOMException.

7. Return `Call(getter, Receiver)`.

7.2.3.6 `CrossOriginSet (O, P, V, Receiver)`

1. Let `desc` be `O.[[GetOwnProperty]](P).

2. Assert: `desc` is not undefined.
3. If `desc.[[Set]]` is present and its value is not undefined, then:
   1. Perform `Call(setter, Receiver, «V»)`.  
   2. Return true.
   4. Throw a **`SecurityError`** DOMException.

7.2.3.7 `CrossOriginOwnPropertyKeys(O)`

1. Let `keys` be a new empty List.
2. For each `e` of `CrossOriginProperties(O)`, append `e.[[Property]]` to `keys`.
3. Return the concatenation of `keys` and « "then", `@@toStringTag`, `@@hasInstance`, `@@isConcatSpreadable" ».

7.3 The **Window** object

These attributes all return window.

window.document

Support in all current engines.
Returns the `Document` associated with `window`.

```javascript
document.defaultView
```
**HTMLDocument**

Support in all current engines.

Firefox 1+ Safari 1+ Chrome 1+  
Opera 12.1+ Edge 79+  
Edge (Legacy) 12+ Internet Explorer 4+  
Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 12.1+

For historical reasons, `Window` objects must also have a writable, configurable, non-enumerable property named `HTMLDocument` whose value is the `Document` interface object.

7.3.1 APIs for creating and navigating browsing contexts by name

```javascript
window = window.open([url [, target [, features ]]])
```

Opens a window to show `url` (defaults to "about:blank"), and returns it. `target` (defaults to "_blank") gives the name of the new window. If a window already exists with that name, it is reused. The `features` argument can contain a set of comma-separated tokens:

- "noopener"
- "noreferrer"
- "popup"

These behave equivalently to the `noopener` and `noreferrer` link types on hyperlinks.

Encourages user agents to provide a minimal web browser user interface for the new window. (Impacts the `visible` getter on all `BarProp` objects as well.)
`globalThis.open("https://email.example/message/CA00KFcWW97r8yg=SsWg7GgCmp4suVX9o85y8BvNRqMjuc5PXg")`

```javascript
window.name [ = value ]
```

**Window/name**

Cancels the document load.

The **window open steps**, given a string `url`, a string `target`, and a string `features`, are as follows:

1. If the **event loop**’s **termination nesting level** is nonzero, return null.
2. Let **source browsing context** be the **entry global object**’s **browsing context**.
3. If `target` is the empty string, then set `target` to ”_blank”.
4. Let `tokenizedFeatures` be the result of **tokenizing features**.
5. Let `noopener` and `noreferrer` be false.
6. If `tokenizedFeatures["noopener"]` **exists**, then:
   1. Set `noopener` to the result of **parsing** `tokenizedFeatures["noopener"]` as a **boolean feature**.
   2. **Remove** `tokenizedFeatures["noopener"]`.
7. If `tokenizedFeatures["noreferrer"]` **exists**, then:
   1. Set `noreferrer` to the result of **parsing** `tokenizedFeatures["noreferrer"]` as a **boolean feature**.
   2. **Remove** `tokenizedFeatures["noreferrer"]`.
8. If `noreferrer` is true, then set `noopener` to true.
9. Let `target browsing context` and `windowType` be the result of applying the rules for choosing a browsing context given `target`, `source browsing context`, and `noopener`.

If there is a user agent that supports control-clicking a link to open it in a new tab, and the user control-clicks on an element whose `onclick` handler uses the `window.open()` API to open a page in an `iframe` element, the user agent could override the selection of the target browsing context to instead target a new tab.

10. If `target browsing context` is null, then return null.

11. If `windowType` is either "new and unrestricted" or "new with no opener", then:

   1. Set the `target browsing context`’s `is popup` to the result of checking if a popup window is requested, given `tokenizedFeatures`.

   2. Set up browsing context features for `target browsing context` given `tokenizedFeatures`. [CSSOMVIEW]

   3. Let `urlRecord` be the URL record `about:blank`.

   4. If `url` is not the empty string, then parse `url` relative to the entry settings object, and set `urlRecord` to the resulting URL record, if any. If the parse a URL algorithm failed, then throw a "SyntaxError" DOMException.

   5. If `urlRecord` matches `about:blank`, then perform the URL and history update steps given `target browsing context`’s active document and `urlRecord`.

      This is necessary in case `url` is something like `about:blank?foo`. If `url` is just plain `about:blank`, this will do nothing.

   6. Otherwise:

      1. Let `request` be a new `request` whose `URL` is `urlRecord`.

      2. If `noreferrer` is true, then set `request`’s `referrer` to "no-referrer".

      3. Navigate `target browsing context` to `request`, with `exceptionsEnabled` set to true, `historyHandling` set to "replace", and the `source browsing context` set to `source browsing context`.

12. Otherwise:

   1. If `url` is not the empty string, then:

      1. Let `urlRecord` be the URL record `about:blank`.

      2. Parse `url` relative to the entry settings object, and set `urlRecord` to the
resulting URL record, if any. If the parse a URL algorithm failed, then throw a “SyntaxError” DOMException.

3. Let request be a new request whose URL is urlRecord.

4. If noreferrer is true, then set request’s referrer to "noreferrer".

5. Navigate target browsing context to request, with exceptionsEnabled set to true and the source browsing context set to source browsing context.

2. Ifnoopener is false, then set target browsing context’s opener browsing context to source browsing context.

13. Ifnoopener is true or windowType is "new with no opener", then return null.

The open(url, target, features) method on Window objects provides a mechanism for navigating an existing browsing context or opening and navigating an auxiliary browsing context.

When the method is invoked, the user agent must run the window open steps with url, target, and features.

To tokenize the features argument:

1. Let tokenizedFeatures be a new ordered map.

2. Let position point at the first code point of features.

3. While position is not past the end of features:

   1. Let name be the empty string.

   2. Let value be the empty string.

   3. Collect a sequence of code points that are feature separators from features given position. This skips past leading separators before the name.

   4. Collect a sequence of code points that are not feature separators from features given position. Set name to the collected characters, converted to ASCII lowercase.

   5. Set name to the result of normalizing the feature name name.

   6. While position is not past the end of features and the code point at position in features is not U+003D (=):
1. If the code point at position in features is U+002C (,), or if it is not a feature separator, then break.

2. Advance position by 1.

This skips to the first U+003D (=) but does not skip past a U+002C (,) or a non-separator.

7. If the code point at position in features is a feature separator:

1. While position is not past the end of features and the code point at position in features is a feature separator:

   1. If the code point at position in features is U+002C (,), then break.

   2. Advance position by 1.

This skips to the first non-separator but does not skip past a U+002C (,).

2. Collect a sequence of code points that are not feature separators code points from features given position. Set value to the collected code points, converted to ASCII lowercase.

8. If name is not the empty string, then set tokenizedFeatures[name] to value.

4. Return tokenizedFeatures.

To check if a window feature is set, given tokenizedFeatures, featureName, and defaultValue:

1. If tokenizedFeatures[featureName] exists, then return the result of parsing tokenizedFeatures[featureName] as a boolean feature.

2. Return defaultValue.

To check if a popup window is requested, given tokenizedFeatures:

1. If tokenizedFeatures is empty, then return false.

2. If tokenizedFeatures["popup"] exists, then return the result of parsing tokenizedFeatures["popup"] as a boolean feature.

3. Let location be the result of checking if a window feature is set, given tokenizedFeatures, "location", and false.

4. Let toolbar be the result of checking if a window feature is set, given tokenizedFeatures, "toolbar", and false.

5. If location and toolbar are both false, then return true.
6. Let `menubar` be the result of checking if a window feature is set, given `tokenizedFeatures`, `menubar`”, and false.

7. If `menubar` is false, then return true.

8. Let `resizable` be the result of checking if a window feature is set, given `tokenizedFeatures`, “`resizable`”, and true.

9. If `resizable` is false, then return true.

10. Let `scrollbars` be the result of checking if a window feature is set, given `tokenizedFeatures`, “`scrollbars`”, and false.

11. If `scrollbars` is false, then return true.

12. Let `status` be the result of checking if a window feature is set, given `tokenizedFeatures`, “`status`”, and false.

13. If `status` is false, then return true.

A code point is a feature separator if it is ASCII whitespace, U+003D (=), or U+002C (,).

For legacy reasons, there are some aliases of some feature names. To normalize a feature name `name`, switch on `name`:

`"screenx"`
   Return “`left`”.

`"screeny"`
   Return “`top`”.

`"innerwidth"`
   Return “`width`”.

`"innerheight"`
   Return “`height`”.

 Anything else
   Return `name`.

To parse a boolean feature given a string `value`:

1. If `value` is the empty string, then return true.

2. If `value` is “`yes`”, then return true.
3. Let `parsed` be the result of parsing `value` as an integer.

4. If `parsed` is an error, then set it to 0.

5. Return false if `parsed` is 0, and true otherwise.

The `name` getter steps are:

1. If `this`’s browsing context is null, then return the empty string.
2. Return `this`’s browsing context’s name.

The `name` setter steps are:

1. If `this`’s browsing context is null, then return.
2. Set `this`’s browsing context’s name to the given value.

The name gets reset when the browsing context is navigated to another origin.

The `close()` method steps are:

1. Let `current` be `this`’s browsing context.
2. If `current` is null or its is closing is true, then return.
3. If all the following are true
   - `current` is script-closable
   - the incumbent global object’s browsing context is familiar with `current`
   - the incumbent global object’s browsing context is allowed to navigate `current`
   then:
   1. Set `current`’s is closing to true.
   2. Queue a task on the DOM manipulation task source to close `current`.

A browsing context is script-closable if it is an auxiliary browsing context that was created by a script (as opposed to by an action of the user), or if it is a top-level browsing context whose session history contains only one Document.

The `closed` getter steps are to return true if `this`’s browsing context is null or its is closing is true; otherwise false.

The `stop()` method steps are to stop document loading given `this`’s associated Document.
7.3.2 Accessing other browsing contexts

`window.length`

Window/length

Support in all current engines.

Firefox1+Safari1+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer4+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android12.1+

Returns the number of document-tree child browsing contexts.

`window[index]`

Returns the indicated document-tree child browsing context.

The number of document-tree child browsing contexts of a Window object W is the result of running these steps:

1. If W’s browsing context is null, then return 0.
2. Return the number of document-tree child browsing contexts of W’s browsing context.

The length getter steps are to return the number of document-tree child browsing contexts of this.

Indexed access to document-tree child browsing contexts is defined through the [[GetOwnProperty]] internal method of the WindowProxy object.

7.3.3 Named access on the Window object

`window[name]`

Returns the indicated element or collection of elements.

As a general rule, relying on this will lead to brittle code. Which IDs end up mapping to this API can vary over time, as new features are added to the web platform, for example. Instead of this, use document.getElementById() or document.querySelector().

The document-tree child browsing context name property set of a Window object window is the return value of running these steps:
1. If `window`'s **browsing context** is null, then return the empty list.

2. Let `childBrowsingContexts` be all **document-tree child browsing contexts** of `window`'s **browsing context** whose **browsing context name** is not the empty string, in order, and including only the first **document-tree child browsing context** with a given **name** if multiple **document-tree child browsing contexts** have the same one.

3. Remove each **browsing context** from `childBrowsingContexts` whose **active document**'s **origin** is not same origin with `window`'s **relevant settings object**'s **origin** and whose **browsing context name** does not match the name of its **container**'s **name** content attribute value.

4. Return the **browsing context names** of `childBrowsingContexts`, in the same order.

This means that in the following example, hosted on https://example.org/, assuming https://elsewhere.example/ sets `window.name` to "spices", evaluating `window.spices` after everything has loaded will yield undefined:

```
<iframe src=https://elsewhere.example.org/></iframe>
<iframe name=spices></iframe>
```

The **Window** object supports named properties. The supported property names of a **Window** object `window` at any moment consist of the following, in **tree order** according to the element that contributed them, ignoring later duplicates:

- `window`'s **document-tree child browsing context name** property set;
- The value of the **name** content attribute for all **embed**, **form**, **img**, and **object** elements that have a non-empty **name** content attribute and are in a document tree with `window`'s **associated Document** as their **root**; and
- The value of the **id** content attribute for all **HTML elements** that have a non-empty **id** content attribute and are in a document tree with `window`'s **associated Document** as their **root**.

To determine the value of a named property `name` in a **Window** object `window`, the user agent must return the value obtained using the following steps:

1. Let `objects` be the list of **named objects** of `window` with the name `name`.

   There will be at least one such object, by definition.

2. If `objects` contains a **browsing context**, then return the **WindowProxy** object of the **nested browsing context** of the first **browsing context container** in **tree order** whose **nested browsing context** is in `objects`.

3. Otherwise, if `objects` has only one element, return that element.
4. Otherwise return an **HTMLCollection** rooted at window’s associated **Document**, whose filter matches only named objects of window with the name *name*. (By definition, these will all be elements.)

**Named objects** of Window object window with the name *name*, for the purposes of the above algorithm, consist of the following:

- **document-tree child browsing contexts** of window’s associated **Document** whose name is *name*;
- **embed, form, img, or object** elements that have a name content attribute whose value is *name* and are in a document tree with window’s associated **Document** as their root; and
- **HTML elements** that have an id content attribute whose value is *name* and are in a document tree with window’s associated **Document** as their root.

7.3.4 Discarding browsing contexts

To **discard** a **Document** document:

1. Set document’s **salvageable** state to false.
2. Run any unloading document cleanup steps for document that are defined by this specification and other applicable specifications.
3. **Abort** document.
4. Remove any tasks associated with document in any task source, without running those tasks.
5. **Discard** all the child browsing contexts of document.
6. For each session history entry entry whose document is equal to document, set entry’s document to null.
7. Set document’s **browsing context** to null.
8. **Remove** document from the owner set of each WorkerGlobalScope object whose set contains document.
9. For each workletGlobalScope in document’s worklet global scopes, terminate workletGlobalScope.

To **discard** a browsing context **browsingContext**, run these steps:

1. **Discard** all Document objects for all the entries in browsingContext’s session history.
2. If `browsingContext` is a top-level browsing context, then remove `browsingContext`.

User agents may discard top-level browsing contexts at any time (typically, in response to user requests, e.g., when a user force-closes a window containing one or more top-level browsing contexts). Other browsing contexts must be discarded once their `WindowProxy` object is eligible for garbage collection, in addition to the other places where this specification requires them to be discarded.

### 7.3.5 Closing browsing contexts

To close a browsing context `browsingContext`, run these steps:

1. Prompt to unload `browsingContext`'s active document. If the user refused to allow the document to be unloaded, then return.

3. Remove `browsingContext` from the user interface (e.g., close or hide its tab in a tabbed browser).

User agents should offer users the ability to arbitrarily close any top-level browsing context.

### 7.3.6 Browser interface elements

For historical reasons, the `Window` interface had some attributes that represented the visibility of certain web browser interface elements.

For privacy and interoperability reasons, those attributes now return values that represent whether the `Window`'s `browsing context`'s is popup property is true or false.

Each interface element is represented by a `BarProp` object:

[MDN BarProp](https://developer.mozilla.org/en-US/docs/Web/API/BarProp)

Support in all current engines.

<table>
<thead>
<tr>
<th>Firefox 1+</th>
<th>Safari 3+</th>
<th>Chrome 29+</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opera 16+</td>
<td>Edge 79+</td>
<td></td>
</tr>
<tr>
<td>Edge (Legacy) 12+</td>
<td>Internet Explorer No</td>
<td></td>
</tr>
<tr>
<td>Firefox Android 4+</td>
<td>Safari iOS 1+</td>
<td>Chrome Android 29+</td>
</tr>
</tbody>
</table>
[Exposed=Window]
interface BarProp {
  readonly attribute boolean visible;
};

window.locationbar.visible

Window/locationbar
Support in all current engines.

Firefox1+Safari3+Chrome1+
Opera15+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android14+

window.menubar.visible

Window/menubar
Support in all current engines.

Firefox1+Safari3+Chrome1+
Opera15+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android14+

window.personalbar.visible

Window/personalbar
Support in all current engines.

Firefox1+Safari3+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android12.1+

window.scrollbars.visible

Window(scrollbars)
Support in all current engines.

Firefox1+Safari3+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android12.1+

`window.statusbar.visible`

![MDN](https://developer.mozilla.org)

**Window/statusbar**

Support in all current engines.

Firefox1+Safari3+Chrome1+
Opera15+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android14+

`window.toolbar.visible`

![MDN](https://developer.mozilla.org)

**Window/toolbar**

Support in all current engines.

Firefox1+Safari3+Chrome1+
Opera15+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android14+

Returns true if the top-level browsing context is not a popup; otherwise, returns false.

![MDN](https://developer.mozilla.org)

**BarProp/visible**

Support in all current engines.

Firefox1+Safari3+Chrome43+
Opera30+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android4+Safari iOS1+Chrome Android43+WebView Android43+Samsung
Internet4.0+Opera Android30+
The `visible` getter steps are:

1. Let `browsingContext` be `this`'s relevant global object's browsing context.
2. If `browsingContext` is null, then return true.
3. Return the negation of `browsingContext`'s top-level browsing context's is popup.

The following BarProp objects must exist for each Window object:

**The location bar BarProp object**

Historically represented the user interface element that contains a control that displays the browser's location bar.

**The menu bar BarProp object**

Historically represented the user interface element that contains a list of commands in menu form, or some similar interface concept.

**The personal bar BarProp object**

Historically represented the user interface element that contains links to the user's favorite pages, or some similar interface concept.

**The scrollbar BarProp object**

Historically represented the user interface element that contains a scrolling mechanism, or some similar interface concept.

**The status bar BarProp object**

Historically represented a user interface element found immediately below or after the document, as appropriate for the user's media, which typically provides information about ongoing network activity or information about elements that the user's pointing device is currently indicating.

**The toolbar BarProp object**

Historically represented the user interface element found immediately above or before the document, as appropriate for the user's media, which typically provides session history traversal controls (back and forward buttons, reload buttons, etc.).

The `locationbar` attribute must return the location bar BarProp object.

The `menubar` attribute must return the menu bar BarProp object.

The `personalbar` attribute must return the personal bar BarProp object.

The `scrollbars` attribute must return the scrollbar BarProp object.

The `statusbar` attribute must return the status bar BarProp object.

The `toolbar` attribute must return the toolbar BarProp object.
For historical reasons, the `status` attribute on the `Window` object must, on getting, return the last string it was set to, and on setting, must set itself to the new value. When the `Window` object is created, the attribute must be set to the empty string. It does not do anything else.

### 7.3.7 Script settings for `Window` objects

To set up a window environment settings object, given a `URL` creation `URL`, a `JavaScript` execution context `execution context`, null or an `environment` `reservedEnvironment`, a `URL` top `LevelCreationURL`, and an `origin` `topLevelOrigin`, run these steps:

1. Let `realm` be the value of `execution context`'s Realm component.
2. Let `window` be `realm`'s `global object`.
3. Let `settings object` be a new `environment settings object` whose algorithms are defined as follows:

   - **The realm execution context**
     Return `execution context`.

   - **The module map**
     Return the `module map` of `window`'s associated `Document`.

   - **The responsible document**
     Return `window`'s associated `Document`.

   - **The API URL character encoding**
     Return the current `character encoding` of `window`'s associated `Document`.

   - **The API base URL**
     Return the current `base URL` of `window`'s associated `Document`.

   - **The origin**
     Return the `origin` of `window`'s associated `Document`.

   - **The policy container**
     Return the `policy container` of `window`'s associated `Document`. 

The **cross-origin isolated capability**

Return true if both of the following hold, and false otherwise:

1. *realm’s agent cluster’s cross-origin-isolation mode* is "**concrete**", and

2. *window’s associated Document* is allowed to use the "**cross-origin-isolated**" feature.

4. If `reservedEnvironment` is non-null, then:

   1. Set `settings object’s id` to `reservedEnvironment’s id`, `target browsing context` to `reservedEnvironment’s target browsing context`, and `active service worker` to `reservedEnvironment’s active service worker`.

   2. Set `reservedEnvironment’s id` to the empty string.

   The identity of the reserved environment is considered to be fully transferred to the created *environment settings object*. The reserved environment is not searchable by the *environment’s id* from this point on.

5. Otherwise, set `settings object’s id` to a new unique opaque string, `settings object’s target browsing context` to null, and `settings object’s active service worker` to null.

6. Set `settings object’s creation URL` to `creationURL`, `settings object’s top-level creation URL` to `topLevelCreationURL`, and `settings object’s top-level origin` to `topLevelOrigin`.

7. Set *realm’s [[HostDefined]] field* to `settings object`.

### 7.4 The **WindowProxy** exotic object

A **WindowProxy** is an exotic object that wraps a **Window** ordinary object, indirectioning most operations through to the wrapped object. Each **browsing context** has an associated **WindowProxy** object. When the **browsing context** is navigated, the **Window** object wrapped by the **browsing context**’s associated **WindowProxy** object is changed.

The **WindowProxy** exotic object must use the ordinary internal methods except where it is explicitly specified otherwise below.

There is no **WindowProxy** interface object.

Every **WindowProxy** object has a `[[Window]]` internal slot representing the wrapped **Window** object.

Although **WindowProxy** is named as a "proxy", it does not do polymorphic dispatch on its target’s internal methods as a real proxy would, due to a desire to reuse machinery between **WindowProxy** and **Location** objects. As long as the **Window** object remains an ordinary
object this is unobservable and can be implemented either way.

7.4.1 [[GetPrototypeOf]] ( )

1. Let \( W \) be the value of the [[Window]] internal slot of \( \text{this} \).
2. If \( ! \text{IsPlatformObjectSameOrigin}(W) \) is true, then return \( ! \text{OrdinaryGetPrototypeOf}(W) \).
3. Return null.

7.4.2 [[SetPrototypeOf]] ( \( V \) )

1. Return \( ! \text{SetImmutablePrototype}(\text{this}, \ V) \).

7.4.3 [[IsExtensible]] ( )

1. Return true.

7.4.4 [[PreventExtensions]] ( )

1. Return false.

7.4.5 [[GetOwnProperty]] ( \( P \) )

1. Let \( W \) be the value of the [[Window]] internal slot of \( \text{this} \).
2. If \( P \) is an array index property name, then:
   1. Let \( \text{index} \) be \( ! \text{ToUint32}(P) \).
   2. Let \( \text{maxProperties} \) be the number of document-tree child browsing contexts of \( W \).
   3. Let \( \text{value} \) be undefined.
   4. If \( \text{maxProperties} \) is greater than 0 and \( \text{index} \) is less than \( \text{maxProperties} \), then set \( \text{value} \) to the \text{WindowProxy} object of the \( \text{indexth} \) document-tree child browsing context of \( W \)'s browsing context, sorted in the order that their browsing context container elements were most recently inserted into \( W \)'s associated Document, the \text{WindowProxy} object of the most recently inserted browsing context container's nested browsing context being last.
5. If \( \text{value} \) is undefined, then:
   1. If \( ! \text{IsPlatformObjectSameOrigin}(W) \) is true, then return undefined.
2. Throw a "**SecurityError**" **DOMException**.

3. If ! `IsPlatformObjectSameOrigin`(`W`) is true, then return ! `OrdinaryGetOwnProperty`(`W`, `P`).

   This is a willful violation of the JavaScript specification’s invariants of the essential internal methods to maintain compatibility with existing web content. See tc39/ecma262 issue #672 for more information. [JAVASCRIPT]

4. Let `property` be ! `CrossOriginGetOwnPropertyHelper`(`W`, `P`).

5. If `property` is not undefined, then return `property`.

6. If `property` is undefined and `P` is in `W`’s document-tree child browsing context name property set, then:

   1. Let `value` be the `WindowProxy` object of the named object of `W` with the name `P`.

   2. Return `PropertyDescriptor`{ `[[Value]]`: value, `[[Enumerable]]`: false, `[[Writable]]`: false, `[[Configurable]]`: true }.

   The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See issue #3183 for details.

7.4.6 `[[DefineOwnProperty]]` (`P`, `Desc`)  

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.

2. If ! `IsPlatformObjectSameOrigin`(`W`) is true, then:

   1. If `P` is an array index property name, return false.

   This is a willful violation of the JavaScript specification’s invariants of the essential internal methods to maintain compatibility with existing web content. See tc39/ecma262 issue #672 for more information. [JAVASCRIPT]

3. Throw a "**SecurityError**" **DOMException**.
7.4.7 [[Get]] (P, Receiver)

1. Let W be the value of the [[Window]] internal slot of this.

2. Check if an access between two browsing contexts should be reported, given the current global object’s browsing context, W’s browsing context, P, and the current settings object.

3. If !IsPlatformObjectSameOrigin(W) is true, then return ? OrdinaryGet(this, P, Receiver).

this is passed rather than W as OrdinaryGet and CrossOriginGet will invoke the [[GetOwnProperty]] internal method.

7.4.8 [[Set]] (P, V, Receiver)

1. Let W be the value of the [[Window]] internal slot of this.

2. Check if an access between two browsing contexts should be reported, given the current global object’s browsing context, W’s browsing context, P, and the current settings object.

3. If !IsPlatformObjectSameOrigin(W) is true, then:
   1. If P is an array index property name, then return false.

this is passed rather than W as CrossOriginSet will invoke the [[GetOwnProperty]] internal method.

7.4.9 [[Delete]] (P)

1. Let W be the value of the [[Window]] internal slot of this.

2. If !IsPlatformObjectSameOrigin(W) is true, then:
   1. If P is an array index property name, then:
      1. Let desc be !this.[[GetOwnProperty]](P).
      2. If desc is undefined, then return true.
3. Return false.

3. Throw a "SecurityError" DOMException.

7.4.10 [[OwnPropertyKeys]] ( )

1. Let W be the value of the [[Window]] internal slot of this.

2. Let keys be a new empty List.

3. Let maxProperties be the number of document-tree child browsing contexts of W.

4. Let index be 0.

5. Repeat while index < maxProperties,

   1. Add ! ToString(index) as the last element of keys.

   2. Increment index by 1.

6. If ! IsPlatformObjectSameOrigin(W) is true, then return the concatenation of keys and ! OrdinaryOwnPropertyKeys(W).

7. Return the concatenation of keys and ! CrossOriginOwnPropertyKeys(W).

7.5 Origin

Origins are the fundamental currency of the web’s security model. Two actors in the web platform that share an origin are assumed to trust each other and to have the same authority. Actors with differing origins are considered potentially hostile versus each other, and are isolated from each other to varying degrees.

For example, if Example Bank’s web site, hosted at bank.example.com, tries to examine the DOM of Example Charity’s web site, hosted at charity.example.org, a "SecurityError" DOMException will be raised.

An origin is one of the following:

An opaque origin

An internal value, with no serialization it can be recreated from (it is serialized as "null" per serialization of an origin), for which the only meaningful operation is testing for equality.
A tuple origin

A **tuple** consists of:

- A **scheme** (an ASCII string).
- A **host** (a host).
- A **port** (null or a 16-bit unsigned integer).
- A **domain** (null or a domain). Null unless stated otherwise.

**Origins** can be shared, e.g., among multiple **Document** objects. Furthermore, **origins** are generally immutable. Only the **domain** of a **tuple origin** can be changed, and only through the **document.domain** API.

The **effective domain** of an **origin** is computed as follows:

1. If **origin** is an **opaque origin**, then return null.
2. If **origin's domain** is non-null, then return **origin's domain**.
3. Return **origin's host**.

The **serialization of an origin** is the string obtained by applying the following algorithm to the given **origin**:

1. If **origin** is an **opaque origin**, then return "null".
2. Otherwise, let **result** be **origin's scheme**.
3. Append "://" to **result**.
4. Append **origin's host**, serialized, to **result**.
5. If **origin's port** is non-null, append a U+003A COLON character (:), and **origin's port**, serialized, to **result**.
6. Return **result**.

The **serialization** of ("https","xn--maraa-rta.example", null, null) is "https://xn--maraa-rta.example".

There used to also be a **Unicode serialization of an origin**. However, it was never widely adopted.

Two **origins**, A and B, are said to be **same origin** if the following algorithm returns true:

1. If A and B are the same **opaque origin**, then return true.
2. If $A$ and $B$ are both tuple origins and their schemes, hosts, and port are identical, then return true.

3. Return false.

Two origins, $A$ and $B$, are said to be same origin-domain if the following algorithm returns true:

1. If $A$ and $B$ are the same opaque origin, then return true.

2. If $A$ and $B$ are both tuple origins, run these substeps:

   1. If $A$ and $B$'s schemes are identical, and their domains are identical and non-null, then return true.

   2. Otherwise, if $A$ and $B$ are same origin and their domains are identical and null, then return true.

3. Return false.

<table>
<thead>
<tr>
<th>$A$</th>
<th>$B$</th>
<th>same origin</th>
<th>same origin-domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>(&quot;https&quot;,&quot;example.org&quot;,null,null)</td>
<td>(&quot;https&quot;,&quot;example.org&quot;,null,null)</td>
<td>✓</td>

<td>x</td>
<td>x</td>
</tr>
</tbody>
</table>

7.5.1 Sites

A scheme-and-host is a tuple of an ASCII string and a host.

A site is an opaque origin or a scheme-and-host.

To obtain a site, given an origin origin, run these steps:

1. If origin is an opaque origin, then return origin.

2. If origin's host's registrable domain is null, then return (origin's scheme, origin's host).

3. Return (origin's scheme, origin's host's registrable domain).

The serialization of a site is the string obtained by applying the following algorithm to the
given site site:

1. If site is an opaque origin, then return "null".
2. Let result be site[0].
3. Append "://" to result.
4. Append site[1], serialized, to result.
5. Return result.

It needs to be clear from context that the serialized value is a site, not an origin, as there is not necessarily a syntactic difference between the two. For example, the origin ("https", "shop.example", null, null) and the site ("https", "shop.example") have the same serialization: "https://shop.example".

Two origins, A and B, are said to be schemelessly same site if the following algorithm returns true:

1. If A and B are the same opaque origin, then return true.
2. If A and B are both tuple origins, then:
   1. Let hostA be A's host, and let hostB be B's host.
   2. If hostA equals hostB and hostA's registrable domain is null, then return true.
   3. If hostA's registrable domain equals hostB's registrable domain and is non-null, then return true.
3. Return false.

Two origins, A and B, are said to be same site if both of the following statements are true:

- A and B are schemelessly same site
- A and B are either both opaque origins, or both tuple origins with the same scheme

Unlike the same origin and same origin-domain concepts, for schemelessly same site and same site, the port and domain components are ignored.

For the reasons explained in URL, the same site and schemelessly same site concepts should be avoided when possible, in favor of same origin checks.

Given that wildlife.museum, museum, and com are public suffixes and that example.com is not:
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>schemelessly same site</th>
<th>same site</th>
</tr>
</thead>
<tbody>
<tr>
<td>(&quot;https&quot;,&quot;example.com&quot;)</td>
<td>(&quot;https&quot;,&quot;sub.example.com&quot;)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>(&quot;https&quot;,&quot;example.com&quot;)</td>
<td>(&quot;https&quot;,&quot;sub.other.example.com&quot;)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>(&quot;https&quot;,&quot;example.com&quot;)</td>
<td>(&quot;http&quot;,&quot;non-secure.example.com&quot;)</td>
<td>✓</td>
<td>✗</td>
</tr>
<tr>
<td>(&quot;https&quot;, &quot;r.wildlife.museum&quot;)</td>
<td>(&quot;https&quot;, &quot;sub.r.wildlife.museum&quot;)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>(&quot;https&quot;, &quot;r.wildlife.museum&quot;)</td>
<td>(&quot;https&quot;, &quot;sub.other.r.wildlife.museum&quot;)</td>

<tr>
<td>(&quot;https&quot;, &quot;wildlife.museum&quot;)</td>
<td>(&quot;https&quot;, &quot;wildlife.museum&quot;)</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

(Here we have omitted the **port** and **domain** components since they are not considered.)

### 7.5.2 Relaxing the same-origin restriction

**Document/domain**

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox1+Safari1+Chrome1+</td>
</tr>
<tr>
<td>Opera12.1+Edge79+</td>
</tr>
<tr>
<td>Edge (Legacy)12+Internet Explorer4+</td>
</tr>
<tr>
<td>Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung</td>
</tr>
<tr>
<td>Internet1.0+Opera Android12.1+</td>
</tr>
</tbody>
</table>

**document.domain** [ = domain ]

Returns the current domain used for security checks.

Can be set to a value that removes subdomains, to change the **origin’s domain** to allow pages on other subdomains of the same domain (if they do the same thing) to access each other. This enables pages on different hosts of a domain to synchronously access each other’s DOMs.

In sandboxed **iframes**, **Documents** with **opaque origins**, **Documents** without a **browsing context**, and when the "**document-domain**" feature is disabled, the setter will throw a
"SecurityError" exception. In cases where `crossOriginIsolated` or `originAgentCluster` return true, the setter will do nothing.

Avoid using the `document.domain` setter. It undermines the security protections provided by the same-origin policy. This is especially acute when using shared hosting; for example, if an untrusted third party is able to host an HTTP server at the same IP address but on a different port, then the same-origin protection that normally protects two different sites on the same host will fail, as the ports are ignored when comparing origins after the `document.domain` setter has been used.

Because of these security pitfalls, this feature is in the process of being removed from the web platform. (This is a long process that takes many years.)

Instead, use `postMessage()` or `MessageChannel` objects to communicate across origins in a safe manner.

The `domain` getter steps are:

1. Let `effectiveDomain` be this's origin's effective domain.
2. If `effectiveDomain` is null, then return the empty string.
3. Return `effectiveDomain`, serialized.

The `domain` setter steps are:

1. If this's browsing context is null, then throw a "SecurityError" DOMException.
2. If this's active sandboxing flag set has its sandboxed `document.domain` browsing context flag set, then throw a "SecurityError" DOMException.
3. If this is not allowed to use the "document-domain" feature, then throw a "SecurityError" DOMException.
4. Let `effectiveDomain` be this's origin's effective domain.
5. If `effectiveDomain` is null, then throw a "SecurityError" DOMException.
6. If the given value is not a registrable domain suffix of and is not equal to `effectiveDomain`, then throw a "SecurityError" DOMException.
7. If the surrounding agent's agent cluster's is origin-keyed is true, then return.
8. Set this's origin's domain to the result of parsing the given value.

To determine if a string `hostSuffixString` is a registrable domain suffix of or is equal to a `host originalHost`, run these steps:
1. If `hostSuffixString` is the empty string, then return false.

2. Let `hostSuffix` be the result of parsing `hostSuffixString`.

3. If `hostSuffix` is failure, then return false.

4. If `hostSuffix` does not equal `originalHost`, then:
   1. If `hostSuffix` or `originalHost` is not a domain, then return false.

      This excludes hosts that are IP addresses.

   2. If `hostSuffix`, prefixed by U+002E (.), does not match the end of `originalHost`, then return false.

3. If one of the following is true
   - `hostSuffix` equals `hostSuffix`'s public suffix
   - `hostSuffix`, prefixed by U+002E (.), matches the end of `originalHost`'s public suffix

   then return false. [URL]

4. Assert: `originalHost`'s public suffix, prefixed by U+002E (.), matches the end of `hostSuffix`.

5. Return true.

---

<table>
<thead>
<tr>
<th><code>hostSuffixString</code></th>

</tbody>
</table>
At the time of writing, *.compute.amazonaws.com is a public suffix.

At the time of writing, amazonaws.com registrable domain.

7.5.3 Origin-keyed agent clusters

```javascript
window.originAgentCluster
```

Returns true if this `Window` belongs to an `agent cluster` which is origin-keyed, in the manner described in this section.

A `Document` delivered over a secure context can request that it be placed in an origin-keyed agent cluster, by using the `Origin-Agent-Cluster` HTTP response header. This header is a structured header whose value must be a boolean. [STRUCTURED-FIELDS]

Per the processing model in the create and initialize a new `Document` object, values that are not the structured header boolean true value (i.e., `'1'`) will be ignored.

The consequences of using this header are that the resulting `Document`’s agent cluster key is its origin, instead of the corresponding site. In terms of observable effects, this means that attempting to relax the same-origin restriction using `document.domain` will instead do nothing, and it will not be possible to send `WebAssembly.Module` objects to cross-origin `Documents` (even if they are same site). Behind the scenes, this isolation can allow user agents to allocate implementation-specific resources corresponding to `agent clusters`, such as processes or threads, more efficiently.

Note that within a browsing context group, the `Origin-Agent-Cluster` header can never cause same-origin `Document` objects to end up in different `agent clusters`, even if one sends the header and the other doesn’t. This is prevented by means of the historical agent cluster key map.

This means that the `originAgentCluster` getter can return false, even if the header is set, if the header was omitted on a previously-loaded same-origin page in the same browsing context group. Similarly, it can return true even when the header is not set.

The `originAgentCluster` getter steps are to return the surrounding agent’s agent cluster’s is origin-keyed.

`Documents` with an opaque origin can be considered unconditionally origin-keyed; for them the header has no effect, and the `originAgentCluster` getter will always return true.

Similarly, `Documents` whose agent cluster’s cross-origin isolation mode is not "none" are automatically origin-keyed. The `Origin-Agent-Cluster` header might be useful as an
additional hint to implementations about resource allocation, since the `Cross-Origin-Opener-Policy` and `Cross-Origin-Embedder-Policy` headers used to achieve cross-origin isolation are more about ensuring that everything in the same address space opts in to being there. But adding it would have no additional observable effects on author code.

### 7.6 Sandboxing

A sandboxing flag set is a set of zero or more of the following flags, which are used to restrict the abilities that potentially untrusted resources have:

**The sandboxed navigation browsing context flag**

This flag prevents content from navigating browsing contexts other than the sandboxed browsing context itself (or browsing contexts further nested inside it), auxiliary browsing contexts (which are protected by the sandboxed auxiliary navigation browsing context flag defined next), and the top-level browsing context (which is protected by the sandboxed top-level navigation without user activation browsing context flag and sandboxed top-level navigation with user activation browsing context flag defined below).

If the sandboxed auxiliary navigation browsing context flag is not set, then in certain cases the restrictions nonetheless allow popups (new top-level browsing contexts) to be opened. These browsing contexts always have one permitted sandboxed navigator, set when the browsing context is created, which allows the browsing context that created them to actually navigate them. (Otherwise, the sandboxed navigation browsing context flag would prevent them from being navigated even if they were opened.)

**The sandboxed auxiliary navigation browsing context flag**

This flag prevents content from creating new auxiliary browsing contexts, e.g. using the `target` attribute or the `window.open()` method.

**The sandboxed top-level navigation without user activation browsing context flag**

This flag prevents content from navigating their top-level browsing context and prevents content from closing their top-level browsing context. It is consulted only when the sandboxed browsing context’s active window does not have transient activation.

When the sandboxed top-level navigation without user activation browsing context flag is not set, content can navigate its top-level browsing context, but other browsing contexts are still protected by the sandboxed navigation browsing context flag and possibly the sandboxed auxiliary navigation browsing context flag.

**The sandboxed top-level navigation with user activation browsing context flag**

This flag prevents content from navigating their top-level browsing context and prevents content from closing their top-level browsing context. It is consulted only when the sandboxed browsing context’s active window has transient activation.
As with the sandboxed top-level navigation without user activation browsing context flag, this flag only affects the top-level browsing context; if it is not set, other browsing contexts might still be protected by other flags.

The **sandboxed plugins browsing context flag**

This flag prevents content from instantiating plugins, whether using the embed element, the object element, or through navigation of their nested browsing context.

The **sandboxed origin browsing context flag**

This flag forces content into a unique origin, thus preventing it from accessing other content from the same origin.

This flag also prevents script from reading from or writing to the `document.cookie` IDL attribute, and blocks access to localStorage.

The **sandboxed forms browsing context flag**

This flag blocks form submission.

The **sandboxed pointer lock browsing context flag**

This flag disables the Pointer Lock API. [POINTERLOCK]

The **sandboxed scripts browsing context flag**

This flag blocks script execution.

The **sandboxed automatic features browsing context flag**

This flag blocks features that trigger automatically, such as automatically playing a video or automatically focusing a form control.

The **sandboxed `document.domain` browsing context flag**

This flag prevents content from using the `document.domain` setter.

The **sandbox propagates to auxiliary browsing contexts flag**

This flag prevents content from escaping the sandbox by ensuring that any auxiliary browsing context it creates inherits the content’s active sandboxing flag set.

The **sandboxed modals flag**

This flag prevents content from using any of the following features to produce modal dialogs:
• `window.alert()`
• `window.confirm()`
• `window.print()`
• `window.prompt()`
• the `beforeunload` event

The sandboxed orientation lock browsing context flag

This flag disables the ability to lock the screen orientation. [SCREENORIENTATION]

The sandboxed presentation browsing context flag

This flag disables the Presentation API. [PRESENTATION]

The sandboxed downloads browsing context flag

This flag prevents content from initiating or instantiating downloads, whether through downloading hyperlinks or through navigation that gets handled as a download.

When the user agent is to parse a sandboxing directive, given a string `input`, a sandboxing flag set `output`, it must run the following steps:

1. Split `input` on ASCII whitespace, to obtain `tokens`.
2. Let `output` be empty.
3. Add the following flags to `output`:
   - The sandboxed navigation browsing context flag.
   - The sandboxed auxiliary navigation browsing context flag, unless `tokens` contains the `allow-popups` keyword.
   - The sandboxed top-level navigation without user activation browsing context flag, unless `tokens` contains the `allow-top-navigation` keyword.
   - The sandboxed top-level navigation with user activation browsing context flag, unless `tokens` contains either the `allow-top-navigation-by-user-activation` keyword or the `allow-top-navigation` keyword.

   This means that if the `allow-top-navigation` is present, the `allow-top-navigation-by-user-activation` keyword will have no effect. For this reason, specifying both is a document conformance error.

   - The sandboxed plugins browsing context flag.
   - The sandboxed origin browsing context flag, unless the `tokens` contains the `allow-same-origin` keyword.
The `allow-same-origin` keyword is intended for two cases.

First, it can be used to allow content from the same site to be sandboxed to disable scripting, while still allowing access to the DOM of the sandboxed content.

Second, it can be used to embed content from a third-party site, sandboxed to prevent that site from opening popups, etc, without preventing the embedded page from communicating back to its originating site, using the database APIs to store data, etc.

- The sandboxed forms browsing context flag, unless `tokens` contains the `allow-forms` keyword.
- The sandboxed pointer lock browsing context flag, unless `tokens` contains the `allow-pointer-lock` keyword.
- The sandboxed scripts browsing context flag, unless `tokens` contains the `allow-scripts` keyword.
- The sandboxed automatic features browsing context flag, unless `tokens` contains the `allow-scripts` keyword (defined above).
  This flag is relaxed by the same keyword as scripts, because when scripts are enabled these features are trivially possible anyway, and it would be unfortunate to force authors to use script to do them when sandboxed rather than allowing them to use the declarative features.
- The sandboxed document.domain browsing context flag.
- The sandbox propagates to auxiliary browsing contexts flag, unless `tokens` contains the `allow-popups-to-escape-sandbox` keyword.
- The sandboxed modals flag, unless `tokens` contains the `allow-modals` keyword.
- The sandboxed orientation lock browsing context flag, unless `tokens` contains the `allow-orientation-lock` keyword.
- The sandboxed presentation browsing context flag, unless `tokens` contains the `allow-presentation` keyword.
- The sandboxed downloads browsing context flag, unless `tokens` contains the `allow-downloads` keyword.

Every top-level browsing context has a popup sandboxing flag set, which is a sandboxing flag
set. When a browsing context is created, its popup sandboxing flag set must be empty. It is populated by the rules for choosing a browsing context and the obtain a browsing context to use for a navigation response algorithm.

Every iframe element has an iframe sandboxing flag set, which is a sandboxing flag set. Which flags in an iframe sandboxing flag set are set at any particular time is determined by the iframe element’s sandbox attribute.

Every Document has an active sandboxing flag set, which is a sandboxing flag set. When the Document is created, its active sandboxing flag set must be empty. It is populated by the navigation algorithm.

Every resource that is obtained by the navigation algorithm has a forced sandboxing flag set, which is a sandboxing flag set. A resource by default has no flags set in its forced sandboxing flag set, but other specifications can define that certain flags are set.

In particular, the forced sandboxing flag set is used by Content Security Policy. [CSP]

To determine the creation sandboxing flags for a browsing context, given null or an element embedder, return the union of the flags that are present in the following sandboxing flag sets:

- If embedder is null, then: the flags set on browsing context’s popup sandboxing flag set.
- If embedder is an element, then: the flags set on embedder’s iframe sandboxing flag set.
- If embedder is an element, then: the flags set on embedder’s node document’s active sandboxing flag set.

After creation, the sandboxing flags for a browsing context are the result of determining the creation sandboxing flags given browsing context and browsing context’s container.

7.7 Cross-origin opener policies

A cross-origin opener policy value allows a document which is navigated to in a top-level browsing context to force the creation of a new top-level browsing context, and a corresponding group. The possible values are:

"unsafe-none"

This is the (current) default and means that the document will occupy the same top-level browsing context as its predecessor, unless that document specified a different cross-origin opener policy.
"same-origin-allow-popups"

This forces the creation of a new top-level browsing context for the document, unless its predecessor specified the same cross-origin opener policy and they are same origin.

"same-origin"

This behaves the same as "same-origin-allow-popups", with the addition that any auxiliary browsing context created needs to contain same origin documents that also have the same cross-origin opener policy or it will appear closed to the opener.

"same-origin-plus-COEP"

This behaves the same as "same-origin", with the addition that it sets the (new) top-level browsing context’s group’s cross-origin isolation mode to one of “logical” or “concrete”.

"same-origin-plus-COEP" cannot be directly set via the `Cross-Origin-Opener-Policy` header, but results from a combination of setting both `Cross-Origin-Opener-Policy: same-origin` and a `Cross-Origin-Embedder-Policy` header whose value is compatible with cross-origin isolation together.

A cross-origin opener policy consists of:

- A value, which is a cross-origin opener policy value, initially "unsafe-none".
- A reporting endpoint, which is string or null, initially null.
- A report-only value, which is a cross-origin opener policy value, initially "unsafe-none".
- A report-only reporting endpoint, which is a string or null, initially null.

To match cross-origin opener policy values, given a cross-origin opener policy value A, an origin originA, a cross-origin opener policy value B, and an origin originB:

1. If A is "unsafe-none" and B is "unsafe-none", then return true.
2. If A is "unsafe-none" or B is "unsafe-none", then return false.
3. If A is B and originA is same origin with originB, then return true.
4. Return false.

7.7.1 The headers
Headers/Cross-Origin-Opener-Policy

Support in all current engines.

<table>
<thead>
<tr>
<th>Engine</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 79+</td>
<td>Safari preview+</td>
</tr>
<tr>
<td>Chrome 83+</td>
<td>Opera No</td>
</tr>
<tr>
<td>Edge (Legacy)</td>
<td>No Internet Explorer No</td>
</tr>
<tr>
<td>Firefox Android 79+</td>
<td>Safari iOS</td>
</tr>
<tr>
<td>Chrome Android 83+</td>
<td>WebView Android No</td>
</tr>
<tr>
<td>Internet Explorer 13.0+</td>
<td>Opera Android No</td>
</tr>
</tbody>
</table>

A Document’s cross-origin opener policy is derived from the `Cross-Origin-Opener-Policy` and the `Cross-Origin-Opener-Policy-Report-Only` HTTP response headers. These headers are structured headers whose value must be a token. [STRUCTURED-FIELDS]

The valid token values are the opener policy values. The token may also have attached parameters; of these, the "report-to" parameter can have a valid URL string identifying an appropriate reporting endpoint. [REPORTING]

Per the processing model described below, user agents will ignore this header if it contains an invalid value. Likewise, user agents will ignore this header if the value cannot be parsed as a token.

To obtain a cross-origin opener policy given a response and an environment:

1. Let policy be a new cross-origin opener policy.

2. If reservedEnvironment is a non-secure context, then return policy.

3. Let value be the result of getting a structured field value given `Cross-Origin-Opener-Policy` and “item” from response’s header list.

4. If parsedItem is not null, then:

   1. If parsedItem[0] is "same-origin", then:

      1. Let coep be the result of obtaining a cross-origin embedder policy from response and reservedEnvironment.

      2. If coep’s value is compatible with cross-origin isolation, then set policy’s value to "same-origin-plus-COEP".

      3. Otherwise, set policy’s value to "same-origin".

   2. If parsedItem[0] is "same-origin-allow-popups", then set policy’s value to "same-origin-allow-popups".
3. If `parsedItem[1]["report-to"]` exists and it is a string, then set policy's reporting endpoint to `parsedItem[1]["report-to"]`.

5. Set `parsedItem` to the result of getting a structured field value given ‘Cross-Origin-Opener-Policy-Report-Only’ and "item" from response’s header list.

6. If `parsedItem` is not null, then:
   1. If `parsedItem[0]` is "same-origin", then:
      1. Let `coep` be the result of obtaining a cross-origin embedder policy from response and reservedEnvironment.
      2. If `coep`'s value is compatible with cross-origin isolation or `coep`'s report-only value is compatible with cross-origin isolation, then set policy’s report-only value to "same-origin-plus-COEP".
         Report only COOP also considers report-only COEP to assign the special "same-origin-plus-COEP" value. This allows developers more freedom in the order of deployment of COOP and COEP.
      3. Otherwise, set policy’s report-only value to "same-origin".
   2. If `parsedItem[0]` is "same-origin-allow-popups", then set policy’s report-only value to "same-origin-allow-popups".
   3. If `parsedItem[1]["report-to"]` exists and it is a string, then set policy’s report-only reporting endpoint to `parsedItem[1]["report-to"]`.

7. Return `policy`.

**7.7.2 Browsing context group switches due to cross-origin opener policy**

To check if COOP values require a browsing context group switch, given a boolean `isInitialAboutBlank`, two origins `responseOrigin` and `activeDocumentNavigationOrigin`, and two cross-origin opener policy values `responseCOOPValue` and `activeDocumentCOOPValue`:

1. If the result of matching `activeDocumentCOOPValue`, `activeDocumentNavigationOrigin`, `responseCOOPValue`, and `responseOrigin` is true, return false.

2. If all of the following are true:
   - `isInitialAboutBlank`,
   - `activeDocumentCOOPValue`'s value is "same-origin-allow-popups".
To check if enforcing report-only COOP would require a browsing context group switch, given a boolean `isInitialAboutBlank`, two origins `responseOrigin`, `activeDocumentNavigationOrigin`, and two cross-origin opener policies `responseCOOP` and `activeDocumentCOOP`:

1. If the result of checking if COOP values require a browsing context group switch given `isInitialAboutBlank`, `responseOrigin`, `activeDocumentNavigationOrigin`, `responseCOOP`'s report-only value and `activeDocumentCOOPReportOnly`'s report-only value is false, then return false.

2. If the result of checking if COOP values require a browsing context group switch given `isInitialAboutBlank`, `responseOrigin`, `activeDocumentNavigationOrigin`, `responseCOOP`'s value and `activeDocumentCOOPReportOnly`'s report-only value is true, then return true.

3. If the result of checking if COOP values require a browsing context group switch given `isInitialAboutBlank`, `responseOrigin`, `activeDocumentNavigationOrigin`, `responseCOOP`'s report-only value and `activeDocumentCOOPReportOnly`'s value is true, then return true.

4. Return false.

A cross-origin opener policy enforcement result is a struct with the following items:

- A boolean `needs a browsing context group switch`, initially false.

- A boolean `would need a browsing context group switch due to report-only`, initially false.

- A URL `url`.

- An origin `origin`.

- A cross-origin opener policy `cross-origin opener policy`.

- A boolean `current context is navigation source`.

To enforce a response's cross-origin opener policy, given a browsing context `browsingContext`, a URL `responseURL`, an origin `responseOrigin`, a cross-origin opener policy `responseCOOP`, a
cross-origin opener policy enforcement result \textit{current\textsc{coope}nforcement\textit{result}}, and a \textit{referrer} \textit{referrer}:

1. Let \textit{new\textsc{coope}nforcement\textit{result}} be a new \textit{cross-origin opener policy enforcement result} whose \textit{needs a browsing context group switch} is \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{needs a browsing context group switch}, \textit{would need a browsing context group switch due to report-only} is \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{would need a browsing context group switch due to report-only}, \textit{url} is \textit{responseURL}, \textit{origin} is \textit{response\textsc{origin}}, \textit{coop} is \textit{response\textsc{coope}}, and \textit{current context is navigation source} is true.

2. Let \textit{isInitial\textit{about}\textit{blank}} be true if \textit{browsing\textit{context}} is still on its initial \textit{about:blank Document}; otherwise, false.

3. If \textit{isInitial\textit{about}\textit{blank}} is true and \textit{browsing\textit{context}}'s \textit{initial URL} is null, set \textit{browsing\textit{context}}'s \textit{initial URL} to \textit{responseURL}.

4. If the result of checking if \textit{COOP} values require a browsing context group switch given \textit{isInitial\textit{about}\textit{blank}}, \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{cross-origin opener policy}'s \textit{value}, \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{origin}, \textit{response\textsc{coope}}'s \textit{value}, and \textit{response\textsc{origin}} is true, then:
   
   1. Set \textit{new\textsc{coope}nforcement\textit{result}}'s \textit{needs a browsing context group switch} to true.

   2. If \textit{browsing\textit{context}}'s \textit{group}’s \textit{browsing context set}’s \textit{size} is greater than 1, then:
      
      1. Queue a violation report for browsing context group switch when navigating to a \textit{COOP response} with \textit{response\textsc{coope}}, "\textit{enforce}", \textit{responseURL}, \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{url}, \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{origin}, \textit{response\textsc{origin}}, and \textit{referrer}.

      2. Queue a violation report for browsing context group switch when navigating away from a \textit{COOP response} with \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{cross-origin opener policy}, "\textit{enforce}", \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{url}, \textit{responseURL}, \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{origin}, \textit{response\textsc{origin}}, and \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{current context is navigation source}.

5. If the result of checking if enforcing report-only \textit{COOP} would require a browsing context group switch given \textit{isInitial\textit{about}\textit{blank}}, \textit{response\textsc{origin}}, \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{origin}, \textit{response\textsc{coope}}, and \textit{current\textsc{coope}nforcement\textit{result}}'s \textit{cross-origin opener policy}, is true, then:

   1. Set \textit{result}'s \textit{would need a browsing context group switch due to report-only} to true.

   2. If \textit{browsing\textit{context}}'s \textit{group}’s \textit{browsing context set}’s \textit{size} is greater than 1, then:
1. Queue a violation report for browsing context group switch when navigating to a COOP response with `responseCOOP`, "reporting", `responseURL`, `currentCOOPEnforcementResult`'s `url`, `currentCOOPEnforcementResult`'s `origin`, `responseOrigin`, and `referrer`.

2. Queue a violation report for browsing context group switch when navigating away from a COOP response with `currentCOOPEnforcementResult`'s cross-origin opener policy, "reporting", `currentCOOPEnforcementResult`'s `url`, `responseURL`, `currentCOOPEnforcementResult`'s `origin`, `responseOrigin`, and `currentCOOPEnforcementResult`'s current context is navigation source.

6. Return `newCOOPEnforcementResult`.

To obtain a browsing context to use for a navigation response, given a browsing contexts `browsingContext`, a sandboxing flag set `sandboxFlags`, a cross-origin opener policy `navigationCOOP`, and a cross-origin opener policy enforcement result `coopEnforcementResult`:

1. Assert: `browsingContext` is a top-level browsing context.

2. If `coopEnforcementResult`'s needs a browsing context group switch is false, then:
   1. If `coopEnforcementResult`'s would need a browsing context group switch due to report-only is true, set `browsing context`'s virtual browsing context group ID to a new unique identifier.
   2. Return `browsingContext`.

3. Let `newBrowsingContext` be the result of creating a new top-level browsing context.

4. If `navigationCOOP`'s value is "same-origin-plus-COEP", then set `newBrowsingContext`'s group's cross-origin isolation mode to either "logical" or "concrete". The choice of which is implementation-defined.

   It is difficult on some platforms to provide the security properties required by the cross-origin isolated capability. "concrete" grants access to it and "logical" does not.

5. If `sandboxFlags` is not empty, then:
   1. Assert `navigationCOOP`'s value is "unsafe-none".
   2. Assert: `newBrowsingContext`'s popup sandboxing flag set is empty.
   3. Set `newBrowsingContext`'s popup sandboxing flag set to a clone of `sandboxFlags`.

This has no effect on `browsingContext`'s **group**, unless `browsingContext` was its sole **top-level browsing context**. In that case, the user agent might delete the `browsing context group` which no longer contains any **browsing contexts**.

7. Return `newBrowsingContext`.

The impact of swapping browsing context groups following a navigation is not fully defined. It is currently under discussion in [issue #5350](https://example.com/issues/5350).

### 7.7.3 Reporting

An **accessor-accessed relationship** is an enum that describes the relationship between two **browsing contexts** between which an access happened. It can take the following values:

**accessor is opener**

The accessor **browsing context** or one of its **ancestors** is the **opener browsing context** of the accessed **browsing context**’s **top-level browsing context**.

**accessor is openee**

The accessed **browsing context** or one of its **ancestors** is the **opener browsing context** of the accessor **browsing context**’s **top-level browsing context**.

**none**

There is no opener relationship between the accessor **browsing context**, the accessor **browsing context**, or any of their **ancestors**.

To **check if an access between two browsing contexts should be reported**, given two **browsing contexts** accessor and accessed, a JavaScript property name `P`, and an **environment settings object** `environment`:

1. If `P` is not a **cross-origin accessible window property name**, then return.

2. If accessor’s **active document’s origin** or any of its ancestors’ **active document’s origins** are not **same origin** with accessor’s **top-level browsing context’s active document’s origin**, or if accessed’s **active document’s origin** or any of its ancestors’ active document’s origins are not **same origin** with accessed’s **top-level browsing context’s active document’s origin**, then return.

   This avoids leaking information about cross-origin iframes to a top level frame with cross-origin opener policy reporting.

3. If accessor’s **top-level browsing context’s virtual browsing context group ID** is accessed’s **top-level browsing context’s virtual browsing context group ID**, then return.

4. Let accessorAccessedRelationship be a new **accessor-accessed relationship** with value
5. If accessed’s top-level browsing context’s opener browsing context is accessor or an ancestor of accessor, then set accessorAccessedRelationship to accessor is opener.

6. If accessor’s top-level browsing context’s opener browsing context is accessed or an ancestor of accessed, then set accessorAccessedRelationship to accessor is openee.

7. Queue violation reports for accesses, given accessorAccessedRelationship, accessor’s top-level browsing context’s active document’s cross-origin opener policy, accessed’s top-level browsing context’s active document’s cross-origin opener policy, accessor’s active document’s URL, accessed’s active document’s URL, accessor’s top-level browsing context’s initial URL, accessed’s top-level browsing context’s initial URL, accessor’s active document’s origin, accessed’s active document’s origin, accessor’s top-level browsing context’s opener origin at creation, accessed’s top-level browsing context’s opener origin at creation, accessor’s top-level browsing context’s active document’s referrer, accessed’s top-level browsing context’s active document’s referrer, P, and environment.

To sanitize a URL to send in a report given a URL url:

1. Let sanitizedURL be a copy of url.

2. Set the username given sanitizedURL and the empty string.

3. Set the password given sanitizedURL and the empty string.

4. Return the serialization of sanitizedURL with exclude fragment set to true.

To queue a violation report for browsing context group switch when navigating to a COOP response given a cross-origin opener policy coop, a string disposition, a URL coopURL, a URL previousResponseURL, two origins coopOrigin and previousResponseOrigin, and a referrer referrer:

1. If coop’s reporting endpoint is null, return.

2. Let coopValue be coop’s value.

3. If disposition is “reporting”, then set coopValue to coop’s report-only value.

4. Let serializedReferrer be an empty string.

5. If referrer is a URL, set serializedReferrer to the serialization of referrer.

6. Let body be a new object containing the following properties:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>disposition</td>
<td>disposition</td>
</tr>
</tbody>
</table>
### 7. Queue body as "coop" for coop’s reporting endpoint with coopURL.

To queue a violation report for browsing context group switch when navigating away from a COOP response given a cross-origin opener policy coop, a string disposition, a URL coopURL, a URL nextResponseURL, two origins coopOrigin and nextResponseOrigin, and a boolean isCOOPResponseNavigationSource:

1. If coop’s reporting endpoint is null, return.
2. Let coopValue be coop’s value.
3. If disposition is "reporting", then set coopValue to coop’s report-only value.
4. Let body be a new object containing the following properties:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>disposition</td>
<td>disposition</td>
</tr>
<tr>
<td>effectivePolicy</td>
<td>coopValue</td>
</tr>
<tr>
<td>nextResponseURL</td>
<td>If coopOrigin and nextResponseOrigin are same origin or nextResponseURL isCOOPResponseNavigationSource is true, this is the sanitization of previousResponseURL, null otherwise.</td>
</tr>
<tr>
<td>type</td>
<td>&quot;navigation-from-response&quot;</td>
</tr>
</tbody>
</table>

5. Queue body as "coop" for coop’s reporting endpoint with coopURL.

To queue violation reports for accesses, given an accessor-accessed relationship accessorAccessedRelationship, two cross-origin opener policies accessorCOOP and accessedCOOP, four URLs accessorURL, accessedURL, accessorInitialURL, accessedInitialURL, four origins accessorOrigin, accessedOrigin, accessorCreatorOrigin and accessedCreatorOrigin, two referrers accessorReferrer and accessedReferrer, a string propertyName, and an environment settings object environment:

1. If coop’s reporting endpoint is null, return.
2. Let coopValue be coop’s value.
3. If disposition is "reporting", then set coopValue to coop’s report-only value.
4. If accessorAccessedRelationship is accessor is opener:

5. Otherwise, if accessorAccessedRelationship is accessor is openee:

   1. **Queue a violation report for access to the opener**, given accessorCOOP, accessorURL, accessedURL, accessorOrigin, accessedOrigin, propertyName, accessorReferrer, and environment.

6. Otherwise:

   1. **Queue a violation report for access to another window**, given accessorCOOP, accessorURL, accessedURL, accessorOrigin, accessedOrigin, propertyName, and environment.

To queue a violation report for access to the opener, given a cross-origin opener policy coop, two URLs coopURL and openerURL, two origins coopOrigin and openerOrigin, a string propertyName, a referrer referrer, and an environment settings object environment:

1. Let sourceFile, lineNumber and columnNumber be the relevant script URL and problematic position which triggered this report.

2. Let serializedReferrer be an empty string.

3. If referrer is a URL, set serializedReferrer to the serialization of referrer.

4. Let body be a new object containing the following properties:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>disposition</td>
<td>&quot;reporting&quot;</td>
</tr>
<tr>
<td>effectivePolicy</td>
<td>coop's report-only value</td>
</tr>
<tr>
<td>property</td>
<td>propertyName</td>
</tr>
<tr>
<td>openerURL</td>
<td>If coopOrigin and openerOrigin are same origin, this is the sanitization of openerURL, null otherwise.</td>
</tr>
<tr>
<td>referrer</td>
<td>serializedReferrer</td>
</tr>
</tbody>
</table>
To queue a violation report for access to an opened window, given a cross-origin opener policy `coop`, three URLs `coopURL`, `openedWindowURL` and `initialWindowURL`, three origins `coopOrigin`, `openedWindowOrigin`, and `openerInitialOrigin`, a string `propertyName`, and an environment settings object `environment`:

1. Let `sourceFile`, `lineNumber` and `columnNumber` be the relevant script URL and problematic position which triggered this report.

2. Let `body` be a new object containing the following properties:

   - **disposition**: "reporting"
   - **effectivePolicy**: `coop"s report-only value`
   - **property**: `propertyName`  
     If `coopOrigin` and `openedWindowOrigin` are same origin, this is the sanitization of `openedWindowURL`, null otherwise.
     If `coopOrigin` and `openerInitialOrigin` are same origin, this is the sanitization of `initialWindowURL`, null otherwise.
   - **openedWindowInitialURL**: `null` for openedWindowURL
   - **sourceFile**: `sourceFile`
   - **lineNumber**: `lineNumber`
   - **columnNumber**: `columnNumber`
   - **type**: "access-to-opener"

3. Queue `body` as "coop" for `coop"s reporting endpoint with `coopURL` and `environment`.

To queue a violation report for access to another window, given a cross-origin opener policy `coop`, two URLs `coopURL` and `otherURL`, two origins `coopOrigin` and `otherOrigin`, a string `propertyName`, and an environment settings object `environment`:

1. Let `sourceFile`, `lineNumber` and `columnNumber` be the relevant script URL and problematic position which triggered this report.

2. Let `body` be a new object containing the following properties:

   - **disposition**: "reporting"
   - **effectivePolicy**: `coop"s report-only value`
3. **Queue body as “coop”** for coop’s **reporting endpoint** with coopURL and environment.

To queue a violation report for access from the opener, given a **cross-origin opener policy** coop, two **URLs** coopURL and openerURL, two **origins** coopOrigin and openerOrigin, a string **propertyName**, and a **referrer** referrer:

1. If coop’s **reporting endpoint** is null, return.

2. Let **serializedReferrer** be an empty string.

3. If referrer is a **URL**, set **serializedReferrer** to the **serialization** of referrer.

4. Let **body** be a new object containing the following properties:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>disposition</td>
<td>&quot;reporting&quot;</td>
</tr>
<tr>
<td>effectivePolicy</td>
<td>coop’s <strong>report-only value</strong></td>
</tr>
<tr>
<td>property</td>
<td><strong>propertyName</strong></td>
</tr>
<tr>
<td>openerURL</td>
<td>If coopOrigin and openerOrigin are same origin, this is the <strong>sanitization</strong> of openerURL, null otherwise.</td>
</tr>
<tr>
<td>referrer</td>
<td><strong>serializedReferrer</strong></td>
</tr>
<tr>
<td>type</td>
<td>“access-to-opener”</td>
</tr>
</tbody>
</table>

5. **Queue body as “coop”** for coop’s **reporting endpoint** with coopURL.

To queue a violation report for access from an opened window, given a **cross-origin opener policy** coop, three **URLs** coopURL, openedWindowURL and initialWindowURL, three **origins** coopOrigin, openedWindowOrigin, and openerInitialOrigin, and a string **propertyName**:

1. If coop’s **reporting endpoint** is null, return.

2. Let **body** be a new object containing the following properties:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>disposition</td>
<td>&quot;reporting&quot;</td>
</tr>
<tr>
<td>effectivePolicy</td>
<td>coopValue</td>
</tr>
<tr>
<td>property</td>
<td></td>
</tr>
<tr>
<td>openerURL</td>
<td></td>
</tr>
<tr>
<td>referrer</td>
<td></td>
</tr>
<tr>
<td>type</td>
<td>&quot;access-to-opener&quot;</td>
</tr>
<tr>
<td>key</td>
<td>value</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------</td>
</tr>
<tr>
<td>property</td>
<td>coop’s report-only value</td>
</tr>
<tr>
<td>openedWindowURL</td>
<td>If coopOrigin and openedWindowOrigin are same origin, this is the sanitization of openedWindowURL, null otherwise.</td>
</tr>
<tr>
<td>openedWindowInitialURL</td>
<td>If coopOrigin and openerInitialOrigin are same origin, this is the sanitization of initialWindowURL, null otherwise.</td>
</tr>
<tr>
<td>type</td>
<td>&quot;access-to-opener&quot;</td>
</tr>
</tbody>
</table>

3. **Queue** body as "coop" for coop’s reporting endpoint with coopURL.

To queue a violation report for access from another window, given a cross-origin opener policy coop, two URLs coopURL and otherURL, two origins coopOrigin and otherOrigin, and a string propertyName:

1. If coop’s reporting endpoint is null, return.

2. Let body be a new object containing the following properties:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>disposition</td>
<td>&quot;reporting&quot;</td>
</tr>
<tr>
<td>effectivePolicy</td>
<td>coop’s report-only value</td>
</tr>
<tr>
<td>property</td>
<td>propertyName</td>
</tr>
<tr>
<td>otherURL</td>
<td>If coopOrigin and otherOrigin are same origin, this is the sanitization of otherURL, null otherwise.</td>
</tr>
<tr>
<td>type</td>
<td>access-to-opener</td>
</tr>
</tbody>
</table>

3. **Queue** body as "coop" for coop’s reporting endpoint with coopURL.

### 7.8 Cross-origin embedder policies

**MDN**

**Headers/Cross-Origin-Embedder-Policy**

Support in all current engines.

<p>| | |</p>
<table>

</tbody>
</table>

An embedder policy value is one of three strings that controls the fetching of cross-origin resources without explicit permission from resource owners.
"unsafe-none"

This is the default value. When this value is used, cross-origin resources can be fetched without giving explicit permission through the CORS protocol or the `Cross-Origin-Resource-Policy` header.

"require-corp"

When this value is used, fetching cross-origin resources requires the server’s explicit permission through the CORS protocol or the `Cross-Origin-Resource-Policy` header.

"credentialless"

When this value is used, fetching cross-origin no-CORS resources omits credentials. In exchange, an explicit `Cross-Origin-Resource-Policy` header is not required. Other requests sent with credentials require the server’s explicit permission through the CORS protocol or the `Cross-Origin-Resource-Policy` header.

Before supporting "credentialless", implementers are strongly encouraged to support both:

- Private Network Access
- Opaque Response Blocking

Otherwise, it would allow attackers to leverage the client’s network position to read non-public resources, using the cross-origin isolated capability.

An embedder policy value is compatible with cross-origin isolation if it is "credentialless" or "require-corp".

An embedder policy consists of:

- A value, which is an embedder policy value, initially "unsafe-none".
- A reporting endpoint string, initially the empty string.
- A report only value, which is an embedder policy value, initially "unsafe-none".
- A report only reporting endpoint string, initially the empty string.

The "coep" report type is a report type whose value is "coep". It is visible to ReportingObservers.

7.8.1 The headers

The `Cross-Origin-Embedder-Policy` and `Cross-Origin-Embedder-Policy-Report-Only` HTTP response header fields allow a server to declare an embedder policy for
an environment settings object. These headers are structured headers whose values must be token. [STRUCTURED-FIELDS]

The valid token values are the embedder policy values. The token may also have attached parameters; of these, the "report-to" parameter can have a valid URL string identifying an appropriate reporting endpoint. [REPORTING]

The processing model fails open (by defaulting to "unsafe-none") in the presence of a header that cannot be parsed as a token. This includes inadvertent lists created by combining multiple instances of the `Cross-Origin-Embedder-Policy` header present in a given response:

`Cross-Origin-Embedder-Policy` Final embedder policy value
---
No header delivered  "unsafe-none"
`require-corp`  "require-corp"
`unknown-value`  "unsafe-none"
`require-corp, unknown-value`  "unsafe-none"
`unknown-value, unknown-value`  "unsafe-none"
`unknown-value, require-corp`  "unsafe-none"
`require-corp, require-corp`  "unsafe-none"

(The same applies to `Cross-Origin-Embedder-Policy-Report-Only`.)

To obtain an embedder policy from a response response and an environment environment:

1. Let policy be a new embedder policy.
2. If environment is a non-secure context, then return policy.
3. Let parsedItem be the result of getting a structured field value with `Cross-Origin-Embedder-Policy` and "item" from response's header list.
4. If parsedItem is non-null and parsedItem[0] is compatible with cross-origin isolation:
   1. Set policy's value to parsedItem[0].
   2. If parsedItem[1]["report-to"] exists, then set policy's endpoint to parsedItem[1]["report-to"].
5. Set parsedItem to the result of getting a structured field value with `Cross-Origin-Embedder-Policy-Report-Only` and "item" from response's header list.
6. If parsedItem is non-null and parsedItem[0] is compatible with cross-origin isolation:
   1. Set policy's value to parsedItem[0].
2. If `parsedItem[1]["report-to"]` exists, then set policy’s endpoint to `parsedItem[1]["report-to"]`.

7. Return `policy`.

### 7.8.2 Embedder policy checks

To check a navigation response’s adherence to its embedder policy given a response `response`, a browsing context `target`, and an embedder policy `responsePolicy`:

1. If `target` is not a child browsing context, then return true.

2. Let `parentPolicy` be `target`’s container document’s policy container’s embedder policy.

3. If `parentPolicy`’s report-only value is compatible with cross-origin isolation and `responsePolicy`’s value is not, then queue a cross-origin embedder policy inheritance violation with `response`, "navigation", `parentPolicy`’s report only reporting endpoint, "reporting", and `target`’s container document’s relevant settings object.

4. If `parentPolicy`’s value is not compatible with cross-origin isolation or `responsePolicy`’s value is compatible with cross-origin isolation, then return true.

5. Queue a cross-origin embedder policy inheritance violation with `response`, "navigation", `parentPolicy`’s reporting endpoint, "enforce", and `target`’s container document’s relevant settings object.

6. Return false.

To check a global object’s embedder policy given a `WorkerGlobalScope` `workerGlobalScope`, an environment settings object `owner`, and a response `response`:

1. If `workerGlobalScope` is not a `DedicatedWorkerGlobalScope` object, then return true.

2. Let `policy` be `workerGlobalScope`’s embedder policy.

3. Let `ownerPolicy` be `owner`’s policy container’s embedder policy.

4. If `ownerPolicy`’s report-only value is compatible with cross-origin isolation and policy’s value is not, then queue a cross-origin embedder policy inheritance violation with `response`, "worker initialization", owner’s policy’s report only reporting endpoint, "reporting", and `owner`.

5. If `ownerPolicy`’s value is not compatible with cross-origin isolation or policy’s value is compatible with cross-origin isolation, then return true.

6. Queue a cross-origin embedder policy inheritance violation with `response`, "worker
initialization", owner’s policy’s reporting endpoint, "enforce", and owner.

7. Return false.

To queue a cross-origin embedder policy inheritance violation given a response response, a string type, a string endpoint, a string disposition, and an environment settings object settings:

1. Let serialized be the result of serializing a response URL for reporting with response.

2. Let body be a new object containing the following properties:

   key     value
   type    type
   blockedURL serialized
   disposition disposition

3. Queue body as the "coep" report type for endpoint on settings.

7.9 Policy containers

A policy container is a struct containing policies that apply to a Document, a WorkerGlobalScope, or a WorkletGlobalScope. It has the following items:

- A CSP list, which is a CSP list. It is initially empty.
- An embedder policy, which is an embedder policy. It is initially a new embedder policy.
- A referrer policy, which is a referrer policy. It is initially the default referrer policy.

Move other policies into the policy container.

To clone a policy container given a policy container policyContainer:

1. Let clone be a new policy container.

2. For each policy in policyContainer’s CSP list, append a copy of policy into clone’s CSP list.

3. Set clone’s embedder policy to a copy of policyContainer’s embedder policy.

4. Set clone’s referrer policy to policyContainer’s referrer policy.

5. Return clone.

To determine whether a URL url requires storing the policy container in history:

1. If url’s scheme is “blob”, then return false.
2. If `url` is `about:srcdoc`, then return false.

3. If `url` is `local`, then return true.

4. Return false.

To create a policy container from a fetch response given a response `response` and an environment-or-null `environment`:

1. If `response`'s URL’s scheme is "blob", then return a clone of `response`'s URL’s blob URL entry’s environment’s policy container.

2. Let `result` be a new policy container.

3. Set `result`’s CSP list to the result of parsing a response’s Content Security Policies given `response`.

4. If `environment` is non-null, then set `result`’s embedder policy to the result of obtaining an embedder policy given `response` and `environment`. Otherwise, set it to “unsafe-none”.

5. Set `result`’s referrer policy to the result of parsing the `Referrer-Policy` header given `response`. [REFERRERPOLICY]

6. Return `result`.

To determine navigation params policy container given a URL `responseURL` and four policy container-or-nulls `historyPolicyContainer`, `initiatorPolicyContainer`, `parentPolicyContainer`, and `responsePolicyContainer`:

1. If `historyPolicyContainer` is not null, then:
   1. Assert: `responseURL` requires storing the policy container in history.
   2. Return a clone of `historyPolicyContainer`.

2. If `responseURL` is `about:srcdoc`, then:
   1. Assert: `parentPolicyContainer` is not null.
   2. Return a clone of `parentPolicyContainer`.

3. If `responseURL` is `local` and `initiatorPolicyContainer` is not null, then return a clone of `initiatorPolicyContainer`.

4. If `responsePolicyContainer` is not null, then return `responsePolicyContainer`.

5. Return a new policy container.
To initialize a worker global scope's policy container given a `WorkerGlobalScope` `workerGlobalScope`, a `response` `response`, and an `environment` `environment`:

1. If `workerGlobalScope`'s `url` is local but its `scheme` is not “blob”:
   1. Assert: `workerGlobalScope`'s `owner set`'s `size` is 1.
   2. Set `workerGlobalScope`'s `policy container` to a clone of `workerGlobalScope`'s `owner set[0]`'s relevant settings object's `policy container`.

2. Otherwise, set `workerGlobalScope`'s `policy container` to the result of creating a policy container from a fetch response given `response` and `environment`.

7.10 Session history and navigation

7.10.1 Browsing sessions

A `browsing session` is ... See whatwg/html issue #4782 and whatwg/html issue #5350 for defining `browsing session`. It is roughly analogous to a top-level `browsing context` except that it cannot be replaced due to a `Cross-Origin-Opener-Policy` header or navigation.

A top-level `browsing context` has an associated `browsing session` which is a `browsing session`.

The `browsing session` of an `environment settings object` `environment` is the result of running these steps:

1. Assert: `environment` has a `responsible document`.

2. Return `environment`'s `responsible document`'s `browsing context`'s top-level browsing context's `browsing session`.

7.10.2 The session history of browsing contexts

The sequence of `Document`s in a `browsing context` is its `session history`. Each `browsing context`, including child `browsing contexts`, has a distinct session history. A `browsing context`'s session history consists of a flat list of `session history entries`.

Each `Document` object in a `browsing context`'s `session history` is associated with a unique `History` object which must all model the same underlying `session history`.

The `history` getter steps are to return this’s associated `Document`’s `History` instance.

A `session history entry` is a `struct` with the following `items`:

- `URL`, a `URL`
Each entry, when first created, has a Document for its document. However, when a Document is not active, it’s possible for it to be discarded to free resources. The URL and other data in the session history entry is then used to bring a new Document into being to take the place of the original, in the case where the user agent finds itself having to navigate to the entry.

- **serialized state**, which is serialized state or null, initially null
- **policy container**, a policy container or null
- **scroll restoration mode**, a scroll restoration mode, initially "auto"
- **scroll position data**, which is scroll position data for the document’s restorable scrollable regions
- **browsing context name**, a browsing context name or null, initially null
- **persisted user state**, which is implementation-defined, initially null

For example, some user agents might want to persist the values of form controls.

User agents that persist the value of form controls are encouraged to also persist their directionality (the value of the element’s dir attribute). This prevents values from being displayed incorrectly after a history traversal when the user had originally entered the values with an explicit, non-default directionality.

Serialized state is a serialization (via StructuredSerializeForStorage) of an object representing a user interface state. We sometimes informally refer to "state objects", which are the objects representing user interface state supplied by the author, or alternately the objects created by deserializing (via StructuredDeserialize) serialized state.

Pages can add serialized state to the session history. These are then deserialized and returned to the script when the user (or script) goes back in the history, thus enabling authors to use the “navigation” metaphor even in one-page applications.

Serialized state is intended to be used for two main purposes: first, storing a preparsed description of the state in the URL so that in the simple case an author doesn’t have to do the parsing (though one would still need the parsing for handling URLs passed around by users, so it’s only a minor optimization). Second, so that the author can store state that one wouldn’t store in the URL because it only applies to the current Document instance and it would have to be reconstructed if a new Document were opened.

An example of the latter would be something like keeping track of the precise coordinate from which a popup div was made to animate, so that if the user goes back, it can be made to animate to the same location. Or alternatively, it could be used to keep a pointer into a cache of
data that would be fetched from the server based on the information in the URL, so that when
going back and forward, the information doesn’t have to be fetched again.

A scroll restoration mode indicates whether the user agent should restore the persisted scroll
position (if any) when traversing to an entry. A scroll restoration mode is one of the following:

"auto"

The user agent is responsible for restoring the scroll position upon navigation.

"manual"

The page is responsible for restoring the scroll position and the user agent does not attempt
to do so automatically.

Several contiguous entries in a session history can share the same document. This can occur
when the initial entry is reached via normal navigation, and the following entry is added via
history.pushState(). Or it can occur via navigation to a fragment.

All entries that share the same document (and that are therefore merely different states of one
particular document) are contiguous by definition.

User agents may discard the documents of entries with non-null documents, as long as the
following conditions are met:

- They must not discard the document of the current entry.

- They must not discard any Document objects which are referenced from script.

Apart from these restrictions, this standard does not specify when user agents should discard an
entry’s document, versus keeping it cached.

Discarding a Document will set the corresponding document item of any session history entries
to null. Subsequent navigations to those entries will result in the creation of a new Document
object, and set the document item to it.

At any point, one of the entries in the session history is the current entry. This is the entry
representing the active document of the browsing context. Which entry is the current entry is
changed by the algorithms defined in this specification, e.g., during session history traversal.

The current entry is usually the initial entry created upon navigation. However, it can also be
one of the contiguous entries that share the same document, as described above.

Each Document in a browsing context can also have a latest entry. This is the entry for that
Document to which the browsing context’s session history was most recently traversed. When
a Document is created, it initially has no latest entry.

Opera3+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung

Internet1.0+Opera Android10.1+
Returns the number of entries in the joint session history.

`window.history.scrollRestoration [ = value ]`

Supported in all current engines.

Firefox 46 + Safari 11 + Chrome 46 + Opera 33 + Edge 79 +

Edge (Legacy) No Internet Explorer No

Firefox Android 46 + Safari iOS 11 + Chrome Android 46 + WebView Android 46 + Samsung Internet 5.0 + Opera Android 33 +

Returns the scroll restoration mode of the current entry in the session history.

Can be set, to change the scroll restoration mode of the current entry in the session history.

`window.history.state`

Supported in all current engines.

Firefox 46 + Safari 6 + Chrome 19 +

Opera 12.1 + Edge 79 +

Edge (Legacy) 12 + Internet Explorer 10 +

Firefox Android 46 + Safari iOS 6 + Chrome Android 25 + WebView Android 37 + Samsung Internet 1.5 + Opera Android 12.1 +

Returns the current serialized state, deserialized into an object.

`window.history.go([ delta ])`

Supported in all current engines.
Goes back or forward the specified number of steps in the joint session history.

A zero delta will reload the current page.

If the delta is out of range, does nothing.

```javascript
window.history.back()
```

History/back

Support in all current engines.

Goes back one step in the joint session history.

If there is no previous page, does nothing.

```javascript
window.history.forward()
```

History/forward

Support in all current engines.
`window.history.pushState(data, "")`  

**History/pushState**

Support in all current engines.

Updates the data stored in the current session history entry to `data`.

(The second parameter exists for historical reasons, and cannot be omitted; passing the
window.history.replaceState(data, "", url)

Updates the data stored in the current session history entry to data, and its URL to url.

If the current Document cannot have its URL rewritten to url, a "SecurityError" DOMException will be thrown.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

The joint session history of a top-level browsing context is the union of all the session histories of all browsing contexts of all the fully active Document objects that share that top-level browsing context, with all the entries that are current entries in their respective session histories removed except for the current entry of the joint session history.

The current entry of the joint session history is the entry that most recently became a current entry in its session history.

Entries in the joint session history are ordered chronologically by the time they were added to their respective session histories. Each entry has an index; the earliest entry has index 0, and the subsequent entries are numbered with consecutively increasing integers (1, 2, 3, etc.).

Since each Document in a browsing context might have a different event loop, the actual state of the joint session history can be somewhat nebulous. For example, two sibling iframe elements could both traverse from one unique origin to another at the same time, so their precise order might not be well-defined; similarly, since they might only find out about each other later, they might disagree about the length of the joint session history.

Each History object has state, initially null.

The length getter steps are:

1. If this’s associated Document is not fully active, then throw a "SecurityError" DOMException.

2. Return the number of entries in the top-level browsing context’s joint session history.

The actual entries are not accessible from script.

The scrollRestoration getter steps are:

1. If this’s associated Document is not fully active, then throw a "SecurityError" DOMException.

2. Return this’s session history’s current entry’s scroll restoration mode.
The `scrollRestoration` setter steps are:

1. If this’s associated `Document` is not fully active, then throw a “`SecurityError`” `DOMException`.
2. Set this’s session history’s current entry’s scroll restoration mode to the given value.

The `state` getter steps are:

1. If this’s associated `Document` is not fully active, then throw a “`SecurityError`” `DOMException`.
2. Return this’s `state`.

The `go(delta)` method steps are:

1. Let `document` be this’s associated `Document`.
2. If `document` is not fully active, then throw a “`SecurityError`” `DOMException`.
3. If `delta` is 0, then act as if the `location.reload()` method was called, and return.
4. Traverse the history by a delta with `delta` and `document`’s browsing context.

The `back()` method steps are:

1. Let `document` be this’s associated `Document`.
2. If `document` is not fully active, then throw a “`SecurityError`” `DOMException`.
3. Traverse the history by a delta with −1 and `document`’s browsing context.

The `forward()` method steps are:

1. Let `document` be this’s associated `Document`.
2. If `document` is not fully active, then throw a “`SecurityError`” `DOMException`.
3. Traverse the history by a delta with +1 and `document`’s browsing context.

Each top-level browsing context has a session history traversal queue, initially empty, to which tasks can be added.

Each top-level browsing context, when created, must begin running the following algorithm, known as the session history event loop for that top-level browsing context, in parallel:

1. Wait until this top-level browsing context’s session history traversal queue is not empty.
2. Pull the first task from this top-level browsing context’s session history traversal queue, and execute it.

3. Return to the first step of this algorithm.

The session history event loop helps coordinate cross-browsing-context transitions of the joint session history: since each browsing context might, at any particular time, have a different event loop (this can happen if the user navigates from example.com to shop.example), transitions would otherwise have to involve cross-event-loop synchronization.

To traverse the history by a delta given delta and browsing context source browsing context, the user agent must append a task to this top-level browsing context’s session history traversal queue, the task consisting of running the following steps:

1. If the index of the current entry of the joint session history plus delta is less than zero or greater than or equal to the number of items in the joint session history, then return.

2. Let specified entry be the entry in the joint session history whose index is the sum of delta and the index of the current entry of the joint session history.

3. Let specified browsing context be the browsing context of the specified entry.

4. If source browsing context is not allowed to navigate specified browsing context, then return.

5. If the specified browsing context’s active document’s unload counter is greater than 0, then return.

6. Queue a global task on the history traversal task source given specified browsing context’s active window to perform the following steps:

   1. If there is an ongoing attempt to navigate specified browsing context that has not yet matured (i.e. it has not passed the point of making its Document the active document), then cancel that attempt to navigate the browsing context.

   2. If the specified browsing context’s active document is not the same Document as the Document of the specified entry, then run these substeps:

      1. Prompt to unload the active document of the specified browsing context. If the user refused to allow the document to be unloaded, then return.

      2. Unload the active document of the specified browsing context.

      3. Traverse the history of the specified browsing context to the specified entry with explicitHistoryNavigation set to true.

When the user navigates through a browsing context, e.g. using a browser’s back and forward
buttons, the user agent must traverse the history by a delta with a delta equivalent to the action specified by the user and the browsing context being operated on.

The **URL and history update steps**, given a Document document, a URL newURL, an optional serialized state-or-null serializedData (default null), and an optional boolean isPush (default false), are:

1. Let browsingContext be document's browsing context.

2. If isPush is true, then:
   1. Remove all the entries in browsingContext's session history after the current entry. If the current entry is the last entry in the session history, then no entries are removed.

   This doesn’t necessarily have to affect the user agent’s user interface.

   2. Remove any tasks queued by the history traversal task source that are associated with any Document objects in the top-level browsing context’s document family.

   3. Save persisted state to the current entry.

   4. Add a session history entry entry to browsingContext’s session history, after the current entry, with
      - newURL as the URL;
      - document as the document;
      - serializedData as the serialized state;
      - the scroll restoration mode of the current entry in the session history as the scroll restoration mode.

   5. Update the current entry to be this newly added entry.

3. Otherwise:

   1. Let entry be browsingContext’s session history’s current entry.

   2. Set entry’s URL to newURL.

   3. If serializedData is not null, then set entry’s serialized state to serializedData.

   4. Update entry so that it represents a GET request, if it currently represents a non-GET request (e.g. it was the result of a POST submission).
What does this mean? This is not a part of the definition of session history entry.

4. Set document’s URL to newURL.

Since this is neither a navigation of the browsing context nor a history traversal, it does not cause a hashchange event to be fired.

5. If serializedData is not null, then:

   1. Let state be StructuredDeserialize(serializedData, document’s relevant Realm). If this throws an exception, catch it, ignore the exception, and set state to null.

   2. Set document’s History instance’s state to state.

6. Set the current entry’s document’s latest entry to the current entry.

The pushState(data, unused, url) method steps are to run the shared history push/replace state steps given this, data, url, and true.

The replaceState(data, unused, url) method steps are to run the shared history push/replace state steps given this, data, url, and false.

The shared history push/replace state steps, given a History history, a value data, a scalar value string—or-null url, and a boolean isPush, are:

1. Let document be history’s associated Document.

2. If document is not fully active, then throw a “SecurityError” DOMException.

3. Optionally, return. (For example, the user agent might disallow calls to these methods that are invoked on a timer, or from event listeners that are not triggered in response to a clear user action, or that are invoked in rapid succession.)

4. Let serializedData be StructuredSerializeForStorage(data). Rethrow any exceptions.

5. Let newURL be the session history’s current entry’s URL.

6. If url is not null, then:

   1. Parse url, relative to the relevant settings object of history.

   2. If that fails, then throw a “SecurityError” DOMException.

   3. Set newURL to the resulting URL record.

   4. If document cannot have its URL rewritten to newURL, then throw a “SecurityError” DOMException.
7. Run the **URL and history update steps** given *document* and *newURL*, with *serializedData* set to *serializedData* and *isPush* set to *isPush*.

User agents may limit the number of state objects added to the session history per page. If a page hits the *implementation-defined* limit, user agents must remove the entry immediately after the first entry for that *Document* object in the session history after having added the new entry. (Thus the state history acts as a FIFO buffer for eviction, but as a LIFO buffer for navigation.)

A *Document* document **can have its URL rewritten** to a **URL** *targetURL* if the following algorithm returns true:

1. Let *documentURL* be *document*’s **URL**.

2. If *targetURL* and *documentURL* differ in their **scheme**, **username**, **password**, **host**, or **port** components, then return false.

3. If *targetURL*’s **scheme** is an **HTTP(S)** scheme, then return true. (Differences in **path**, **query**, and **fragment** are allowed for **http:** and **https:** **URLs**.)

4. If *targetURL*’s **scheme** is “**file**”, and *targetURL* and *documentURL* differ in their **path** component, then return false. (Differences in **query** and **fragment** are allowed for **file:** **URLs**.)

5. If *targetURL* and *documentURL* differ in their **path** component or **query** components, then return false. (Only differences in **fragment** are allowed for other types of **URLs**.)

6. Return true.

<table>
<thead>
<tr>
<th><em>document</em>’s <strong>URL</strong></th>
<th><em>targetURL</em></th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="https://example.com/home">https://example.com/home</a></td>

</tr>
</tbody>
</table>
Note how only the URL of the Document matters, and not its origin. They can mismatch in cases like about:blank Document with inherited origins, in sandboxed iframe, or when the document.domain setter has been used.

Consider a game where the user can navigate along a line, such that the user is always at some coordinate, and such that the user can bookmark the page corresponding to a particular coordinate, to return to it later.

A static page implementing the x=5 position in such a game could look like the following:

```html
<!DOCTYPE HTML>
<!-- this is https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate 5 on the line.</p>
<a href="?x=6">Advance to 6</a> or
<a href="?x=4">retreat to 4</a>?
</p>
```

The problem with such a system is that each time the user clicks, the whole page has to be reloaded. Here instead is another way of doing it, using script:

```html
<!DOCTYPE HTML>
<!-- this starts off as https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate <span id="coord">5</span> on the line.</p>
<a href="?x=6" onclick="go(1); return false;">Advance to 6</a> or
<a href="?x=4" onclick="go(-1); return false;">retreat to 4</a>?
</p>
```
In systems without script, this still works like the previous example. However, users that do have script support can now navigate much faster, since there is no network access for the same experience. Furthermore, contrary to the experience the user would have with just a naïve script-based approach, bookmarking and navigating the session history still work.

In the example above, the `data` argument to the `pushState()` method is the same information as would be sent to the server, but in a more convenient form, so that the script doesn’t have to parse the URL each time the user navigates.

Most applications want to use the same `scroll restoration mode` value for all of their history entries. To achieve this they can set the `scrollRestoration` attribute as soon as possible (e.g., in the first `script` element in the document’s `head` element) to ensure that any entry added to the history session gets the desired scroll restoration mode.

```html
<head>
  <script>
    if ('scrollRestoration' in history) 
      history.scrollRestoration = 'manual';
  </script>
</head>
```

7.10.4 Implementation notes for session history

*This section is non-normative.*

The `History` interface is not meant to place restrictions on how implementations represent the
session history to the user.

For example, session history could be implemented in a tree-like manner, with each page having multiple “forward” pages. This specification doesn’t define how the linear list of pages in the *history* object are derived from the actual session history as seen from the user’s perspective.

Similarly, a page containing two *iframes* has a *history* object distinct from the *iframes’* *history* objects, despite the fact that typical web browsers present the user with just one “Back” button, with a session history that interleaves the navigation of the two inner frames and the outer page.

**Security:** It is suggested that to avoid letting a page “hijack” the history navigation facilities of a UA by abusing `pushState()`, the UA provide the user with a way to jump back to the previous page (rather than just going back to the previous state). For example, the back button could have a drop down showing just the pages in the session history, and not showing any of the states. Similarly, an aural browser could have two “back” commands, one that goes back to the previous state, and one that jumps straight back to the previous page.

For both `pushState()` and `replaceState()`, user agents are encouraged to prevent abuse of these APIs via too-frequent calls or over-large state objects. As detailed above, the algorithm explicitly allows user agents to ignore any such calls when appropriate.

Each **Window** object is associated with a unique instance of a **Location** object, allocated when the **Window** object is created.

The **Location** exotic object is defined through a mishmash of IDL, invocation of JavaScript internal methods post-creation, and overridden JavaScript internal methods. Coupled with its scary security policy, please take extra care while implementing this excrescence.

To create a **Location** object, run these steps:

1. Let `location` be a new **Location** platform object.
2. Let `valueOf` be `location`'s relevant Realm.\[[\%Object.prototype.valueOf\]]\).
3. Perform `location.\[[\%DefineOwnProperty\]\]`("valueOf", { [[Value]]: valueOf, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }).
4. Perform `location.\[[\%DefineOwnProperty\]\] @@toPrimitive`, { [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }).
5. Set the value of the [[DefaultProperties]] internal slot of `location` to `location.\[[\%OwnPropertyKeys\]\]()`.
6. Return `location`.

The addition of `valueOf` and `@@toPrimitive` own data properties, as well as the fact that all of **Location**’s IDL attributes are marked [LegacyUnforgeable], is required by legacy code that consulted the **Location** interface, or stringified it, to determine the document URL, and then used it in a security-sensitive way. In particular, the `valueOf`, `@@toPrimitive`, and [LegacyUnforgeable] stringifier mitigations ensure that code such as `foo[location] = bar` or `location + ""` cannot be misdirected.

```
document.location [ = value ]
window.location [ = value ]
```

Returns a **Location** object with the current page’s location.

Can be set, to navigate to another page.
The `Document` object’s `location` getter steps are to return this’s relevant global object’s `Location` object, if this is fully active, and null otherwise.

The `Window` object’s `location` getter steps are to return this’s `Location` object.

`Location` objects provide a representation of the URL of the active document of their `Document`’s browsing context, and allow the current entry of the browsing context’s session history to be changed, by adding or replacing entries in the history object.

```javascript
[Exposed=Window]
interface Location {
  // but see also additional creation steps and overridden
  [LegacyUnforgeable] stringifier attribute USVString href;
  [LegacyUnforgeable] readonly attribute USVString origin;
  [LegacyUnforgeable] attribute USVString protocol;
  [LegacyUnforgeable] attribute USVString host;
  [LegacyUnforgeable] attribute USVString hostname;
  [LegacyUnforgeable] attribute USVString port;
  [LegacyUnforgeable] attribute USVString pathname;
  [LegacyUnforgeable] attribute USVString search;
  [LegacyUnforgeable] attribute USVString hash;

  [LegacyUnforgeable] undefined assign(USVString url);
  [LegacyUnforgeable] undefined replace(USVString url);
  [LegacyUnforgeable] undefined reload();

  [LegacyUnforgeable, SameObject] readonly attribute DOMStringList ancestorOrigins;
};
```

`location.toString()`
`location.href`

Support in all current engines.

`Location/toString`

Support in all current engines.
Returns the `Location` object’s URL.

Can be set, to navigate to the given URL.

```javascript
location.origin
```

Location/origin

Support in all current engines.

Firefox21+Safari5.1+Chrome8+
Opera15+Edge79+
Edge (Legacy)12+Internet Explorer11
Firefox Android21+Safari iOS5+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android14+

Returns the `Location` object’s URL’s origin.

```javascript
location.protocol
```

Location/protocol

Support in all current engines.

Firefox1+Safari1+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer3+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android12.1+

Returns the `Location` object’s URL’s scheme.

Can be set, to navigate to the same URL with a changed scheme.

```javascript
location.host
```

✔️MDN
Returns the `Location` object’s URL’s host and port (if different from the default port for the scheme).

Can be set, to navigate to the same URL with a changed host and port.

```javascript
location.hostname
```

Returns the `Location` object’s URL’s host.

Can be set, to navigate to the same URL with a changed host.

```javascript
location.port
```

Returns the `Location` object’s URL’s port.
Can be set, to navigate to the same URL with a changed port.

`location.pathname`

Location/pathname

Support in all current engines.

Firefox1+Safari1+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer3+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android12.1+

Returns the `Location` object’s URL’s path.

Can be set, to navigate to the same URL with a changed path.

`location.search`

Location/search

Support in all current engines.

Firefox1+Safari1+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer3+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android12.1+

Returns the `Location` object’s URL’s query (includes leading “?” if non-empty).

Can be set, to navigate to the same URL with a changed query (ignores leading “?”).

`location.hash`

Location/hash

Support in all current engines.

Firefox1+Safari1+Chrome1+
Opera12.1+Edge79+
Returns the `Location` object’s URL’s fragment (includes leading “#” if non-empty).

Can be set, to navigate to the same URL with a changed fragment (ignores leading “#”).

```javascript
location.assign(url)
```

Support in all current engines.

```javascript
location.replace(url)
```

Support in all current engines.

```javascript
location.reload()
```

Support in all current engines.
Reloads the current page.

```javascript
location.ancestorOrigins
```

MDN

Location/ancestorOrigins

Returns a `DOMStringList` object listing the origins of the ancestor browsing contexts, from the parent browsing context to the top-level browsing context.

A `Location` object has an associated `relevant Document`, which is this `Location` object’s relevant global object’s browsing context’s active document, if this `Location` object’s relevant global object’s browsing context is non-null, and null otherwise.

A `Location` object has an associated `url`, which is this `Location` object’s `relevant Document`’s `URL`, if this `Location` object’s `relevant Document` is non-null, and `about:blank` otherwise.

A `Location` object has an associated `ancestor origins list`. When a `Location` object is created, its `ancestor origins list` must be set to a `DOMStringList` object whose associated list is the list of strings that the following steps would produce:

1. Let `output` be a new list of strings.

2. Let `current` be the `browsing context` of the `Document` with which this `Location` object is associated.

3. Loop: If `current` has no `parent browsing context`, jump to the step labeled `end`.

4. Let `current` be `current`’s `parent browsing context`.

5. Append the serialization of `current`’s active document’s `origin` to `output`.

6. Return to the step labeled `loop`. 
7. *End*: Return *output*.

To *Location*-object *navigate*, given a *URL* *url* and an optional *history handling behavior* *historyHandling* (default "default"):

1. Let *browsingContext* be this *Location* object’s relevant global object’s *browsing context*.
2. Let *sourceBrowsingContext* be the incumbent global object’s *browsing context*.
3. If *browsingContext* is still on its initial *about:blank Document*, then set *historyHandling* to "replace".
4. If this *Location* object’s relevant *Document* is not yet completely loaded, and the incumbent global object does not have *transient activation*, then set *historyHandling* to "replace".
5. Navigate *browsingContext* to *url*, with *exceptionsEnabled* set to true, *historyHandling* set to *historyHandling*, and the source browsing context set to *sourceBrowsingContext*.

The *href* getter steps are:

1. If this’s relevant *Document* is non-null and its origin is not same origin-domain with the entry settings object’s origin, then throw a "SecurityError" DOMException.
2. Return this’s *url*, serialized.

The *href* setter steps are:

1. If this’s relevant *Document* is null, then return.
2. Parse the given value relative to the entry settings object. If that failed, throw a *TypeError* exception.
3. *Location*-object *navigate* given the resulting URL record.

The *href* setter intentionally has no security check.

The *origin* getter steps are:

1. If this’s relevant *Document* is non-null and its origin is not same origin-domain with the entry settings object’s origin, then throw a "SecurityError" DOMException.
2. Return the serialization of this’s *url*’s origin.

The *protocol* getter steps are:
1. If this’s relevant Document is non-null and its origin is not same origin-domain with the entry settings object’s origin, then throw a “SecurityError” DOMException.

2. Return this’s url’s scheme, followed by “:”.

The protocol setter steps are:

1. If this’s relevant Document is null, then return.

2. If this’s relevant Document’s origin is not same origin-domain with the entry settings object’s origin, then throw a “SecurityError” DOMException.

3. Let copyURL be a copy of this’s url.

4. Let possibleFailure be the result of basic URL parsing the given value, followed by “:”, with copyURL as url and scheme start state as state override.

Because the URL parser ignores multiple consecutive colons, providing a value of “https:” (or even “https:::”) is the same as providing a value of “https”.

5. If possibleFailure is failure, then throw a “SyntaxError” DOMException.

6. If copyURL’s scheme is not an HTTP(S) scheme, then terminate these steps.

7. Location-object navigate to copyURL.

The host getter steps are:

1. If this’s relevant Document is non-null and its origin is not same origin-domain with the entry settings object’s origin, then throw a “SecurityError” DOMException.

2. Let url be this’s url.

3. If url’s host is null, return the empty string.

4. If url’s port is null, return url’s host, serialized.

5. Return url’s host, serialized, followed by “:” and url’s port, serialized.

The host setter steps are:

1. If this’s relevant Document is null, then return.

2. If this’s relevant Document’s origin is not same origin-domain with the entry settings object’s origin, then throw a “SecurityError” DOMException.

3. Let copyURL be a copy of this’s url.
4. If `copyURL` has an opaque path, then return.

5. Basic URL parse the given value, with `copyURL` as `url` and `host state` as `state override`.

6. `[location]-object navigate` to `copyURL`.

The `hostname` getter steps are:

1. If this’s relevant `Document` is non-null and its `origin` is not same origin-domain with the entry settings object’s `origin`, then throw a “SecurityError” `DOMException`.

2. If this’s `url`’s `host` is null, return the empty string.

3. Return this’s `url`’s `host`, serialized.

The `hostname` setter steps are:

1. If this’s relevant `Document` is null, then return.

2. If this’s relevant `Document`’s `origin` is not same origin-domain with the entry settings object’s `origin`, then throw a “SecurityError” `DOMException`.

3. Let `copyURL` be a copy of this’s `url`.

4. If `copyURL` has an opaque path, then return.

5. Basic URL parse the given value, with `copyURL` as `url` and `hostname state` as `state override`.

6. `[location]-object navigate` to `copyURL`.

The `port` getter steps are:

1. If this’s relevant `Document` is non-null and its `origin` is not same origin-domain with the entry settings object’s `origin`, then throw a “SecurityError” `DOMException`.

2. If this’s `url`’s `port` is null, return the empty string.

3. Return this’s `url`’s `port`, serialized.

The `port` setter steps are:

1. If this’s relevant `Document` is null, then return.

2. If this’s relevant `Document`’s `origin` is not same origin-domain with the entry settings object’s `origin`, then throw a “SecurityError” `DOMException`.

3. Let `copyURL` be a copy of this’s `url`.
4. If `copyURL` cannot have a username/password/port, then return.

5. If the given value is the empty string, then set `copyURL`'s `port` to null.

6. Otherwise, basic URL parse the given value, with `copyURL` as `url` and `port state` as `state override`.

7. **Location**-object navigate to `copyURL`.

The **pathname** getter steps are:

1. If this's relevant **Document** is non-null and its `origin` is not same origin-domain with the entry settings object’s `origin`, then throw a “`SecurityError`” `DOMException`.

2. Return the result of `URL path serializing` this **Location** object’s `url`.

The **pathname** setter steps are:

1. If this’s relevant **Document** is null, then return.

2. If this’s relevant **Document**’s `origin` is not same origin-domain with the entry settings object’s `origin`, then throw a “`SecurityError`” `DOMException`.

3. Let `copyURL` be a copy of this’s `url`.

4. If `copyURL` has an opaque path, then return.

5. Set `copyURL`’s `path` to the empty list.

6. Basic URL parse the given value, with `copyURL` as `url` and `path start state` as `state override`.

7. **Location**-object navigate to `copyURL`.

The **search** getter steps are:

1. If this’s relevant **Document** is non-null and its `origin` is not same origin-domain with the entry settings object’s `origin`, then throw a “`SecurityError`” `DOMException`.

2. If this’s `url`’s `query` is either null or the empty string, return the empty string.

3. Return ”?”, followed by this’s `url`’s `query`.

The **search** setter steps are:

1. If this’s relevant **Document** is null, then return.

2. If this’s relevant **Document**’s `origin` is not same origin-domain with the entry settings
object’s origin, then throw a "SecurityError" DOMException.

3. Let copyURL be a copy of this’s url.

4. If the given value is the empty string, set copyURL’s query to null.

5. Otherwise, run these substeps:
   1. Let input be the given value with a single leading “?” removed, if any.
   2. Set copyURL’s query to the empty string.
   3. Basic URL parse input, with null, the relevant Document’s document’s character encoding, copyURL as url, and query state as state override.

6. Location-object navigate to copyURL.

The hash getter steps are:
   1. If this’s relevant Document is non-null and its origin is not same origin-domain with the entry settings object’s origin, then throw a "SecurityError" DOMException.
   2. If this’s url’s fragment is either null or the empty string, return the empty string.
   3. Return "#", followed by this’s url’s fragment.

The hash setter steps are:
   1. If this’s relevant Document is null, then return.
   2. If this’s relevant Document’s origin is not same origin-domain with the entry settings object’s origin, then throw a "SecurityError" DOMException.
   3. Let copyURL be a copy of this’s url.
   4. Let input be the given value with a single leading "#" removed, if any.
   5. Set copyURL’s fragment to the empty string.
   6. Basic URL parse input, with copyURL as url and fragment state as state override.
   7. Location-object navigate to copyURL.

Unlike the equivalent API for the a and area elements, the hash setter does not special case the empty string, to remain compatible with deployed scripts.

The assign(url) method steps are:
1. If this’s relevant Document is null, then return.

2. If this’s relevant Document’s origin is not same origin-domain with the entry settings object’s origin, then throw a "SecurityError" DOMException.

3. Parse url relative to the entry settings object. If that failed, throw a "SyntaxError" DOMException.

4. Location-object navigate given the resulting URL record.

The replace(url) method steps are:

1. If this’s relevant Document is null, then return.

2. Parse url relative to the entry settings object. If that failed, throw a "SyntaxError" DOMException.

3. Location-object navigate given the resulting URL record and "replace".

The replace() method intentionally has no security check.

The reload() method steps are to run the appropriate steps from the following list:

If this’s relevant Document is null

Return.

If this’s relevant Document’s origin is not same origin-domain with the entry settings object’s origin

Throw a "SecurityError" DOMException.

If the currently executing task is the dispatch of a resize event in response to the user resizing the browsing context

Repaint the browsing context and return.

If the browsing context’s active document is an iframe srcdoc document

Reprocess the iframe attributes of the browsing context’s container.

Otherwise

Navigate the browsing context to this’s relevant Document’s URL, with exceptionsEnabled set to true, historyHandling set to "reload", and the source browsing context set to the browsing context being navigated.
When a user requests that the active document of a browsing context be reloaded through a user interface element, the user agent should navigate the browsing context to the same resource as that Document, with historyHandling set to "reload". In the case of non-idempotent methods (e.g., HTTP POST), the user agent should prompt the user to confirm the operation first, since otherwise transactions (e.g., purchases or database modifications) could be repeated. User agents may allow the user to explicitly override any caches when reloading.

The ancestorOrigins getter steps are:

1. If this’s relevant Document is null, then return an empty list.
2. If this’s relevant Document’s origin is not same origin-domain with the entry settings object’s origin, then throw a "SecurityError" DOMException.
3. Otherwise, return this’s ancestor origins list.

The details of how the ancestorOrigins attribute works are still controversial and might change. See issue #1918 for more information.

As explained earlier, the Location exotic object requires additional logic beyond IDL for security purposes. The Location object must use the ordinary internal methods except where it is explicitly specified otherwise below.

Also, every Location object has a [[DefaultProperties]] internal slot representing its own properties at time of its creation.

7.10.5.1 [[GetPrototypeOf]] ()

1. If ! IsPlatformObjectSameOrigin(this) is true, then return ! OrdinaryGetPrototypeOf(this).

2. Return null.

7.10.5.2 [[SetPrototypeOf]] ( V )

1. Return ! SetImmutablePrototype(this, V).

7.10.5.3 [[IsExtensible]] ()

1. Return true.

7.10.5.4 [[PreventExtensions]] ()

1. Return false.
7.10.5.5 [[GetOwnProperty]] \( P \)

1. If \(! \text{IsPlatformObjectSameOrigin}(\text{this})\) is true, then:
   1. Let \( \text{desc} \) be \(! \text{OrdinaryGetOwnProperty}(\text{this}, P)\).
   2. If the value of the [[DefaultProperties]] internal slot of \( \text{this} \) contains \( P \), then set \( \text{desc}.[[\text{Configurable}]] \) to true.
   3. Return \( \text{desc} \).
2. Let \( \text{property} \) be \(! \text{CrossOriginGetOwnPropertyHelper}(\text{this}, P)\).
3. If \( \text{property} \) is not undefined, then return \( \text{property} \).
4. Return ? \( \text{CrossOriginPropertyFallback}(P) \).

7.10.5.6 [[DefineOwnProperty]] \( P, \text{Desc} \)

1. If \(! \text{IsPlatformObjectSameOrigin}(\text{this})\) is true, then:
   1. If the value of the [[DefaultProperties]] internal slot of \( \text{this} \) contains \( P \), then return false.
   2. Return ? \( \text{OrdinaryDefineOwnProperty}(\text{this}, P, \text{Desc}) \).
2. Throw a “\text{SecurityError}” \text{DOMException}.

7.10.5.7 [[Get]] \( P, \text{Receiver} \)

1. If \(! \text{IsPlatformObjectSameOrigin}(\text{this})\) is true, then return ? \( \text{OrdinaryGet}(\text{this}, P, \text{Receiver}) \).
2. Return ? \( \text{CrossOriginGet}(\text{this}, P, \text{Receiver}) \).

7.10.5.8 [[Set]] \( P, V, \text{Receiver} \)

1. If \(! \text{IsPlatformObjectSameOrigin}(\text{this})\) is true, then return ? \( \text{OrdinarySet}(\text{this}, P, V, \text{Receiver}) \).
2. Return ? \( \text{CrossOriginSet}(\text{this}, P, V, \text{Receiver}) \).

7.10.5.9 [[Delete]] \( P \)

1. If \(! \text{IsPlatformObjectSameOrigin}(\text{this})\) is true, then return ? \( \text{OrdinaryDelete}(\text{this}, P) \).
2. Throw a “\text{SecurityError}” \text{DOMException}.
7.10.5.10 [[OwnPropertyKeys]] ( )

1. If ! IsPlatformObjectSameOrigin(this) is true, then return ! OrdinaryOwnPropertyKeys(this).

2. Return ! CrossOriginOwnPropertyKeys(this).

7.11 Browsing the web

7.11.1 Navigating across documents

Certain actions cause the browsing context to navigate to a new resource. A user agent may provide various ways for the user to explicitly cause a browsing context to navigate, in addition to those defined in this specification.

For example, following a hyperlink, form submission, and the window.open() and location.assign() methods can all cause a browsing context to navigate.

A resource has a URL, but that might not be the only information necessary to identify it. For example, a form submission that uses HTTP POST would also have the HTTP method and payload. Similarly, an iframe srcdoc document needs to know the data it is to use.

Much of the navigation process is concerned with determining how to create a new Document, which ultimately happens in the create and initialize a Document object algorithm. The parameters to this algorithm are tracked via a navigation params struct, which has the following items:

- **id**
  - A navigation id.

- **request**
  - null or a request that started the navigation

- **response**
  - a response that ultimately was navigated to (potentially a network error)

- **origin**
  - an origin to use for the new Document

- **policy container**
  - a policy container to use for the new Document

- **final sandboxing flag set**
  - a sandboxing flag set to impose on the new Document

- **cross-origin opener policy**
  - a cross-origin opener policy to use for the new Document
**COOP enforcement result**
a cross-origin opener policy enforcement result, used for reporting and potentially for causing a browsing context group switch

**reserved environment**
null or an environment reserved for the new Document

**browsing context**
the browsing context to be navigated (or discarded, if a browsing context group switch occurs)

**history handling**
a history handling behavior

**has cross-origin redirects**
a boolean

Once a navigation params struct is created, this standard does not mutate any of its items. They are only passed onward to other algorithms.

After Document creation, the session history gets updated. A history handling behavior is used to track the desired type of session history update throughout the navigation process. It is one of the following:

**“default”**
A regular navigation which adds a new entry to the session history.

**“entry update”**
A navigation to an existing session history entry to recreate that entry’s document, which was previously discarded.

**“reload”**
A navigation intended to reload the current page and replace the current session history entry.

**“replace”**
A non-reload navigation that will replace the current session history entry.

Navigation always involves source browsing context, which is the browsing context which was responsible for starting the navigation.

As explained in issue #1130 the use of a browsing context as source might not be the correct architecture.

A navigation has a navigation id, which is a unique string.

To navigate a browsing context browsingContext to a resource resource, with an optional boolean exceptionsEnabled (default false), an optional history handling behavior
historyHandling (default "default"), an optional policy container-or-null historyPolicyContainer (default null), an optional string navigationType (default "other"), and an optional navigation id navigationId (default null):

1. If resource is a URL, then set resource to a new request whose URL is resource.

2. If resource is a request and historyHandling is "reload", then set resource's reload-navigation flag.

3. If the source browsing context is not allowed to navigate browsingContext, then:
   
   1. If exceptionsEnabled is given and is true, then throw a "SecurityError" DOMException.
   
   2. Otherwise, the user agent may instead offer to open resource in a new top-level browsing context or in the top-level browsing context of the source browsing context, at the user's option, in which case the user agent must navigate that designated top-level browsing context to resource as if the user had requested it independently.

   Doing so, however, can be dangerous, as it means that the user is overriding the author's explicit request to sandbox the content.

4. If navigationId is null:
   
   1. historyHandling is "reload", and browsingContext's active document's navigation id is not null, let navigationId be browsingContext's active document’s navigation id. Otherwise let navigation id be the result of generating a random UUID, [UUID]

5. If browsingContext’s active document’s unload counter is greater than 0, then invoke WebDriver BiDi navigation failed with a WebDriver BiDi navigation status whose id is navigationId, status is "canceled", and url is resource’s url, and return.

6. If historyHandling is not "reload", resource is a request, resource’s URL equals browsingContext’s active document’s URL with exclude fragments set to true, and resource’s URL’s fragment is non-null, then:
   
   1. Navigate to a fragment given browsingContext, resource’s URL, historyHandling, and navigationId.

   2. Return.

7. If historyHandling is "default", resource is a request, and either resource’s URL equals browsingContext’s active document’s URL or resource’s URL’s scheme is "javascript", then set historyHandling to "replace".
8. Let `incumbentNavigationOrigin` be the origin of the incumbent settings object, or if no script was involved, the origin of the node document of the element that initiated the navigation.

9. Let `initiatorPolicyContainer` be a clone of the source browsing context’s active document’s policy container.

10. If `resource` is a request, then set resource’s policy container to `initiatorPolicyContainer`.

11. Cancel any preexisting but not yet mature attempt to navigate `browsingContext`, including canceling any instances of the fetch algorithm started by those attempts. If one of those attempts has already created and initialized a new Document object, abort that Document also. (Navigation attempts that have matured already have session history entries, and are therefore handled during the update the session history with the new page algorithm, later.)

12. Prompt to unload the active document of `browsingContext`. If the user refused to allow the document to be unloaded, then return a new WebDriver BiDi navigation status whose id is `navigationId` and status is “canceled”.

   If this instance of the navigation algorithm gets canceled while this step is running, the prompt to unload algorithm must nonetheless be run to completion.

14. If `browsingContext` is a child browsing context, then put it in the delaying load events mode.

   The user agent must take this child browsing context out of the delaying load events mode when this navigation algorithm later matures, or when it terminates (whether due to having run all the steps, or being canceled, or being aborted), whichever happens first.

15. Let `sandboxFlags` be the result of determining the creation sandboxing flags given `browsingContext` and `browsingContext`’s container.

16. Let `allowedToDownload` be the result of running the allowed to download algorithm given the source browsing context and `browsingContext`.

17. Let `hasTransientActivation` be true if the source browsing context’s active window has transient activation; otherwise false.

18. Let `navigationStatus` be

19. Invoke WebDriver BiDi navigation started with `browsingContext`, and a new WebDriver BiDi navigation status whose id is `navigationId`, url is resource’s url, and status is “pending”.

20. Return, and continue running these steps in parallel.

21. This is the step that attempts to obtain \texttt{resource}, if necessary. Jump to the first appropriate substep:

\textbf{If} \texttt{resource} \textbf{is a} \texttt{response} \textbf{If} \texttt{resource} \textbf{is a} \texttt{request} whose \texttt{URL}’s \texttt{scheme} is “javascript”

\begin{enumerate}
\item Assert: \texttt{browsingContext} is not a top-level browsing context.
\item Let \texttt{finalSandboxFlags} be the union of \texttt{browsingContext}’s sandboxing flags and \texttt{resource}’s forced sandboxing flag set.
\item Let \texttt{responseOrigin} be the result of determining the origin given \texttt{browsingContext}, \texttt{resource}’s \texttt{url}, \texttt{finalSandboxFlags}, and \texttt{incumbentNavigationOrigin}.
\item Let \texttt{coop} be a new cross-origin opener policy.
\item Let \texttt{coopEnforcementResult} be a new cross-origin opener policy enforcement result whose needs a browsing context group switch is false, would need a browsing context group switch due to report-only is false, \texttt{url} is \texttt{resource}’s \texttt{url}, \texttt{origin} is \texttt{responseOrigin}, cross-origin opener policy is \texttt{coop}, and current context is navigation source is false.
\item Let \texttt{policyContainer} be the result of determining navigation params policy container given \texttt{resource}’s \texttt{url}, \texttt{historyPolicyContainer}, \texttt{initiatorPolicyContainer}, \texttt{browsingContext}’s parent browsing context’s active document’s policy container, and null.
\item Let \texttt{navigationParams} be a new navigation params whose \texttt{id} is \texttt{navigationId}, \texttt{request} is null, \texttt{response} is \texttt{resource}, \texttt{origin} is \texttt{responseOrigin}, policy container is \texttt{policyContainer}, final sandboxing flag set is \texttt{finalSandboxFlags}, cross-origin opener policy is \texttt{coop}, COOP enforcement result is \texttt{coopEnforcementResult}, reserved environment is null, browsing context is \texttt{browsingContext}, history handling is \texttt{historyHandling}, and has cross-origin redirects is false.
\item Run \texttt{process a navigate response} with \texttt{navigationType}, \texttt{allowedToDownload}, \texttt{hasTransientActivation}, and \texttt{navigationParams}.
\end{enumerate}

\textbf{If} \texttt{resource} \textbf{is a} \texttt{request} whose \texttt{URL}’s \texttt{scheme} is “javascript”

Queue a global task on the DOM manipulation task source given \texttt{browsingContext}’s active window to run these steps:

\begin{enumerate}
\item Let \texttt{response} be the result of executing a \texttt{javascript: URL request} given \texttt{resource}, \texttt{browsingContext}, and \texttt{incumbentNavigationOrigin}.
\end{enumerate}
2. Let finalSandboxFlags be the union of browsingContext’s sandboxing flags and response’s forced sandboxing flag set.

3. Let coopEnforcementResult be a new cross-origin opener policy enforcement result whose needs a browsing context group switch is false, would need a browsing context group switch due to report-only is false, url is resource’s URL, origin is browsingContext’s active document’s origin, cross-origin opener policy is browsingContext’s active document’s cross-origin opener policy, and current context is navigation source is false.

4. Let navigationParams be a new navigation params whose id is navigationId, request is resource, response is response, origin is browsingContext’s active document’s origin, policy container is browsingContext’s active document’s policy container, final sandboxing flag set is finalSandboxFlags, cross-origin opener policy is browsingContext’s active document’s cross-origin opener policy, COOP enforcement result is coopEnforcementResult, reserved environment is null, browsing context is browsingContext, history handling is historyHandling, and has cross-origin redirects is false.

5. Run process a navigate response with navigationType, allowedToDownload, hasTransientActivation, and navigationParams.

So for example a javascript: URL in an href attribute of an a element would only be evaluated when the link was followed, while such a URL in the src attribute of an iframe element would be evaluated in the context of the iframe’s nested browsing context when the iframe is being set up. Once evaluated, its return value (if it was a string) would replace that browsing context’s active document, thus also changing the corresponding Window object.

If resource is a request whose URL’s scheme is a fetch scheme

Run process a navigate fetch given navigationId, resource, the source browsing context, browsingContext, navigationType, sandboxFlags, historyPolicyContainer, initiatorPolicyContainer, allowedToDownload, hasTransientActivation, incumbentNavigationOrigin, and historyHandling.

Otherwise, resource is a request whose URL’s scheme is neither “javascript” nor a fetch scheme

Run process a navigate URL scheme given resource’s URL, browsingContext, sandboxFlags, and hasTransientActivation.

To process a navigate fetch, given a navigation id navigationId, request request, two browsing contexts sourceBrowsingContext and browsingContext, a string navigationType, a sandboxing flag set sandboxFlags, two policy containers historyPolicyContainer and initiatorPolicyContainer, a boolean allowedToDownload, a boolean hasTransientActivation, an
1. Let response be null.

2. Set request’s client to sourceBrowsingContext’s active document’s relevant settings object, destination to “document”, mode to “navigate”, credentials mode to “include”, use-URL-credentials flag, redirect mode to “manual”, and replaces client id to browsingContext’s active document’s relevant settings object’s id.

3. If hasTransientActivation is true, then set request’s user-activation to true.

4. If browsingContext’s container is non-null:
   
   1. If the browsingContext’s container has a browsing context scope origin, then set request’s origin to that browsing context scope origin.
   
   2. Set request’s destination to browsingContext’s container’s local name.

5. Let responseOrigin be null.

6. Let currentContextIsSource be the result of whether browsingContext’s active document is same origin with sourceBrowsingContext’s active document.

7. Let coopEnforcementResult be a new cross-origin opener policy enforcement result whose needs a browsing context group switch is false, would need a browsing context group switch due to report-only is false, url is browsingContext’s active document’s url, origin is browsingContext’s active document’s origin, cross-origin opener policy is browsingContext’s active document’s cross-origin opener policy, and current context is navigation source is currentContextIsSource.

8. Let finalSandboxFlags be an empty sandboxing flag set.

9. Let responseCOOP be a new cross-origin opener policy.

10. Let locationURL be null.

11. Let currentURL be request’s current URL.

12. Let hasCrossOriginRedirects be false.

13. While true:

   1. If locationURL is non-null, then:
      
      1. If locationURL’s origin is not the same as currentURL’s origin, then set hasCrossOriginRedirects to true.
      
      2. Set currentURL to locationURL.
2. If request's reserved client is not null and currentURL's origin is not the same as request's reserved client's creation URL's origin, then:

   1. Run the environment discarding steps for request's reserved client.
   2. Set request's reserved client to null.

3. If request's reserved client is null, then:

   1. Let topLevelCreationURL be currentURL.
   2. Let topLevelOrigin be null.
   3. If browsingContext is not a top-level browsing context, then:
      1. Let parentEnvironment be browsingContext's container's relevant settings object.
      2. Set topLevelCreationURL to parentEnvironment's top-level creation URL and topLevelOrigin to parentEnvironment's top-level origin.
   4. Set request's reserved client to a new environment whose id is a unique opaque string, target browsing context is browsingContext, creation URL is currentURL, top-level creation URL is topLevelCreationURL, and top-level origin is topLevelOrigin.

      The created environment's active service worker is set in the Handle Fetch algorithm during the fetch if the request URL matches a service worker registration. [SW]

4. If the result of Should navigation request of type be blocked by Content Security Policy? given request and navigationType is “Blocked”, then set response to a network error and break. [CSP]

5. Otherwise:

   1. If response is null, fetch request.
   2. Otherwise, perform HTTP-redirect fetch using request and response.
   3. Wait for the task on the networking task source to process response and set response to the result.
   4. Set finalSandboxFlags to the union of browsingContext's sandboxing flags and response's forced sandboxing flag set.
   5. Set responseOrigin to the result of determining the origin given
browsingContext, request’s `URL`, finalSandboxFlags, and incumbentNavigationOrigin.

6. If `browsingContext` is a top-level browsing context, then:

   1. Set `responseCOOP` to the result of obtaining a cross-origin opener policy given `response` and request’s reserved client.

   2. If `sandboxFlags` is not empty and `responseCOOP`’s value is not "unsafe-none", then set `response` to an appropriate network error and break.

      This results in a network error as one cannot simultaneously provide a clean slate to a response using cross-origin opener policy and sandbox the result of navigating to that response.

   3. Set `coopEnforcementResult` to the result of enforcing the response’s cross-origin opener policy given `browsingContext`, `request`’s `URL`, `responseOrigin`, `responseCOOP`, `coopEnforcementResult` and request’s `referrer`.

7. If `response` is not a network error, `browsingContext` is a child browsing context, and the result of performing a cross-origin resource policy check with `browsingContext`’s container document’s `origin`, `browsingContext`’s container document’s relevant settings object, `request`’s `destination`, `response`, and true is blocked, then set `response` to a network error and break.

   Here we’re running the cross-origin resource policy check against the parent browsing context rather than `sourceBrowsingContext`. This is because we care about the same-originness of the embedded content against the parent context, not the navigation source.

8. Set `locationURL` to `response`’s location URL given `currentURL`’s fragment.

9. If `locationURL` is not a URL whose scheme is an HTTP(S) scheme, then break.

   Navigation handles redirects manually as navigation is the only place in the web platform that cares for redirects to `mailto:` URLs and such.

By the end of this loop we will be in one of these scenarios:

- `response` is a network error.

- `locationURL` is failure, because of an unparsable ‘`Location`’ header.
- `locationURL` is null, because we successfully fetched a non-`network error` HTTP(S) response with no `Location` header.

- `locationURL` is a URL with a non-HTTP(S) scheme.

14. If `locationURL` is failure, then set `response` to a `network error`.

15. Otherwise, if `locationURL` is a URL whose scheme is a `fetch scheme` or "javascript", then set `response` to a `network error`.

16. Otherwise, if `locationURL` is a URL, then process a navigate URL scheme given `locationURL`, `browsingContext`, `sandboxFlags`, and `hasTransientActivation`, and return.

17. Let `responsePolicyContainer` be the result of creating a policy container from a fetch response given `response` and request's `reserved client`.

18. Let `resultPolicyContainer` be the result of determining navigation params policy container given response's `URL`, `historyPolicyContainer`, `initiatorPolicyContainer`, null, and `responsePolicyContainer`.

19. Let `navigationParams` be a new navigation params whose `id` is `navigationId`, `request` is `response`, `origin` is `responseOrigin`, `policy container` is `resultPolicyContainer`, `final sandboxing flag set` is `finalSandboxFlags`, `cross-origin opener policy` is `responseCOOP`, `COOP enforcement result` is `coopEnforcementResult`, `reserved environment` is `request's reserved client`, `browsing context` is `browsingContext`, `history handling` is `historyHandling`, and `has cross-origin redirects` is `hasCrossOriginRedirects`.

20. Run process a navigate response with `navigationType`, `allowedToDownload`, `hasTransientActivation`, and `navigationParams`.

To process a navigate response, given a string `navigationType`, a boolean `allowedToDownload`, a boolean `hasTransientActivation`, and a navigation params `navigationParams`:

1. Let `response` be `navigationParams's response`.

2. Let `browsingContext` be `navigationParams's browsing context`.

3. Let `failure` be false.

4. If `response` is a `network error`, then set `failure` to true.

   Otherwise, if the result of Should navigation response to navigation request of type in target be blocked by Content Security Policy? given `navigationParams's request`, `response`, `navigationParams's policy container's CSP list`, `navigationType`, and `browsingContext` is "Blocked", then set `failure` to true. [CSP]

   Otherwise, if `navigationParams's reserved environment` is non-null and the result of
checking a navigation response’s adherence to its embedder policy given response, browsingContext, and navigationParams’s policy container’s embedder policy is false, then set failure to true.

Otherwise, if the result of checking a navigation response’s adherence to ‘X-Frame-Options’ given response, browsingContext, and navigationParams’s origin is false, then set failure to true.

5. If failure is true, then:

1. Display the inline content with an appropriate error shown to the user given browsingContext.

2. Run the environment discarding steps for navigationParams’s reserved environment.

3. Invoke WebDriver BiDi navigation failed with browsingContext and a new WebDriver BiDi navigation status whose id is navigationParams’s id, status is “canceled”, and url is response’s URL.

4. Return.

This is where the network errors defined and propagated by Fetch, such as DNS or TLS errors, end up being displayed to users. [FETCH]

6. If response’s status is 204 or 205, then return.

7. If response has a `Content-Disposition` header specifying the attachment disposition type, then:

1. If allowedToDownload is true, then handle response as a download.

2. Invoke WebDriver BiDi download started with browsingContext and a new WebDriver BiDi navigation status whose id is navigationParams’s id, status is “complete”, and url is response’s URL.

3. Return.

8. Let type be the computed type of response.

9. If the user agent has been configured to process resources of the given type using some mechanism other than rendering the content in a browsing context, then skip this step. Otherwise, if the type is one of the following types, jump to the appropriate entry in the following list, and process response as described there:

   an HTML MIME type
   Follow the steps given in the HTML document section providing navigationParams. Once the steps have completed, return.
an **XML MIME type** that is not an explicitly supported XML MIME type

Follow the steps given in the **XML document** section providing **navigationParams** and **type**. Once the steps have completed, return.

a **JavaScript MIME type**

a **JSON MIME type** that is not an explicitly supported JSON MIME type

"text/css"
"text/plain"
"text/vtt"

Follow the steps given in the **plain text file** section providing **navigationParams** and **type**. Once the steps have completed, return.

"multipart/x-mixed-replace"

Follow the steps given in the **multipart/x-mixed-replace** section providing **navigationParams**. Once the steps have completed, return.

A supported image, video, or audio type

Follow the steps given in the **media** section providing **navigationParams** and **type**. Once the steps have completed, return.

"application/pdf"
"text/pdf"

If the user agent’s **PDF viewer supported** is true, then either follow the steps given in the **plugin** section providing **navigationParams** and **type**, or **display the inline content** given **browsingContext**. Once the steps have completed, return.

See **issue #6003** for discussion on picking one of these two behaviors to standardize.

Otherwise, proceed onward.

An explicitly supported XML MIME type is an **XML MIME type** for which the user agent is configured to use an external application to render the content (either a **plugin** rendering directly in **browsingContext**, or a separate application), or one for which the user agent has dedicated processing rules (e.g., a web browser with a built-in Atom feed viewer would be said to explicitly support the **application/atom+xml** MIME type), or one for which the user agent has a dedicated handler.

An explicitly supported JSON MIME type is a **JSON MIME type** for which the user agent is configured to use an external application to render the content (either a **plugin** rendering directly in **browsingContext**, or a separate application), or one for which the user agent has dedicated processing rules, or one for which the user agent has a dedicated handler.

10. If, given **type**, the new resource is to be handled by displaying some sort of inline content, e.g., a native rendering of the content or an error message because the specified type is not supported, then **display the inline content** given **browsingContext**, and then return.
11. Otherwise, the document’s type is such that the resource will not affect `browsingContext`, e.g., because the resource is to be handed to an external application or because it is an unknown type that will be processed as a download. Hand-off to external software given `response`, `browsingContext`, `navigationParams`'s final sandboxing flag set, and `hasTransientActivation`.

To process a navigate URL scheme, given a `URL url`, a `browsing context` `browsingContext`, a `sandboxing flag set` `sandboxFlags`, and a boolean `hasTransientActivation`:

1. If `url` is to be handled using a mechanism that does not affect `browsingContext`, e.g., because `url`'s scheme is handled externally, then hand-off to external software given `url`, `browsingContext`, `sandboxFlags`, and `hasTransientActivation`.

2. Otherwise, `url` is to be handled by displaying some sort of inline content, e.g., an error message because the specified scheme is not one of the supported protocols, or an inline prompt to allow the user to select a registered handler for the given scheme. Display the inline content given `browsingContext`.

In the case of a registered handler being used, `navigate` will be invoked with a new URL.

To hand-off to external software given a `URL` or `response resource`, a `browsing context` `browsingContext`, a `sandboxing flag set` `sandboxFlags`, and a boolean `hasTransientActivation`, user agents should:

1. If `browsingContext` is not a top-level browsing context, and none of:
   - `sandboxFlags` contains the `allow-top-navigation-by-user-activation` token and `hasTransientActivation` is true
   - `sandboxFlags` contains the `allow-top-navigation` token
   - `sandboxFlags` contains the `allow-popups` token

   hold, then return without invoking the external software package.

   Navigation inside an iframe toward external software can be seen by users as a new popup or a new top-level navigation. Therefore, we enforcing sandbox flags appropriately.

2. Perform the appropriate handoff of resource while attempting to mitigate the risk that this is an attempt to exploit the target software. For example, user agents could prompt the user to confirm that the source browsing context’s active document’s origin is to be allowed to invoke the external software in question. In particular, if `hasTransientActivation` is false, then the user agent should not invoke the external software package without prior user confirmation.

   For example, there could be a vulnerability in the target software’s URL handler which a hostile page would attempt to exploit by tricking a user into clicking a link.
To execute a `javascript:` URL request, given a request request, a browsing context browsingContext, and an origin initiatorOrigin:

1. Let response be a response whose status is 204.

2. If both of the following are true:
   - initiatorOrigin is same origin-domain with browsingContext’s active document’s origin.
   - The result of Should navigation request of type be blocked by Content Security Policy? given request and navigationType is “Allowed”. [CSP]

   then:

   1. Let urlString be the result of running the URL serializer on request’s URL.
   2. Let encodedScriptSource be the result of removing the leading “javascript:” from urlString.
   3. Let scriptSource be the UTF-8 decoding of the percent-decoding of encodedScriptSource.
   4. Append browsingContext’s active document’s URL to request’s URL list.
   5. Let settings be browsingContext’s active document’s relevant settings object.
   6. Let baseURL be settings’s API base URL.
   7. Let script be the result of creating a classic script given scriptSource, settings, baseURL, and the default classic script fetch options.
   8. Let evaluationStatus be the result of running the classic script script.
   9. Let result be undefined if evaluationStatus is an abrupt completion or evaluationStatus.[[Value]] is empty, or evaluationStatus.[[Value]] otherwise.
   10. If Type(result) is String, then set response to a response whose header list is « (‘Content-Type’, ‘text/html;charset=utf-8’) », and whose body is the result of UTF-8 encoding result.

   The encoding to UTF-8 means that unpaired surrogates will not roundtrip, once the HTML parser decodes the response body.

3. Return response.

In addition to the specific issues linked above, `javascript:` URLs have a dedicated label on the issue tracker documenting various problems with their specification.
Some of the sections below, to which the above algorithm defers in certain cases, use the following steps to create and initialize a Document object, given a type, contentType, and navigation params navigationParams:

1. Let browsingContext be the result of the obtaining a browsing context to use for a navigation response given navigationParams's browsing context, navigationParams's final sandboxing flag set, navigationParams's cross-origin opener policy, and navigationParams's COOP enforcement result.

2. Let permissionsPolicy be the result of creating a permissions policy from a response given browsingContext, navigationParams's origin, and navigationParams's response. [PERMISSIONSPOLICY]

   The creating a permissions policy from a response algorithm makes use of the passed origin. If document.domain has been used for browsingContext's container document, then its origin cannot be same origin-domain with the passed origin, because these steps run before the document is created, so it cannot itself yet have used document.domain. Note that this means that Permissions Policy checks are less permissive compared to doing a same origin check instead.

   See below for some examples of this in action.

3. Let creationURL be navigationParams's response's URL.

4. If navigationParams's request is non-null, then set creationURL to navigationParams's request's current URL.

5. If browsingContext is still on its initial about:blank Document, and navigationParams's history handling is "replace", and browsingContext's active document's origin is same origin-domain with navigationParams's origin, then do nothing.

   This means that both the initial about:blank Document, and the new Document that is about to be created, will share the same Window object.

6. Otherwise:

   1. Let oacHeader be the result of getting a structured field value given 'Origin-Agent-Cluster' and "item" from response's header list.

   2. Let requestsOAC be true if oacHeader is not null and oacHeader[0] is the boolean true; otherwise false.

   3. If navigationParams's reserved environment is a non-secure context, then set requestsOAC to false.
4. Let agent be the result of obtaining a similar-origin window agent given navigationParams's origin, browsingContext's group, and requestsOAC.

5. Let realm execution context be the result of creating a new JavaScript realm given agent and the following customizations:
   - For the global object, create a new Window object.
   - For the global this binding, use browsingContext's WindowProxy object.

6. Let topLevelCreationURL be creationURL.

7. Let topLevelOrigin be navigationParams's origin.

8. If browsingContext is not a top-level browsing context, then:
   1. Let parentEnvironment be browsingContext's container's relevant settings object.
   2. Set topLevelCreationURL to parentEnvironment's top-level creation URL.
   3. Set topLevelOrigin to parentEnvironment's top-level origin.

9. Set up a window environment settings object with creationURL, realm execution context, navigationParams's reserved environment, topLevelCreationURL, and topLevelOrigin.

This is the usual case, where the new Document we're about to create gets a new Window to go along with it.

7. Let document be a new Document, whose type is type, content type is contentType, origin is navigationParams's origin, policy container is navigationParams's policy container, permissions policy is permissionsPolicy, active sandboxing flag set is navigationParams's final sandboxing flag set, and cross-origin opener policy is navigationParams's cross-origin opener policy, and navigation id is navigationParams's id.

The new Window's associated Document is set to document later, when the caller of this algorithm updates the session history with the new page. That algorithm sets the active document as part of its larger role of synchronizing the Window, Document, browsing context, and session history.

8. Set document's URL to creationURL.

9. Set document's current document readiness to "loading".
10. Run CSP initialization for a Document given document. [CSP]

11. If navigationParams’s request is non-null, then:

   1. Set document’s referrer to the empty string.
   2. Let referrer be navigationParams’s request’s referrer.
   3. If referrer is a URL record, then set document’s referrer to the serialization of referrer.

   Per Fetch, referrer will be either a URL record or “no-referrer” at this point.

12. Set document’s load timing info to a new document load timing info.

13. Let historyHandling be navigationParams’s history handling.

14. Let navigationType be the result of switching on navigationParams’s history handling:

   "default"
   "replace"
     "navigate"
   "reload"
     "reload"
   "entry_update"
     "back_forward"

15. Let redirectCount be 0 if navigationParams’s has cross-origin redirects is true; otherwise navigationParams’s request’s redirect count.

16. Create the navigation timing entry for document, with navigationParams's response’s timing info, response’s service worker timing info, redirectCount, and navigationType.

17. If navigationParams's response has a Refresh header, then:

   1. Let value be the isomorphic decoding of the value of the header.
   2. Run the shared declarative refresh steps with document and value.

   We do not currently have a spec for how to handle multiple Refresh headers. This is tracked as issue #2900.

In this example, the child document is not allowed to use PaymentRequest, despite being same origin-domain at the time the child document tries to use it. At the time the child
document is initialized, only the parent document has set `document.domain`, and the child document has not.

```html
<!-- https://foo.example.com/a.html -->
<!doctype html>
<script>
document.domain = 'example.com';
</script>
<iframe src=b.html></iframe>

<!-- https://bar.example.com/b.html -->
<!doctype html>
<script>
document.domain = 'example.com'; // This happens after the document is initialized
new PaymentRequest(...); // Not allowed to use
</script>

In this example, the child document is allowed to use `PaymentRequest`, despite not being `same origin-domain` at the time the child document tries to use it. At the time the child document is initialized, none of the documents have set `document.domain` yet so `same origin-domain` falls back to a normal `same origin` check.

```html
<!-- https://example.com/a.html -->
<!doctype html>
<iframe src=b.html></iframe>
<!-- The child document is now initialized, before the script below is run. -->
<script>
document.domain = 'example.com';
</script>

<!-- https://example.com/b.html -->
<!doctype html>
<script>
new PaymentRequest(...); // Allowed to use
</script>
```

Some of the sections below, to which the above algorithm defers in certain cases, require the user agent to `update the session history with the new page`, given some `navigation params` `navigationParams` and a `Document` `newDocument`. When a user agent is required to do this, it must `queue a global task` on the `networking task source`, given the `relevant global object` of the `Document` object of the `current entry` (not the new one), to run the following steps:

1. Let `sessionHistory` be `navigationParams`'s `browsing context`'s `session history`.
2. Let `unloadTimingInfo` be a new `document unload timing info`.
3. Let `previousDocument` be `sessionHistory`'s `current entry`'s `document`.
4. **Unload** previousDocument with *unloadTimingInfo*.

   If this instance of the *navigation* algorithm is canceled while this step is running the *unload a document* algorithm, then the *unload a document* algorithm must be allowed to run to completion, but this instance of the *navigation* algorithm must not run beyond this step. (In particular, for instance, the cancelation of this algorithm does not abort any event dispatch or script execution occurring as part of unloading the document or its descendants.)

5. If *navigationParams*'s *has cross-origin redirects* is false, and *newDocument*'s *origin* is the *same* as *previousDocument*'s *origin*, then set *newDocument*'s *previous document unload timing* to *unloadTimingInfo*.

6. Switch on *navigationParams*'s *history handling*:

   "entry update"
   "reload"

   1. Let *oldDocument* be *sessionHistory*'s *current entry*'s *document*.

   2. For each *entry* of *sessionHistory*: if *entry*'s *document* is *oldDocument*, then set *entry*'s *document* to *newDocument*.

   3. Traverse the history to *sessionHistory*'s *current entry* with *historyHandling* set to *navigationParams*'s *history handling*.

   "replace"

   1. Let *newEntry* be a new *session history entry* whose *URL* is *newDocument*'s *URL* and *document* is *newDocument*.

   Some browsers copy over the serialized state *sessionHistory*'s *current entry* in cases where its *URL equals* that of *newDocument*, but this is inconsistent. See [issue #6213](#) for more discussion on this.

   2. If *newDocument*'s *URL requires storing the policy container in history*, set *newEntry*'s *policy container* to *navigationParams*'s *policy container*.

   3. Insert *newEntry* into *sessionHistory* after its *current entry*.

   4. Traverse the history to *newEntry* with *historyHandling* set to "replace".

   "default"

   1. Remove all the entries in *sessionHistory* after its *current entry*. (If the *current entry* is the last entry in the session history, then no entries are removed.)
This doesn’t necessarily have to affect the user agent’s user interface.

2. Let newEntry be a new session history entry whose URL is newDocument’s URL and document is newDocument.

3. If newDocument’s URL requires storing the policy container in history, then set newEntry’s policy container to navigationParams’s policy container.

4. Append newEntry to sessionHistory.

5. Traverse the history to newEntry.

7. The navigation algorithm has now matured.

8. Try to scroll to the fragment for newDocument.

To try to scroll to the fragment for a Document document, perform the following steps in parallel:

1. Wait for an implementation-defined amount of time. (This is intended to allow the user agent to optimize the user experience in the face of performance concerns.)

2. Queue a global task on the networking task source given document’s relevant global object to run these steps:

   1. If document has no parser, or its parser has stopped parsing, or the user agent has reason to believe the user is no longer interested in scrolling to the fragment, then abort these steps.

   2. Scroll to the fragment given in document’s URL. If this does not find an indicated part of the document, then try to scroll to the fragment for document.

7.11.2 Page load processing model for HTML files

When an HTML document is to be loaded, given navigation params navigationParams, the user agent must queue a task on the networking task source to:

1. Let document be the result of creating and initializing a Document object given “html”, “text/html”, and navigationParams.

2. Create an HTML parser and associate it with the document. Each task that the networking task source places on the task queue while fetching runs must then fill the parser’s input byte stream with the fetched bytes and cause the HTML parser to perform the appropriate processing of the input stream.

The input byte stream converts bytes into characters for use in the tokenizer. This process relies, in part, on character encoding information found in the real Content-Type metadata of the resource; the computed type is not used for this purpose.
When no more bytes are available, the user agent must queue a global task on the networking task source given the newly-created Document’s relevant global object for the parser to process the implied EOF character, which eventually causes a Load event to be fired.

After creating the Document object, but before any script execution, certainly before the parser stops, the user agent must update the session history with the new page given navigationParams and the newly-created Document.

7.11.3 Page load processing model for XML files

When faced with displaying an XML file inline, provided navigation params navigationParams and a string type, user agents must follow the requirements defined in XML and Namespaces in XML, XML Media Types, DOM, and other relevant specifications to create and initialize a Document object document, given "xml", type, and navigationParams. They must also create a corresponding XML parser. [XML] [XMLNS] [RFC7303] [DOM]

At the time of writing, the XML specification community had not actually yet specified how XML and the DOM interact.

The actual HTTP headers and other metadata, not the headers as mutated or implied by the algorithms given in this specification, are the ones that must be used when determining the character encoding according to the rules given in the above specifications. Once the character encoding is established, the document’s character encoding must be set to that character encoding.

Then, with document, the user agent must update the session history with the new page given navigationParams and document. User agents may do this before the complete document has been parsed (thus achieving incremental rendering), and must do this before any scripts are to be executed.

Once parsing is complete, the user agent must set document’s navigation id to null.

For HTML documents this is reset when parsing is complete, after firing the load event.

Error messages from the parse process (e.g., XML namespace well-formedness errors) may be reported inline by mutating the Document.

7.11.4 Page load processing model for text files

When a plain text document is to be loaded, provided navigation params navigationParams and a string type, the user agent must queue a task on the networking task source to:

1. Let document be the result of creating and initializing a Document object given “html”, type, and navigationParams.

2. Set document’s parser cannot change the mode flag to true.
3. Set document’s **mode** to “no-quirks”.

4. Create an [HTML parser](https://html.spec.whatwg.org/multipage/parser.html) and associate it with the *document*. Act as if the tokenizer had emitted a start tag token with the tag name "pre" followed by a single U+000A LINE FEED (LF) character, and switch the HTML parser’s tokenizer to the PLAINTEXT state. Each [task](https://w3c.github.io/htmlcury/) that the networking task source places on the task queue while fetching runs must then fill the parser’s [input byte stream](https://html.spec.whatwg.org/multipage/parser.html#input-byte-stream) with the fetched bytes and cause the HTML parser to perform the appropriate processing of the input stream.

The rules for how to convert the bytes of the plain text document into actual characters, and the rules for actually rendering the text to the user, are defined by the specifications for the [computed MIME type](https://html.spec.whatwg.org/multipage/media-types.html) of the resource (i.e., *type*).

The document’s character encoding must be set to the character encoding used to decode the document.

When no more bytes are available, the user agent must [queue a global task](https://html.spec.whatwg.org/multipage/unload.html) on the networking task source given the newly-created Document’s relevant global object for the parser to process the implied EOF character, which eventually causes a [load](https://html.spec.whatwg.org/multipage/unload.html) event to be fired.

After creating the [Document](https://html.spec.whatwg.org/multipage/document.html) object, but potentially before the page has finished parsing, the user agent must [update the session history](https://html.spec.whatwg.org/multipage/history.html) with the new page given [navigationParams](https://html.spec.whatwg.org/multipage/history.html) and the newly-created Document.

User agents may add content to the [head](https://html.spec.whatwg.org/multipage/element-definitions.html#head) element of the Document, e.g., linking to a style sheet, providing script, or giving the document a [title](https://html.spec.whatwg.org/multipage/infrastructure.html#title). In particular, if the user agent supports the Format=Flowed feature of RFC 3676 then the user agent would need to apply extra styling to cause the text to wrap correctly and to handle the quoting feature. This could be performed using, e.g., a CSS extension.

### 7.11.5 Page load processing model for multipart/x-mixed-replace resources

When a resource with the type `multipart/x-mixed-replace` is to be loaded in a [browsing context](https://html.spec.whatwg.org/multipage/browsing-context.html), the user agent must parse the resource using the rules for multipart types. [RFC2046](https://tools.ietf.org/html/rfc2046)

This algorithm is passed [navigation params](https://html.spec.whatwg.org/multipage/history.html), but it’s unclear how exactly to use them.

For each body part obtained from the resource, the user agent must run [process a navigate response](https://html.spec.whatwg.org/multipage/browsing-context.html#process-a-navigate-response) using the new body part and the same [browsing context](https://html.spec.whatwg.org/multipage/browsing-context.html), with [history handling](https://html.spec.whatwg.org/multipage/history.html) set to “replace” if a previous body part from the same resource resulted in a **creating and initializing a Document object**, and otherwise using the same setup as the [navigate](https://html.spec.whatwg.org/multipage/history.html) attempt that caused this section to be invoked in the first place.

For the purposes of algorithms processing these body parts as if they were complete stand-alone resources, the user agent must act as if there were no more bytes for those resources whenever the boundary following the body part is reached.
Thus, load events (and for that matter unload events) do fire for each body part loaded.

7.11.6 Page load processing model for media

When an image, video, or audio resource is to be loaded, provided navigation params navigationParams and a string type, the user agent should:

1. Let document be the result of creating and initializing a Document object given “html”, type, and navigationParams.
2. Set document’s mode to ”no-quirks”.
3. Append an html element to document.
4. Append a head element to the html element.
5. Append a body element to the html element.
6. Append an element host element for the media, as described below, to the body element.
7. Set the appropriate attribute of the element host element, as described below, to the address of the image, video, or audio resource.

The element host element to create for the media is the element given in the table below in the second cell of the row whose first cell describes the media. The appropriate attribute to set is the one given by the third cell in that same row.

<table>
<thead>
<tr>
<th>Type of media</th>
<th>Element for the media</th>
<th>Appropriate attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>Image</td>
<td>img</td>
<td>src</td>
</tr>
<tr>
<td>Video</td>
<td>video</td>
<td>src</td>
</tr>
<tr>
<td>Audio</td>
<td>audio</td>
<td>src</td>
</tr>
</tbody>
</table>

Then, the user agent must act as if it had stopped parsing.

After creating the Document object, but potentially before the page has finished fully loading, the user agent must update the session history with the new page given navigationParams and the newly-created Document.

User agents may add content to the head element of the Document, or attributes to the element host element, e.g., to link to a style sheet, to provide a script, to give the document a title, or to make the media autoplay.

7.11.7 Page load processing model for content that uses plugins

When a resource that requires an external resource to be rendered is to be loaded, provided
navigation params `navigationParams` and a string `type`, the user agent should:

1. Let `document` be the result of creating and initializing a `Document` object given "html", `type`, and `navigationParams`.
2. Set `document`'s `mode` to "no-quirks".
3. Mark `document` as being a plugin document
4. Append an `html` element to `document`.
5. Append a `head` element to the `html` element.
6. Append a `body` element to the `html` element.
7. Append an `embed` to the `body` element.
8. Set the `src` attribute of the `embed` element to the address of the resource.

The term plugin document is used by Content Security Policy as part of the mechanism that ensures `iframe` can’t be used to evade plugin-types directives. [CSP]

Then, the user agent must act as if it had stopped parsing.

After creating the `Document` object, but potentially before the page has finished fully loading, the user agent must update the session history with the new page given `navigationParams` and the newly-created `Document`.

User agents may add content to the `head` element of the `Document`, or attributes to the `embed` element, e.g. to link to a style sheet or to give the document a `title`.

If the `Document`’s active sandboxing flag set has its sandboxed plugins browsing context flag set, the synthesized `embed` element will fail to render the content.

7.11.8 Page load processing model for inline content that doesn’t have a DOM

When the user agent is to display a user agent page inline, provided a `browsing context` `browsingContext`, the user agent should:

1. Let `navigationParams` be a new `navigation params` whose `request` is null, `response` is null, `origin` is a new `opaque origin`, final sandboxing flag set is an empty set, cross-origin opener policy is a new `cross-origin opener policy`, COOP enforcement result is a new `cross-origin opener policy enforcement result`, reserved environment is null, and `browsing context` is `browsingContext`.

The algorithm called in the next step is not prepared to deal with a null `response`. Probably we should synthesize one instead.
2. Let $document$ be the result of creating and initializing a $Document$ object given “html”, “text/html”, and $navigationParams$.

3. Set $document$’s mode to "no-quirks”.

4. Either associate $document$ with a custom rendering that is not rendered using the normal $Document$ rendering rules, or mutate $document$ until it represents the content the user agent wants to render.

Once the page has been set up, the user agent must act as if it had stopped parsing.

After creating the $Document$ object, but potentially before the page has been completely set up, the user agent must update the session history with the new page given $navigationParams$ and the newly-created $Document$.

7.11.9 Navigating to a fragment

To navigate to a fragment given a browsing context $browsingContext$, a URL $url$, a history handling behavior $historyHandling$, and a navigation id $navigationId$:

1. If $historyHandling$ is not "replace”, then remove all the entries in $browsingContext$’s session history after the current entry. (If the current entry is the last entry in the session history, then no entries are removed.)

   This doesn’t necessarily have to affect the user agent’s user interface.

2. Remove any tasks queued by the history traversal task source that are associated with any $Document$ objects in $browsingContext$’s top-level browsing context’s document family.

3. Append a new session history entry to the session history whose URL is $url$, document is the current entry’s document, policy container is the current entry’s policy-container and scroll restoration mode is the current entry’s scroll restoration mode.

4. Traverse the history to the new entry, with $historyHandling$ set to $historyHandling$ and with nonBlockingEvents set to true. This will scroll to the fragment given in what is now the document’s URL.

5. Invoke WebDriver BiDi fragment navigated with $browsingContext$, and a new WebDriver BiDi navigation status whose id is $navigationId$, $url$ is resource’s $url$, and status is “complete”.

If the scrolling fails because the relevant ID has not yet been parsed, then the original navigation algorithm will take care of the scrolling instead, as the last few steps of its update the session history with the new page algorithm.
When the user agent is required to *scroll to the fragment* and *the indicated part of the document*, if any, is *being rendered*, the user agent must either change the scrolling position of the document using the following algorithm, or perform some other action such that *the indicated part of the document* is brought to the user’s attention. If there is no indicated part, or if the indicated part is not *being rendered*, then the user agent must do nothing. The aforementioned algorithm is as follows:

1. If there is no *indicated part of the document*, set the Document’s target element to null.

2. If the *indicated part of the document* is the top of the document, then:
   1. Set the Document’s target element to null.
   2. Scroll to the beginning of the document for the Document. [CSSOMVIEW]

3. Otherwise:
   1. Let target be element that is *the indicated part of the document*.
   2. Set the Document’s target element to target.
   3. Run the ancestor details revealing algorithm on target.
   4. Scroll target into view, with behavior set to "auto", block set to "start", and inline set to "nearest". [CSSOMVIEW]
   5. Run the focusing steps for target, with the Document’s viewport as the fallback target.
   6. Move the sequential focus navigation starting point to target.

*The indicated part of the document* is the one that the fragment, if any, identifies. The semantics of the fragment in terms of mapping it to a node is defined by the specification that defines the MIME type used by the Document (for example, the processing of fragments for XML MIME types is the responsibility of RFC7303). [RFC7303]

There is also a target element for each Document, which is used in defining the :target pseudo-class and is updated by the above algorithm. It is initially null.

For HTML documents (and HTML MIME types), the following processing model must be followed to determine what *the indicated part of the document* is.

1. Let fragment be the document’s URL’s fragment.

2. If fragment is the empty string, then *the indicated part of the document* is the top of the document; return.

3. If find a potential indicated element with fragment returns non-null, then the return
value is the indicated part of the document; return.

4. Let fragmentBytes be the result of percent-decoding fragment.

5. Let decodedFragment be the result of running UTF-8 decode without BOM on fragmentBytes.

6. If find a potential indicated element with decodedFragment returns non-null, then the return value is the indicated part of the document; return.

7. If decodedFragment is an ASCII case-insensitive match for the string top, then the indicated part of the document is the top of the document; return.

8. There is no indicated part of the document.

To find a potential indicated element given a string fragment, run these steps:

1. If there is an element in the document tree that has an ID equal to fragment, then return the first such element in tree order.

2. If there is an a element in the document tree that has a name attribute whose value is equal to fragment, then return the first such element in tree order.

3. Return null.

7.11.10 History traversal

To traverse the history to a session history entry entry, with an optional history handling behavior historyHandling (default "default"), an optional boolean nonBlockingEvents (default false), and an optional boolean explicitHistoryNavigation (default false):

This algorithm is not just invoked when explicitly going back or forwards in the session history — it is also invoked in other situations, for example when navigating a browsing context, as part of updating the session history with the new page.

1. If entry’s document is null, then:

   1. Assert: historyHandling is "default".

   2. Let request be a new request whose URL is entry’s URL.

   3. If explicitHistoryNavigation is true, then set request’s history-navigation flag.

   4. Navigate the browsing context to request with historyHandling set to “entry update” and with historyPolicyContainer set to entry’s policy container. The navigation must be done using the same source browsing context as was used the first time entry was created.
The "navigate" algorithm reinvokes this "traverse" algorithm to complete the traversal, at which point entry’s document is non-null.

If the resource was obtained using a non-idempotent action, for example a POST form submission, or if the resource is no longer available, for example because the computer is now offline and the page wasn’t cached, navigating to it again might not be possible. In this case, the navigation will result in a different page than previously; for example, it might be an error message explaining the problem or offering to resubmit the form.

5. Return.

2. Save persisted state to the current entry.

3. Let newDocument be entry’s document.

4. If newDocument is different than the current entry’s document, or historyHandling is "entry update" or "reload", then:

   1. If newDocument’s suspended timer handles is not empty:

      1. Assert: newDocument’s suspension time is not zero.

      2. Let suspendDuration be the current high resolution time minus newDocument’s suspension time.

      3. Let activeTimers be newDocument’s relevant global object’s map of active timers.

      4. For each handle in newDocument’s suspended timer handles, if activeTimers[handle] exists, then increase activeTimers[handle] by suspendDuration.

2. Remove any tasks queued by the history traversal task source that are associated with any Document objects in the top-level browsing context’s document family.

3. If newDocument’s origin is not same origin with the current entry’s document’s origin, then:

   1. Let entriesToUpdate be all entries in the session history whose document’s origin is same origin as the active document and that are contiguous with the current entry.

   2. For each entryToUpdate of entriesToUpdate, set entryToUpdate’s browsing context name to the current browsing context name.

   3. If the browsing context is a top-level browsing context, but not an
auxiliary browsing context whose disowned is false, then set the browsing context’s name to the empty string.

4. Set the active document of the browsing context to newDocument.

5. If entry’s browsing context name is not null, then:
   
   1. Set the browsing context’s name to entry’s browsing context name.
   
   2. Let entriesToUpdate be all entries in the session history whose document’s origin is same origin as the new active document’s origin and that are contiguous with entry.
   
   3. For each entryToUpdate of entriesToUpdate, set entryToUpdate’s browsing context name to null.

6. If newDocument has any form controls whose autofill field name is "off", invoke the reset algorithm of each of those elements.

7. If newDocument’s current document readiness “complete”, then queue a global task on the DOM manipulation task source given newDocument’s relevant global object to run the following steps:
   
   1. If newDocument's page showing flag is true, then abort these steps.
   
   2. Set newDocument’s page showing flag to true.
   
   3. Update the visibility state of newDocument to "hidden".
   
   4. Fire a page transition event named pageshow at newDocument’s relevant global object with true.

5. Set newDocument’s URL to entry’s URL.

6. Set newDocument’s is initial about:blank to false.

The spec currently allows keeping the initial about:blank Document in session history, but this is probably a bug: see issue #6491 (and especially this comment). If we fix that then we can convert this step into an assert that newDocument’s is initial about:blank is false, i.e., an assert that we never traverse back to the initial about:blank Document.

7. Let hashChanged be false, and let oldURL and newURL be null.

8. If entry’s URL’s fragment is not identical to the current entry’s URL’s fragment, and entry’s document equals the current entry’s document, then set hashChanged to true, set oldURL to the current entry’s URL, and set newURL to entry’s URL.
9. If `historyHandling` is "replace", then remove the entry immediately before `entry` in the session history.

10. If `entry`'s persisted user state is null, and its URL's fragment is non-null, then scroll to the fragment.

11. Set the current entry to `entry`.

12. Let `targetRealm` be the current Realm Record.

13. Let `state` be null.

14. If `entry`'s serialized state is not null, then set `state` to `StructuredDeserialize(entry's serialized state, targetRealm)`. If this throws an exception, catch it and ignore the exception.

15. Set `newDocument`'s `History` object's `state` to `state`.

16. Let `stateChanged` be true if `newDocument` has a latest entry, and that entry is not `entry`; otherwise let it be false.

17. Set `newDocument`'s latest entry to `entry`.

18. If `nonBlockingEvents` is false, then run the following steps immediately. Otherwise, queue a global task on the DOM manipulation task source given `newDocument`'s relevant global object to run the following steps instead.

   1. If `stateChanged` is true, then fire an event named `popstate` at `newDocument`'s relevant global object, using `PopStateEvent`, with the `state` attribute initialized to `state`.

   2. Restore persisted state from `entry`.

   3. If `hashChanged` is true, then fire an event named `hashchange` at the browsing context's active window, using `HashChangeEvent`, with the `oldURL` attribute initialized to `oldURL` and the `newURL` attribute initialized to `newURL`.

7.11.10.1 Persisted history entry state

To save persisted state to a session history entry: 

1. Set the scroll position data of `entry` to contain the scroll positions for all of `entry`'s document's restorable scrollable regions.

2. Optionally, update `entry`'s persisted user state to reflect any state that the user agent wishes to persist, such as the values of form fields.

To restore persisted state from a session history entry: 

1. If entry’s scroll restoration mode is "auto", then the user agent may use entry’s scroll position data to restore the scroll positions of entry’s document’s restorable scrollable regions.

The user agent not restoring scroll positions does not imply that scroll positions will be left at any particular value (e.g., (0,0)). The actual scroll position depends on the navigation type and the user agent’s particular caching strategy. So web applications cannot assume any particular scroll position but rather are urged to set it to what they want it to be.

2. Optionally, update other aspects of entry’s document and its rendering, for instance values of form fields, that the user agent had previously recorded in entry’s persisted user state.

This can even include updating the dir attribute of textarea elements or input elements whose type attribute is in either the Text state or the Search state, if the persisted state includes the directionality of user input in such controls.

Restoring the value of form controls as part of this process does not fire any input or change events, but can trigger the formStateRestoreCallback of form-associated custom elements.

The restorable scrollable regions of a Document document are document’s viewport, and all of document’s scrollable regions excepting any child browsing contexts of document.

Child browsing context scroll restoration is handled by the history entry for those browsing contexts’ Documents.

7.11.10.2 The PopStateEvent interface

[Exposed=Window]
interface PopStateEvent : Event {
  constructor(DOMString type, optional PopStateEventInit eventInitDict = {});
}
readonly attribute any state;
};

dictionary PopStateEventInit : EventInit {
    any state = null;
};

event.state

Returns a copy of the information that was provided to pushState() or replaceState().

The state attribute must return the value it was initialized to. It represents the context information for the event, or null, if the state represented is the initial state of the Document.

7.11.10.3 The HashChangeEvent interface

[Exposed=Window]
interface HashChangeEvent : Event {
    constructor(DOMString type, optional HashChangeEventInit eventInitDict = {})

    readonly attribute USVString oldURL;
    readonly attribute USVString newURL;
};

dictionary HashChangeEventInit : EventInit {
    USVString oldURL = "";
    USVString newURL = "";
};

event.oldURL

✔️ MDN
HashChangeEvent/oldURL

Support in all current engines.

Firefox6+Safari5.1+Chrome8+
Opera12.1+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox AndroidYesSafari iOS6+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android12.1+

Returns the URL of the session history entry that was previously current.

event.newURL

✔MDN

HashChangeEvent/newURL

Support in all current engines.

Firefox6+Safari5.1+Chrome8+

Firefox Android 14+Safari iOS 4+Chrome Android 18+WebView Android 37+Samsung Internet 1.0+Opera Android 14+

For the pageshow event, returns false if the page is newly being loaded (and the load event will fire). Otherwise, returns true.

For the pagehide event, returns false if the page is going away for the last time. Otherwise, returns true, meaning that the page might be reused if the user navigates back to this page (if the Document’s salvageable state stays true).

Things that can cause the page to be unsalvageable include:

- The user agent decided to not keep the Document alive in a session history entry after unload
- Having iframes that are not salvageable
- Active WebSocket objects
- Aborting a Document

The persisted attribute must return the value it was initialized to. It represents the context information for the event.

To fire a page transition event named eventName at a Window window with a boolean
Persisted, fire an event named `eventName` at `window`, using `PageTransitionEvent`, with the `persisted` attribute initialized to `persisted`, the `cancelable` attribute initialized to true, the `bubbles` attribute initialized to true, and `legacy target override flag` set.

The values for `cancelable` and `bubbles` don’t make any sense, since canceling the event does nothing and it’s not possible to bubble past the `Window` object. They are set to true for historical reasons.

7.11.11 Loading documents

A `Document` has a completely loaded time (a time or null), which is initially null.

A `Document` is considered completely loaded if its `completely loaded time` is non-null.

To completely finish loading a `Document` document:

1. Assert: `document`’s `browsing context` is non-null.
2. Set `document`’s `completely loaded time` to the current time.
3. Let `container` be `document`’s `browsing context`’s `container`.

   This will be null in the case where `document` is the initial `about:blank Document` in a `frame` or `iframe`, since at the point of `browsing context creation` which calls this algorithm, the container relationship has not yet been established. (That happens in a subsequent step of `create a new nested browsing context`.)

   The consequence of this is that the following steps do nothing, i.e., we do not fire an asynchronous `load` event on the container element for such cases. Instead, a synchronous `load` event is fired in a special initial-insertion case in the `shared attribute processing steps` for `iframe` and `frame` elements.

   4. If `container` is an `iframe` element, then queue an element task on the DOM manipulation task source given `container` to run the `iframe load event steps` given `container`.

   5. Otherwise, if `container` is non-null, then queue an element task on the DOM manipulation task source given `container` to fire an event named `load` at `container`.

7.11.12 Unloading documents

A `Document` has a salvageable state, which must initially be true, and a `page showing` flag, which must initially be false. The `page showing` flag is used to ensure that scripts receive `pageshow` and `pagehide` events in a consistent manner (e.g. that they never receive two `pagehide` events in a row without an intervening `pageshow`, or vice versa).
A **Document** has a **DOMHighResTimeStamp** suspension time, initially 0.

A **Document** has a list of suspended timer handles, initially empty.

**Event loops** have a **termination nesting level** counter, which must initially be 0.

**Document** objects have an **unload counter**, which is used to ignore certain operations while the below algorithms run. Initially, the counter must be set to zero.

To prompt to unload, given a **Document** object `document` and optionally a `recursiveFlag`, run these steps:

1. Increase the event loop’s **termination nesting level** by 1.

2. Increase the document’s **unload counter** by 1.

3. Let `event` be the result of creating an event using **BeforeUnloadEvent**.

4. Initialize `event`’s **type** attribute to **beforeunload** and its **cancelable** attribute true.

5. Dispatch: Dispatch `event` at document’s relevant global object.

6. Decrease the event loop’s **termination nesting level** by 1.

7. If all of the following are true:

   - `document`’s active sandboxing flag set does not have its sandboxed modals flag set
   - `document`’s relevant global object has sticky activation
   - `event`’s **canceled flag** is set, or the **returnValue** attribute of `event` is not the empty string

   then the user agent may ask the user to confirm that they wish to unload the document.

The message shown to the user is not customizable, but instead determined by the user agent. In particular, the actual value of the **returnValue** attribute is ignored.

The user agent is encouraged to avoid asking the user for confirmation if it judges that doing so would be annoying, deceptive, or pointless.

If the user agent asks the user for confirmation, it must **pause** while waiting for the user’s response.

If the user did not confirm the page navigation, then the user agent refused to allow the document to be unloaded.
8. If the `recursiveFlag` is not set, then:

   1. Let `descendants` be the list of the descendant browsing contexts of `document`.
   2. For each `browsingContext` in `descendants`:
      1. Prompt to unload `browsingContext`'s active document with the `recursiveFlag` set.
      2. If the user refused to allow the document to be unloaded, then the user implicitly also refused to allow `document` to be unloaded; break.

9. Decrease the `document`'s `unload counter` by 1.

To unload a `Document` `document`, given an optional `recursiveFlag` and a `document unload timing info` or-null `unloadTimingInfo` (default null):

1. Increase the event loop's termination nesting level by one.

2. Increase `document`'s `unload counter` by 1.

3. If the user agent does not intend to keep `document` alive in a session history entry (such that it can be reused later on history traversal), set `document`'s `salvageable` state to false.

4. If `document`'s `page showing` flag is true:
   1. Set `document`'s `page showing` flag to false.
   2. Fire a page transition event named `pagehide` at `document`'s relevant global object with `document`'s `salvageable` state.
   3. Update the visibility state of `newDocument` to "hidden".

5. If `unloadTimingInfo` is not null, then set `unloadTimingInfo`'s unload event start time to the current high resolution time given `document`'s relevant global object.

6. If `document`'s `salvageable` state is false, then fire an event named `unload` at `document`'s relevant global object, with legacy target override flag set.

7. If `unloadTimingInfo` is not null, then set `unloadTimingInfo`'s unload event end time to the current high resolution time given `document`'s relevant global object.

8. Decrease the event loop's termination nesting level by one.

9. Set `document`'s `suspension time` to the current high resolution time.

10. Set `document`'s `suspended timer handles` to the result of getting the keys for the map of
active timers.

11. Run any unloading document cleanup steps for document that are defined by this specification and other applicable specifications.

12. If the recursiveFlag is not set, then:

1. Let descendants be the list of the descendant browsing contexts of document.

2. For each browsingContext in descendants:

   1. Unload the active document of browsingContext with the recursiveFlag set.

   2. If the salvageable state of the active document of browsingContext is false, then set the salvageable state of document to false also.

3. If document’s salvageable state is false, then discard document.

This specification defines the following unloading document cleanup steps. Other specifications can define more. Given a Document document:

1. Let window be document’s relevant global object.

2. For each WebSocket object webSocket whose relevant global object is window, make disappear webSocket.

   If this affected any WebSocket objects, then set document’s salvageable state to false.

3. If document’s salvageable state is false, then:

   1. For each EventSource object eventSource whose relevant global object is equal to window, forcibly close eventSource.

   2. Clear window’s map of active timers.

7.11.12.1 The BeforeUnloadEvent interface

✔ MDN

BeforeUnloadEvent

Support in all current engines.

Firefox1.5+Safari7+Chrome30+
[Exposed=Window]

interface BeforeUnloadEvent : Event {
    attribute DOMString returnValue;
};

There are no BeforeUnloadEvent-specific initialization methods.

The BeforeUnloadEvent interface is a legacy interface which allows prompting to unload to be controlled not only by canceling the event, but by setting the returnValue attribute to a value besides the empty string. Authors should use the preventDefault() method, or other means of canceling events, instead of using returnValue.

The returnValue attribute controls the process of prompting to unload. When the event is created, the attribute must be set to the empty string. On getting, it must return the last value it was set to. On setting, the attribute must be set to the new value.

This attribute is a DOMString only for historical reasons. Any value besides the empty string will be treated as a request to ask the user for confirmation.

7.11.13 Aborting a document load

To abort a Document document:

1. Abort the active documents of every child browsing context. If this results in any of those Document objects having their salvageable state set to false, then set document's salvageable state to false also.

2. Cancel any instances of the fetch algorithm in the context of document, discarding any tasks queued for them, and discarding any further data received from the network for them. If this resulted in any instances of the fetch algorithm being canceled or any queued tasks or any network data getting discarded, then set document's salvageable state to false.

3. If document's navigation id is non-null, then:
   1. Invoke WebDriver BiDi navigation aborted with document's browsing context, and new WebDriver BiDi navigation status whose whose id is document's navigation id, status is "canceled", and url is document's URL.
   2. Set document's navigation id to null.

4. If document has an active parser, then:
1. Set document’s active parser was aborted to true.

2. Abort that parser.

3. Set document’s salvageable state to false.

User agents may allow users to explicitly invoke the stop document loading for a Document.

To stop document loading given a Document object document, run these steps:

1. Let browsingContext be document’s browsing context.

2. If browsingContext’s active document is not document, then return.

3. If there is an existing attempt to navigate browsingContext and document’s unload counter is 0, then cancel that navigation.

7.11.14 The `X-Frame-Options` header

The `X-Frame-Options` HTTP response header is a legacy way of controlling whether and how a Document may be loaded inside of a child browsing context. It is obsoleted by the frame-ancestors CSP directive, which provides more granular control over the same situations. It was originally defined in HTTP Header Field X-Frame-Options, but the definition and processing model here supersedes that document. [CSP] [RFC7034]

In particular, HTTP Header Field X-Frame-Options specified an `ALLOW-FROM` variant of the header, but that is not to be implemented.

Per the below processing model, if both a CSP frame-ancestors directive and an `X-Frame-Options` header are used in the same response, then `X-Frame-Options` is ignored.

For web developers and conformance checkers, its value ABNF is:

```
X-Frame-Options = "DENY" / "SAMEORIGIN"
```

To check a navigation response’s adherence to `X-Frame-Options`, given navigationParams navigationParams, a browsing context browsingContext, and an origin destinationOrigin:

1. If browsingContext is not a child browsing context, then return true.

2. For each policy of navigationParams’s policy container’s CSP list:
   1. If policy’s disposition is not "enforce", then continue.
   
   2. If policy’s directive set contains a frame-ancestors directive, then return
true.

3. Let `rawXFrameOptions` be the result of getting, decoding, and splitting `X-Frame-Options` from `navigationParams`'s response's header list.

4. Let `xFrameOptions` be a new `set`.

5. **For each** value of `rawXFrameOptions`, **append** value, converted to ASCII lowercase, to `xFrameOptions`.

6. If `xFrameOptions`'s `size` is greater than 1, and `xFrameOptions` contains any of "deny", "allowall", or "sameorigin", then return false.

   The intention here is to block any attempts at applying `X-Frame-Options` which were trying to do something valid, but appear confused.

   This is the only impact of the legacy `ALLOWALL` value on the processing model.

7. If `xFrameOptions`'s `size` is greater than 1, then return true.

   This means it contains multiple invalid values, which we treat the same way as if the header was omitted entirely.

8. If `xFrameOptions[0]` is "deny", then return false.

9. If `xFrameOptions[0]` is "sameorigin", then:

   2. **While** `containerDocument` is not null:

      1. If `containerDocument`'s `origin` is not same origin with `destinationOrigin`, then return false.

      2. Let `containerBC` be `containerDocument`'s browsing context.

      3. Set `containerDocument` to `containerBC`'s container document, if `containerBC` is non-null; otherwise, null.

10. Return true.

    If we've reached this point then we have a lone invalid value (which could potentially be one the legacy `ALLOWALL` or `ALLOW-FROM` forms). These are treated as if the header were omitted entirely.

The following table illustrates the processing of various values for the header, including non-conformant ones:
The following table illustrates how various non-conformant cases involving multiple values are processed:

<table>
<thead>
<tr>
<th>X-Frame-Options</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAMEORIGIN, SAMEORIGIN</td>
<td>same-origin embedding allowed</td>
</tr>
<tr>
<td>SAMEORIGIN, DENY</td>
<td>embedding disallowed</td>
</tr>
<tr>
<td>SAMEORIGIN,</td>
<td>embedding disallowed</td>
</tr>
<tr>
<td>SAMEORIGIN, ALLOWALL</td>
<td>embedding disallowed</td>
</tr>
<tr>
<td>SAMEORIGIN, INVALID</td>
<td>embedding disallowed</td>
</tr>
<tr>
<td>ALLOWALL, INVALID</td>
<td>embedding disallowed</td>
</tr>
<tr>
<td>INVALID</td>
<td>embedding allowed</td>
</tr>
</tbody>
</table>

The same results are obtained whether the values are delivered in a single header whose value is comma-delimited, or in multiple headers.

8 Web application APIs

8.1 Scripting

8.1.1 Introduction

Various mechanisms can cause author-provided executable code to run in the context of a document. These mechanisms include, but are probably not limited to:

- Processing of script elements.
- Navigating to javascript: URLs.
- Event handlers, whether registered through the DOM using addEventListener(), by explicit event handler content attributes, by event handler IDL attributes, or otherwise.
- Processing of technologies like SVG that have their own scripting features.

8.1.2 Agents and agent clusters

8.1.2.1 Integration with the JavaScript agent formalism

JavaScript defines the concept of an agent. This section gives the mapping of that language-
level concept on to the web platform.

Conceptually, the agent concept is an architecture-independent, idealized “thread” in which JavaScript code runs. Such code can involve multiple globals/realms that can synchronously access each other, and thus needs to run in a single execution thread.

Two Window objects having the same agent does not indicate they can directly access all objects created in each other’s realms. They would have to be same origin-domain; see IsPlatformObjectSameOrigin.

The following types of agents exist on the web platform:

Similar-origin window agent

Contains various Window objects which can potentially reach each other, either directly or by using document.domain.

If the encompassing agent cluster’s is origin-keyed is true, then all the Window objects will be same origin, can reach each other directly, and document.domain will no-op.

Two Window objects that are same origin can be in different similar-origin window agents, for instance if they are each in their own browsing context group.

Dedicated worker agent

Contains a single DedicatedWorkerGlobalScope.

Shared worker agent

Contains a single SharedWorkerGlobalScope.

Service worker agent

Contains a single ServiceWorkerGlobalScope.

Worklet agent

Contains a single WorkletGlobalScope object.

Although a given worklet can have multiple realms, each such realm needs its own agent, as each realm can be executing code independently and at the same time as the others.

Only shared and dedicated worker agents allow the use of JavaScript Atomics APIs to potentially block.

To create an agent, given a boolean canBlock:

1. Let signifier be a new unique internal value.
2. Let candidateExecution be a new candidate execution.

3. Let agent be a new agent whose [[CanBlock]] is canBlock, [[Signifier]] is signifier, [[CandidateExecution]] is candidateExecution, and [[IsLockFree1]], [[IsLockFree2]], and [[LittleEndian]] are set at the implementation’s discretion.

4. Set agent's event loop to a new event loop.

5. Return agent.

The relevant agent for a platform object platformObject is platformObject's relevant Realm's agent. This pointer is not yet defined in the JavaScript specification; see tc39/ecma262#1357.

The agent equivalent of the current Realm Record is the surrounding agent.

8.1.2.2 Integration with the JavaScript agent cluster formalism

JavaScript also defines the concept of an agent cluster, which this standard maps to the web platform by placing agents appropriately when they are created using the obtain a similar-origin window agent or obtain a worker/worklet agent algorithms.

The agent cluster concept is crucial for defining the JavaScript memory model, and in particular among which agents the backing data of SharedArrayBuffer objects can be shared.

Conceptually, the agent cluster concept is an architecture-independent, idealized "process boundary" that groups together multiple "threads" (agents). The agent clusters defined by the specification are generally more restrictive than the actual process boundaries implemented in user agents. By enforcing these idealized divisions at the specification level, we ensure that web developers see interoperable behavior with regard to shared memory, even in the face of varying and changing user agent process models.

An agent cluster has an associated cross-origin isolation mode, which is a cross-origin isolation mode. It is initially "none".

An agent cluster has an associated is origin-keyed (a boolean), which is initially false.

The following defines the allocation of the agent clusters of similar-origin window agents.

An agent cluster key is a site or tuple origin. Without web developer action to achieve origin-keyed agent clusters, it will be a site.

An equivalent formulation is that an agent cluster key can be a scheme-and-host or an origin.

To obtain a similar-origin window agent, given an origin origin, a browsing context group group, and a boolean requestsOAC, run these steps:
1. Let site be the result of obtaining a site with origin.

2. Let key be site.

3. If group's cross-origin isolation mode is not "none", then set key to origin.

4. Otherwise, if group's historical agent cluster key map[origin] exists, then set key to group's historical agent cluster key map[origin].

5. Otherwise:
   
   1. If requestsOAC is true, then set key to origin.
   
   2. Set group's historical agent cluster key map[origin] to key.

6. If group's agent cluster map[key] does not exist, then:
   
   1. Let agentCluster be a new agent cluster.
   
   2. Set agentCluster's cross-origin isolation mode to group's cross-origin isolation mode.
   
   3. Set agentCluster's is origin-keyed to true if key equals origin; otherwise false.
   
   4. Add the result of creating an agent, given false, to agentCluster.
   
   5. Set group's agent cluster map[key] to agentCluster.

7. Return the single similar-origin window agent contained in group's agent cluster map[key].

This means that there is only one similar-origin window agent per browsing context agent cluster. (However, dedicated worker and worklet agents might be in the same cluster.)

The following defines the allocation of the agent clusters of all other types of agents.

To obtain a worker/worklet agent, given an environment settings object or null outside settings, a boolean isTopLevel, and a boolean canBlock, run these steps:

1. Let agentCluster be null.

2. If isTopLevel is true, then:
   
   1. Set agentCluster to a new agent cluster.
   
   2. Set agentCluster's is origin-keyed to true.
These workers can be considered to be origin-keyed. However, this is not exposed through any APIs (in the way that \texttt{originAgentCluster} exposes the origin-keyedness for windows).

3. Otherwise:

   1. Assert: \texttt{outside settings} is not null.
   2. Let \texttt{ownerAgent} be \texttt{outside settings}'s \texttt{Realm}'s agent.
   3. Set \texttt{agentCluster} to the agent cluster which contains \texttt{ownerAgent}.

4. Let \texttt{agent} be the result of creating an agent given \texttt{canBlock}.

5. Add \texttt{agent} to \texttt{agentCluster}.

6. Return \texttt{agent}.

To obtain a dedicated/shared worker agent, given an \texttt{environment settings object} \texttt{outside settings} and a boolean \texttt{isShared}, return the result of obtaining a worker/worklet agent given \texttt{outside settings}, \texttt{isShared}, and true.

To obtain a worklet agent, given an \texttt{environment settings object} \texttt{outside settings}, return the result of obtaining a worker/worklet agent given \texttt{outside settings}, false, and false.

To obtain a service worker agent, return the result of obtaining a worker/worklet agent given null, true, and false.

The following pairs of global objects are each within the same \texttt{agent cluster}, and thus can use \texttt{SharedArrayBuffer} instances to share memory with each other:

- A \texttt{Window} object and a dedicated worker that it created.
- A worker (of any type) and a dedicated worker it created.
- A \texttt{Window} object \texttt{A} and the \texttt{Window} object of an \texttt{iframe} element that \texttt{A} created that could be \texttt{same origin-domain} with \texttt{A}.
- A \texttt{Window} object and a \texttt{same origin-domain Window} object that opened it.
- A \texttt{Window} object and a worklet that it created.

The following pairs of global objects are \texttt{not} within the same \texttt{agent cluster}, and thus cannot share memory:

- A \texttt{Window} object and a shared worker it created.
- A worker (of any type) and a shared worker it created.
- A \texttt{Window} object and a service worker it created.
- A \texttt{Window} object and the \texttt{Window} object of an \texttt{iframe} element that \texttt{A} created that cannot be \texttt{same origin-domain} with \texttt{A}.
- Any two `Window` objects whose `browsing contexts` do not have a non-null `opener` or `ancestor` relationship. This holds even if the two `Window` objects are `same origin`.

8.1.3 Realms and their counterparts

The JavaScript specification introduces the `realm` concept, representing a global environment in which script is run. Each realm comes with an `implementation-defined global object`; much of this specification is devoted to defining that global object and its properties.

For web specifications, it is often useful to associate values or algorithms with a realm/global object pair. When the values are specific to a particular type of realm, they are associated directly with the global object in question, e.g., in the definition of the `Window` or `WorkerGlobalScope` interfaces. When the values have utility across multiple realms, we use the `environment settings object` concept.

Finally, in some cases it is necessary to track associated values before a realm/global object/environment settings object even comes into existence (for example, during navigation). These values are tracked in the `environment` concept.

8.1.3.1 Environments

An environment is an object that identifies the settings of a current or potential execution environment. An environment has the following fields:

An `id`

An opaque string that uniquely identifies this environment.

A `creation URL`

A URL that represents the location of the resource with which this environment is associated.

In the case of an environment settings object, this URL might be distinct from the environment settings object’s responsible document’s URL, due to mechanisms such as `history.pushState()`.

A `top-level creation URL`

Null or a URL that represents the creation URL of the “top-level” environment. It is null for workers and worklets.

A `top-level origin`

A for now implementation-defined value, null, or an origin. For a "top-level" potential execution environment it is null (i.e., when there is no response yet); otherwise it is the "top-level" environment’s origin. For a dedicated worker or worklet it is the top-level origin of its
creator. For a shared or service worker it is an implementation-defined value.

This is distinct from the top-level creation URL's origin when sandboxing, workers, and worklets are involved.

A target browsing context

Null or a target browsing context for a navigation request.

An active service worker

Null or a service worker that controls the environment.

An execution ready flag

A flag that indicates whether the environment setup is done. It is initially unset.

Specifications may define environment discarding steps for environments. The steps take an environment as input.

The environment discarding steps are run for only a select few environments: the ones that will never become execution ready because, for example, they failed to load.

8.1.3.2 Environment settings objects

An environment settings object is an environment that additionally specifies algorithms for:

A realm execution context

A JavaScript execution context shared by all scripts that use this settings object, i.e. all scripts in a given JavaScript realm. When we run a classic script or run a module script, this execution context becomes the top of the JavaScript execution context stack, on top of which another execution context specific to the script in question is pushed. (This setup ensures ParseScript and Source Text Module Record's Evaluate know which Realm to use.)

A module map

A module map that is used when importing JavaScript modules.

A responsible document

A Document that is assigned responsibility for actions taken by the scripts that use this environment settings object.

For example, the URL of the responsible document is used to set the URL of the Document after it has been reset using document.open().

If the responsible event loop is not a window event loop, then the environment settings
An API URL character encoding

A character encoding used to encode URLs by APIs called by scripts that use this environment settings object.

An API base URL

A URL used by APIs called by scripts that use this environment settings object to parse URLs.

An origin

An origin used in security checks.

A policy container

A policy container containing policies used for security checks.

A cross-origin isolated capability

A boolean representing whether scripts that use this environment settings object are allowed to use APIs that require cross-origin isolation.

An environment settings object also has an outstanding rejected promises weak set and an about-to-be-notified rejected promises list, used to track unhandled promise rejections. The outstanding rejected promises weak set must not create strong references to any of its members, and implementations are free to limit its size, e.g. by removing old entries from it when new ones are added.

An environment settings object’s responsible event loop is its global object’s relevant agent’s event loop.

8.1.3.3 Realms, settings objects, and global objects

A global object is a JavaScript object that is the [[GlobalObject]] field of a JavaScript realm.

In this specification, all JavaScript realms are created with global objects that are either Window or WorkerGlobalScope objects.

There is always a 1-to-1-to-1 mapping between JavaScript realms, global objects, and environment settings objects:

- A JavaScript realm has a [[HostDefined]] field, which contains the Realm’s settings object.
- A JavaScript realm has a [[GlobalObject]] field, which contains the Realm’s global
• Each **global object** in this specification is created during the **creation** of a corresponding **JavaScript realm**, known as the **global object’s Realm**.

• Each **global object** in this specification is created alongside a corresponding **environment settings object**, known as its **relevant settings object**.

• An **environment settings object’s realm execution context**’s Realm component is the **environment settings object’s Realm**.

• An **environment settings object’s Realm** then has a **[[GlobalObject]]** field, which contains the **environment settings object’s global object**.

To create a **new JavaScript realm** in an **agent** agent, optionally with instructions to create a global object or a global **this** binding (or both), the following steps are taken:

1. Perform **InitializeHostDefinedRealm()** with the provided customizations for creating the global object and the global **this** binding.

2. Let **realm execution context** be the **running JavaScript execution context**.

   This is the **JavaScript execution context** created in the previous step.

3. Remove **realm execution context** from the **JavaScript execution context stack**.

4. Let **realm** be **realm execution context’s Realm component**.

5. Set **realm’s agent** to **agent**. This pointer is not yet defined in the JavaScript specification; see [tc39/ecma262#1357](#1357).

6. If **agent’s agent cluster’s cross-origin isolation mode** is **“none”**, then:

   1. Let **global** be **realm’s global object**.

   2. Let **status** be ![global][Delete](*SharedArrayBuffer*).

   3. Assert: **status** is true.

   This is done for compatibility with web content and there is some hope that this can be removed in the future. Web developers can still get at the constructor through **new WebAssembly.Memory({ shared: true, initial: 0, maximum: 0 }).buffer.constructor**.

7. Return **realm execution context**.

When defining algorithm steps throughout this specification, it is often important to indicate
what JavaScript realm is to be used—or, equivalently, what global object or environment settings object is to be used. In general, there are at least four possibilities:

**Entry**
This corresponds to the script that initiated the currently running script action: i.e., the function or script that the user agent called into when it called into author code.

**Incumbent**
This corresponds to the most-recently-entered author function or script on the stack, or the author function or script that originally scheduled the currently-running callback.

**Current**
This corresponds to the currently-running function object, including built-in user-agent functions which might not be implemented as JavaScript. (It is derived from the current JavaScript realm.)

**Relevant**
Every platform object has a relevant Realm, which is roughly the JavaScript realm in which it was created. When writing algorithms, the most prominent platform object whose relevant Realm might be important is the this value of the currently-running function object. In some cases, there can be other important relevant Realms, such as those of any arguments.

Note how the entry, incumbent, and current concepts are usable without qualification, whereas the relevant concept must be applied to a particular platform object.

The incumbent and entry concepts should not be used by new specifications, as they are excessively complicated and unintuitive to work with. We are working to remove almost all existing uses from the platform: see issue #1430 for incumbent, and issue #1431 for entry.

In general, web platform specifications should use the relevant concept, applied to the object being operated on (usually the this value of the current method). This mismatches the JavaScript specification, where current is generally used as the default (e.g. in determining the JavaScript realm whose Array constructor should be used to construct the result in Array.prototype.map). But this inconsistency is so embedded in the platform that we have to accept it going forward.

Consider the following pages, with a.html being loaded in a browser window, b.html being loaded in an iframe as shown, and c.html and d.html omitted (they can simply be empty documents):

```html
<!doctype html>
<html lang="en">
<title>Entry page</title>

<iframe src="b.html"></iframe>
<button onclick="frames[0].hello()">Hello</button>
```
Each page has its own browsing context, and thus its own JavaScript realm, global object, and environment settings object.

When the `print()` method is called in response to pressing the button in `a.html`, then:

- The **entry Realm** is that of `a.html`.
- The **incumbent Realm** is that of `b.html`.
- The **current Realm** is that of `c.html` (since it is the `print()` method from `c.html` whose code is running).
- The **relevant Realm** of the object on which the `print()` method is being called is that of `d.html`.

One reason why the **relevant** concept is generally a better default choice than the **current** concept is that it is more suitable for creating an object that is to be persisted and returned multiple times. For example, the `navigator.getBattery()` method creates promises in the relevant Realm for the `Navigator` object on which it is invoked. This has the following impact: [BATTERY]
console.log(promise instanceof Promise); // logs false
console.log(promise instanceof frames[0].Promise); // logs true
frames[0].hello();
</script>
</iframe>

<!-- inner.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant Realm demo: inner page</title>
<script>
function hello() {
    const promise = navigator.getBattery();

    console.log(promise instanceof Promise); // logs true
    console.log(promise instanceof parent.Promise); // logs false
}
</script>

If the algorithm for the `getBattery()` method had instead used the current Realm, all the results would be reversed. That is, after the first call to `getBattery()` in outer.html, the Navigator object in inner.html would be permanently storing a Promise object created in outer.html’s JavaScript realm, and calls like that inside the hello() function would thus return a promise from the “wrong” realm. Since this is undesirable, the algorithm instead uses the relevant Realm, giving the sensible results indicated in the comments above.

The rest of this section deals with formally defining the entry, incumbent, current, and relevant concepts.

8.1.3.3.1 Entry

The process of calling scripts will push or pop realm execution contexts onto the JavaScript execution context stack, interspersed with other execution contexts.

With this in hand, we define the entry execution context to be the most recently pushed item in the JavaScript execution context stack that is a realm execution context. The entry Realm is the entry execution context’s Realm component.

Then, the entry settings object is the environment settings object of the entry Realm.

Similarly, the entry global object is the global object of the entry Realm.
8.1.3.2 Incumbent

All JavaScript execution contexts must contain, as part of their code evaluation state, a skip-when-determining-incumbent counter value, which is initially zero. In the process of preparing to run a callback and cleaning up after running a callback, this value will be incremented and decremented.

Every event loop has an associated backup incumbent settings object stack, initially empty. Roughly speaking, it is used to determine the incumbent settings object when no author code is on the stack, but author code is responsible for the current algorithm having been run in some way. The process of preparing to run a callback and cleaning up after running a callback manipulate this stack. [WEBIDL]

When Web IDL is used to invoke author code, or when HostEnqueuePromiseJob invokes a promise job, they use the following algorithms to track relevant data for determining the incumbent settings object:

To prepare to run a callback with an environment settings object settings:

1. Push settings onto the backup incumbent settings object stack.
2. Let context be the topmost script-having execution context.
3. If context is not null, increment context's skip-when-determining-incumbent counter.

To clean up after running a callback with an environment settings object settings:

1. Let context be the topmost script-having execution context.
   This will be the same as the topmost script-having execution context inside the corresponding invocation of prepare to run a callback.
2. If context is not null, decrement context's skip-when-determining-incumbent counter.
3. Assert: the topmost entry of the backup incumbent settings object stack is settings.
4. Remove settings from the backup incumbent settings object stack.

Here, the topmost script-having execution context is the topmost entry of the JavaScript execution context stack that has a non-null ScriptOrModule component, or null if there is no such entry in the JavaScript execution context stack.

With all this in place, the incumbent settings object is determined as follows:

1. Let context be the topmost script-having execution context.
2. If context is null, or if context's skip-when-determining-incumbent counter is greater than zero, then:
1. Assert: the **backup incumbent settings object stack** is not empty.

   This assert would fail if you try to obtain the **incumbent settings object** from inside an algorithm that was triggered neither by **calling scripts** nor by Web IDL **invoking** a callback. For example, it would trigger if you tried to obtain the **incumbent settings object** inside an algorithm that ran periodically as part of the **event loop**, with no involvement of author code. In such cases the **incumbent** concept cannot be used.

2. Return the topmost entry of the **backup incumbent settings object stack**.

3. Return *context*'s Realm component’s **settings object**.

Then, the **incumbent Realm** is the **Realm** of the **incumbent settings object**.

Similarly, the **incumbent global object** is the **global object** of the **incumbent settings object**.

The following series of examples is intended to make it clear how all of the different mechanisms contribute to the definition of the **incumbent** concept:

Consider the following starter example:

```html
<!DOCTYPE html>
<iframe></iframe>
<script>
  frames[0].postMessage("some data", "*");
</script>
```

There are two interesting **environment settings objects** here: that of **window**, and that of **frames[0]**. Our concern is: what is the **incumbent settings object** at the time that the algorithm for **postMessage()** executes?

It should be that of **window**, to capture the intuitive notion that the author script responsible for causing the algorithm to happen is executing in **window**, not **frames[0]**. This makes sense: the **window post message steps** use the **incumbent settings object** to determine the **source** property of the resulting **MessageEvent**, and in this case **window** is definitely the source of the message.

Let us now explain how the steps given above give us our intuitively-desired result of **window**'s **relevant settings object**.

When the **window post message steps** look up the **incumbent settings object**, the topmost script-having execution context will be that corresponding to the **script** element: it was pushed onto the JavaScript execution context stack as part of **ScriptEvaluation** during the **run a classic script** algorithm. Since there are no Web IDL callback invocations involved, the context’s **skip-when-determining-incumbent counter** is zero, so it is used to determine the **incumbent settings**
object; the result is the environment settings object of window.

(Note how the environment settings object of frames[0] is the relevant settings object of this at the time the postMessage() method is called, and thus is involved in determining the target of the message. Whereas the incumbent is used to determine the source.)

Consider the following more complicated example:

```html
<!DOCTYPE html>
<iframe></iframe>
<script>
  const bound = frames[0].postMessage.bind(frames[0], "some data", "*");
  window.setTimeout(bound);
</script>
```

This example is very similar to the previous one, but with an extra indirection through Function.prototype.bind as well as setTimeout(). But, the answer should be the same: invoking algorithms asynchronously should not change the incumbent concept.

This time, the result involves more complicated mechanisms:

When bound is converted to a Web IDL callback type, the incumbent settings object is that corresponding to window (in the same manner as in our starter example above). Web IDL stores this as the resulting callback value’s callback context.

When the task posted by setTimeout() executes, the algorithm for that task uses Web IDL to invoke the stored callback value. Web IDL in turn calls the above prepare to run a callback algorithm. This pushes the stored callback context onto the backup incumbent settings object stack. At this time (inside the timer task) there is no author code on the stack, so the topmost script-having execution context is null, and nothing gets its skip-when-determining-incumbent counter incremented.

Invoking the callback then calls bound, which in turn calls the postMessage() method of frames[0]. When the postMessage() algorithm looks up the incumbent settings object, there is still no author code on the stack, since the bound function just directly calls the built-in method. So the topmost script-having execution context will be null: the JavaScript execution context stack only contains an execution context corresponding to postMessage(), with no ScriptEvaluation context or similar below it.

This is where we fall back to the backup incumbent settings object stack. As noted above, it will contain as its topmost entry the relevant settings object of window. So that is what is used as the incumbent settings object while executing the postMessage() algorithm.

Consider this final, even more convoluted example:

```html
<!-- a.html -->
<!DOCTYPE html>
```
Again there are two interesting environment settings objects in play: that of a.html, and that of b.html. When the `location.assign()` method triggers the Location-object navigate algorithm, what will be the incumbent settings object? As before, it should intuitively be that of a.html: the click listener was originally scheduled by a.html, so even if something involving b.html causes the listener to fire, the incumbent responsible is that of a.html.

The callback setup is similar to the previous example: when `bound` is converted to a Web IDL callback type, the incumbent settings object is that corresponding to a.html, which is stored as the callback’s callback context.

When the `click()` method is called inside b.html, it dispatches a click event on the button that is inside a.html. This time, when the prepare to run a callback algorithm executes as part of event dispatch, there is author code on the stack; the topmost script-having execution context is that of the onLoad function, whose `skip-when-determining-incumbent counter` gets incremented. Additionally, a.html’s environment settings object (stored as the EventHandler’s callback context) is pushed onto the backup incumbent settings object stack.

Now, when the Location-object navigate algorithm looks up the incumbent settings object, the topmost script-having execution context is still that of the onLoad function (due to the fact we are using a bound function as the callback). Its `skip-when-determining-incumbent counter` value is one, however, so we fall back to the backup incumbent settings object stack. This gives us the environment settings object of a.html, as expected.

Note that this means that even though it is the iframe inside a.html that navigates, it is a.html itself that is used as the source browsing context, which determines among other things the request client. This is perhaps the only justifiable use of the incumbent concept on the web platform; in all other cases the consequences of using it are simply confusing and we hope to one day switch them to use current or relevant as appropriate.
The JavaScript specification defines the **current Realm Record**, sometimes abbreviated to the "current Realm". [JAVASCRIPT]

Then, the current settings object is the environment settings object of the current Realm Record.

Similarly, the current global object is the global object of the current Realm Record.

**8.1.3.3.4 Relevant**

The relevant Realm for a platform object is the value of its [[Realm]] field.

Then, the relevant settings object for a platform object o is the environment settings object of the relevant Realm for o.

Similarly, the relevant global object for a platform object o is the global object of the relevant Realm for o.

**8.1.3.4 Enabling and disabling scripting**

*Scripting is enabled* for an environment settings object settings when all of the following conditions are true:

- The user agent supports scripting.
- The user has not disabled scripting for settings at this time. (User agents may provide users with the option to disable scripting globally, or in a finer-grained manner, e.g., on a per-origin basis, down to the level of individual environment settings objects.)
- Either settings's global object is not a Window object, or settings's global object’s associated Document’s active sandboxing flag set does not have its sandboxed scripts browsing context flag set.

*Scripting is disabled* for an environment settings object when scripting is not enabled for it, i.e., when any of the above conditions are false.

---

*Scripting is enabled* for a node node if node’s node document’s browsing context is non-null, and scripting is enabled for node’s relevant settings object.

*Scripting is disabled* for a node when scripting is not enabled, i.e., when its node document’s browsing context is null or when scripting is disabled for its relevant settings object.
8.1.3.5 Secure contexts

An environment is a secure context if the following algorithm returns true:

1. If environment is an environment settings object, then:
   1. Let global be environment’s global object.
   2. If global is a WorkerGlobalScope, then:
      1. If global’s owner set[0]’s relevant settings object is a secure context, then return true.
      We only need to check the 0th item since they will necessarily all be consistent.
      2. Return false.
   3. If global is a WorkletGlobalScope, then return true.

   Worklets can only be created in secure contexts.

2. If the result of Is url potentially trustworthy? given environment’s top-level creation URL is “Potentially Trustworthy”, then return true.

3. Return false.

An environment is a non-secure context if it is not a secure context.

8.1.4 Script processing model

8.1.4.1 Scripts

A script is one of three possible structs. All scripts have:

A settings object

An environment settings object, containing various settings that are shared with other scripts in the same context.

A record

One of the following:

- a script record, for classic scripts;
- a Source Text Module Record, for JavaScript module scripts;
• a Synthetic Module Record, for CSS module scripts and JSON module scripts

• null, representing a parsing failure.

A parse error

A JavaScript value, which has meaning only if the record is null, indicating that the corresponding script source text could not be parsed.

This value is used for internal tracking of immediate parse errors when creating scripts, and is not to be used directly. Instead, consult the error to rethrow when determining "what went wrong" for this script.

An error to rethrow

A JavaScript value representing an error that will prevent evaluation from succeeding. It will be re-thrown by any attempts to run the script.

This could be the script’s parse error, but in the case of a module script it could instead be the parse error from one of its dependencies, or an error from resolve a module specifier.

Since this exception value is provided by the JavaScript specification, we know that it is never null, so we use null to signal that no error has occurred.

Fetch options

A script fetch options, containing various options related to fetching this script or module scripts that it imports.

A base URL

A base URL used for resolving module specifiers. This will either be the URL from which the script was obtained, for external scripts, or the document base URL of the containing document, for inline scripts.

A classic script is a type of script that has the following additional item:

A muted errors boolean

A boolean which, if true, means that error information will not be provided for errors in this script. This is used to mute errors for cross-origin scripts, since that can leak private information.

A module script is another type of script. It has no additional items.

Module scripts can be classified into three types:

• A module script is a JavaScript module script if its record is a Source Text Module Record.
• A **module script** is a *CSS module script* if its **record** is a **Synthetic Module Record**, and it was created via the **create a CSS module script** algorithm. CSS module scripts represent a parsed CSS stylesheet.

• A **module script** is a *JSON module script* if its **record** is a **Synthetic Module Record**, and it was created via the **create a JSON module script** algorithm. JSON module scripts represent a parsed JSON document.

As CSS stylesheets and JSON documents do not import dependent modules, and do not throw exceptions on evaluation, the **fetch options** and **base URL** of **CSS module scripts** and **JSON module scripts** are always null.

The **active script** is determined by the following algorithm:

1. Let **record** be **GetActiveScriptOrModule**().
2. If **record** is null, return null.
3. Return **record**.[[HostDefined]].

The **active script** concept is so far only used by the **import()** feature, to determine the **base URL** to use for resolving relative module specifiers.

8.1.4.2 Fetching scripts

This section introduces a number of algorithms for fetching scripts, taking various necessary inputs and resulting in **classic** or **module scripts**.

---

**Script fetch options** is a **struct** with the following **items**:

**cryptographic nonce**

The **cryptographic nonce metadata** used for the initial fetch and for fetching any imported modules

**integrity metadata**

The **integrity metadata** used for the initial fetch

**parser metadata**

The **parser metadata** used for the initial fetch and for fetching any imported modules

**credentials mode**

The **credentials mode** used for the initial fetch (for **module scripts**) and for fetching any imported modules (for both **module scripts** and **classic scripts**).
**referrer policy**

The [referrer policy](#) used for the initial fetch and for fetching any imported modules.

Recall that via the `import()` feature, classic scripts can import module scripts.

The default classic script fetch options are a script fetch options whose cryptographic nonce is the empty string, integrity metadata is the empty string, parser metadata is "not-parser-inserted", credentials mode is "same-origin", and referrer policy is the empty string.

Given a request request and a script fetch options options, we define:

### set up the classic script request

Set request's cryptographic nonce metadata to options's cryptographic nonce, its integrity metadata to options's integrity metadata, its parser metadata to options's parser metadata, and its referrer policy to options's referrer policy.

### set up the module script request

Set request's cryptographic nonce metadata to options's cryptographic nonce, its integrity metadata to options's integrity metadata, its parser metadata to options's parser metadata, its credentials mode to options's credentials mode, and its referrer policy to options's referrer policy.

For any given script fetch options options, the descendant script fetch options are a new script fetch options whose items all have the same values, except for the integrity metadata, which is instead the empty string.

The algorithms below can be customized by optionally supplying a custom perform the fetch hook, which takes a request and an is top-level flag. The algorithm must complete with a response (which may be a network error), either synchronously (when using fetch a classic worker-imported script) or asynchronously (otherwise). The is top-level flag will be set for all classic script fetches, and for the initial fetch when fetching an external module script graph, fetching a module worker script graph, or fetching an import() module script graph, but not for the fetches resulting from import statements encountered throughout the graph.

By default, not supplying the perform the fetch will cause the below algorithms to simply fetch the given request, with algorithm-specific customizations to the request and validations of the resulting response.

To layer your own customizations on top of these algorithm-specific ones, supply a perform the fetch hook that modifies the given request, fetches it, and then performs specific validations of the resulting response (completing with a network error if the validations fail).

The hook can also be used to perform more subtle customizations, such as keeping a cache of responses and avoiding performing a fetch at all.
Service Workers is an example of a specification that runs these algorithms with its own options for the hook. [SW]

Now for the algorithms themselves.

To fetch a classic script given a url, a settings object, some options, a CORS setting, and a character encoding, run these steps. The algorithm will asynchronously complete with either null (on failure) or a new classic script (on success).

1. Let request be the result of creating a potential-CORS request given url, "script", and CORS setting.

2. Set request's client to settings object.

3. Set up the classic script request given request and options.

4. If the caller specified custom steps to perform the fetch, perform them on request, with the is top-level flag set. Return from this algorithm, and when the custom perform the fetch steps complete with response response, run the remaining steps.

   Otherwise, fetch request. Return from this algorithm, and run the remaining steps as part of the fetch’s process response for the response response.

   response can be either CORS-same-origin or CORS-cross-origin. This only affects how error reporting happens.

5. Set response to response’s unsafe response.

6. If response’s type is "error", or response’s status is not an ok status, then asynchronously complete this algorithm with null, and return.

   For historical reasons, this algorithm does not include MIME type checking, unlike the other script-fetching algorithms in this section.

7. If response’s Content Type metadata, if any, specifies a character encoding, and the user agent supports that encoding, then set character encoding to that encoding (ignoring the passed-in value).

8. Let source text be the result of decoding response’s body to Unicode, using character encoding as the fallback encoding.

   The decode algorithm overrides character encoding if the file contains a BOM.

9. Let muted errors be true if response was CORS-cross-origin, and false otherwise.

10. Let script be the result of creating a classic script given source text, settings object, response’s url, options, and muted errors.
11. Asynchronously complete this algorithm with `script`.

To fetch a classic worker script given a `url`, a `fetch client settings object`, a `destination`, and a `script settings object`, run these steps. The algorithm will asynchronously complete with either null (on failure) or a new `classic script` (on success).

1. Let `request` be a new `request` whose `URL` is `url`, `client` is `fetch client settings object`, `destination` is `destination`, `mode` is "same-origin", `credentials mode` is "same-origin", `parser metadata` is "not parser-inserted", and whose `use-URL-credentials flag` is set.

2. If the caller specified custom steps to perform the fetch, perform them on `request`, with the `is top-level` flag set. Return from this algorithm, and when the custom perform the fetch steps complete with `response` response, run the remaining steps.

   Otherwise, `fetch` `request`. Return from this algorithm, and run the remaining steps as part of the fetch’s `process response` for the `response` response.

4. If either of the following conditions are met:
   - `response`’s `type` is "error"; or
   - `response`’s `status` is not an `ok status`,

   then asynchronously complete this algorithm with null, and return.

5. If both of the following conditions are met:
   - `response`’s `url`’s `scheme` is an HTTP(S) scheme; and
   - the result of extracting a MIME type from `response`’s `header list` is not a JavaScript MIME type,

   then asynchronously complete this algorithm with null, and return.

Other fetch schemes are exempted from MIME type checking for historical web-compatibility reasons. We might be able to tighten this in the future; see issue #3255.

6. Let `source text` be the result of UTF-8 decoding `response`’s `body`.

7. Let `script` be the result of creating a classic script using `source text`, `script settings object`, `response`’s `url`, and the default classic script fetch options.

8. Asynchronously complete this algorithm with `script`.

To fetch a classic worker-imported script given a `url` and a `settings object`, run these steps. The
algorithm will synchronously complete with a [classic script](#) on success, or throw an exception on failure.

1. Let `request` be a new `request` whose URL is `url`, `client` is `settings object`, `destination` is "script", `parser metadata` is "not parser-inserted", `synchronous flag` is set, and whose `use-URL-credentials flag` is set.

2. If the caller specified custom steps to [perform the fetch](#), perform them on `request`, with the `is top-level` flag set. Let `response` be the result.

   Otherwise, fetch `request`, and let `response` be the result.

   Unlike other algorithms in this section, the fetching process is synchronous here. Thus any [perform the fetch](#) steps will also finish their work synchronously.

3. Set `response` to `response`'s [unsafe response](#).

4. If any of the following conditions are met:
   * `response`'s `type` is "error";
   * `response`'s `status` is not an [ok status](#);
   * the result of extracting a MIME type from `response`'s header list is not a [JavaScript MIME type](#),

   then throw a "[NetworkError](#)" [DOMException](#).

5. Let `source text` be the result of [UTF-8 decoding](#) `response`'s body.

6. Let `muted errors` be true if `response` was [CORS-cross-origin](#), and false otherwise.

7. Let `script` be the result of [creating a classic script](#) given `source text`, `settings object`, `response`'s `url`, the [default classic script fetch options](#), and `muted errors`.

8. Return `script`.

To [fetch an external module script graph](#) given a `url`, a `settings object`, and some `options`, run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#) (on success).

1. Fetch a single module script given `url`, `settings object`, "script", `options`, `settings object`, "client", and with the `top-level module fetch flag` set. If the caller of this algorithm specified custom [perform the fetch](#) steps, pass those along as well. Wait until the algorithm asynchronously completes with `result`.

2. If `result` is null, asynchronously complete this algorithm with null, and return.
3. Let visited set be « (url, "javascript") ».

4. Fetch the descendants of and link result given settings object, destination, and visited set. When this asynchronously completes with final result, asynchronously complete this algorithm with final result.

To fetch an import() module script graph given a moduleRequest, a base URL, a settings object, and some options, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script (on success).

1. Let url be the result of resolving a module specifier given base URL and moduleRequest.[[Specifier]].

2. If url is failure, then asynchronously complete this algorithm with null, and return.

3. Assert: moduleRequest.[[Assertions]] does not contain any Record entry such that entry.[[Key]] is not "type", because we only asked for "type" assertions in HostGetSupportedImportAssertions.

4. If moduleRequest.[[Assertions]] has a Record entry such that entry.[[Key]] is "type", then let module type be entry.[[Value]]. Otherwise let module type be "javascript".

5. If the result of running the module type allowed steps given module type and settings object is false, then asynchronously complete this algorithm with null, and return.

6. Fetch a single module script given url, settings object, "script", options, settings object, "client", moduleRequest, and with the top-level module fetch flag set. If the caller of this algorithm specified custom perform the fetch steps, pass those along as well. Wait until the algorithm asynchronously completes with result.

7. If result is null, asynchronously complete this algorithm with null, and return.

8. Let visited set be « (url, module type) ».

9. Fetch the descendants of and link result given settings object, destination, and visited set. When this asynchronously completes with final result, asynchronously complete this algorithm with final result.

To fetch a modulepreload module script graph given a url, a destination, a settings object, and some options, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script (on success), although it will perform optional steps even after completing.

1. Fetch a single module script given url, settings object, destination, options, settings object, "client", and with the top-level module fetch flag set. Wait until algorithm asynchronously completes with result.

2. Asynchronously complete this algorithm with result, but do not return.
3. If \( \text{result} \) is not null, optionally perform the following steps:

1. Let \( \text{visited set} \) be « (url, "javascript") ».

2. Fetch the descendants of and link \( \text{result} \) given \textit{settings object}, \textit{destination}, and \textit{visited set}.

Generally, performing these steps will be beneficial for performance, as it allows pre-loading the modules that will invariably be requested later, via algorithms such as \textit{fetch an external module script graph} that fetch the entire graph. However, user agents might wish to skip them in bandwidth-constrained situations, or situations where the relevant fetches are already in flight.

To \textit{fetch an inline module script graph} given a \textit{source text}, \textit{base URL}, \textit{settings object}, and \textit{options}, run these steps. The algorithm will asynchronously complete with either null (on failure) or a \textit{module script} (on success).

1. Let \( \text{script} \) be the result of \textit{creating a JavaScript module script} using \textit{source text}, \textit{settings object}, \textit{base URL}, and \textit{options}.

2. If \( \text{script} \) is null, asynchronously complete this algorithm with null, and return.

3. Let \( \text{visited set} \) be an empty \textit{set}.

4. Fetch the descendants of and link \( \text{script} \), given \textit{settings object}, the destination "script", and \textit{visited set}. When this asynchronously completes with \textit{final result}, asynchronously complete this algorithm with \textit{final result}.

To \textit{fetch a module worker script graph} given a \textit{url}, a \textit{fetch client settings object}, a \textit{destination}, a \textit{credentials mode}, and a \textit{module map settings object}, \textit{fetch a worklet/module worker script graph} given \textit{url}, \textit{fetch client settings object}, \textit{destination}, \textit{credentials mode}, and \textit{module map settings object}, asynchronously completing with the asynchronous completion result of that algorithm.

To \textit{fetch a worklet script graph} given a \textit{url}, a \textit{fetch client settings object}, a \textit{destination}, a \textit{credentials mode}, a \textit{module map settings object}, and a \textit{module responses map}, \textit{fetch a worklet/module worker script graph} given \textit{url}, \textit{fetch client settings object}, \textit{destination}, \textit{credentials mode}, \textit{module map settings object}, and \textit{module responses map}, asynchronously completing with the asynchronous completion result of that algorithm. Use the following custom steps to \textit{perform the fetch} given \textit{response}:

1. Let \( \text{requestURL} \) be request’s \textit{URL}.

2. If \( \text{moduleResponsesMap[requestURL]} \) is "fetching", wait \textbf{in parallel} until that entry’s value changes, then \textit{queue a task} on the \textit{networking task source} to proceed with running the following steps.

3. If \( \text{moduleResponsesMap[requestURL]} \) exists, then asynchronously complete the \textit{perform the fetch} steps with \( \text{moduleResponsesMap[requestURL]} \).
4. Set moduleResponsesMap[requestURL] to “fetching”.

5. Fetch request. To process response for the response response:
   1. Set moduleResponsesMap[requestURL] to response.
   2. Asynchronously complete the perform the fetch steps with response.

The following algorithms are meant for internal use by this specification only as part of fetching an external module script graph or other similar concepts above, and should not be used directly by other specifications.

This diagram illustrates how these algorithms relate to the ones above, as well as to each other:

To fetch a worklet/module worker script graph given a url, a fetch client settings object, a destination, a credentials mode, and a module map settings object, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script (on success).

1. Let options be a script fetch options whose cryptographic nonce is the empty string, integrity metadata is the empty string, parser metadata is "not-parser-inserted", credentials mode is credentials mode, and referrer policy is the empty string.

2. Fetch a single module script given url, fetch client settings object, destination, options, module map settings object, "client", and with the top-level module fetch flag set. If the caller of this algorithm specified custom perform the fetch steps, pass those along as well. Wait until the algorithm asynchronously completes with result.

3. If result is null, asynchronously complete this algorithm with null, and return.

4. Let visited set be « (url, "javascript") ».

5. Fetch the descendants of and link result given fetch client settings object, destination, and visited set. When this asynchronously completes with final result, asynchronously complete this algorithm with final result.

To fetch the descendants of and link a module script module script, given a fetch client settings
object, a destination, and a visited set, run these steps. The algorithm will asynchronously complete with either null (on failure) or with module script (on success).

1. Fetch the descendants of module script, given fetch client settings object, destination, and visited set.

2. Return from this algorithm, and run the following steps when fetching the descendants of a module script asynchronously completes with result.

3. If result is null, then asynchronously complete this algorithm with result.

   In this case, there was an error fetching one or more of the descendants. We will not attempt to link.

4. Let parse error be the result of finding the first parse error given result.

5. If parse error is null, then:

   1. Let record be result's record.

   2. Perform record.Link().

      This step will recursively call Link on all of the module’s unlinked dependencies.

      If this throws an exception, set result's error to rethrow to that exception.

6. Otherwise, set result's error to rethrow to parse error.

7. Asynchronously complete this algorithm with result.

To fetch the descendants of a module script module script, given a fetch client settings object, a destination, and a visited set, run these steps. The algorithm will asynchronously complete with either null (on failure) or with module script (on success).

1. If module script’s record is null, then asynchronously complete this algorithm with module script and return.

2. Let record be module script’s record.

3. If record is not a Cyclic Module Record, or if record.[[RequestedModules]] is empty, asynchronously complete this algorithm with module script.

4. Let moduleRequests be a new empty list.

5. For each ModuleRequest Record requested of record.[[RequestedModules]],

   1. Let url be the result of resolving a module specifier given module script’s base URL and requested.[[Specifier]].
2. Assert: url is never failure, because resolving a module specifier must have been previously successful with these same two arguments.

3. If requested.[[Assertions]] has a Record entry such that entry.[[Key]] is "type", then let module type be entry.[[Value]]. Otherwise let module type be "javascript".

4. If visited set does not contain (url, module type), then:
   1. Append requested to moduleRequests.
   2. Append (url, module type) to visited set.

6. Let options be the descendant script fetch options for module script's fetch options.

7. Assert: options is not null, as module script is a JavaScript module script.

8. For each moduleRequest in moduleRequests, perform the internal module script graph fetching procedure given moduleRequest, fetch client settings object, destination, options, module script's settings object, visited set, and module script's base URL. If the caller of this algorithm specified custom perform the fetch steps, pass those along while performing the internal module script graph fetching procedure.

These invocations of the internal module script graph fetching procedure should be performed in parallel to each other.

If any of the invocations of the internal module script graph fetching procedure asynchronously complete with null, asynchronously complete this algorithm with null, and return.

Otherwise, wait until all of the internal module script graph fetching procedure invocations have asynchronously completed. Asynchronously complete this algorithm with module script.

To perform the internal module script graph fetching procedure given a moduleRequest, a fetch client settings object, a destination, some options, a module map settings object, a visited set, and a referrer, perform these steps. The algorithm will asynchronously complete with either null (on failure) or a module script (on success).

1. Let url be the result of resolving a module specifier given referrer and moduleRequest.[[Specifier]].

2. Assert: url is never failure, because resolving a module specifier must have been previously successful with these same two arguments.

3. If moduleRequest.[[Assertions]] has a Record entry such that entry.[[Key]] is “type”, then let module type be entry.[[Value]]. Otherwise let module type be "javascript".
4. Assert: \texttt{visited set contains} (\texttt{url}, \texttt{module type}).

5. \textbf{Fetch a single module script} given \texttt{url}, \texttt{fetch client settings object}, \texttt{destination}, \texttt{options}, \texttt{module map settings object}, \texttt{referrer}, \texttt{moduleRequest}, and with the top-level module \texttt{fetch flag} unset. If the caller of this algorithm specified custom \texttt{perform the fetch} steps, pass those along while \texttt{fetching a single module script}.

6. Return from this algorithm, and run the following steps when \texttt{fetching a single module script} asynchronously completes with \texttt{result}:

7. If \texttt{result} is null, asynchronously complete this algorithm with null, and return.

8. \textbf{Fetch the descendants of} \texttt{result} given \texttt{fetch client settings object}, \texttt{destination}, and \texttt{visited set}.

9. When the appropriate algorithm asynchronously completes with \texttt{final result}, asynchronously complete this algorithm with \texttt{final result}.

To \textit{fetch a single module script}, given a \texttt{url}, a \texttt{fetch client settings object}, a \texttt{destination}, some \texttt{options}, a \texttt{module map settings object}, a \texttt{referrer}, an optional \texttt{moduleRequest}, and a \texttt{top-level module fetch flag}, run these steps. The algorithm will asynchronously complete with either null (on failure) or a \texttt{module script} (on success).

1. Let \texttt{module type} be \textquote{javascript}.

2. If \texttt{moduleRequest} was given and \texttt{moduleRequest.[[Assertions]]} has a \texttt{Record} entry such that \texttt{entry.[[Key]]} is \textquote{type}, then:
   
   1. Assert: No more than one such \texttt{Record} exists.
   
   2. Set \texttt{module type} to \texttt{entry.[[Value]]}.

3. Assert: the result of running the \texttt{module type allowed} steps given \texttt{module type} and \texttt{module map settings object} is true. Otherwise we would not have reached this point because a failure would have been raised when inspecting \texttt{moduleRequest.[[Assertions]]} in \textit{create a JavaScript module script} or \textit{fetch an import()} module script graph.

4. Let \texttt{moduleMap} be \texttt{module map settings object}'s \texttt{module map}.

5. If \texttt{moduleMap([url, module type])} is \textquote{fetching}, wait \texttt{in parallel} until that entry’s value changes, then \texttt{queue a task} on the \texttt{networking task source} to proceed with running the following steps.

6. If \texttt{moduleMap([url, module type]) exists}, asynchronously complete this algorithm with \texttt{moduleMap[url / module type]}, and return.

7. Set \texttt{moduleMap([url, module type])} to \textquote{fetching}.
8. Let request be a new request whose URL is url, destination is destination, mode is "cors", referer is referer, and client is fetch client settings object.

9. If destination is "worker", "sharedworker", or "serviceworker", and the top-level module fetch flag is set, then set request's mode to "same-origin".

10. Set up the module script request given request and options.

11. If the caller specified custom steps to perform the fetch, perform them on request, setting the is top-level flag if the top-level module fetch flag is set. Return from this algorithm, and when the custom perform the fetch steps complete with response response, run the remaining steps. Otherwise, fetch request. Return from this algorithm, and run the remaining steps as part of the fetch's process response for the response response. response is always CORS-same-origin.

12. If either of the following conditions are met:
   ○ response's type is "error"; or
   ○ response's status is not an ok status.

   then set moduleMap[(url, module type)] to null, asynchronously complete this algorithm with null, and return.

13. Let source text be the result of UTF-8 decoding response's body.

14. Let MIME type be the result of extracting a MIME type from response's header list.

15. Let module script be null.

16. If MIME type is a JavaScript MIME type and module type is "javascript", then set module script to the result of creating a JavaScript module script given source text, module map settings object, response's url, and options.

17. If the MIME type essence of MIME type is "text/css" and module type is "css", then set module script to the result of creating a CSS module script given source text and module map settings object.

18. If MIME type essence is a JSON MIME type and module type is "json", then set module script to the result of creating a JSON module script given source text and module map settings object.

19. Set moduleMap[(url, module type)] to module script, and asynchronously complete this algorithm with module script.
It is intentional that the module map is keyed by the request URL, whereas the base URL for the module script is set to the response URL. The former is used to deduplicate fetches, while the latter is used for URL resolution.

To find the first parse error given a root moduleScript and an optional discoveredSet:

1. Let moduleMap be moduleScript's settings object's module map.
2. If discoveredSet was not given, let it be an empty set.
3. Append moduleScript to discoveredSet.
4. If moduleScript's record is null, then return moduleScript's parse error.
5. If moduleScript's record is not a Cyclic Module Record, then return null.
6. Let moduleRequests be the value of moduleScript's record's [[RequestedModules]] internal slot.
7. For each moduleRequest of moduleRequests:
   1. Let childURL be the result of resolving a module specifier given moduleScript's base URL and moduleRequest.[[Specifier]]. (This will never fail, as otherwise moduleScript would have been marked as itself having a parse error.)
   2. If moduleRequest.[[Assertions]] has a Record entry such that entry.[[Key]] is "type", then let module type be entry.[[Value]]. Otherwise let module type be "javascript".
   3. Let childModule be moduleMap[(childURL, module type)].
   4. Assert: childModule is a module script (i.e., it is not "fetching" or null); by now all module scripts in the graph rooted at moduleScript will have successfully been fetched.
   5. If discoveredSet already contains childModule, continue.
   6. Let childParseError be the result of finding the first parse error given childModule and discoveredSet.
   7. If childParseError is not null, return childParseError.
8. Return null.

8.1.4.3 Creating scripts

To create a classic script, given a string source, an environment settings object settings, a URL baseURL, some script fetch options options, and an optional muted errors boolean:
1. If \textit{muted errors} was not provided, let it be false.

2. If \textit{muted errors} is true, then set \textit{baseURL} to \texttt{about:blank}.

   When \textit{muted errors} is true, \textit{baseURL} is the script’s CORS-cross-origin response’s \texttt{url}, which shouldn’t be exposed to JavaScript. Therefore, \textit{baseURL} is sanitized here.

3. If \textit{scripting is disabled} for \textit{settings}, then set \textit{source} to the empty string.

4. Let \textit{script} be a new \texttt{classic script} that this algorithm will subsequently initialize.

5. Set \textit{script’s} \texttt{settings object} to \textit{settings}.

6. Set \textit{script’s} base URL to \textit{baseURL}.

7. Set \textit{script’s} \texttt{fetch options} to \textit{options}.

8. Set \textit{script’s} \texttt{muted errors} to \textit{muted errors}.

9. Set \textit{script’s} \texttt{parse error} and \texttt{error to rethrow} to null.

10. Let \textit{result} be \texttt{ParseScript}(\textit{source}, \textit{settings’s} \texttt{Realm}, \textit{script}).

    Passing \textit{script} as the last parameter here ensures \textit{result}.[[HostDefined]] will be \textit{script}.

11. If \textit{result} is a list of errors, then:

    1. Set \textit{script’s} \texttt{parse error} and its \texttt{error to rethrow} to \textit{result}[0].

    2. Return \textit{script}.

12. Set \textit{script’s} record to \textit{result}.

13. Return \textit{script}.

To create a \textit{JavaScript module script}, given a string \textit{source}, an \textit{environment settings object} \textit{settings}, a URL \textit{baseURL}, and some \textit{script fetch options} \textit{options}:

1. If \textit{scripting is disabled} for \textit{settings}, then set \textit{source} to the empty string.

2. Let \textit{script} be a new \texttt{module script} that this algorithm will subsequently initialize.

3. Set \textit{script’s} \texttt{settings object} to \textit{settings}.

4. Set \textit{script’s} base URL to \textit{baseURL}.

5. Set \textit{script’s} \texttt{fetch options} to \textit{options}.
6. Set script’s parse error and error to rethrow to null.

7. Let result be ParseModule(source, settings's Realm, script).

   Passing script as the last parameter here ensures result.[[HostDefined]] will be script.

8. If result is a list of errors, then:
   1. Set script’s parse error to result[0].
   2. Return script.

9. Assert: requested.[[Assertions]] does not contain any Record entry such that entry.[[Key]] is not "type", because we only asked for "type" assertions in HostGetSupportedImportAssertions.

10. For each ModuleRequest record requested of result.[[RequestedModules]]:
    1. Let url be the result of resolving a module specifier given script's base URL and requested.[[Specifier]].
    2. If requested.[[Assertions]] has a Record entry such that entry.[[Key]] is "type", then let module type be entry.[[Value]]. Otherwise let module type be "javascript".
    3. If url is failure, or if the result of running the module type allowed steps given module type and settings is false, then:
       1. Let error be a new TypeError exception.
       2. Set script’s parse error to error.
       3. Return script.

This step is essentially validating all of the requested module specifiers and type assertions. We treat a module with unresolvable module specifiers or unsupported type assertions the same as one that cannot be parsed; in both cases, a syntactic issue makes it impossible to ever contemplate linking the module later.

11. Set script’s record to result.

12. Return script.

To create a CSS module script, given a string source and an environment settings object settings:

1. Let script be a new module script that this algorithm will subsequently initialize.
2. Set script’s settings object to settings.

3. Set script’s base URL and fetch options to null.

4. Set script’s parse error and error to rethrow to null.

5. Let sheet be the result of running the steps to create a constructed CSSStyleSheet with an empty dictionary as the argument.

6. Run the steps to synchronously replace the rules of a CSSStyleSheet on sheet given source.

   If this throws an exception, set script’s parse error to that exception, and return script.

   The steps to synchronously replace the rules of a CSSStyleSheet will throw if source contains any @import rules. This is by-design for now because there is not yet an agreement on how to handle these for CSS module scripts; therefore they are blocked altogether until a consensus is reached.

7. Set script’s record to the result of CreateDefaultExportSyntheticModule(sheet).

8. Return script.

To create a JSON module script, given a string source and an environment settings object settings:

1. Let script be a new module script that this algorithm will subsequently initialize.

2. Set script’s settings object to settings.

3. Set script’s base URL and fetch options to null.

4. Set script’s parse error and error to rethrow to null.

5. Let result be ParseJSONModule(source).

   If this throws an exception, set script’s parse error to that exception, and return script.

6. Set script’s record to result.

7. Return script.

The module type allowed steps, given a string module type and an environment settings object settings, are as follows:

1. If module type is not “javascript”, “css”, or “json”, then return false.

2. If module type is “css” and the CSSStyleSheet interface is not exposed in setting’s
3. Return true.

8.1.4.4 Calling scripts

To run a classic script given a classic script script and an optional boolean rethrow errors (default false):

1. Let settings be the settings object of script.
2. Check if we can run script with settings. If this returns "do not run" then return NormalCompletion(empty).
3. Prepare to run script given settings.
4. Let evaluationStatus be null.
5. If script’s error to rethrow is not null, then set evaluationStatus to Completion {
   [[Type]$: throw, [[Value]$: script’s error to rethrow, [[Target]$: empty }
6. Otherwise, set evaluationStatus to ScriptEvaluation(script’s record).
   If ScriptEvaluation does not complete because the user agent has aborted the running script, leave evaluationStatus as null.
7. If evaluationStatus is an abrupt completion, then:
   1. If rethrow errors is true and script’s muted errors is false, then:
      1. Clean up after running script with settings.
      2. Rethrow evaluationStatus.[[Value]].
   2. If rethrow errors is true and script’s muted errors is true, then:
      1. Clean up after running script with settings.
      2. Throw a "NetworkError" DOMException.
   3. Otherwise, rethrow errors is false. Perform the following steps:
      1. Report the exception given by evaluationStatus.[[Value]] for script.
      2. Clean up after running script with settings.
      3. Return evaluationStatus.
8. Clean up after running script with settings.

9. If evaluationStatus is a normal completion, then return evaluationStatus.

10. If we’ve reached this point, evaluationStatus was left as null because the script was aborted prematurely during evaluation. Return Completion { [[Type]]: throw, [[Value]]: a new “QuotaExceededError” DOMException, [[Target]]: empty }.

To run a module script given a module script script and an optional boolean preventErrorReporting (default false):

1. Let settings be the settings object of script.

2. Check if we can run script with settings. If this returns “do not run”, then return a promise resolved with undefined.

3. Prepare to run script given settings.

4. Let evaluationPromise be null.

5. If script’s error to rethrow is not null, then set evaluationPromise to a promise rejected with script’s error to rethrow.

6. Otherwise:

   1. Let record be script’s record.

   2. Set evaluationPromise to record.Evaluate().

      This step will recursively evaluate all of the module’s dependencies.

      If Evaluate fails to complete as a result of the user agent aborting the running script, then set evaluationPromise to a promise rejected with a new “QuotaExceededError” DOMException.

7. If preventErrorReporting is false, then upon rejection of evaluationPromise with reason, report the exception given by reason for script.

8. Clean up after running script with settings.

9. Return evaluationPromise.

The steps to check if we can run script with an environment settings object settings are as follows. They return either “run” or “do not run”.

1. If the global object specified by settings is a Window object whose Document object is not fully active, then return “do not run”.

   ```
2. If scripting is disabled for settings, then return "do not run".

3. Return "run".

The steps to prepare to run script with an environment settings object settings are as follows:

1. Push settings's realm execution context onto the JavaScript execution context stack; it is now the running JavaScript execution context.

2. Add settings to the currently running task's script evaluation environment settings object set.

The steps to clean up after running script with an environment settings object settings are as follows:

1. Assert: settings's realm execution context is the running JavaScript execution context.

2. Remove settings's realm execution context from the JavaScript execution context stack.

3. If the JavaScript execution context stack is now empty, perform a microtask checkpoint. (If this runs scripts, these algorithms will be invoked reentrantly.)

These algorithms are not invoked by one script directly calling another, but they can be invoked reentrantly in an indirect manner, e.g. if a script dispatches an event which has event listeners registered.

The running script is the script in the [[HostDefined]] field in the ScriptOrModule component of the running JavaScript execution context.

8.1.4.5 Killing scripts

Although the JavaScript specification does not account for this possibility, it’s sometimes necessary to abort a running script. This causes any ScriptEvaluation or Source Text Module Record Evaluate invocations to cease immediately, emptying the JavaScript execution context stack without triggering any of the normal mechanisms like finally blocks. [JAVASCRIPT]

User agents may impose resource limitations on scripts, for example CPU quotas, memory limits, total execution time limits, or bandwidth limitations. When a script exceeds a limit, the user agent may either throw a QuotaExceededError DOMException, abort the script without an exception, prompt the user, or throttle script execution.

For example, the following script never terminates. A user agent could, after waiting for a few seconds, prompt the user to either terminate the script or let it continue.

```html
<script>
  while (true) { /* loop */ }
</script>
```
User agents are encouraged to allow users to disable scripting whenever the user is prompted either by a script (e.g. using the `window.alert()` API) or because of a script’s actions (e.g. because it has exceeded a time limit).

If scripting is disabled while a script is executing, the script should be terminated immediately.

User agents may allow users to specifically disable scripts just for the purposes of closing a browsing context.

For example, the prompt mentioned in the example above could also offer the user with a mechanism to just close the page entirely, without running any `unload` event handlers.

8.1.4.6 Runtime script errors

`self.reportError(e)`

Dispatches an `error` event at the global object for the given value `e`, in the same fashion as an unhandled exception.

When the user agent is required to `report an error` for a particular `script` with a particular position `line:col`, using a particular target `target`, it must run these steps, after which the error is either `handled` or `not handled`:

1. If `target` is in error reporting mode, then return; the error is `not handled`.

2. Let `target` be in error reporting mode.

   (This is a tracking vector.)

3. Let `message` be an implementation-defined string describing the error in a helpful manner.

4. Let `errorValue` be the value that represents the error: in the case of an uncaught exception, that would be the value that was thrown; in the case of a JavaScript error that would be an `Error` object. If there is no corresponding value, then the null value must be used instead.

5. Let `urlString` be the result of applying the `URL serializer` to the `URL record` that corresponds to the resource from which `script` was obtained.

The resource containing the script will typically be the file from which the `Document` was parsed, e.g. for inline `script` elements or `event handler content attributes`; or the JavaScript file that the script was in, for external scripts. Even for dynamically-generated scripts, user agents are strongly encouraged to attempt to keep track of the original source of a script. For example, if an external script uses the `document.write()` API to insert an inline `script` element during parsing, the URL of the resource containing the script would ideally be reported as being the external
script, and the line number might ideally be reported as the line with the `document.write()` call or where the string passed to that call was first constructed. Naturally, implementing this can be somewhat non-trivial.

User agents are similarly encouraged to keep careful track of the original line numbers, even in the face of `document.write()` calls mutating the document as it is parsed, or event handler content attributes spanning multiple lines.

6. If `script`'s muted errors is true, then set `message` to "Script error.", `urlString` to the empty string, `line` and `col` to 0, and `errorValue` to null.

7. Let `notHandled` be true.

8. If `target` implements `EventTarget`, then set `notHandled` to the result of firing an event named `error` at `target`, using `ErrorEvent`, with the `cancelable` attribute initialized to true, the `message` attribute initialized to `message`, the `filename` attribute initialized to `urlString`, the `lineno` attribute initialized to `line`, the `colno` attribute initialized to `col`, and the `error` attribute initialized to `errorValue`.

9. Let `target` no longer be in error reporting mode.

10. If `notHandled` is false, then the error is handled. Otherwise, the error is not handled.

Returning true in an event handler cancels the event per the event handler processing algorithm.

When the user agent is to report an exception `E`, the user agent must report the error for the relevant `script`, with the problematic position (line number and column number) in the resource containing the script, using the global object specified by the script's settings object as the target. If the error is still not handled after this, then the error may be reported to a developer console.

The existence of both report an error and report an exception is confusing, and both algorithms have known problems. You can track future cleanup in this area in issue #958.

The `reportError(e)` method steps are to report the exception `e`.

✔️ MDN

`ErrorEvent`

Support in all current engines.

Firefox 30+ Safari 6+ Chrome 10+
Opera 11+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 30+ Safari iOS 6+ Chrome Android 18+ WebView Android 37+ Samsung
The **ErrorEvent** interface is defined as follows:

```javascript
[Exposed=(Window, Worker)]
interface ErrorEvent : Event {
    constructor(DOMString type, optional ErrorEventInit eventInitDict = {});

    readonly attribute DOMString message;
    readonly attribute USVString filename;
    readonly attribute unsigned long lineno;
    readonly attribute unsigned long colno;
    readonly attribute any error;
};
```

```javascript
dictionary ErrorEventInit : EventInit {
    DOMString message = "";
    USVString filename = "";
    unsigned long lineno = 0;
    unsigned long colno = 0;
    any error = null;
};
```

The **message** attribute must return the value it was initialized to. It represents the error message.

The **filename** attribute must return the value it was initialized to. It represents the URL of the script in which the error originally occurred.

The **lineno** attribute must return the value it was initialized to. It represents the line number where the error occurred in the script.

The **colno** attribute must return the value it was initialized to. It represents the column number where the error occurred in the script.

The **error** attribute must return the value it was initialized to. Where appropriate, it is set to the object representing the error (e.g., the exception object in the case of an uncaught DOM exception).

8.1.4.7 Unhandled promise rejections

[✔ MDN](https://developer.mozilla.org/en-US/docs/Web/API/Window/rejectionhandled_event)

Support in all current engines.
In addition to synchronous runtime script errors, scripts may experience asynchronous promise rejections, tracked via the `unhandledrejection` and `rejectionhandled` events. Tracking these rejections is done via the `HostPromiseRejectionTracker` abstract operation, but reporting them is defined here.

To notify about rejected promises on a given environment settings object:

1. Let `list` be a copy of `settings object`'s about-to-be-notified rejected promises list.
2. If `list` is empty, return.
4. Let `global` be `settings object`'s global object.
5. Queue a global task on the DOM manipulation task source given `global` to run the following substep:
   1. For each promise `p` in `list`:
      1. If `p`'s [[PromiseIsHandled]] internal slot is true, continue to the next iteration of the loop.
      2. Let `notHandled` be the result of firing an event named `unhandledrejection` at `global`, using `PromiseRejectionEvent`, with the `cancelable` attribute initialized to true, the `promise` attribute initialized to `p`, and the `reason` attribute initialized to the value of `p`'s [[PromiseResult]] internal slot.
      3. If `notHandled` is false, then the promise rejection is handled. Otherwise, the promise rejection is not handled.
      4. If `p`'s [[PromiseIsHandled]] internal slot is false, add `p` to `settings object`'s outstanding rejected promises weak set.

This algorithm results in promise rejections being marked as handled or not handled. These concepts parallel handled and not handled script errors. If a rejection is still not handled after this, then the rejection may be reported to a developer console.
PromiseRejectionEvent

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 69+ Safari 11+ Chrome 49+</td>
<td>Yes</td>
</tr>

The PromiseRejectionEvent interface is defined as follows:

```javascript
[Exposed=(Window, Worker)]
interface PromiseRejectionEvent : Event {
    constructor (DOMString type, PromiseRejectionEventInit eventInitDict);

    readonly attribute Promise<any> promise;
    readonly attribute any reason;
};
```

### PromiseRejectionEvent/promise

Support in all current engines.

Firefox 69+ Safari 11+ Chrome 49+
Opera 36+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 68+ Safari iOS 11.3+ Chrome Android 49+ WebView Android 49+ Samsung Internet 5.0+ Opera Android 36+

The promise attribute must return the value it was initialized to. It represents the promise which this notification is about.

### PromiseRejectionEvent/reason

Support in all current engines.
The `reason` attribute must return the value it was initialized to. It represents the rejection reason for the promise.

8.1.5 JavaScript specification host hooks

The JavaScript specification contains a number of implementation-defined abstract operations, that vary depending on the host environment. This section defines them for user agent hosts.

8.1.5.1 HostEnsureCanCompileStrings(callerRealm, calleeRealm)

JavaScript contains an implementation-defined HostEnsureCanCompileStrings(callerRealm, calleeRealm) abstract operation. User agents must use the following implementation:

[JAVASCRIPT]

8.1.5.2 HostPromiseRejectionTracker(promise, operation)

JavaScript contains an implementation-defined HostPromiseRejectionTracker(promise, operation) abstract operation. User agents must use the following implementation:

[JAVASCRIPT]

1. Let `script` be the running script.

2. If `script`'s muted errors is true, terminate these steps.

3. Let `settings object` be `script`'s settings object.

4. If `operation` is "reject",

   1. Add `promise` to `settings object`'s about-to-be-notified rejected promises list.

5. If `operation` is "handle",

   1. If `settings object`'s about-to-be-notified rejected promises list contains `promise`, then remove `promise` from that list and return.

   2. If `settings object`'s outstanding rejected promises weak set does not contain `promise`, then return.

   3. Remove `promise` from `settings object`'s outstanding rejected promises weak set.
4. Let global be settings object’s global object.

5. Queue a global task on the DOM manipulation task source given global to fire an event named rejectionhandled at global, using PromiseRejectionEvent, with the promise attribute initialized to promise, and the reason attribute initialized to the value of promise’s [[PromiseResult]] internal slot.

8.1.5.3 Job-related host hooks

Reference/Global_Objects/Promise#Incumbent_settings_object_tracking

Support in one engine only.

Firefox50+SafariNoChromeNo
OperaNoEdgeNo
Edge (Legacy)NoInternet ExplorerNo
Firefox Android50+Safari iOSNoChrome AndroidNoWebView AndroidNoSamsung InternetNoOpera AndroidNo

The JavaScript specification defines Jobs to be scheduled and run later by the host, as well as JobCallback Records which encapsulate JavaScript functions that are called as part of jobs. The JavaScript specification contains a number of implementation-defined abstract operations that lets the host define how jobs are scheduled and how JobCallbacks are handled. HTML uses these abstract operations to track the incumbent settings object in promises and FinalizationRegistry callbacks by saving and restoring the incumbent settings object and a JavaScript execution context for the active script in JobCallbacks. This section defines them for user agent hosts.

8.1.5.3.1 HostCallJobCallback(callback, V, argumentsList)

JavaScript contains an implementation-defined HostCallJobCallback(callback, V, argumentsList) abstract operation to let hosts restore state when invoking JavaScript callbacks from inside tasks. User agents must use the following implementation: [JAVASCRIPT]

1. Let incumbent settings be callback.[[HostDefined]].[[IncumbentSettings]].

2. Let script execution context be callback.[[HostDefined]].[[ActiveScriptContext]].

3. Prepare to run a callback with incumbent settings.

   This affects the incumbent concept while the callback runs.

4. If script execution context is not null, then push script execution context onto the
JavaScript execution context stack.

This affects the `active script` while the callback runs.

5. Let `result` be `Call(callback.([Callback]), V, argumentsList)`.

6. If `script execution context` is not null, then `pop script execution context` from the JavaScript execution context stack.

7. Clean up after running a callback with `incumbent settings`.

8. Return `result`.

8.1.5.3.2 `HostEnqueueFinalizationRegistryCleanupJob(finalizationRegistry)`

JavaScript has the ability to register objects with `FinalizationRegistry` objects, in order to schedule a cleanup action if they are found to be garbage collected. The JavaScript specification contains an `implementation-defined` `HostEnqueueFinalizationRegistryCleanupJob(finalizationRegistry)` abstract operation to schedule the cleanup action.

The timing and occurrence of cleanup work is `implementation-defined` in the JavaScript specification. User agents might differ in when and whether an object is garbage collected, affecting both whether the return value of the `WeakRef.prototype.deref()` method is `undefined`, and whether `FinalizationRegistry` cleanup callbacks occur. There are well-known cases in popular web browsers where objects are not accessible to JavaScript, but they remain retained by the garbage collector indefinitely. HTML clears kept-alive `WeakRef` objects in the `perform a microtask checkpoint` algorithm. Authors would be best off not depending on the timing details of garbage collection implementations.

Cleanup actions do not take place interspersed with synchronous JavaScript execution, but rather happen in queued `tasks`. User agents must use the following implementation:

```javascript
1. Let `global` be `finalizationRegistry.([[Realm]])`'s `global object`.

2. Queue a global task on the JavaScript engine task source given `global` to perform the following steps:
   1. Let `entry` be `finalizationRegistry.([CleanupCallback])([[Callback]].[[Realm]])`'s `environment settings object`.
   
   2. Check if we can run script with `entry`. If this returns "do not run", then return.

   3. Prepare to run script with `entry`.

      This affects the `entry` concept while the cleanup callback runs.
```
4. Let result be the result of performing
   CleanupFinalizationRegistry(finalizationRegistry).

5. **Clean up after running script** with entry.

6. If result is an abrupt completion, then **report the exception** given by
   result.[[Value]].

8.1.5.3.3 *HostEnqueuePromiseJob*(job, realm)

JavaScript contains an implementation-defined *HostEnqueuePromiseJob*(job, realm) abstract operation to schedule Promise-related operations. HTML schedules these operations in the microtask queue. User agents must use the following implementation: [JAVASCRIPT]

1. If realm is not null, then let job settings be the settings object for realm. Otherwise, let job settings be null.

   If realm is not null, it is the Realm of the author code that will run. When job is returned by *NewPromiseReactionJob*, it is the realm of the promise’s handler function. When job is returned by *NewPromiseResolveThenableJob*, it is the realm of the then function.

   If realm is null, either no author code will run or author code is guaranteed to throw. For the former, the author may not have passed in code to run, such as in promise.then(null, null). For the latter, it is because a revoked Proxy was passed. In both cases, all the steps below that would otherwise use job settings get skipped.

2. **Queue a microtask** on the surrounding agent’s event loop to perform the following steps:

   1. If job settings is not null, then check if we can run script with job settings. If this returns "do not run" then return.

   2. If job settings is not null, then prepare to run script with job settings.

      This affects the entry concept while the job runs.

3. Let result be job().

   job is an abstract closure returned by *NewPromiseReactionJob* or *NewPromiseResolveThenableJob*. The promise’s handler function when job is returned by *NewPromiseReactionJob*, and the then function when job is returned by *NewPromiseResolveThenableJob*, are wrapped in JobCallback Records. HTML saves the incumbent settings object and a JavaScript execution context for to the active script in *HostMakeJobCallback* and restores them in *HostCallJobCallback*. 
4. If \textit{job settings} is not null, then \textbf{clean up after running script} with \textit{job settings}.

5. If \textit{result} is an \textbf{abrupt completion}, then \textbf{report the exception} given by \textit{result}[[Value]].

8.1.5.3.4 \textit{HostMakeJobCallback}(callable)

JavaScript contains an \textbf{implementation-defined \textit{HostMakeJobCallback}(callable)} abstract operation to let hosts attach state to JavaScript callbacks that are called from inside \textit{tasks}. User agents must use the following implementation: \[\text{[JAVASCRIPT]}\]

1. Let \textit{incumbent settings} be the \textbf{incumbent settings object}.
2. Let \textit{active script} be the \textbf{active script}.
3. Let \textit{script execution context} be null.
4. If \textit{active script} is not null, set \textit{script execution context} to a new \textit{JavaScript execution context}, with its Function field set to null, its Realm field set to \textit{active script}'s settings object's Realm, and its ScriptOrModule set to \textit{active script}'s record.

As seen below, this is used in order to propagate the current \textbf{active script} forward to the time when the job callback is invoked.

A case where \textit{active script} is non-null, and saving it in this way is useful, is the following:

\texttt{Promise.resolve('import(`./example.mjs`)').then(eval);}

Without this step (and the steps that use it in \textit{HostCallJobCallback}), there would be no \textbf{active script} when the \textbf{import()} expression is evaluated, since \textbf{eval()} is a built-in function that does not originate from any particular \textbf{script}.

With this step in place, the active script is propagated from the above code into the job, allowing \textbf{import()} to use the original script's \textbf{base URL} appropriately.

\textit{active script} can be null if the user clicks on the following button:

\texttt{<button onclick="Promise.resolve('import(`./example.mjs`)').then(eval)">Click me</button>}

In this case, the JavaScript function for the \textit{event handler} will be created by the \textbf{get the current value of the event handler} algorithm, which creates a function with null \textbf{[[ScriptOrModule]]} value. Thus, when the promise machinery calls \textit{HostMakeJobCallback}, there will be no \textbf{active script} to pass along.

As a consequence, this means that when the \textbf{import()} expression is evaluated, there will still be no \textbf{active script}. Fortunately that is handled by our implementations of
HostResolveImportedModule and HostImportModuleDynamically, by falling back to using the current settings object’s API base URL.

5. Return the JobCallback Record \{ [[Callback]]: callable, [[HostDefined]]: { [[IncumbentSettings]]: incumbent settings, [[ActiveScriptContext]]: script execution context \} \}.

8.1.5.4 Module-related host hooks

The JavaScript specification defines a syntax for modules, as well as some host-agnostic parts of their processing model. This specification defines the rest of their processing model: how the module system is bootstrapped, via the script element with type attribute set to “module”, and how modules are fetched, resolved, and executed. [JAVASCRIPT]

Although the JavaScript specification speaks in terms of “scripts” versus “modules”, in general this specification speaks in terms of classic scripts versus module scripts, since both of them use the script element.

\texttt{modulePromise = import(specifier)}

Returns a promise for the module namespace object for the module script identified by specifier. This allows dynamic importing of module scripts at runtime, instead of statically using the Import statement form. The specifier will be resolved relative to the active script's base URL.

The returned promise will be rejected if an invalid specifier is given, or if a failure is encountered while fetching or evaluating the resulting module graph.

This syntax can be used inside both classic and module scripts. It thus provides a bridge into the module-script world, from the classic-script world.

\texttt{url = import.meta.url}

Returns the active module script’s base URL.

This syntax can only be used inside module scripts.

A module map is a map keyed by tuples consisting of a URL record and a string. The URL record is the request URL at which the module was fetched, and the string indicates the type of the module (e.g. “javascript”). The module map’s values are either a module script, null (used to represent failed fetches), or a placeholder value “fetching”. Module maps are used to ensure that imported module scripts are only fetched, parsed, and evaluated once per Document or worker.

Since module maps are keyed by (URL, module type), the following code will create three separate entries in the module map, since it results in three different (URL, module type) tuples (all with “javascript” type):
import "https://example.com/module.mjs";
import "https://example.com/module.mjs#map-buster";
import "https://example.com/module.mjs?debug=true";

That is, URL queries and fragments can be varied to create distinct entries in the module map; they are not ignored. Thus, three separate fetches and three separate module evaluations will be performed.

In contrast, the following code would only create a single entry in the module map, since after applying the URL parser to these inputs, the resulting URL records are equal:

import "https://example.com/module2.mjs";
import "https://example.com/module2.mjs";
import "https://example.com\module2.mjs";
import "https://example.com/foo/../module2.mjs";

So in this second example, only one fetch and one module evaluation will occur.

Note that this behavior is the same as how shared workers are keyed by their parsed constructor url.

Since module type is also part of the module map key, the following code will create two separate entries in the module map (the type is "javascript" for the first, and "css" for the second):

```html
<script>
    import "https://example.com/module";
</script>
<script>
    import "https://example.com/module" assert { type: "css" };
</script>
```

This can result in two separate fetches and two separate module evaluations being performed. This is a willful violation of a constraint recommended (but not required) by the import assertions specification stating that each call to HostResolveImportedModule with the same referencingScriptOrModule, moduleRequest.[[Specifier]]) pair must return the same Module Record. [JSIMPORTASSERTIONS]

In practice, due to the as-yet-unspecified memory cache (see issue #6110) the resource may only be fetched once in WebKit and Blink-based browsers. Additionally, as long as all module types are mutually exclusive, the module type check in fetch a single module script will fail for at least one of the imports, so at most one module evaluation will occur.

The purpose of including the type in the module map key is so that an import with the wrong type assertion does not prevent a different import of the same specifier but with the correct type from succeeding.

To resolve a module specifier given a URL base URL and a string specifier, perform the
following steps. It will return either a URL record or failure.

1. Apply the URL parser to specifier. If the result is not failure, return the result.

2. If specifier does not start with the character U+002F SOLIDUS (/), the two-character sequence U+002E FULL STOP, U+002F SOLIDUS (./), or the three-character sequence U+002E FULL STOP, U+002E FULL STOP, U+002F SOLIDUS (../), return failure.

This restriction is in place so that in the future we can allow custom module loaders to give special meaning to "bare" import specifiers, like import "jquery" or import "web/crypto". For now any such imports will fail, instead of being treated as relative URLs.

3. Return the result of applying the URL parser to specifier with base URL.

The following are valid module specifiers according to the above algorithm:

- https://example.com/apples.mjs
- http://example.com/pears.js (becomes http://example.com/pears.js as step 1 parses with no base URL)
- //example.com/bananas
- ./strawberries.mjs.cgi
- ../lychees
- /limes.jsx
- data:text/javascript,export default 'grapes';
- blob:https://whatwg.org/d0360e2f-caee-469f-9a2f-87d5b0456f6f

The following are valid module specifiers according to the above algorithm, but will invariably cause failures when they are fetched:

- javascript:export default 'artichokes';
- data:text/plain,export default 'kale';
- about:legumes
- wss://example.com/celery

The following are not valid module specifiers according to the above algorithm:

- https://eggplant:b/c
- pumpkins.js
- .tomato
- ..zucchini.mjs
- .\yam.es
Support in all current engines.

Firefox 62+ Safari 11.1+ Chrome 64+
Opera 51+ Edge 79+
Edge (Legacy) No
Internet Explorer No
Firefox Android 62+ Safari iOS 12+ Chrome Android 64+ WebView Android 64+ Samsung Internet 9.0+ Opera Android 47+

JavaScript contains an implementation-defined HostGetImportMetaProperties abstract operation. User agents must use the following implementation:

```javascript
1. Let module script be moduleRecord.[[HostDefined]].
2. Assert: module script's base URL is not null, as module script is a JavaScript module script.
3. Let urlString be module script's base URL, serialized.
4. Return « Record { [[Key]]: "url", [[Value]]: urlString } ».
```

8.1.5.4.2 HostImportModuleDynamically(referencingScriptOrModule, moduleRequest, promiseCapability)

JavaScript contains an implementation-defined HostImportModuleDynamically abstract operation. User agents must use the following implementation:

```javascript
1. Let settings object be the current settings object.
2. If settings object's global object implements WorkletGlobalScope or ServiceWorkerGlobalScope, then:
   1. Let completion be Completion { [[Type]]: throw, [[Value]]: a new TypeError, [[Target]]: empty }.
   2. Perform FinishDynamicImport(referencingScriptOrModule, moduleRequest, promiseCapability, completion).
3. Return.
4. Let base URL be settings object's API base URL.
5. Let fetch options be the default classic script fetch options.
6. If referencingScriptOrModule is not null, then:
   1. Let referencing script be referencingScriptOrModule.[[HostDefined]].
```
2. Set settings object to referencing script's settings object.

3. Set base URL to referencing script's base URL.

4. Set fetch options to the descendant script fetch options for referencing script's fetch options.

5. Assert: Neither base URL nor fetch options is null, as referencing script is a classic script or a JavaScript module script.

As explained above for HostResolveImportedModule, in the common case, referencingScriptOrModule is non-null.

6. Fetch an import() module script graph given moduleRequest, base URL, settings object, and fetch options. Wait until the algorithm asynchronously completes with result.

7. Let promise be null.

8. If result is null, then set promise to a promise rejected with a new TypeError.

9. Otherwise, set promise to the result of running a module script given result and true.

11. Return undefined.

8.1.5.4.3 HostResolveImportedModule(referencingScriptOrModule, moduleRequest)

JavaScript contains an implementation-defined HostResolveImportedModule abstract operation. User agents must use the following implementation: [JAVASCRIPT]

1. Let settings object be the current settings object.

2. Let base URL be settings object's API base URL.

3. If referencingScriptOrModule is not null, then:
   1. Let referencing script be referencingScriptOrModule.[[HostDefined]].
   2. Set settings object to referencing script's settings object.
   3. Set base URL to referencing script's base URL.
   4. Assert: base URL is not null, as referencing script is a classic script or a JavaScript module script.

   referencingScriptOrModule is not usually null, but will be so for event handlers per the
get the current value of the event handler algorithm. For example, given:

```html
<button onclick="import('./foo.mjs')">Click me</button>
```

If a `click` event occurs, then at the time the `import()` expression runs, `GetActiveScriptOrModule` will return null, which will be passed to this abstract operation when `HostResolveImportedModule` is called by `FinishDynamicImport`.

4. Let `moduleMap` be `settings object`'s module map.

5. Let `url` be the result of resolving a module specifier given base URL and `moduleRequest.[[Specifier]]`.

6. Assert: `url` is never failure, because resolving a module specifier must have been previously successful with these same two arguments (either while creating the corresponding module script, or in fetch an import() module script graph).

7. If `moduleRequest.[[Assertions]]` has a Record entry such that `entry.[[Key]]` is “type”, then let `module type` be `entry.[[Value]]`. Otherwise let `module type` be “javascript”.

8. Let `resolved module script` be `moduleMap[(url, module type)]`. (This entry must exist for us to have gotten to this point.)

9. Assert: `resolved module script` is a module script (i.e., is not null or “fetching”).

10. Assert: `resolved module script`'s record is not null.

11. Return `resolved module script`'s record.

8.1.5.4.4 `HostGetSupportedImportAssertions()`

The Import Assertions proposal contains an implementation-defined `HostGetSupportedImportAssertions` abstract operation. User agents must use the following implementation: `[JSIMPORTASSERTIONS]`

1. Return « "type" ».

8.1.6 Event loops

8.1.6.1 Definitions

To coordinate events, user interaction, scripts, rendering, networking, and so forth, user agents must use event loops as described in this section. Each agent has an associated event loop, which is unique to that agent.

The event loop of a similar-origin window agent is known as a window event loop. The event loop of a dedicated worker agent, shared worker agent, or service worker agent is known as a
worker event loop. And the event loop of a worklet agent is known as a worklet event loop.

Event loops do not necessarily correspond to implementation threads. For example, multiple window event loops could be cooperatively scheduled in a single thread.

However, for the various worker agents that are allocated with [[CanBlock]] set to true, the JavaScript specification does place requirements on them regarding forward progress, which effectively amount to requiring dedicated per-agent threads in those cases.

An event loop has one or more task queues. A task queue is a set of tasks.

Task queues are sets, not queues, because step one of the event loop processing model grabs the first runnable task from the chosen queue, instead of dequeuing the first task.

The microtask queue is not a task queue.

Tasks encapsulate algorithms that are responsible for such work as:

Events

  Dispatching an Event object at a particular EventTarget object is often done by a dedicated task.

  Not all events are dispatched using the task queue; many are dispatched during other tasks.

Parsing

  The HTML parser tokenizing one or more bytes, and then processing any resulting tokens, is typically a task.

Callbacks

  Calling a callback is often done by a dedicated task.

Using a resource

  When an algorithm fetches a resource, if the fetching occurs in a non-blocking fashion then the processing of the resource once some or all of the resource is available is performed by a task.

Reacting to DOM manipulation

  Some elements have tasks that trigger in response to DOM manipulation, e.g. when that element is inserted into the document.

Formally, a task is a struct which has:
**Steps**

A series of steps specifying the work to be done by the task.

**A source**

One of the task sources, used to group and serialize related tasks.

**A document**

A Document associated with the task, or null for tasks that are not in a window event loop.

**A script evaluation environment settings object set**

A set of environment settings objects used for tracking script evaluation during the task.

A task is runnable if its document is either null or fully active.

Per its source field, each task is defined as coming from a specific task source. For each event loop, every task source must be associated with a specific task queue.

Essentially, task sources are used within standards to separate logically-different types of tasks, which a user agent might wish to distinguish between. Task queues are used by user agents to coalesce task sources within a given event loop.

For example, a user agent could have one task queue for mouse and key events (to which the user interaction task source is associated), and another to which all other task sources are associated. Then, using the freedom granted in the initial step of the event loop processing model, it could give keyboard and mouse events preference over other tasks three-quarters of the time, keeping the interface responsive but not starving other task queues. Note that in this setup, the processing model still enforces that the user agent would never process events from any one task source out of order.

Each event loop has a currently running task, which is either a task or null. Initially, this is null. It is used to handle reentrancy.

Each event loop has a microtask queue, which is a queue of microtasks, initially empty. A microtask is a colloquial way of referring to a task that was created via the queue a microtask algorithm.

Each event loop has a performing a microtask checkpoint boolean, which is initially false. It is used to prevent reentrant invocation of the perform a microtask checkpoint algorithm.

Each window event loop has a DOMHighResTimeStamp last render opportunity time, initially set to zero.

Each window event loop has a DOMHighResTimeStamp last idle period start time, initially set to zero.

To get the same-loop windows for a window event loop loop, return all Window objects whose relevant agent’s event loop is loop.
8.1.6.2 Queuing tasks

To queue a task on a task source source, which performs a series of steps steps, optionally given an event loop event loop and a document document:

1. If event loop was not given, set event loop to the implied event loop.
2. If document was not given, set document to the implied document.
3. Let task be a new task.
4. Set task’s steps to steps.
5. Set task’s source to source.
6. Set task’s document to the document.
7. Set task’s script evaluation environment settings object set to an empty set.
8. Let queue be the task queue to which source is associated on event loop.
9. Append task to queue.

Failing to pass an event loop and document to queue a task means relying on the ambiguous and poorly-specified implied event loop and implied document concepts. Specification authors should either always pass these values, or use the wrapper algorithms queue a global task or queue an element task instead. Using the wrapper algorithms is recommended.

To queue a global task on a task source source, with a global object global and a series of steps steps:

1. Let event loop be global’s relevant agent’s event loop.
2. Let document be global’s associated Document, if global is a Window object; otherwise null.
3. Queue a task given source, event loop, document, and steps.

To queue an element task on a task source source, with an element element and a series of steps steps:

1. Let global be element’s relevant global object.
2. Queue a global task given source, global, and steps.

To queue a microtask which performs a series of steps steps, optionally given an event loop event loop and a document document:
1. If event loop was not given, set event loop to the implied event loop.

2. If document was not given, set document to the implied document.

3. Let microtask be a new task.

4. Set microtask’s steps to steps.

5. Set microtask’s source to the microtask task source.

6. Set microtask’s document to document.

7. Set microtask’s script evaluation environment settings object set to an empty set.

8. Enqueue microtask on event loop’s microtask queue.

It is possible for a microtask to be moved to a regular task queue, if, during its initial execution, it spins the event loop. This is the only case in which the source, document, and script evaluation environment settings object set of the microtask are consulted; they are ignored by the perform a microtask checkpoint algorithm.

The implied event loop when queuing a task is the one that can deduced from the context of the calling algorithm. This is generally unambiguous, as most specification algorithms only ever involve a single agent (and thus a single event loop). The exception is algorithms involving or specifying cross-agent communication (e.g., between a window and a worker); for those cases, the implied event loop concept must not be relied upon and specifications must explicitly provide an event loop when queuing a task or microtask.

The implied document when queuing a task on an event loop event loop is determined as follows:

1. If event loop is not a window event loop, then return null.

2. If the task is being queued in the context of an element, then return the element’s node document.

3. If the task is being queued in the context of a browsing context, then return the browsing context’s active document.

4. If the task is being queued by or for a script, then return the script’s settings object’s responsible document.

5. Assert: this step is never reached, because one of the previous conditions must be true. Really?

Both implied event loop and implied document are vaguely-defined and have a lot of action-at-a-distance. The hope is to remove these, especially implied document. See issue #4980.
An **event loop** must continually run through the following steps for as long as it exists:

1. Let `taskQueue` be one of the event loop's **task queues**, chosen in an implementation-defined manner, with the constraint that the chosen task queue must contain at least one **runnable task**. If there is no such task queue, then jump to the **microtasks** step below.

   Remember that the **microtask queue** is not a task queue, so it will not be chosen in this step. However, a task queue to which the **microtask task source** is associated might be chosen in this step. In that case, the task chosen in the next step was originally a **microtask**, but it got moved as part of spinning the event loop.

2. Let `oldestTask` be the first runnable task in `taskQueue`, and remove it from `taskQueue`.

3. Set the event loop's currently running task to `oldestTask`.

4. Let `taskStartTime` be the current high resolution time.

5. Perform `oldestTask`'s steps.

6. Set the event loop's currently running task back to null.

7. **Microtasks:** Perform a microtask checkpoint.

8. Let `hasARenderingOpportunity` be false.

9. Let `now` be the current high resolution time. [HRT]

10. Report the task’s duration by performing the following steps:

    1. Let **top-level browsing contexts** be an empty set.

    2. For each environment settings object `settings` of `oldestTask`'s **script evaluation environment settings object** set, append setting's **top-level browsing context** to **top-level browsing contexts**.

    3. Report long tasks, passing in `taskStartTime`, `now` (the end time of the task), **top-level browsing contexts**, and `oldestTask`.

11. **Update the rendering:** if this is a **window event loop**, then:

    1. Let `docs` be all **Document** objects whose relevant agent’s event loop is this event loop, sorted arbitrarily except that the following conditions must be met:

       - Any **Document** `B` whose **browsing context**'s container document is `A` must be listed after `A` in the list.
- If there are two documents \( A \) and \( B \) whose browsing contexts are both child browsing contexts whose container documents are another Document \( C \), then the order of \( A \) and \( B \) in the list must match the shadow-including tree order of their respective browsing context containers in \( C \)'s node tree.

In the steps below that iterate over \( docs \), each Document must be processed in the order it is found in the list.

2. **Rendering opportunities**: Remove from \( docs \) all Document objects whose browsing context do not have a rendering opportunity.

A browsing context has a rendering opportunity if the user agent is currently able to present the contents of the browsing context to the user, accounting for hardware refresh rate constraints and user agent throttling for performance reasons, but considering content presentable even if it’s outside the viewport.

Browsing context rendering opportunities are determined based on hardware constraints such as display refresh rates and other factors such as page performance or whether the document’s visibility state is "visible". Rendering opportunities typically occur at regular intervals.

This specification does not mandate any particular model for selecting rendering opportunities. But for example, if the browser is attempting to achieve a 60Hz refresh rate, then rendering opportunities occur at a maximum of every 60th of a second (about 16.7ms). If the browser finds that a browsing context is not able to sustain this rate, it might drop to a more sustainable 30 rendering opportunities per second for that browsing context, rather than occasionally dropping frames. Similarly, if a browsing context is not visible, the user agent might decide to drop that page to a much slower 4 rendering opportunities per second, or even less.

3. If \( docs \) is not empty, then set hasARenderingOpportunity to true and set this event loop’s last render opportunity time to taskStartTime.

4. **Unnecessary rendering**: Remove from \( docs \) all Document objects which meet both of the following conditions:

   - The user agent believes that updating the rendering of the Document’s browsing context would have no visible effect, and
   - The Document’s map of animation frame callbacks is empty.

5. Remove from \( docs \) all Document objects for which the user agent believes that it’s preferrable to skip updating the rendering for other reasons.

The step labeled Rendering opportunities prevents the user agent from updating the rendering when it is unable to present new content to the user (there’s no
The step labeled *unnecessary rendering* prevents the user agent from updating the rendering when there’s no new content to draw.

This step enables the user agent to prevent the steps below from running for other reasons, for example, to ensure certain tasks are executed immediately after each other, with only microtask checkpoints interleaved (and without, e.g., animation frame callbacks interleaved). Concretely, a user agent might wish to coalesce timer callbacks together, with no intermediate rendering updates.

6. For each fully active Document in docs, flush autofocus candidates for that Document if its browsing context is a top-level browsing context.

7. For each fully active Document in docs, run the resize steps for that Document, passing in now as the timestamp. [CSSOMVIEW]

8. For each fully active Document in docs, run the scroll steps for that Document, passing in now as the timestamp. [CSSOMVIEW]

9. For each fully active Document in docs, evaluate media queries and report changes for that Document, passing in now as the timestamp. [CSSOMVIEW]

10. For each fully active Document in docs, update animations and send events for that Document, passing in now as the timestamp. [WEBANIMATIONS]

11. For each fully active Document in docs, run the fullscreen steps for that Document, passing in now as the timestamp. [FULLSCREEN]

12. For each fully active Document in docs, if the user agent detects that the backing storage associated with a CanvasRenderingContext2D or an OffscreenCanvasRenderingContext2D, context, has been lost, then it must run the context lost steps for each such context:

   1. Let canvas be the value of context’s canvas attribute, if context is a CanvasRenderingContext2D, or the associated OffscreenCanvas object for context otherwise.

   2. Set context’s context lost to true.

   3. Reset the rendering context to its default state given context.

   4. Let shouldRestore be the result of firing an event named contextlost at canvas, with the cancelable attribute initialized to true.

   5. If shouldRestore is false, then abort these steps.
6. Attempt to restore context by creating a backing storage using context’s attributes and associating them with context. If this fails, then abort these steps.

7. Set context’s context lost to false.

8. Fire an event named contextrestored at canvas.

13. For each fully active Document in docs, run the animation frame callbacks for that Document, passing in now as the timestamp.

14. For each fully active Document in docs, run the update intersection observations steps for that Document, passing in now as the timestamp.

15. Invoke the mark paint timing algorithm for each Document object in docs.

16. For each fully active Document in docs, update the rendering or user interface of that Document and its browsing context to reflect the current state.

12. If all of the following are true

- this is a window event loop
- there is no task in this event loop’s task queues whose document is fully active
- this event loop’s microtask queue is empty
- hasARenderingOpportunity is false

then:

1. Let computeDeadline be the following steps:

   1. Let deadline be this event loop’s last idle period start time plus 50.

      The cap of 50ms in the future is to ensure responsiveness to new user input within the threshold of human perception.

   2. Let hasPendingRenders be false.

   3. For each windowInSameLoop of the same-loop windows for this event loop:

      1. If windowInSameLoop’s map of animation frame callbacks is not empty, or if the user agent believes that the windowInSameLoop might have pending rendering updates, set hasPendingRenders to true.

      2. Let timerCallbackEstimates be the result of getting the values of windowInSameLoop’s map of active timers.
3. For each \texttt{timeoutDeadline} of \texttt{timerCallbackEstimates}, if \texttt{timeoutDeadline} is less than \texttt{deadline}, set \texttt{deadline} to \texttt{timeoutDeadline}.

4. If \texttt{hasPendingRenders} is true, then:

   1. Let \texttt{nextRenderDeadline} be this event loop’s last render opportunity time plus (1000 divided by the current refresh rate). The refresh rate can be hardware- or implementation-specific. For a refresh rate of 60Hz, the \texttt{nextRenderDeadline} would be about 16.67ms after the last render opportunity time.

   2. If \texttt{nextRenderDeadline} is less than \texttt{deadline}, then return \texttt{nextRenderDeadline}.

5. Return \texttt{deadline}.

2. For each \texttt{win} of the same-loop windows for this event loop, perform the start an idle period algorithm for \texttt{win} with \texttt{computeDeadline}. \texttt{REQUESTIDLECALLBACK}

13. If this is a worker event loop, then:

   1. If this event loop’s agent’s single realm’s global object is a supported \texttt{DedicatedWorkerGlobalScope} and the user agent believes that it would benefit from having its rendering updated at this time, then:

      1. Let \texttt{now} be the current high resolution time. \texttt{HRT}

      2. Run the animation frame callbacks for that \texttt{DedicatedWorkerGlobalScope}, passing in \texttt{now} as the timestamp.

      3. Update the rendering of that dedicated worker to reflect the current state.

      Similar to the notes for updating the rendering in a window event loop, a user agent can determine the rate of rendering in the dedicated worker.

   2. If there are no tasks in the event loop’s task queues and the \texttt{WorkerGlobalScope} object’s closing flag is true, then destroy the event loop, aborting these steps, resuming the run a worker steps described in the Web workers section below.

---

When a user agent is to perform a microtask checkpoint:

1. If the event loop’s performing a microtask checkpoint is true, then return.
2. Set the **event loop's performing a microtask checkpoint** to true.

3. While the **event loop's microtask queue** is not empty:
   
   1. Let `oldestMicrotask` be the result of **dequeuing** from the **event loop's microtask queue**.
   
   2. Set the **event loop's currently running task** to `oldestMicrotask`.
   
   3. Run `oldestMicrotask`.
      
      This might involve invoking scripted callbacks, which eventually calls the **clean up after running script** steps, which call this **perform a microtask checkpoint** algorithm again, which is why we use the **performing a microtask checkpoint** flag to avoid reentrancy.
   
   4. Set the **event loop's currently running task** back to null.

4. For each **environment settings object** whose responsible **event loop** is this **event loop**, **notify about rejected promises** on that **environment settings object**.

5. **Cleanup Indexed Database transactions**.

6. Perform **ClearKeptObjects**().

   When `WeakRef.prototype.deref()` returns an object, that object is kept alive until the next invocation of **ClearKeptObjects()**, after which it is again subject to garbage collection.

7. Set the **event loop's performing a microtask checkpoint** to false.

---

When an algorithm running **in parallel** is to **await a stable state**, the user agent must **queue a microtask** that runs the following steps, and must then stop executing (execution of the algorithm resumes when the microtask is run, as described in the following steps):

1. Run the algorithm’s **synchronous section**.

2. Resumes execution of the algorithm **in parallel**, if appropriate, as described in the algorithm’s steps.

Steps in **synchronous sections** are marked with ⌛.

Algorithm steps that say to **spin the event loop** until a condition **goal** is met are equivalent to substituting in the following algorithm steps:

1. Let `task` be the **event loop's currently running task**.
task could be a microtask.

2. Let task source be task’s source.

3. Let old stack be a copy of the JavaScript execution context stack.

4. Empty the JavaScript execution context stack.

5. Perform a microtask checkpoint.

   If task is a microtask this step will be a no-op due to performing a microtask checkpoint being true.

6. In parallel:

   1. Wait until the condition goal is met.

   2. Queue a task on task source to:

      1. Replace the JavaScript execution context stack with old stack.

      2. Perform any steps that appear after this spin the event loop instance in the original algorithm.

         This resumes task.

7. Stop task, allowing whatever algorithm that invoked it to resume.

   This causes the event loop’s main set of steps or the perform a microtask checkpoint algorithm to continue.

Unlike other algorithms in this and other specifications, which behave similar to programming-language function calls, spin the event loop is more like a macro, which saves typing and indentation at the usage site by expanding into a series of steps and operations.

An algorithm whose steps are:

1. Do something.

2. Spin the event loop until awesomeness happens.

3. Do something else.

is a shorthand which, after "macro expansion", becomes

1. Do something.

2. Let old stack be a copy of the JavaScript execution context stack.
3. Empty the JavaScript execution context stack.

4. Perform a microtask checkpoint.

5. In parallel:
   1. Wait until awesomeness happens.
   2. Queue a task on the task source in which "do something" was done to:
      1. Replace the JavaScript execution context stack with old stack.
      2. Do something else.

Here is a more full example of the substitution, where the event loop is spun from inside a task that is queued from work in parallel. The version using spin the event loop:

1. In parallel:
   1. Do parallel thing 1.
   2. Queue a task on the DOM manipulation task source to:
      1. Do task thing 1.
      2. Spin the event loop until awesomeness happens.
      3. Do task thing 2.
   3. Do parallel thing 2.

The fully expanded version:

1. In parallel:
   1. Do parallel thing 1.
   2. Let old stack be null.
   3. Queue a task on the DOM manipulation task source to:
      1. Do task thing 1.
      2. Set old stack to a copy of the JavaScript execution context stack.
      3. Empty the JavaScript execution context stack.
      4. Perform a microtask checkpoint.
4. Wait until awesomeness happens.

5. Queue a task on the DOM manipulation task source to:
   1. Replace the JavaScript execution context stack with old stack.
   2. Do task thing 2.

6. Do parallel thing 2.

Some of the algorithms in this specification, for historical reasons, require the user agent to pause while running a task until a condition goal is met. This means running the following steps:

1. If necessary, update the rendering or user interface of any Document or browsing context to reflect the current state.

2. Wait until the condition goal is met. While a user agent has a paused task, the corresponding event loop must not run further tasks, and any script in the currently running task must block. User agents should remain responsive to user input while paused, however, albeit in a reduced capacity since the event loop will not be doing anything.

Pausing is highly detrimental to the user experience, especially in scenarios where a single event loop is shared among multiple documents. User agents are encouraged to experiment with alternatives to pausing, such as spinning the event loop or even simply proceeding without any kind of suspended execution at all, insofar as it is possible to do so while preserving compatibility with existing content. This specification will happily change if a less-drastic alternative is discovered to be web-compatible.

In the interim, implementers should be aware that the variety of alternatives that user agents might experiment with can change subtle aspects of event loop behavior, including task and microtask timing. Implementations should continue experimenting even if doing so causes them to violate the exact semantics implied by the pause operation.

8.1.6.4 Generic task sources

The following task sources are used by a number of mostly unrelated features in this and other specifications.

The DOM manipulation task source

This task source is used for features that react to DOM manipulations, such as things that happen in a non-blocking fashion when an element is inserted into the document.
The user interaction task source

This task source is used for features that react to user interaction, for example keyboard or mouse input.

Events sent in response to user input (e.g. click events) must be fired using tasks queued with the user interaction task source. [UIEVENTS]

The networking task source

This task source is used for features that trigger in response to network activity.

The history traversal task source

This task source is used to queue calls to history.back() and similar APIs.

8.1.6.5 Dealing with the event loop from other specifications

Writing specifications that correctly interact with the event loop can be tricky. This is compounded by how this specification uses concurrency-model-independent terminology, so we say things like “event loop” and “in parallel” instead of using more familiar model-specific terms like “main thread” or “on a background thread”.

By default, specification text generally runs on the event loop. This falls out from the formal event loop processing model, in that you can eventually trace most algorithms back to a task queued there.

The algorithm steps for any JavaScript method will be invoked by author code calling that method. And author code can only be run via queued tasks, usually originating somewhere in the script processing model.

From this starting point, the overriding guideline is that any work a specification needs to perform that would otherwise block the event loop must instead be performed in parallel with it. This includes (but is not limited to):

- performing heavy computation;
- displaying a user-facing prompt;
- performing operations which could require involving outside systems (i.e. “going out of process”).

The next complication is that, in algorithm sections that are in parallel, you must not create or manipulate objects associated to a specific JavaScript realm, global, or environment settings object. (Stated in more familiar terms, you must not directly access main-thread artifacts from a background thread.) Doing so would create data races observable to JavaScript code, since after all, your algorithm steps are running in parallel to the JavaScript code.
You can, however, manipulate specification-level data structures and values from *Infra*, as those are realm-agnostic. They are never directly exposed to JavaScript without a specific conversion taking place (often via Web IDL). [INFRA] [WEBIDL]

To affect the world of observable JavaScript objects, then, you must **queue a global task** to perform any such manipulations. This ensures your steps are properly interleaved with respect to other things happening on the **event loop**. Furthermore, you must choose a **task source** when **queuing a global task**; this governs the relative order of your steps versus others. If you are unsure which **task source** to use, pick one of the **generic task sources** that sounds most applicable. Finally, you must indicate which **global object** your queued task is associated with; this ensures that if that global object is inactive, the task does not run.

The base primitive, on which **queue a global task** builds, is the **queue a task** algorithm. In general, **queue a global task** is better because it automatically picks the right **event loop** and, where appropriate, **document**. Older specifications often use **queue a task** combined with the **implied event loop** and **implied document** concepts, but this is discouraged.

Putting this all together, we can provide a template for a typical algorithm that needs to do work asynchronously:

1. Do any synchronous setup work, while still on the **event loop**. This may include converting **realm**-specific JavaScript values into realm-agnostic specification-level values.
2. Perform a set of potentially-expensive steps **in parallel**, operating entirely on realm-agnostic values, and producing a realm-agnostic result.
3. **Queue a global task**, on a specified **task source** and given an appropriate **global object**, to convert the realm-agnostic result back into observable effects on the observable world of JavaScript objects on the **event loop**.

The following is an algorithm that “encrypts” a passed-in list of **scalar value strings** input, after parsing them as URLs:

1. Let **urls** be an empty list.
2. **For each** string of **input**:
   1. Let **parsed** be the result of parsing **string** relative to the **current settings object**.
   2. If **parsed** is failure, return a promise rejected with a “**SyntaxError**” **DOMException**.
   3. Let **serialized** be the result of applying the **URL serializer** to **parsed**.
   4. **Append** **serialized** to **urls**.
3. Let **realm** be the **current Realm Record**.
4. Let $p$ be a new promise.

5. Run the following steps \textit{in parallel}:

   1. Let $\text{encryptedURLs}$ be an empty \texttt{list}.

   2. \textbf{For each} $\text{url}$ of $\text{urls}$:

      1. Wait 100 milliseconds, so that people think we’re doing heavy-duty encryption.

      2. Let $\text{encrypted}$ be a new \texttt{string} derived from $\text{url}$, whose $n$th \texttt{code unit} is equal to $\text{url}$’s $n$th \texttt{code unit} plus 13.

   3. \textbf{Append} $\text{encrypted}$ to $\text{encryptedURLs}$.

3. \textbf{Queue a global task} on the \texttt{networking task source}, given $\text{realm}$’s \texttt{global object}, to perform the following steps:

   1. Let $\text{array}$ be the result of \texttt{converting $\text{encryptedURLs}$ to a JavaScript array}, in $\text{realm}$.

   2. Resolve $p$ with $\text{array}$.

Here are several things to notice about this algorithm:

- It does its URL parsing up front, on the \texttt{event loop}, before going to the \textit{in parallel} steps. This is necessary, since parsing depends on the \texttt{current settings object}, which would no longer be current after going \textit{in parallel}.

- Alternately, it could have saved a reference to the \texttt{current settings object}’s \texttt{API base URL} and used it during the \textit{in parallel} steps; that would have been equivalent. However, we recommend instead doing as much work as possible up front, as this example does. Attempting to save the correct values can be error prone; for example, if we’d saved just the \texttt{current settings object}, instead of its \texttt{API base URL}, there would have been a potential race.

- It implicitly passes a \texttt{list} of \texttt{strings} from the initial steps to the \textit{in parallel} steps. This is OK, as both \texttt{lists} and \texttt{strings} are \texttt{realm}-agnostic.

- It performs "expensive computation" (waiting for 100 milliseconds per input URL) during the \textit{in parallel} steps, thus not blocking the main \texttt{event loop}.

- Promises, as observable JavaScript objects, are never created and manipulated during the \textit{in parallel} steps. $p$ is created before entering those steps, and then is manipulated during a \texttt{task} that is \texttt{queued} specifically for that purpose.
• The creation of a JavaScript array object also happens during the queued task, and is careful to specify which realm it creates the array in since that is no longer obvious from context.

(On these last two points, see also whatwg/webidl issue #135 and whatwg/webidl issue #371, where we are still mulling over the subtleties of the above promise-resolution pattern.)

Another thing to note is that, in the event this algorithm was called from a Web IDL-specified operation taking a sequence<USVString>, there was an automatic conversion from realm-specific JavaScript objects provided by the author as input, into the realm-agnostic sequence<USVString> Web IDL type, which we then treat as a list of scalar value strings. So depending on how your specification is structured, there may be other implicit steps happening on the main event loop that play a part in this whole process of getting you ready to go in parallel.

8.1.7 Events

8.1.7.1 Event handlers

MDN

Events/Event_handlers

Many objects can have event handlers specified. These act as non-capture event listeners for the object on which they are specified. [DOM]

An event handler is a struct with two items:

- a value, which is either null, a callback object, or an internal raw uncompiled handler. The EventHandler callback function type describes how this is exposed to scripts. Initially, an event handler’s value must be set to null.

- a listener, which is either null or an event listener responsible for running the event handler processing algorithm. Initially, an event handler’s listener must be set to null.

Event handlers are exposed in two ways.

The first way, common to all event handlers, is as an event handler IDL attribute.

The second way is as an event handler content attribute. Event handlers on HTML elements and some of the event handlers on Window objects are exposed in this way.

For both of these two ways, the event handler is exposed through a name, which is a string that always starts with "on" and is followed by the name of the event for which the handler is intended.
Most of the time, the object that exposes an **event handler** is the same as the object on which the corresponding **event listener** is added. However, the **body** and **frameset** elements expose several **event handlers** that act upon the element’s **Window** object, if one exists. In either case, we call the object an **event handler** acts upon the **target** of that **event handler**.

To determine the **target** of an **event handler**, given an **EventTarget** object `eventTarget` on which the **event handler** is exposed, and an **event handler name** `name`, the following steps are taken:

1. If `eventTarget` is not a **body** element or a **frameset** element, then return `eventTarget`.

2. If `name` is not the name of an attribute member of the **WindowEventHandlers** interface mixin and the **Window-reflecting body element event handler set** does not contain `name`, then return `eventTarget`.

3. If `eventTarget`'s **node document** is not an **active document**, then return null.

   This could happen if this object is a **body** element without a corresponding **Window** object, for example.

   This check does not necessarily prevent **body** and **frameset** elements that are not the **body element** of their **node document** from reaching the next step. In particular, a **body** element created in an **active document** (perhaps with `document.createElement()`) but not **connected** will also have its corresponding **Window** object as the **target** of several **event handlers** exposed through it.

4. Return `eventTarget`'s **node document**’s relevant global object.

Each **EventTarget** object that has one or more **event handlers** specified has an associated **event handler map**, which is a **map** of strings representing **names** of **event handlers** to **event handlers**.

When an **EventTarget** object that has one or more **event handlers** specified is created, its **event handler map** must be initialized such that it contains an **entry** for each **event handler** that has that object as **target**, with **items** in those **event handlers** set to their initial values.

The order of the **entries** of **event handler map** could be arbitrary. It is not observable through any algorithms that operate on the map.

**Entries** are not created in the **event handler map** of an object for **event handlers** that are merely exposed on that object, but have some other object as their **targets**.

An **event handler IDL attribute** is an IDL attribute for a specific **event handler**. The name of the IDL attribute is the same as the **name** of the **event handler**.
The getter of an event handler IDL attribute with name *name*, when called, must run these steps:

1. Let `eventTarget` be the result of determining the target of an event handler given this object and *name*.
2. If `eventTarget` is null, then return null.
3. Return the result of getting the current value of the event handler given `eventTarget` and *name*.

The setter of an event handler IDL attribute with name *name*, when called, must run these steps:

1. Let `eventTarget` be the result of determining the target of an event handler given this object and *name*.
2. If `eventTarget` is null, then return.
3. If the given value is null, then deactivate an event handler given `eventTarget` and *name*.
4. Otherwise:
   1. Let `handlerMap` be `eventTarget`'s event handler map.
   2. Let `eventHandler` be `handlerMap[\text{name}]`.
   3. Set `eventHandler`'s value to the given value.
   4. Activate an event handler given `eventTarget` and *name*.

Certain event handler IDL attributes have additional requirements, in particular the onmessage attribute of MessagePort objects.

---

An event handler content attribute is a content attribute for a specific event handler. The name of the content attribute is the same as the name of the event handler.

Event handler content attributes, when specified, must contain valid JavaScript code which, when parsed, would match the FunctionBody production after automatic semicolon insertion.

The following attribute change steps are used to synchronize between event handler content attributes and event handlers: [DOM]

1. If `namespace` is not null, or `localName` is not the name of an event handler content attribute on `element`, then return.
2. Let eventTarget be the result of determining the target of an event handler given element and localName.

3. If eventTarget is null, then return.

4. If value is null, then deactivate an event handler given eventTarget and localName.

5. Otherwise:
   1. If the Should element’s inline behavior be blocked by Content Security Policy? algorithm returns "Blocked" when executed upon element, "script attribute", and value, then return. [CSP]
   2. Let handlerMap be eventTarget’s event handler map.
   3. Let eventHandler be handlerMap[localName].
   4. Let location be the script location that triggered the execution of these steps.
   5. Set eventHandler’s value to the internal raw uncompiled handler value/location.
   6. Activate an event handler given eventTarget and localName.

Per the DOM Standard, these steps are run even if oldValue and value are identical (setting an attribute to its current value), but not if oldValue and value are both null (removing an attribute that doesn’t currently exist). [DOM]

To deactivate an event handler given an EventTarget object eventTarget and a string name that is the name of an event handler, run these steps:

1. Let handlerMap be eventTarget’s event handler map.
2. Let eventHandler be handlerMap[name].
3. Set eventHandler’s value to null.
4. Let listener be eventHandler’s listener.
5. If listener is not null, then remove an event listener with eventTarget and listener.
6. Set eventHandler’s listener to null.

To erase all event listeners and handlers given an EventTarget object eventTarget, run these steps:

1. If eventTarget has an associated event handler map, then for each name → eventHandler of eventTarget’s associated event handler map, deactivate an event
To activate an event handler given an `EventTarget` object `eventTarget` and a string `name` that is the name of an event handler, run these steps:

1. Let `handlerMap` be `eventTarget`'s event handler map.
2. Let `eventHandler` be `handlerMap`[`name`].
3. If `eventHandler`'s `listener` is not null, then return.
4. Let `callback` be the result of creating a Web IDL `EventListener` instance representing a reference to a function of one argument that executes the steps of the event handler processing algorithm, given `eventTarget`, `name`, and its argument.

   The `EventListener`'s callback context can be arbitrary; it does not impact the steps of the event handler processing algorithm. [DOM]

   The callback is emphatically not the event handler itself. Every event handler ends up registering the same callback, the algorithm defined below, which takes care of invoking the right code, and processing the code's return value.

5. Let `listener` be a new event listener whose type is the event handler event type corresponding to `eventHandler` and `callback` is `callback`.

   To be clear, an event listener is different from an `EventListener`.

6. Add an event listener with `eventTarget` and `listener`.
7. Set `eventHandler`'s `listener` to `listener`.

The event listener registration happens only if the event handler's value is being set to non-null, and the event handler is not already activated. Since listeners are called in the order they were registered, assuming no deactivation occurred, the order of event listeners for a particular event type will always be:

1. the event listeners registered with `addEventListener()` before the first time the event handler's value was set to non-null
2. then the callback to which it is currently set, if any
3. and finally the event listeners registered with `addEventListener()` after the first time the event handler's value was set to non-null.
This example demonstrates the order in which event listeners are invoked. If the button in this example is clicked by the user, the page will show four alerts, with the text "ONE", "TWO", "THREE", and "FOUR" respectively.

```html
<button id="test">Start Demo</button>
<script>
  var button = document.getElementById('test');
  button.addEventListener('click', function () { alert('ONE') }, false);
  button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler listener is registered here
  button.addEventListener('click', function () { alert('THREE') }, false);
  button.onclick = function () { alert('TWO'); };
  button.addEventListener('click', function () { alert('FOUR') }, false);
</script>
```

However, in the following example, the event handler is deactivated after its initial activation (and its event listener is removed), before being reactivated at a later time. The page will show five alerts with "ONE", "TWO", "THREE", "FOUR", and "FIVE" respectively, in order.

```html
<button id="test">Start Demo</button>
<script>
  var button = document.getElementById('test');
  button.addEventListener('click', function () { alert('ONE') }, false);
  button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler is activated here
  button.addEventListener('click', function () { alert('TWO') }, false);
  button.onclick = null; // but deactivated here
  button.addEventListener('click', function () { alert('THREE') }, false);
  button.onclick = function () { alert('FOUR'); };// and re-activated here
  button.addEventListener('click', function () { alert('FIVE') }, false);
</script>
```

The interfaces implemented by the event object do not influence whether an event handler is triggered or not.

The event handler processing algorithm for an EventTarget object eventTarget, a string name representing the name of an event handler, and an Event object event is as follows:

1. Let callback be the result of getting the current value of the event handler given eventTarget and name.

2. If callback is null, then return.

3. Let special error event handling be true if event is an ErrorEvent object, event's type is error, and event's currentTarget implements the WindowOrWorkerGlobalScope mixin. Otherwise, let special error event handling be false.

4. Process the Event object event as follows:
If special error event handling is true

Invoke callback with five arguments, the first one having the value of event's `message` attribute, the second having the value of event's `filename` attribute, the third having the value of event's `lineno` attribute, the fourth having the value of event's `colno` attribute, the fifth having the value of event's `error` attribute, and with the `callback this value` set to event's `currentTarget`. Let return value be the callback's return value. [WEBIDL]

Otherwise

Invoke callback with one argument, the value of which is the `Event` object event, with the `callback this value` set to event's `currentTarget`. Let return value be the callback's return value. [WEBIDL]

If an exception gets thrown by the callback, end these steps and allow the exception to propagate. (It will propagate to the DOM event dispatch logic, which will then report the exception.)

5. Process return value as follows:

If `event` is a `BeforeUnloadEvent` object and `event's type` is `beforeunload`

In this case, the event handler IDL attribute’s type will be `OnBeforeUnloadEventHandler`, so return value will have been coerced into either null or a `DOMString`.

If return value is not null, then:

1. Set event's `canceled` flag.

2. If event's `returnValue` attribute’s value is the empty string, then set event's `returnValue` attribute’s value to return value.

If special error event handling is true

If return value is true, then set event's `canceled` flag.

Otherwise

If return value is false, then set event's `canceled` flag.

If we’ve gotten to this “Otherwise” clause because event’s `type` is `beforeunload` but event is not a `BeforeUnloadEvent` object, then return value will never be false, since in such cases return value will have been coerced into either null or a `DOMString`. 
The `EventHandler` callback function type represents a callback used for event handlers. It is represented in Web IDL as follows:

```idl
[LegacyTreatNonObjectAsNull]
callback EventHandlerNonNull = any (Event event);
typedef EventHandlerNonNull? EventHandler;
```

In JavaScript, any `Function` object implements this interface.

For example, the following document fragment:

```html
<body onload="alert(this)" onclick="alert(this)"/>
```

...leads to an alert saying "[object Window]" when the document is loaded, and an alert saying "[object HTMLBodyElement]" whenever the user clicks something in the page.

The return value of the function affects whether the event is canceled or not: as described above, if the return value is false, the event is canceled.

There are two exceptions in the platform, for historical reasons:

- The `onerror` handlers on global objects, where returning `true` cancels the event.
- The `onbeforeunload` handler, where returning any non-null and non-undefined value will cancel the event.

For historical reasons, the `onerror` handler has different arguments:

```idl
[LegacyTreatNonObjectAsNull]
callback OnErrorEventHandlerNonNull = any ((Event or DOMString) event, optional);
typedef OnErrorEventHandlerNonNull? OnErrorEventHandler;
```

```javascript
window.onerror = (message, source, lineno, colno, error) => { ... };
```

Similarly, the `onbeforeunload` handler has a different return value:

```idl
[LegacyTreatNonObjectAsNull]
callback OnBeforeUnloadEventHandlerNonNull = DOMString? (Event event);
typedef OnBeforeUnloadEventHandlerNonNull? OnBeforeUnloadEventHandler;
```

An *internal raw uncompiled handler* is a tuple with the following information:

- An uncompiled script body
- A location where the script body originated, in case an error needs to be reported

When the user agent is to get the current value of the event handler given an `EventTarget` object `eventTarget` and a string `name` that is the `name` of an event handler, it must run these
steps:

1. Let `handlerMap` be `eventTarget`'s [event handler map](#).

2. Let `eventHandler` be `handlerMap[name]`.

3. If `eventHandler`’s [value](#) is an [internal raw uncompiled handler](#), then:
   
   1. If `eventTarget` is an element, then let `element` be `eventTarget`, and `document` be `element`'s [node document](#). Otherwise, `eventTarget` is a [Window](#) object, let `element` be null, and `document` be `eventTarget`'s [associated Document](#).
   
   2. If [scripting is disabled](#) for `document`, then return null.

   3. Let `body` be the uncompiled script body in `eventHandler`’s [value](#).

   4. Let `location` be the location where the script body originated, as given by `eventHandler`’s [value](#).

   5. If `element` is not null and `element` has a [form owner](#), let `form owner` be that [form owner](#). Otherwise, let `form owner` be null.

   6. Let `settings object` be the [relevant settings object](#) of `document`.

   7. If `body` is not parsable as [FunctionBody](#) or if parsing detects an [early error](#), then follow these substeps:
      
      1. Set `eventHandler`’s [value](#) to null.

      This does not [deactivate](#) the event handler, which additionally [removes](#) the event handler’s [listener](#) (if present).

      2. [Report the error](#) for the appropriate [script](#) and with the appropriate position (line number and column number) given by `location`, using `settings object`’s [global object](#). If the error is still [not handled](#) after this, then the error may be reported to a developer console.

      3. Return null.

8. Push `settings object`’s [realm execution context](#) onto the JavaScript execution [context stack](#); it is now the [running JavaScript execution context](#).

   This is necessary so the subsequent invocation of [OrdinaryFunctionCreate](#) takes place in the correct [JavaScript Realm](#).

9. Let `function` be the result of calling [OrdinaryFunctionCreate](#), with arguments:
**sourceText**

If **name** is **onerror** and **eventTarget** is a **Window** object

The string formed by concatenating "function ", **name**,"(event,
source, lineno, colno, error) ", U+000A LF, **body**, U+000A LF, and "."

Otherwise

The string formed by concatenating "function ", **name**,"(event)
{}, U+000A LF, **body**, U+000A LF, and "."

**ParameterList**

If **name** is **onerror** and **eventTarget** is a **Window** object

Let the function have five arguments, named **event**, **source**, **lineno**, **colno**, and **error**.

Otherwise

Let the function have a single argument called **event**.

**body**

The result of parsing **body** above.

**thisMode**

non-lexical-this

**scope**

1. Let **realm** be **settings object**’s **Realm**.

2. Let **scope** be **realm**.\[\[GlobalEnv\]\].

3. If **eventHandler** is an element’s **event handler**, then set **scope** to **NewObjectEnvironment**(document, true, **scope**).

   (Otherwise, **eventHandler** is a **Window** object’s **event handler**.)

4. If **form owner** is not null, then set **scope** to **NewObjectEnvironment**(form owner, true, **scope**).

5. If **element** is not null, then set **scope** to **NewObjectEnvironment**(element, true, **scope**).

6. Return **scope**.

10. Remove **settings object**’s **realm execution context** from the **JavaScript execution context stack**.
11. Set `function.[[ScriptOrModule]]` to null.

This is done because the default behavior, of associating the created function with the nearest `script` on the stack, can lead to path-dependent results. For example, an event handler which is first invoked by user interaction would end up with null `[[ScriptOrModule]]` (since then this algorithm would be first invoked when the `active script` is null), whereas one that is first invoked by dispatching an event from script would have its `[[ScriptOrModule]]` set to that script.

Instead, we just always set `[[ScriptOrModule]]` to null. This is more intuitive anyway; the idea that the first script which dispatches an event is somehow responsible for the event handler code is dubious.

In practice, this only affects the resolution of relative URLs via `import()`, which consult the base URL of the associated script. Nulling out `[[ScriptOrModule]]` means that `HostResolveImportedModule` and `HostImportModuleDynamically` will fall back to the current settings object’s API base URL.

12. Set `eventHandler`'s value to the result of creating a Web IDL `EventHandler` callback function object whose object reference is `function` and whose `callback context` is `settings object`.

4. Return `eventHandler`'s value.

8.1.7.2 Event handlers on elements, `Document` objects, and `Window` objects

The following are the event handlers (and their corresponding event handler event types) that must be supported by all HTML elements, as both event handler content attributes and event handler IDL attributes; and that must be supported by all `Document` and `Window` objects, as event handler IDL attributes:

<table>

8.1.7.3 Event firing

Certain operations and methods are defined as firing events on elements. For example, the click() method on the HTMLElement interface is defined as firing a click event on the element. [UIEVENTS]

Firing a synthetic pointer event named e at target, with an optional not trusted flag, means running these steps:

1. Let event be the result of creating an event using PointerEvent.
2. Initialize event’s type attribute to e.
3. Initialize event’s bubbles and cancelable attributes to true.
4. Set event’s composed flag.
5. If the not trusted flag is set, initialize event’s isTrusted attribute to false.
6. Initialize event’s ctrlKey, shiftKey, altKey, and metaKey attributes according to
the current state of the key input device, if any (false for any keys that are not available).

7. Initialize event’s view attribute to target’s node document’s window object, if any, and null otherwise.

8. event’s getModifierState() method is to return values appropriately describing the current state of the key input device.

9. Return the result of dispatching event at target.

Firing a click event at target means firing a synthetic pointer event named click at target.

8.2 The WindowOrWorkerGlobalScope mixin

The WindowOrWorkerGlobalScope mixin is for use of APIs that are to be exposed on Window and WorkerGlobalScope objects.

Other standards are encouraged to further extend it using partial interface mixin WindowOrWorkerGlobalScope { ... }; along with an appropriate reference.

typedef (DOMString or Function) TimerHandler;

interface mixin WindowOrWorkerGlobalScope {
  [Replaceable] readonly attribute USVString origin;
  readonly attribute boolean isSecureContext;
  readonly attribute boolean crossOriginIsolated;
  undefined reportError(any e);

  // base64 utility methods
  DOMString btoa(DOMString data);
  ByteString atob(DOMString data);

  // timers
  long setTimeout(TimerHandler handler, optional long timeout = 0, any... arguments);
  undefined clearTimeout(optional long handle = 0);
  long setInterval(TimerHandler handler, optional long timeout = 0, any... arguments);
  undefined clearInterval(optional long handle = 0);

  // microtask queuing
  undefined queueMicrotask(VoidFunction callback);

  // ImageBitmap
  Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, optional ImageBitmapOptions options);
  Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, long sx, long sy, any... arguments);

// structured cloning
any structuredClone(any value, optional StructuredSerializeOptions options = {});
Window includes WindowOrWorkerGlobalScope;
WorkerGlobalScope includes WindowOrWorkerGlobalScope;

self.isSecureContext

isSecureContext

Support in all current engines.

Firefox49+ Safari11.1+ Chrome47+
Opera34+ Edge79+
Edge (Legacy)15+ Internet ExplorerNo
Firefox Android49+ Safari iOS11.3+ Chrome Android47+ WebView Android47+ Samsung
Internet5.0+ Opera Android34+

Returns whether or not this global object represents a secure context. [SECURE- CONTEXTS]

self.origin

origin

Support in all current engines.

Firefox54+ Safari11+ Chrome59+
Opera46+ Edge79+
Edge (Legacy)18 Internet ExplorerNo
Firefox Android54+ Safari iOS11+ Chrome Android59+ WebView Android59+ Samsung
Internet7.0+ Opera Android43+

Returns the global object’s origin, serialized as string.

self.crossOriginIsolated

crossOriginIsolated

Firefox72+ Safari No Chrome87+
Opera73+ Edge87+
Edge (Legacy) No Internet Explorer No
Returns whether scripts running in this global are allowed to use APIs that require cross-origin isolation. This depends on the `Cross-Origin-Opener-Policy` and `Cross-Origin-Embedder-Policy` HTTP response headers and the "cross-origin-isolated" feature.

Developers are strongly encouraged to use `self.origin` over `location.origin`. The former returns the `origin` of the environment, the latter of the URL of the environment. Imagine the following script executing in a document on `https://stargate.example`:

```javascript
var frame = document.createElement("iframe")
frame.onload = function() {
  var frameWin = frame.contentWindow
  console.log(frameWin.location.origin) // "null"
  console.log(frameWin.origin) // "https://stargate.example"
}
document.body.appendChild(frame)

self.origin is a more reliable security indicator.

The `isSecureContext` getter steps are to return true if this’s relevant settings object is a secure context, or false otherwise.

The `origin` getter steps are to return this’s relevant settings object’s `origin`, serialized.

The `crossOriginIsolated` getter steps are to return this’s relevant settings object’s cross-origin isolated capability.

### 8.3 Base64 utility methods

The `atob()` and `btoa()` methods allow developers to transform content to and from the base64 encoding.

In these APIs, for mnemonic purposes, the "b" can be considered to stand for "binary", and the "a" for "ASCII". In practice, though, for primarily historical reasons, both the input and output of these functions are Unicode strings.

```javascript
result = self.btoa(data)
```
Takes the input data, in the form of a Unicode string containing only characters in the
range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF
respectively, and converts it to its base64 representation, which it returns.

Throws an "InvalidCharacterError" DOMException exception if the input string
contains any out-of-range characters.

```
result = self.atob(data)
```

Support in all current engines.

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>Safari</td>
<td>Chrome</td>
<td>Safari</td>
<td>Chrome</td>
</tr>
<tr>
<td>1+1+</td>
<td>3+3+</td>
<td>4+4+</td>
<td>1+1+</td>
<td>4+4+</td>
</tr>
<tr>
<td>Opera</td>
<td>Edge</td>
<td>Internet Explorer</td>
<td>Opera</td>
<td>Edge</td>
</tr>
<tr>
<td>10.5+</td>
<td>79+</td>
<td>10+</td>
<td>10.5+</td>
<td>79+</td>
</tr>
</tbody>
</table>

Takes the input data, in the form of a Unicode string containing base64-encoded binary
data, decodes it, and returns a string consisting of characters in the range U+0000 to
U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively,
corresponding to that binary data.

Throws an "InvalidCharacterError" DOMException if the input string is not valid
base64 data.

The `btoa(data)` method must throw an "InvalidCharacterError" DOMException if
data contains any character whose code point is greater than U+00FF. Otherwise, the user
agent must convert data to a byte sequence whose nth byte is the eight-bit representation
of the nth code point of data, and then must apply forgiving-base64 encode to that byte sequence
and return the result.

The `atob(data)` method steps are:

1. Let `decodedData` be the result of running forgiving-base64 decode on data.
2. If `decodedData` is failure, then throw an "InvalidCharacterError"
   DOMException.
3. Return `decodedData`.

### 8.4 Dynamic markup insertion

APIs for dynamically inserting markup into the document interact with the parser, and thus their behavior varies depending on whether they are used with HTML documents (and the HTML parser) or XML documents (and the XML parser).

`Document` objects have a **throw-on-dynamic-markup-insertion counter**, which is used in conjunction with the create an element for the token algorithm to prevent custom element constructors from being able to use `document.open()`, `document.close()`, and `document.write()` when they are invoked by the parser. Initially, the counter must be set to zero.

#### 8.4.1 Opening the input stream

```javascript
document = document.open()
```

**Document/open**

**Support in all current engines.**

<table>
<thead>
<tr>
<th>Browser</th>
<th>Compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 1+</td>
<td>+</td>
</tr>
<tr>
<td>Safari 11+</td>
<td>+</td>
</tr>
<tr>
<td>Chrome 64+</td>
<td>+</td>
</tr>
<tr>
<td>Opera 51+</td>
<td>+</td>
</tr>
<tr>
<td>Edge (Legacy) 12+</td>
<td>+</td>
</tr>
<tr>
<td>Internet Explorer 4+</td>
<td>+</td>
</tr>
<tr>
<td>Firefox Android 4+</td>
<td>+</td>
</tr>
<tr>
<td>Safari iOS 11+</td>
<td>+</td>
</tr>
<tr>
<td>Chrome Android 64+</td>
<td>+</td>
</tr>
<tr>
<td>WebView Android 64+</td>
<td>+</td>
</tr>
<tr>
<td>Samsung Internet 9.0+</td>
<td>+</td>
</tr>
<tr>
<td>Opera Android 47+</td>
<td>+</td>
</tr>
</tbody>
</table>

Causes the `Document` to be replaced in-place, as if it was a new `Document` object, but reusing the previous object, which is then returned.

The resulting `Document` has an HTML parser associated with it, which can be given data to parse using `document.write()`.

The method has no effect if the `Document` is still being parsed.

Throws an "InvalidStateError" `DOMException` if the `Document` is an `XML document`.

Throws an "InvalidStateError" `DOMException` if the parser is currently executing a custom element constructor.

```javascript
window = document.open(url, name, features)
```

Works like the `window.open()` method.
Document objects have an active parser was aborted boolean, which is used to prevent scripts from invoking the document.open() and document.write() methods (directly or indirectly) after the document’s active parser has been aborted. It is initially false.

The document open steps, given a document, are as follows:

1. If document is an XML document, then throw an "InvalidStateError" DOMException exception.

2. If document’s throw-on-dynamic-markup-insertion counter is greater than 0, then throw an "InvalidStateError" DOMException.

3. Let entryDocument be the entry global object’s associated Document.

4. If document’s origin is not same origin to entryDocument’s origin, then throw a "SecurityError" DOMException.

5. If document has an active parser whose script nesting level is greater than 0, then return document.

   This basically causes document.open() to be ignored when it’s called in an inline script found during parsing, while still letting it have an effect when called from a non-parser task such as a timer callback or event handler.

6. Similarly, if document’s unload counter is greater than 0, then return document.

   This basically causes document.open() to be ignored when it’s called from a beforeunload, pagehide, or unload event handler while the Document is being unloaded.

7. If document’s active parser was aborted is true, then return document.

   This notably causes document.open() to be ignored if it is called after a navigation has started, but only during the initial parse. See issue #4723 for more background.

8. If document’s browsing context is non-null and there is an existing attempt to navigate document’s browsing context, then stop document loading given document.

   Issue #3447 looks into the distinction between an ongoing instance of the navigate algorithm versus tasks to navigate that are still queued. For the purpose of implementing this step, both an ongoing instance of the navigate algorithm and tasks queued to navigate should be counted towards "an existing attempt to navigate," at least until that issue is resolved.

9. For each shadow-including inclusive descendant node of document, erase all event listeners and handlers given node.
10. If `document` is the associated `Document` of `document`'s relevant global object, then erase all event listeners and handlers given `document`'s relevant global object.

11. Replace all with null within `document`, without firing any mutation events.

12. If `document` is fully active, then:
   
   1. Let `newURL` be a copy of `entryDocument`'s `URL`.
   
   2. If `entryDocument` is not `document`, then set `newURL`'s `fragment` to null.
   
   3. Run the URL and history update steps with `document` and `newURL`.

13. Set `document`'s `is initial about:blank` to false.

14. If `document`'s `iframe load in progress` flag is set, then set `document`'s `mute iframe load` flag.

15. Set `document` to no-quirks mode.

16. Create a new HTML parser and associate it with `document`. This is a script-created parser (meaning that it can be closed by the `document.open()` and `document.close()` methods, and that the tokenizer will wait for an explicit call to `document.close()` before emitting an end-of-file token). The encoding confidence is irrelevant.

17. Set the insertion point to point at just before the end of the `input stream` (which at this point will be empty).

18. Update the current document readiness of `document` to "loading".

   This causes a `readystatechange` event to fire, but the event is actually unobservable to author code, because of the previous step which erased all event listeners and handlers that could observe it.

The document open steps do not affect whether a `Document` is ready for post-load tasks or completely loaded.

The `open(unused1, unused2)` method must return the result of running the document open steps with this.

The `unused1` and `unused2` arguments are ignored, but kept in the IDL to allow code that calls the function with one or two arguments to continue working. They are necessary due to Web IDL overload resolution algorithm rules, which would throw a `TypeError` exception for such calls had the arguments not been there. whatwg/webidl issue #581 investigates changing the algorithm to allow for their removal. [WEBIDL]
The `open(url, name, features)` method must run these steps:

1. If this is not an active document, then throw an "InvalidAccessError" DOMException exception.

2. Return the result of running the `window open steps` with `url, name, and features`.

8.4.2 Closing the input stream

```markdown
**document.close()**

MDN

Document/close

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox1+</td>
<td>Safari11+</td>
</tr>
<tr>
<td>Chrome64+</td>
<td>Opera51+</td>
</tr>
<tr>
<td>Edge79+</td>
<td>Edge (Legacy)12+</td>
</tr>
<tr>
<td>Internet Explorer4+</td>
<td>Firefox Android4+</td>
</tr>
<tr>
<td>Safari iOS11+</td>
<td>Chrome Android64+</td>
</tr>
<tr>
<td>WebView Android64+</td>
<td>Samsung</td>
</tr>
<tr>
<td>Internet9.0+</td>
<td>Opera Android47+</td>
</tr>
</tbody>
</table>

Closes the input stream that was opened by the `document.open()` method.

Throws an "InvalidStateError" DOMException if the Document is an XML document.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor.

The `close()` method must run the following steps:

1. If the Document object is an XML document, then throw an "InvalidStateError" DOMException.

2. If the Document object’s throw-on-dynamic-markup-insertion counter is greater than zero, then throw an "InvalidStateError" DOMException.

3. If there is no script-created parser associated with the document, then return.

4. Insert an explicit "EOF" character at the end of the parser’s input stream.

5. If there is a pending parsing-blocking script, then return.

6. Run the tokenizer, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the explicit "EOF" character or spins the event loop.
8.4.3 `document.write()`

`document.write(...text)`

Document/write

Support in all current engines.

<table>
<thead>
<tr>
<th>Engine</th>

<td>10.1+</td>
</tr>
</tbody>
</table>

In general, adds the given string(s) to the Document’s input stream.

This method has very idiosyncratic behavior. In some cases, this method can affect the state of the HTML parser while the parser is running, resulting in a DOM that does not correspond to the source of the document (e.g. if the string written is the string `&lt;plaintext&gt;` or `&lt;!- -&gt;`). In other cases, the call can clear the current page first, as if `document.open()` had been called. In yet more cases, the method is simply ignored, or throws an exception. Users agents are explicitly allowed to avoid executing script elements inserted via this method. And to make matters even worse, the exact behavior of this method can in some cases be dependent on network latency, which can lead to failures that are very hard to debug. For all these reasons, use of this method is strongly discouraged.

Throws an "InvalidStateError" DOMException when invoked on XML documents.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor.

Document objects have an ignore-destructive-writes counter, which is used in conjunction with the processing of script elements to prevent external scripts from being able to use `document.write()` to blow away the document by implicitly calling `document.open()`.

Initially, the counter must be set to zero.

The document write steps, given a Document object document and a string input, are as follows:

1. If document is an XML document, then throw an "InvalidStateError" DOMException.

2. If document's throw-on-dynamic-markup-insertion counter is greater than 0, then throw an "InvalidStateError" DOMException.
3. If `document`'s active parser was aborted is true, then return.

4. If the insertion point is undefined, then:
   
   1. If `document`'s unload counter is greater than 0 or `document`'s ignore-destructive-writes counter is greater than 0, then return.
   
   2. Run the document open steps with `document`.

5. Insert `input` into the input stream just before the insertion point.

6. If there is no pending parsing-blocking script, have the HTML parser process `input`, one code point at a time, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the insertion point or when the processing of the tokenizer is aborted by the tree construction stage (this can happen if a script end tag token is emitted by the tokenizer).

   If the `document.write()` method was called from script executing inline (i.e. executing because the parser parsed a set of script tags), then this is a reentrant invocation of the parser. If the parser pause flag is set, the tokenizer will abort immediately and no HTML will be parsed, per the tokenizer’s parser pause flag check.

The `document.write(...)` method steps are to run the document write steps with this and a string that is the concatenation of all arguments passed.

8.4.4 `document.writeln()`

doctype.writeln(...text)

Support in all current engines.

Firefox 1.0+ Safari 1.1+ Chrome 64+
Opera 51+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 4+
Firefox Android 4.4+Safari iOS 11.1+Chrome Android 64+WebView Android 64+Samsung Internet 9.0+Opera Android 47+

Adds the given string(s) to the Document’s input stream, followed by a newline character. If necessary, calls the open() method implicitly first.

Throws an "InvalidStateError" DOMException when invoked on XML documents.

Throws an "InvalidStateError" DOMException if the parser is currently executing a
custom element constructor.

The `document.writeln(...)` method steps are to run the `document write steps` with `this` and a string that is the concatenation of all arguments passed and U+000A LINE FEED.

### 8.5 DOM parsing

**DOMParser**

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>

<td>Yes</td>
</tr>
</tbody>
</table>

Constructs a new `DOMParser` object.

```javascript
document = parser.parseFromString(string, type)
```

**DOMParser/parseFromString**

Support in all current engines.
Parses string using either the HTML or XML parser, according to type, and returns the resulting Document. type can be "text/html" (which will invoke the HTML parser), or any of "text/xml", "application/xml", "application/xhtml+xml", or "image/svg+xml" (which will invoke the XML parser).

For the XML parser, if string cannot be parsed, then the returned Document will contain elements describing the resulting error.

Note that script elements are not evaluated during parsing, and the resulting document’s encoding will always be UTF-8.

Values other than the above for type will cause a TypeError exception to be thrown.

The design of DOMParser, as a class that needs to be constructed and then have its parseFromString() method called, is an unfortunate historical artifact. If we were designing this functionality today it would be a standalone function.

[Exposed=Window]
interface DOMParser {
  constructor();

  [NewObject] Document parseFromString(DOMString string, DOMParserSupportedType type);
}

enum DOMParserSupportedType {
  "text/html",
  "text/xml",
  "application/xml",
  "application/xhtml+xml",
  "image/svg+xml"
};

The new DOMParser() constructor steps are to do nothing.

The parseFromString(string, type) method steps are:

1. Let document be a new Document, whose content type is type and url is this’s relevant global object’s associated Document’s URL.

   The document’s encoding will be left as its default, of UTF-8. In particular, any XML declarations or meta elements found while parsing string will have no effect.
2. Switch on type:

"text/html"

1. Set document's type to "html".

2. Create an HTML parser parser, associated with document.

3. Place string into the input stream for parser. The encoding confidence is irrelevant.

4. Start parser and let it run until it has consumed all the characters just inserted into the input stream.

This might mutate the document's mode.

Since document does not have a browsing context, scripting is disabled.

Otherwise

1. Create an XML parser parse, associated with document, and with XML scripting support disabled.

2. Parse string using parser.

3. If the previous step resulted in an XML well-formedness or XML namespace well-formedness error, then:

   1. Assert: document has no child nodes.

   2. Let root be the result of creating an element given document, "parsererror", and "http://www.mozilla.org/newlayout/xml/parsererror.xml".

   3. Optionally, add attributes or children to root to describe the nature of the parsing error.

   4. Append root to document.

8.6 Timers

The setTimeout() and setInterval() methods allow authors to schedule timer-based callbacks.

handle = self.setTimeout(handler [, timeout [, ...arguments ] ] )
**setTimeout**

Support in all current engines.

Firefox1+Safari1+Chrome1+  
Opera4+Edge79+  
Edge (Legacy)12+Internet Explorer4+  
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung  
Internet1.0+Opera Android10.1+

Schedules a timeout to run `handler` after `timeout` milliseconds. Any arguments are passed straight through to the `handler`.

```javascript
handle = self.setTimeout(code [, timeout ])
```

Schedules a timeout to compile and run `code` after `timeout` milliseconds.

```javascript
self.clearTimeout(handle)
```

**clearTimeout**

Support in all current engines.

Firefox1+Safari1+Chrome1+  
Opera4+Edge79+  
Edge (Legacy)12+Internet Explorer4+  
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android37+Samsung  
Internet1.0+Opera Android10.1+

Cancels the timeout set with `setTimeout()` or `setInterval()` identified by `handle`.

```javascript
handle = self.clearTimeout(handler [, timeout [, ...arguments ] ])
```

**setInterval**

Support in all current engines.

Firefox1+Safari1+Chrome1+  
Opera4+Edge79+  
Edge (Legacy)12+Internet Explorer4+  
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung
Schedules a timeout to run `handler` every `timeout` milliseconds. Any `arguments` are passed straight through to the `handler`.

```javascript
handle = self.setInterval(code [, timeout ])
```

Schedules a timeout to compile and run `code` every `timeout` milliseconds.

```javascript
self.clearInterval(handle)
```

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>1+</td>
</tr>
<tr>
<td>Safari</td>
<td>1+</td>
</tr>
<tr>
<td>Chrome</td>
<td>1+</td>
</tr>
<tr>
<td>Opera</td>
<td>4+</td>
</tr>
<tr>
<td>Edge</td>
<td>12+</td>
</tr>
<tr>
<td>Edge (Legacy)</td>
<td>12+</td>
</tr>
<tr>
<td>Internet Explorer</td>
<td>4+</td>
</tr>
<tr>
<td>Firefox Android</td>
<td>4+</td>
</tr>
<tr>
<td>Safari iOS</td>
<td>1+</td>
</tr>
<tr>

<td>18+</td>
</tr>
<tr>
<td>WebView Android</td>
<td>37+</td>
</tr>
<tr>
<td>Samsung</td>
<td>1.0</td>
</tr>
<tr>
<td>Opera Android</td>
<td>10.1+</td>
</tr>
</tbody>
</table>

Cancels the timeout set with `setInterval()` or `setTimeout()` identified by `handle`.

Timers can be nested; after five such nested timers, however, the interval is forced to be at least four milliseconds.

This API does not guarantee that timers will run exactly on schedule. Delays due to CPU load, other tasks, etc, are to be expected.

Objects that implement the `WindowOrWorkerGlobalScope` mixin have a `map of active timers`, which is a `map`, initially empty. Each `key` in this map is identified by a number, which must be unique within the list for the lifetime of the object that implements the `WindowOrWorkerGlobalScope` mixin, and each `value` is a `DOMHighResTimeStamp`, representing the expiry time for that timer.

To get the `list of active timers` for `WindowOrWorkerGlobalScope` `global`, return the result of `getting the keys` for `global`'s `map of active timers`.

The `setTimeout(handler, timeout, ...arguments)` method must return the value returned by the `timer initialization steps`, passing them the method’s arguments, the object on which the method for which the algorithm is running is implemented (a `Window` or `WorkerGlobalScope` object) as the `method context`, and the `repeat` flag set to false.

The `setInterval(handler, timeout, ...arguments)` method must return the value returned by the `timer initialization steps`, passing them the method’s arguments, the object on
which the method for which the algorithm is running is implemented (a `Window` or `WorkerGlobalScope` object) as the *method context*, and the *repeat* flag set to true.

The `clearTimeout(handle)` and `clearInterval(handle)` methods must remove map of active timers[handle] of the `WindowOrWorkerGlobalScope` object on which the method was invoked, if any, where *handle* is the argument passed to the method.

Because `clearTimeout()` and `clearInterval()` clear entries from the same map, either method can be used to clear timers created by `setTimeout()` or `setInterval()`.

The **timer initialization steps**, which are invoked with some method arguments, a *method context*, a *repeat* flag which can be true or false, and optionally (and only if the *repeat* flag is true) a *previous handle*, are as follows:

1. Let *method context proxy* be *method context* if that is a `WorkerGlobalScope` object, or else the `WindowProxy` that corresponds to *method context*.

2. If *previous handle* was provided, let *handle* be *previous handle*; otherwise, let *handle* be an implementation-defined integer that is greater than zero that will identify the timeout to be set by this call in the list of active timers.

3. Let *callerRealm* be the current Realm Record, and *calleeRealm* be *method context*’s JavaScript realm.

4. Let *initiating script* be the active script.

5. Assert: *initiating script* is not null, since this algorithm is always called from some script.

6. Let *task* be a *task* that runs the following substeps:

   1. If *handle* does not exist in *method context*’s map of active timers, then abort these steps.

   2. Run the appropriate set of steps from the following list:

      If the first method argument is a **Function**

      Invoke the `Function`. Use the third and subsequent method arguments (if any) as the arguments for invoking the `Function`. Use *method context proxy* as the *callback this value*. If this throws an exception, catch it, and report the exception.

      Otherwise

      1. Perform `HostEnsureCanCompileStrings(callerRealm, calleeRealm)`. If this throws an exception, catch it, report the exception, and abort
these steps.

2. Let \textit{script source} be the first method argument.

3. Let \textit{settings object} be \textit{method context}’s \textit{environment settings object}.

4. Let \textit{base URL} be \textit{initiating script}’s base URL.

5. Assert: \textit{base URL} is not null, as \textit{initiating script} is a \textit{classic script} or a JavaScript module script.

6. Let \textit{fetch options} be a \textit{script fetch options} whose cryptographic nonce is \textit{initiating script}’s fetch options’ cryptographic nonce, integrity metadata is the empty string, parser metadata is “not-parser-inserted”, credentials mode is \textit{initiating script}’s fetch options’ credentials mode, and referrer policy is \textit{initiating script}’s fetch options’ referrer policy.

   The effect of these options ensures that the string compilation done by \texttt{setTimeout()} and \texttt{setInterval()} behaves equivalently to that done by \texttt{eval()}. That is, module script fetches via \texttt{import()} will behave the same in both contexts.

7. Let \textit{script} be the result of \textit{creating a classic script} given \textit{script source}, \textit{settings object}, \textit{base URL}, and \textit{fetch options}.

8. \textbf{Run the classic script} \textit{script}.

   3. If the \textit{repeat} flag is true, then call \textbf{timer initialization steps} again, passing them the same method arguments, the same \textit{method context}, with the \textit{repeat} flag still set to true, and with the \textit{previous handle} set to \textit{handler}.

7. Let \textit{timeout} be the second method argument.

8. If the currently running \textit{task} is a task that was created by this algorithm, then let \textit{nesting level} be the \textit{task}’s \textit{timer nesting level}. Otherwise, let \textit{nesting level} be zero.

   The \textit{task}’s \textit{timer nesting level} is used both for nested calls to \texttt{setTimeout()}, and for the repeating timers created by \texttt{setInterval()}. (Or, indeed, for any combination of the two.) In other words, it represents nested invocations of this algorithm, not of a particular method.

9. If \textit{timeout} is less than 0, then set \textit{timeout} to 0.

10. If \textit{nesting level} is greater than 5, and \textit{timeout} is less than 4, then set \textit{timeout} to 4.

11. Increment \textit{nesting level} by one.
12. Let task’s timer nesting level be nesting level.

13. Let startTime be the current high resolution time.

14. Set map of active timers[handle] to startTime plus timeout.

15. Return handle, and then continue running this algorithm in parallel.

16. If method context is a Window object, wait until the Document associated with method context has been fully active for a further timeout milliseconds (not necessarily consecutively).

   Otherwise, method context is a WorkerGlobalScope object; wait until timeout milliseconds have passed with the worker not suspended (not necessarily consecutively).

17. Wait until any invocations of this algorithm that had the same method context, that started before this one, and whose timeout is equal to or less than this one’s, have completed.

   Argument conversion as defined by Web IDL (for example, invoking toString() methods on objects passed as the first argument) happens in the algorithms defined in Web IDL, before this algorithm is invoked.

   So for example, the following rather silly code will result in the log containing "ONE TWO ":

   ```javascript
   var log = '';
   function logger(s) { log += s + ' '; }
   setTimeout({ toString: function () {
     setTimeout('logger('ONE')", 100);
     return "logger('TWO')";
   } }, 100);
   ```

18. Optionally, wait a further implementation-defined length of time.

   This is intended to allow user agents to pad timeouts as needed to optimize the power usage of the device. For example, some processors have a low-power mode where the granularity of timers is reduced; on such platforms, user agents can slow timers down to fit this schedule instead of requiring the processor to use the more accurate mode with its associated higher power usage.

19. Queue a global task on the timer task source given method context to run task.

   Once the task has been processed, if the repeat flag is false, it is safe to remove the entry for handle from the list of active timers (there is no way for the entry’s existence to be detected past this point, so it does not technically matter one way or the other).
To run tasks of several milliseconds back to back without any delay, while still yielding back to the browser to avoid starving the user interface (and to avoid the browser killing the script for hogging the CPU), simply queue the next timer before performing work:

```javascript
function doExpensiveWork() {
    var done = false;
    // ...
    // this part of the function takes up to five milliseconds
    // set done to true if we're done
    // ...
    return done;
}

function rescheduleWork() {
    var handle = setTimeout(rescheduleWork, 0); // preschedule next iteration
    if (doExpensiveWork())
        clearTimeout(handle); // clear the timeout if we don't need it
}

function scheduleWork() {
    setTimeout(rescheduleWork, 0);
}

scheduleWork(); // queues a task to do lots of work
```

### 8.7 Microtask queuing

[MDN](https://developer.mozilla.org)

queueMicrotask

Support in all current engines.

**self.queueMicrotask(callback)**

Queues a microtask to run the given callback.

The `queueMicrotask(callback)` method must queue a microtask to invoke callback, and if callback throws an exception, report the exception.

The `queueMicrotask()` method allows authors to schedule a callback on the microtask
queue. This allows their code to run once the JavaScript execution context stack is next empty, which happens once all currently executing synchronous JavaScript has run to completion. This doesn’t yield control back to the event loop, as would be the case when using, for example, setTimeout(f, 0).

Authors ought to be aware that scheduling a lot of microtasks has the same performance downsides as running a lot of synchronous code. Both will prevent the browser from doing its own work, such as rendering. In many cases, requestAnimationFrame() or requestIdleCallback() is a better choice. In particular, if the goal is to run code before the next rendering cycle, that is the purpose of requestAnimationFrame().

As can be seen from the following examples, the best way of thinking about queueMicrotask() is as a mechanism for rearranging synchronous code, effectively placing the queued code immediately after the currently executing synchronous JavaScript has run to completion.

The most common reason for using queueMicrotask() is to create consistent ordering, even in the cases where information is available synchronously, without introducing undue delay.

For example, consider a custom element firing a load event, that also maintains an internal cache of previously-loaded data. A naïve implementation might look like:

```javascript
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    this._setData(this._cache[url]);
    this.dispatchEvent(new Event("load"));
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

This naïve implementation is problematic, however, in that it causes its users to experience inconsistent behavior. For example, code such as

```javascript
element.addEventListener("load", () => console.log("loaded"));
console.log("1");
element.loadData();
console.log("2");
```

will sometimes log “1, 2, loaded” (if the data needs to be fetched), and sometimes log “1, loaded, 2” (if the data is already cached). Similarly, after the call to loadData(), it will be inconsistent whether or not the data is set on the element.
To get a consistent ordering, `queueMicrotask()` can be used:

```javascript
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    queueMicrotask(() => {
      this._setData(this._cache[url]);
      this.dispatchEvent(new Event("load"));
    });
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

By essentially rearranging the queued code to be after the JavaScript execution context stack empties, this ensures a consistent ordering and update of the element’s state.

Another interesting use of `queueMicrotask()` is to allow uncoordinated “batching” of work by multiple callers. For example, consider a library function that wants to send data somewhere as soon as possible, but doesn’t want to make multiple network requests if doing so is easily avoidable. One way to balance this would be like so:

```javascript
const queuedToSend = [];

function sendData(data) {
  queuedToSend.push(data);

  if (queuedToSend.length === 1) {
    queueMicrotask(() => {
      const stringToSend = JSON.stringify(queuedToSend);
      queuedToSend.length = 0;

      fetch("/endpoint", stringToSend);
    });
  }
}
```

With this architecture, multiple subsequent calls to `sendData()` within the currently executing synchronous JavaScript will be batched together into one `fetch()` call, but with no intervening event loop tasks preempting the fetch (as would have happened with similar code that instead used `setTimeout()`).
8.8 User prompts

8.8.1 Simple dialogs

```
window.alert(message)
```

**Support in all current engines.**

Firefox1+Safari1+Chrome1+
Opera3+Edge79+
Edge (Legacy)12+Internet Explorer4+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+

Displays a modal alert with the given message, and waits for the user to dismiss it.

```
result = window.confirm(message)
```

**Support in all current engines.**

Firefox1+Safari1+Chrome1+
Opera3+Edge79+
Edge (Legacy)12+Internet Explorer4+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+

Displays a modal OK/Cancel prompt with the given message, waits for the user to dismiss it, and returns true if the user clicks OK and false if the user clicks Cancel.

```
result = window.prompt(message [, default])
```

**Support in all current engines.**

Firefox1+Safari1+Chrome1+
Opera3+Edge79+
Edge (Legacy)12+Internet Explorer4+
Displays a modal text control prompt with the given message, waits for the user to dismiss it, and returns the value that the user entered. If the user cancels the prompt, then returns null instead. If the second argument is present, then the given value is used as a default.

Logic that depends on tasks or microtasks, such as media elements loading their media data, are stalled when these methods are invoked.

The `alert()` and `alert(message)` method steps are:

1. If we cannot show simple dialogs for this, then return.
2. If the method was invoked with no arguments, then let `message` be the empty string; otherwise, let `message` be the method’s first argument.
3. Set `message` to the result of normalizing newlines given `message`.
4. Set `message` to the result of optionally truncating `message`.
5. Show `message` to the user, treating U+000A LF as a line break.
6. Optionally, pause while waiting for the user to acknowledge the message.

This method is defined using two overloads, instead of using an optional argument, for historical reasons. The practical impact of this is that `alert(undefined)` is treated as `alert("undefined")`, but `alert()` is treated as `alert("\")`.

The `confirm(message)` method steps are:

1. If we cannot show simple dialogs for this, then return false.
2. Set `message` to the result of normalizing newlines given `message`.
3. Set `message` to the result of optionally truncating `message`.
4. Show `message` to the user, treating U+000A LF as a line break, and ask the user to respond with a positive or negative response.
5. Pause until the user responds either positively or negatively.
6. If the user responded positively, return true; otherwise, the user responded negatively: return false.

The `prompt(message, default)` method steps are:

1. If we cannot show simple dialogs for this, then return null.
2. Set `message` to the result of normalizing newlines given `message`.

3. Set `message` to the result of optionally truncating `message`.

4. Set `default` to the result of optionally truncating `default`.

5. Show `message` to the user, treating U+000A LF as a line break, and ask the user to either respond with a string value or abort. The response must be defaulted to the value given by `default`.

6. Pause while waiting for the user’s response.

7. If the user aborts, then return null; otherwise, return the string that the user responded with.

To **optionally truncate a simple dialog string** `s`, return either `s` itself or some string derived from `s` that is shorter. User agents should not provide UI for displaying the elided portion of `s`, as this makes it too easy for abusers to create dialogs of the form "Important security alert! Click ‘Show More’ for full details!".

For example, a user agent might want to only display the first 100 characters of a message. Or, a user agent might replace the middle of the string with "…". These types of modifications can be useful in limiting the abuse potential of unnaturally large, trustworthy-looking system dialogs.

We **cannot show simple dialogs** for a `window` window when the following algorithm returns true:

1. If the active sandboxing flag set of `window`'s associated `Document` has the sandboxed modals flag set, then return true.

2. If `window`'s relevant settings object’s `origin` and `window`'s relevant settings object’s `top-level origin` are not same origin-domain, then return true.

3. If `window`'s relevant agent’s `event loop`'s `termination nesting level` is nonzero, then optionally return true.

4. Optionally, return true. (For example, the user agent might give the user the option to ignore all modal dialogs, and would thus abort at this step whenever the method was invoked.)

5. Return false.

### 8.8.2 Printing

✔️MDN
**Window/print**

Support in all current engines.

Firefox1+Safari1.1+Chrome1+
Opera6+Edge79+
Edge (Legacy)12+Internet Explorer5+
Firefox AndroidNoSafari iOS1+Chrome Android18+WebView Android1+Samsung
Internet1.0+Opera Android10.1+

**window.print()**

Prompts the user to print the page.

The `print()` method steps are:

1. Let `document` be this’s associated `Document`.
2. If `document` is not fully active, then return.
3. If `document`’s `unload counter` is greater than 0, then return.
4. If `document` is ready for post-load tasks, then run the printing steps for `document`.
5. Otherwise, set `document`’s `print when loaded` flag.

User agents should also run the printing steps whenever the user asks for the opportunity to obtain a physical form (e.g. printed copy), or the representation of a physical form (e.g. PDF copy), of a document.

The printing steps for a `Document` `document` are:

1. The user agent may display a message to the user or return (or both).

   For instance, a kiosk browser could silently ignore any invocations of the `print()` method.

   For instance, a browser on a mobile device could detect that there are no printers in the vicinity and display a message saying so before continuing to offer a "save to PDF" option.

2. If the active sandboxing flag set of `document` has the sandboxed modals flag set, then return.

   If the printing dialog is blocked by a `Document`’s sandbox, then neither the `beforeprint` nor `afterprint` events will be fired.

3. The user agent must fire an event named `beforeprint` at the relevant global object of
document, as well as any child browsing contexts in it.

The beforeprint event can be used to annotate the printed copy, for instance adding the time at which the document was printed.

4. The user agent should offer the user the opportunity to obtain a physical form (or the representation of a physical form) of document. The user agent may wait for the user to either accept or decline before returning; if so, the user agent must pause while the method is waiting. Even if the user agent doesn't wait at this point, the user agent must use the state of the relevant documents as they are at this point in the algorithm if and when it eventually creates the alternate form.

5. The user agent must fire an event named afterprint at the relevant global object of document, as well as any child browsing contexts in it.

The afterprint event can be used to revert annotations added in the earlier event, as well as showing post-printing UI. For instance, if a page is walking the user through the steps of applying for a home loan, the script could automatically advance to the next step after having printed a form or other.

8.9 System state and capabilities

8.9.1 The Navigator object

Support in all current engines.

<table>

Instances of Navigator represent the identity and state of the user agent (the client). They also serve as a generic global under which various APIs are located in this and other specifications.

```javascript
[Exposed=Window]
interface Navigator {
  // objects implementing this interface also implement the interfaces given below
};
Navigator includes NavigatorID;
Navigator includes NavigatorLanguage;
```
Navigator includes NavigatorOnline;
Navigator includes NavigatorContentUtils;
Navigator includes NavigatorCookies;
Navigator includes NavigatorPlugins;
Navigator includes NavigatorConcurrentHardware;

These interface mixins are defined separately so that WorkerNavigator can reuse parts of the Navigator interface.

Each Window has an associated Navigator, which is a Navigator object. Upon creation of the Window object, its associated Navigator must be set to a new Navigator object created in the Window object’s relevant Realm.

The navigator and clientInformation getter steps are to return this’s associated Navigator.

8.9.1.1 Client identification

interface mixin NavigatorID {
  readonly attribute DOMString appCodeName; // constant "Mozilla"
  readonly attribute DOMString appName; // constant "Netscape"
  readonly attribute DOMString appVersion;
  readonly attribute DOMString platform;
  readonly attribute DOMString product; // constant "Gecko"
  [Exposed=Window] readonly attribute DOMString productSub;
  readonly attribute DOMString userAgent;
  [Exposed=Window] readonly attribute DOMString vendor;
  [Exposed=Window] readonly attribute DOMString vendorSub; // constant ""
};

In certain cases, despite the best efforts of the entire industry, web browsers have bugs and limitations that web authors are forced to work around.

This section defines a collection of attributes that can be used to determine, from script, the

The navigator and clientInformation getter steps are to return this’s associated Navigator.
kind of user agent in use, in order to work around these issues.

The user agent has a `navigator compatibility mode`, which is either *Chrome*, *Gecko*, or *WebKit*.

The `navigator compatibility mode` constrains the `NavigatorID` mixin to the combinations of attribute values and presence of `taintEnabled()` and `oscpu` that are known to be compatible with existing web content.

Client detection should always be limited to detecting known current versions; future versions and unknown versions should always be assumed to be fully compliant.

```javascript
self.navigator.appCodeName
```

Returns the string “Mozilla”.

```javascript
self.navigator.appName
```

Returns the string “Netscape”.

```javascript
self.navigator.appVersion
```

Returns the version of the browser.

```javascript
self.navigator.platform
```

Returns the name of the platform.

```javascript
self.navigator.product
```

Returns the string “Gecko”.

```javascript
window.navigator.productSub
```

Returns either the string “20030107”, or the string “20100101”.

```javascript

</tbody>
</table>

Returns either the empty string, the string "Apple Computer, Inc.", or the string "Google Inc."

```javascript
window.navigator.vendorSub
```

Returns the empty string.

**appCodeName**

Must return the string "Mozilla".

**appName**

Must return the string "Netscape".

**appVersion**

Must return either the string "4.0" or a string representing the version of the browser in detail, e.g. "1.0 (VMS; en-US) Mellblomenator/9000".
**platform**

Must return either the empty string or a string representing the platform on which the browser is executing, e.g. "MacIntel", "Win32", "FreeBSD i386", "WebTV OS".

**product**

Must return the string "Gecko".

**productSub**

Must return the appropriate string from the following list:

If the **navigator compatibility mode** is Chrome or WebKit

The string "20030107".

If the **navigator compatibility mode** is Gecko

The string "20100101".

**userAgent**

Must return the default `User-Agent` value.

**vendor**

Must return the appropriate string from the following list:

If the **navigator compatibility mode** is Chrome

The string "Google Inc.".

If the **navigator compatibility mode** is Gecko

The empty string.

If the **navigator compatibility mode** is WebKit

The string "Apple Computer, Inc.".

**vendorSub**

Must return the empty string.

If the **navigator compatibility mode** is Gecko, then the user agent must also support the following partial interface:
partial interface mixin NavigatorID {
  [Exposed=Window] boolean taintEnabled(); // constant false
  [Exposed=Window] readonly attribute DOMString oscpu;
};

The `taintEnabled()` method must return false.

The `oscpu` attribute’s getter must return either the empty string or a string representing the platform on which the browser is executing, e.g. “Windows NT 10.0; Win64; x64”, “Linux x86_64”.

(This is a tracking vector.) Any information in this API that varies from user to user can be used to profile the user. In fact, if enough such information is available, a user can actually be uniquely identified. For this reason, user agent implementers are strongly urged to include as little information in this API as possible.

8.9.1.2 Language preferences

interface mixin NavigatorLanguage {
  readonly attribute DOMString language;
  readonly attribute FrozenArray<DOMString> languages;

Firefox 32+ Safari 10.1+ Chrome 37+ Opera 24+ Edge 79+
Edge (Legacy) 16+ Internet Explorer No
Firefox Android 32+ Safari iOS 10.3+ Chrome Android 37+ WebView Android 37+ Samsung Internet 3.0+ Opera Android 24+

Returns an array of language tags representing the user’s preferred languages, with the most preferred language first.

The most preferred language is the one returned by navigator.language.

A languagechange event is fired at the Window or WorkerGlobalScope object when the user agent’s understanding of what the user’s preferred languages are changes.

language

Must return a valid BCP 47 language tag representing either a plausible language or the user’s most preferred language. [BCP47]

languages

Must return a frozen array of valid BCP 47 language tags representing either one or more plausible languages, or the user’s preferred languages, ordered by preference with the most preferred language first. The same object must be returned until the user agent needs to return different values, or values in a different order. [BCP47]
Whenever the user agent needs to make the `navigator.languages` attribute of a `Window` or `WorkerGlobalScope` object global return a new set of language tags, the user agent must queue a global task on the DOM manipulation task source given global to fire an event named `languagechange` at global, and wait until that task begins to be executed before actually returning a new value.

To determine a plausible language, the user agent should bear in mind the following:

- Any information in this API that varies from user to user can be used to profile or identify the user.
- If the user is not using a service that obfuscates the user’s point of origin (e.g. the Tor anonymity network), then the value that is least likely to distinguish the user from other users with similar origins (e.g. from the same IP address block) is the language used by the majority of such users. [TOR]
- If the user is using an anonymizing service, then the value “en-US” is suggested; if all users of the service use that same value, that reduces the possibility of distinguishing the users from each other.

To avoid introducing any more fingerprinting vectors, user agents should use the same list for the APIs defined in this function as for the HTTP `Accept-Language` header.

8.9.1.3 Browser state

```javascript
interface mixin NavigatorOnLine {
    readonly attribute boolean onLine;
};
```

**self.** `navigator.onLine`  

✔️ MDN

`Navigator/onLine`

Support in all current engines.

Returns false if the user agent is definitely offline (disconnected from the network). Returns true if the user agent might be online.

The events **online** and **offline** are fired when the value of this attribute changes.

The **onLine** attribute must return false if the user agent will not contact the network when the user follows links or when a script requests a remote page (or knows that such an attempt would fail), and must return true otherwise.

When the value that would be returned by the `navigator.onLine` attribute of a **Window** or **WorkerGlobalScope** changes from true to false, the user agent must queue a global task on the networking task source given `global` to fire an event named **offline** at `global`.

On the other hand, when the value that would be returned by the `navigator.onLine` attribute of a **Window** or **WorkerGlobalScope** changes from false to true, the user agent must queue a global task on the networking task source given `global` to fire an event named **online** at the **Window** or **WorkerGlobalScope** object.

This attribute is inherently unreliable. A computer can be connected to a network without having Internet access.

In this example, an indicator is updated as the browser goes online and offline.

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>Online status</title>
  <script>
    function updateIndicator() {
      document.getElementById('indicator').textContent = navigator.onLine ? 'online' : 'offline';
    }
  </script>
</head>
<body onload="updateIndicator()" ononline="updateIndicator()" onoffline="updateIndicator()">
  <p>The network is: <span id="indicator">(state unknown)</span></p>
</body>
</html>
```
8.9.1.4 Custom scheme handlers: the \texttt{registerProtocolHandler()} method

\texttt{Navigator/registerProtocolHandler}

|          | Firefox 3+ | Safari | Chrome 13+ | Opera 11.6+ | Edge 79+ | Edge (Legacy) | No Internet Explorer | No

\texttt{interface mixin NavigatorContentUtils} {
  [SecureContext] undefined \texttt{registerProtocolHandler(DOMString scheme, USVString url)}
  [SecureContext] undefined \texttt{unregisterProtocolHandler(DOMString scheme, USVString url)}
};

\texttt{window.navigator.registerProtocolHandler(scheme, url)}

Registers a handler for \textit{scheme} at \textit{url}. For example, an online telephone messaging service could register itself as a handler of the \texttt{sms:} scheme, so that if the user clicks on such a link, they are given the opportunity to use that web site. \texttt{[SMS]}

The string "\%s" in \textit{url} is used as a placeholder for where to put the URL of the content to be handled.

Throws a \texttt{“SecurityError” DOMException} if the user agent blocks the registration (this might happen if trying to register as a handler for "http", for instance).

Throws a \texttt{“SyntaxError” DOMException} if the "\%s" string is missing in \textit{url}.

\texttt{window.navigator.unregisterProtocolHandler(scheme, url)}

Unregisters the handler given by the arguments.

Throws a \texttt{“SecurityError” DOMException} if the user agent blocks the deregistration (this might happen if with invalid schemes, for instance).

Throws a \texttt{“SyntaxError” DOMException} if the "\%s" string is missing in \textit{url}.

The \texttt{registerProtocolHandler(scheme, url)} method steps are:

1. Let (\texttt{normalizedScheme, normalizedURLString}) be the result of running \texttt{normalize\_protocol\_handler\_parameters} with \textit{scheme}, \textit{url}, and \textit{this}'s relevant settings object.

2. In parallel: register a protocol handler for \texttt{normalizedScheme} and \texttt{normalizedURLString}. User agents may, within the constraints described, do whatever they like. A user agent
could, for instance, prompt the user and offer the user the opportunity to add the site to a shortlist of handlers, or make the handlers their default, or cancel the request. User agents could also silently collect the information, providing it only when relevant to the user.

User agents should keep track of which sites have registered handlers (even if the user has declined such registrations) so that the user is not repeatedly prompted with the same request.

When the **user agent uses this handler** for a **URL** `inputURL`:

1. **Assert**: `inputURL`'s **scheme** is `normalizedScheme`.
2. Let `inputURLString` be the **serialization** of `inputURL`.
3. Let `encodedURL` be the result of running **UTF-8 percent-encode** on `inputURLString` using the **component percent-encode set**.
4. Let `handlerURLString` be `normalizedURLString`.
5. Replace the first instance of “%s” in `handlerURLString` with `encodedURL`.
6. Let `resultURL` be the result of **parsing** `handlerURLString`.
7. **Navigate** an appropriate **browsing context** to `resultURL`.

If the user had visited a site at `https://example.com/` that made the following call:

```javascript
navigator.registerProtocolHandler('web+soup', 'soup?url=%s')
```

...and then, much later, while visiting `https://www.example.net/`, clicked on a link such as:

```html
<a href="web+soup:chicken-kïwi">Download our Chicken Kïwi soup!</a>
```

...then the UA might navigate to the following URL:

`https://example.com/soup?url=web+soup:chicken-k%C3%AFwi`

This site could then do whatever it is that it does with soup (synthesize it and ship it to the user, or whatever).

This does not define when the handler is used. To some extent, the **processing model for navigating across documents** defines some cases where it is relevant, but in general user agents may use this information wherever they would otherwise consider handing schemes to native plugins or helper applications.

The **unregisterProtocolHandler**(scheme, url) method steps are:
1. Let \((\text{normalizedScheme}, \text{normalizedURLString})\) be the result of running \texttt{normalize protocol handler parameters} with \texttt{scheme}, \texttt{url}, and \texttt{this’s relevant settings object}.

2. \text{In parallel}: unregister the handler described by \texttt{normalizedScheme} and \texttt{normalizedURLString}.

To \texttt{normalize protocol handler parameters}, given a string \texttt{scheme}, a string \texttt{url}, and an \texttt{environment settings object} \texttt{environment}, run these steps:

1. Set \texttt{scheme} to \texttt{scheme}, \texttt{converted to ASCII lowercase}.

2. If \texttt{scheme} is neither a \texttt{safelisted scheme} nor a string starting with \texttt{“web+”} followed by one or more \texttt{ASCII lower alphas}, then throw a \texttt{“SecurityError” DOMException}.

This means that including a colon in \texttt{scheme} (as in \texttt{“mailto:”}) will throw.

The following schemes are the \texttt{safelisted schemes}:

- bitcoin
- geo
- im
- irc
- ircs
- magnet
- mailto
- matrix
- mms
- news
- nntp
- openpgp4fpr
- sip
- sms
- smsto
- ssh
- tel
- urn
- webcal
- wta
- xmpp

This list can be changed. If there are schemes that ought to be added, please send feedback.

3. If \texttt{url} does not contain \texttt{“%s”}, then throw a \texttt{“SyntaxError” DOMException}.
4. Parse url relative to environment.

5. If that fails, then throw a "SyntaxError" DOMException.

   This is forcibly the case if the %s placeholder is in the host or port of the URL.

6. If the resulting URL record’s scheme is not an HTTP(S) scheme or the resulting URL record’s origin is not same origin with environment’s origin, then throw a "SecurityError" DOMException.

7. Assert: the result of Is url potentially trustworthy? given the resulting URL record is "Potentially Trustworthy".

   Because normalize protocol handler parameters is run within a secure context, this is implied by the same origin condition.

8. Return (scheme, resulting URL string).

   The resulting URL string will by definition not be a valid URL string as it includes the string "%s" which is not a valid component in a URL.

8.9.1.4.1 Security and privacy

Custom scheme handlers can introduce a number of concerns, in particular privacy concerns.

**Hijacking all web usage.** User agents should not allow schemes that are key to its normal operation, such as an HTTP(S) scheme, to be rerouted through third-party sites. This would allow a user’s activities to be trivially tracked, and would allow user information, even in secure connections, to be collected.

**Hijacking defaults.** User agents are strongly urged to not automatically change any defaults, as this could lead the user to send data to remote hosts that the user is not expecting. New handlers registering themselves should never automatically cause those sites to be used.

**Registration spamming.** User agents should consider the possibility that a site will attempt to register a large number of handlers, possibly from multiple domains (e.g., by redirecting through a series of pages each on a different domain, and each registering a handler for web+spam: — analogous practices abusing other web browser features have been used by pornography web sites for many years). User agents should gracefully handle such hostile attempts, protecting the user.

**Hostile handler metadata.** User agents should protect against typical attacks against strings embedded in their interface, for example ensuring that markup or escape characters in such strings are not executed, that null bytes are properly handled, that over-long strings do not cause crashes or buffer overruns, and so forth.

**Leaking private data.** Web page authors may reference a custom scheme handler using URL
data considered private. They might do so with the expectation that the user’s choice of
handler points to a page inside the organization, ensuring that sensitive data will not be
exposed to third parties. However, a user may have registered a handler pointing to an external
site, resulting in a data leak to that third party. Implementers might wish to consider allowing
administrators to disable custom handlers on certain subdomains, content types, or schemes.

**Leaking credentials.** User agents must never send username or password information in the
URLs that are escaped and included sent to the handler sites. User agents may even avoid
attempting to pass to web-based handlers the URLs of resources that are known to require
authentication to access, as such sites would be unable to access the resources in question
without prompting the user for credentials themselves (a practice that would require the user to
know whether to trust the third-party handler, a decision many users are unable to make or
even understand).

**Interface interference.** User agents should be prepared to handle intentionally long arguments
to the methods. For example, if the user interface exposed consists of an “accept” button and a
“deny” button, with the “accept” binding containing the name of the handler, it’s important that
a long name not cause the “deny” button to be pushed off the screen.

8.9.1.5 Cookies

```javascript
interface mixin NavigatorCookies {
  readonly attribute boolean cookieEnabled;
};
```

`window.navigator.cookieEnabled` ✔ MDN

**Navigator/cookieEnabled**

Support in all current engines.

<table>
<thead>
<tr>
<th>Engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox1+Safari1+Chrome1+</td>
</tr>
<tr>
<td>Opera12.1+Edge79+</td>
</tr>
<tr>
<td>Edge (Legacy)12+Internet Explorer4+</td>
</tr>
<tr>
<td>Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung</td>
</tr>
<tr>
<td>Internet1.0+Opera Android12.1+</td>
</tr>
</tbody>
</table>

Returns false if setting a cookie will be ignored, and true otherwise.

The `cookieEnabled` attribute must return true if the user agent attempts to handle cookies
according to *HTTP State Management Mechanism*, and false if it ignores cookie change
requests. [COOKIES]
8.9.1.6 PDF viewing support

**window.navigator.pdfViewerEnabled**

Returns true if the user agent supports inline viewing of PDF files when navigating to them, or false otherwise. In the latter case, PDF files will be handled by external software.

```javascript
interface mixin NavigatorPlugins {
    [SameObject] readonly attribute PluginArray plugins;
    [SameObject] readonly attribute MimeToArray mimeTypes;
    boolean javaEnabled();
    readonly attribute boolean pdfViewerEnabled;
};

[Exposed=Window, LegacyUnenumerableNamedProperties]
interface PluginArray {
    undefined refresh();
   readonly attribute unsigned long length;
    getter Plugin? item(unsigned long index);
    getter Plugin? namedItem(DOMString name);
};

[Exposed=Window, LegacyUnenumerableNamedProperties]
interface MimeToArray {
    readonly attribute unsigned long length;
    getter MimeType? item(unsigned long index);
    getter MimeType? namedItem(DOMString name);
};

[Exposed=Window, LegacyUnenumerableNamedProperties]
interface Plugin {
    readonly attribute DOMString name;
    readonly attribute DOMString description;
    readonly attribute DOMString filename;
    readonly attribute unsigned long length;
    getter MimeType? item(unsigned long index);
    getter MimeType? namedItem(DOMString name);
};

[Exposed=Window]
interface MimeType {
    readonly attribute DOMString type;
    readonly attribute DOMString description;
    readonly attribute DOMString suffixes;
}
Although these days detecting PDF viewer support can be done via `navigator.pdfViewerEnabled`, for historical reasons, there are a number of complex and intertwined interfaces that provide the same capability, which legacy code relies on. This section specifies both the simple modern variant and the complicated historical one.

Each user agent has a *PDF viewer supported* boolean, whose value is *implementation-defined* (and might vary according to user preferences).

This value also impacts the navigation processing model.

Each `Window` object has a *PDF viewer plugin objects* list. If the user agent’s *PDF viewer supported* is false, then it is the empty list. Otherwise, it is a list containing five `Plugin` objects, whose names are, respectively:

0. "PDF Viewer"
1. "Chrome PDF Viewer"
2. "Chromium PDF Viewer"
3. "Microsoft Edge PDF Viewer"
4. "WebKit built-in PDF"

The values of the above list form the *PDF viewer plugin names* list.

These names were chosen based on evidence of what websites historically search for, and thus what is necessary for user agents to expose in order to maintain compatibility with existing content. They are ordered alphabetically. The “PDF Viewer” name was then inserted in the 0th position so that the `enabledPlugin` getter could point to a generic plugin name.

Each `Window` object has a *PDF viewer mime type objects* list. If the user agent’s *PDF viewer supported* is false, then it is the empty list. Otherwise, it is a list containing two `MimeType` objects, whose types are, respectively:

0. "application/pdf"
1. "text/pdf"

The values of the above list form the *PDF viewer mime types* list.

Each `NavigatorPlugins` object has a `plugins array`, which is a new `PluginArray`, and a `mime types array`, which is a new `MimeTypeArray`.

The `NavigatorPlugins` mixin’s `plugins` getter steps are to return this’s `plugins array`.

The `NavigatorPlugins` mixin’s `mimeTypes` getter steps are to return this’s `mime types`
The **NavigatorPlugins** mixin’s `javaEnabled()` method steps are to return `false`.

The **NavigatorPlugins** mixin’s `pdfViewerEnabled` getter steps are to return the user agent’s PDF viewer supported.

The **PluginArray** interface supports named properties. If the user agent’s PDF viewer supported is true, then they are the PDF viewer plugin names. Otherwise, they are the empty list.

The **PluginArray** interface’s `namedItem(name)` method steps are:

1. For each **Plugin** plugin of this’s relevant global object’s PDF viewer plugin objects: if plugin’s name is name, then return plugin.
2. Return null.

The **PluginArray** interface supports indexed properties. The supported property indices are the indices of this’s relevant global object’s PDF viewer plugin objects.

The **PluginArray** interface’s `item(index)` method steps are:

1. Let plugins be this’s relevant global object’s PDF viewer plugin objects.
2. If `index < plugins's size`, then return `plugins[index]`.
3. Return null.

The **PluginArray** interface’s `length` getter steps are to return this’s relevant global object’s PDF viewer plugin objects’s size.

The **PluginArray** interface’s `refresh()` method steps are to do nothing.

The **MimeTypeArray** interface supports named properties. If the user agent’s PDF viewer supported is true, then they are the PDF viewer mime types. Otherwise, they are the empty list.

The **MimeTypeArray** interface’s `namedItem(name)` method steps are:

1. For each **MimeType** mimeType of this’s relevant global object’s PDF viewer mime type objects: if mimeType’s type is name, then return mimeType.
2. Return null.

The **MimeTypeArray** interface supports indexed properties. The supported property indices
are the \textit{indices} of this’s relevant global object’s PDF viewer mime type objects.

The \texttt{MimeTypeArray} interface’s \texttt{item(index)} method steps are:

1. Let \texttt{mimeTypes} be this’s relevant global object’s PDF viewer mime type objects.
2. If \texttt{index < mimeTypes’s size}, then return \texttt{mimeTypes[index]}.
3. Return null.

The \texttt{MimeTypeArray} interface’s \texttt{length} getter steps are to return this’s relevant global object’s PDF viewer mime type objects’s size.

Each \texttt{Plugin} object has a \textit{name}, which is set when the object is created.

The \texttt{Plugin} interface’s \texttt{name} getter steps are to return this’s \texttt{name}.

The \texttt{Plugin} interface’s \texttt{description} getter steps are to return “Portable Document Format”.

The \texttt{Plugin} interface’s \texttt{filename} getter steps are to return ”\texttt{internal-pdf-viewer}”.

The \texttt{Plugin} interface supports named properties. If the user agent’s PDF viewer supported is true, then they are the PDF viewer mime types. Otherwise, they are the empty list.

The \texttt{Plugin} interface’s \texttt{namedItem(name)} method steps are:

1. For each \texttt{MimeType} \texttt{mimeType} of this’s relevant global object’s PDF viewer mime type objects: if \texttt{mimeType’s type} is \texttt{name}, then return \texttt{mimeType}.
2. Return null.

The \texttt{Plugin} interface supports indexed properties. The supported property \texttt{indices} are the \texttt{indices} of this’s relevant global object’s PDF viewer mime type objects.

The \texttt{Plugin} interface’s \texttt{item(index)} method steps are:

1. Let \texttt{mimeTypes} be this’s relevant global object’s PDF viewer mime type objects.
2. If \texttt{index < mimeType’s size}, then return \texttt{mimeTypes[index]}.
3. Return null.

The \texttt{Plugin} interface’s \texttt{length} getter steps are to return this’s relevant global object’s PDF viewer mime type objects’s size.
Each `MimeType` object has a `type`, which is set when the object is created.

The `MimeType` interface’s `type` getter steps are to return `this`’s `type`.

The `MimeType` interface’s `description` getter steps are to return “Portable Document Format”.

The `MimeType` interface’s `suffixes` getter steps are to return “pdf”.

The `MimeType` interface’s `enabledPlugin` getter steps are to return `this`’s relevant global object’s PDF viewer plugin objects[0] (i.e., the generic “PDF Viewer” one).

8.10 Images

```
interface ImageBitmap {
    readonly attribute unsigned long width;
    readonly attribute unsigned long height;
    undefined close();
};
```

typedef (CanvasImageSource or Blob or ImageData) ImageBitmapSource;

dictionary ImageBitmapOptions {
    `ImageOrientation` imageOrientation = "none";
    `PremultiplyAlpha` premultiplyAlpha = "default";
    `ColorSpaceConversion` colorSpaceConversion = "default";
    [EnforceRange] unsigned long resizeWidth;
    [EnforceRange] unsigned long resizeHeight;
}
An `ImageBitmap` object represents a bitmap image that can be painted to a canvas without undue latency.

The exact judgement of what is undue latency of this is left up to the implementer, but in general if making use of the bitmap requires network I/O, or even local disk I/O, then the latency is probably undue; whereas if it only requires a blocking read from a GPU or system RAM, the latency is probably acceptable.

```javascript
promise = self.createImageBitmap(image [, options ])
```

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 42</td>
<td>✔</td>
</tr>
<tr>
<td>Safari 15+</td>
<td>✔</td>
</tr>
<tr>
<td>Chrome 50+</td>
<td>✔</td>
</tr>
<tr>
<td>Opera</td>
<td>✔</td>
</tr>
<tr>
<td>Edge 79+</td>
<td>✔</td>
</tr>
<tr>
<td>Edge (Legacy)</td>
<td>No</td>
</tr>
<tr>

</tr>
</tbody>
</table>

```javascript
promise = self.createImageBitmap(image, sx, sy, sw, sh [, options ])
```

Takes `image`, which can be an `img` element, an SVG image element, a `video` element, a `canvas` element, a `Blob` object, an `ImageData` object, or another `ImageBitmap` object, and returns a promise that is resolved when a new `ImageBitmap` is created.

If no `ImageBitmap` object can be constructed, for example because the provided `image` data is not actually an image, then the promise is rejected instead.

If `sx`, `sy`, `sw`, and `sh` arguments are provided, the source image is cropped to the given pixels, with any pixels missing in the original replaced by transparent black. These coordinates are in the source image’s pixel coordinate space, not in CSS pixels.

If `options` is provided, the `ImageBitmap` object’s bitmap data is modified according to `options`. For example, if the `premultiplyAlpha` option is set to “premultiply”, the bitmap data’s color channels are premultiplied by its alpha channel.

Rejects the promise with an “InvalidStateError” `DOMException` if the source image is not in a valid state (e.g., an `img` element that hasn’t loaded successfully, an `ImageBitmap` object whose `[[Detached]]` internal slot value is true, an `ImageData` object whose `data` attribute value’s `[[ViewedArrayBuffer]]` internal slot is detached, or a `Blob` whose data cannot be interpreted as a bitmap image).
Rejects the promise with a "SecurityError" DOMException if the script is not allowed to access the image data of the source image (e.g. a video that is CORS-cross-origin, or a canvas being drawn on by a script in a worker from another origin).

`imageBitmap.close()`

**ImageBitmap/close**

Firefox 46+ Safari No Chrome 52+
Opera 37+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 46+ Safari iOS No Chrome Android 52+ WebView Android 52+ Samsung Internet 6.0+ Opera Android 37+

Releases `imageBitmap`'s underlying bitmap data.

`imageBitmap.width`

**ImageBitmap/width**

Firefox 42+ Safari No Chrome 50+
Opera 37+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 42+ Safari iOS No Chrome Android 50+ WebView Android 50+ Samsung Internet 5.0+ Opera Android 37+

Returns the intrinsic width of the image, in CSS pixels.

`imageBitmap.height`

**ImageBitmap/height**

Firefox 42+ Safari No Chrome 50+
Opera 37+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 42+ Safari iOS No Chrome Android 50+ WebView Android 50+ Samsung Internet 5.0+ Opera Android 37+

Returns the intrinsic height of the image, in CSS pixels.

An `ImageBitmap` object whose [[Detached]] internal slot value is false always has associated bitmap data, with a width and a height. However, it is possible for this data to be corrupted. If
an **ImageBitmap** object’s media data can be decoded without errors, it is said to be **fully decodable**.

An **ImageBitmap** object’s bitmap has an **origin-clean** flag, which indicates whether the bitmap is tainted by content from a different **origin**. The flag is initially set to true and may be changed to false by the steps of **createImageBitmap()**.

**ImageBitmap** objects are **serializable objects** and **transferable objects**.

Their **serialization steps**, given **value** and **serialized**, are:

1. If **value**’s **origin-clean** flag is not set, then throw a **“DataCloneError” DOMException**.
2. Set **serialized.[[BitmapData]]** to a copy of **value**’s **bitmap data**.

Their **deserialization steps**, given **serialized** and **value**, are:

1. Set **value**’s **bitmap data** to **serialized.[[BitmapData]]**.

Their **transfer steps**, given **value** and **dataHolder**, are:

1. If **value**’s **origin-clean** flag is not set, then throw a **“DataCloneError” DOMException**.
2. Set **dataHolder.[[BitmapData]]** to **value**’s **bitmap data**.
3. Unset **value**’s **bitmap data**.

Their **transfer-receiving steps**, given **dataHolder** and **value**, are:

1. Set **value**’s **bitmap data** to **dataHolder.[[BitmapData]]**.

The **createImageBitmap(image, options)** and **createImageBitmap(image sx, sy, sw, sh, options)** methods, when invoked, must run these steps:

1. Let **p** be a new promise.
2. If either **sw** or **sh** is given and is 0, then return **p** rejected with a **RangeError**.
3. If either **options**’s **resizeWidth** or **options**’s **resizeHeight** is present and is 0, then return **p** rejected with an **“InvalidStateError” DOMException**.
4. **Check the usability of the image argument**. If this throws an exception or returns **bad**, then return **p** rejected with an **“InvalidStateError” DOMException**.
5. Let `imageBitmap` be a new `ImageBitmap` object.

6. Switch on `image`:

   ```html
   <img class="image">
   <svg class="SVG image">
   ```

   1. If `image`'s media data has no **intrinsic dimensions** (e.g., it’s a vector graphic with no specified content size) and either `options`'s `resizeWidth` or `options`'s `resizeHeight` is not present, then return `p` rejected with an "**InvalidStateError**" `DOMException`.

   2. If `image`'s media data has no **intrinsic dimensions** (e.g., it’s a vector graphics with no specified content size), it should be rendered to a bitmap of the size specified by the `resizeWidth` and the `resizeHeight` options.

   3. Set `imageBitmap`'s **bitmap data** to a copy of `image`'s media data, **cropped to the source rectangle with formatting**. If this is an animated image, `imageBitmap`'s **bitmap data** must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.

   4. If `image` is not `origin-clean`, then set the `origin-clean` flag of `imageBitmap`'s bitmap to false.

   5. Run this step **in parallel**:

      1. Resolve `p` with `imageBitmap`.

   ```html
   <video class="video">
   ```

   1. If `image`'s `networkState` attribute is `NETWORK_EMPTY`, then return `p` rejected with an "InvalidStateError" `DOMException`.

   2. Set `imageBitmap`'s **bitmap data** to a copy of the frame at the current playback position, at the media resource’s **intrinsic width** and **intrinsic height** (i.e., after any aspect-ratio correction has been applied), **cropped to the source rectangle with formatting**.

   3. If `image` is not `origin-clean`, then set the `origin-clean` flag of `imageBitmap`'s bitmap to false.

   4. Run this step **in parallel**:

      1. Resolve `p` with `imageBitmap`. 
canvas

1. Set `imageBitmap`'s bitmap data to a copy of `image`'s bitmap data, cropped to the source rectangle with formatting.

2. Set the `origin-clean` flag of the `imageBitmap`'s bitmap to the same value as the `origin-clean` flag of `image`'s bitmap.

3. Run this step in parallel:
   1. Resolve `p` with `imageBitmap`.

Blob

Run these step in parallel:

1. Let `imageData` be the result of reading `image`'s data. If an error occurs during reading of the object, then reject `p` with an `InvalidStateError` DOMException and abort these steps.

2. Apply the image sniffing rules to determine the file format of `imageData`, with MIME type of `image` (as given by `image`'s `type` attribute) giving the official type.

3. If `imageData` is not in a supported image file format (e.g., it’s not an image at all), or if `imageData` is corrupted in some fatal way such that the image dimensions cannot be obtained (e.g., a vector graphic with no intrinsic size), then reject `p` with an `InvalidStateError` DOMException and abort these steps.

4. Set `imageBitmap`'s bitmap data to `imageData`, cropped to the source rectangle with formatting. If this is an animated image, `imageBitmap`'s bitmap data must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.

5. Resolve `p` with `imageBitmap`.

ImageData

1. Let `buffer` be `image`'s `data` attribute value's `[[ViewedArrayBuffer]]` internal slot.

2. If `IsDetachedBuffer(buffer)` is true, then return `p` rejected with an `InvalidStateError` DOMException.

3. Set `imageBitmap`'s bitmap data to `image`'s image data, cropped to the
4. Run this step **in parallel**:
   1. Resolve \( p \) with \( \text{imageBitmap} \).

**ImageBitmap**

1. Set \( \text{imageBitmap}'s \) bitmap data to a copy of \( \text{image}'s \) bitmap data, cropped to the source rectangle with formatting.

2. Set the origin-clean flag of \( \text{imageBitmap}'s \) bitmap to the same value as the origin-clean flag of \( \text{image}'s \) bitmap.

3. Run this step **in parallel**:
   1. Resolve \( p \) with \( \text{imageBitmap} \).

**VideoFrame**

1. Set \( \text{imageBitmap}'s \) bitmap data to a copy of \( \text{image}'s \) visible pixel data, cropped to the source rectangle with formatting.

2. Run this step **in parallel**:
   1. Resolve \( p \) with \( \text{imageBitmap} \).

7. Return \( p \).

When the steps above require that the user agent **crop bitmap data to the source rectangle with formatting**, the user agent must run the following steps:

1. Let \( \text{input} \) be the **bitmap data** being transformed.

2. If \( sx, sy, sw \) and \( sh \) are specified, let \( \text{sourceRectangle} \) be a rectangle whose corners are the four points \((sx, sy), (sx+sw, sy),(sx+sw, sy+sh), (sx,sy+sh)\). Otherwise let \( \text{sourceRectangle} \) be a rectangle whose corners are the four points \((0,0), (\text{width of } \text{input}, 0), (\text{width of } \text{input}, \text{height of } \text{input}), (0, \text{height of } \text{input})\).

   If either \( sw \) or \( sh \) are negative, then the top-left corner of this rectangle will be to the left or above the \((sx, sy)\) point.

3. Let \( \text{outputWidth} \) be determined as follows:

   If the \( \text{resizeWidth} \) member of \( \text{options} \) is specified
   the value of the \( \text{resizeWidth} \) member of \( \text{options} \)

   If the \( \text{resizeWidth} \) member of \( \text{options} \) is not specified, but the \( \text{resizeHeight} \)
the width of sourceRectangle, times the value of the resizeHeight member of options, divided by the height of sourceRectangle, rounded up to the nearest integer

If neither resizeWidth nor resizeHeight are specified
the width of sourceRectangle

4. Let outputHeight be determined as follows:

If the resizeHeight member of options is specified
the value of the resizeHeight member of options

If the resizeHeight member of options is not specified, but the resizeWidth member is specified
the height of sourceRectangle, times the value of the resizeWidth member of options, divided by the width of sourceRectangle, rounded up to the nearest integer

If neither resizeWidth nor resizeHeight are specified
the height of sourceRectangle

5. Place input on an infinite transparent black grid plane, positioned so that its top left corner is at the origin of the plane, with the x-coordinate increasing to the right, and the y-coordinate increasing down, and with each pixel in the input image data occupying a cell on the plane’s grid.

6. Let output be the rectangle on the plane denoted by sourceRectangle.

7. Scale output to the size specified by outputWidth and outputHeight. The user agent should use the value of the resizeQuality option to guide the choice of scaling algorithm.

8. If the value of the imageOrientation member of options is "flipY", output must be flipped vertically, disregarding any image orientation metadata of the source (such as EXIF metadata), if any. [EXIF]

If the value is "none", no extra step is required.

9. If image is an img element or a Blob object, let val be the value of the colorSpaceConversion member of options, and then run these substeps:

   1. If val is "default", the color space conversion behavior is implementation-specific, and should be chosen according to the default color space that the implementation uses for drawing images onto the canvas.

   2. If val is "none", output must be decoded without performing any color space conversions. This means that the image decoding algorithm must ignore color profile metadata embedded in the source data as well as the display device color profile.
10. Let val be the value of `premultiplyAlpha` member of `options`, and then run these substeps:

   1. If `val` is "default", the alpha premultiplication behavior is implementation-specific, and should be chosen according to implementation deems optimal for drawing images onto the canvas.

   2. If `val` is "premultiply", the output that is not premultiplied by alpha must have its color components multiplied by alpha and that is premultiplied by alpha must be left untouched.

   3. If `val` is "none", the output that is not premultiplied by alpha must be left untouched and that is premultiplied by alpha must have its color components divided by alpha.

11. Return `output`.

The `close()` method steps are:

   1. Set this's `[[Detached]]` internal slot value to true.

   2. Unset this's bitmap data.

The `width` getter steps are:

   1. If this's `[[Detached]]` internal slot's value is true, then return 0.

   2. Return this's width, in CSS pixels.

The `height` getter steps are:

   1. If this's `[[Detached]]` internal slot's value is true, then return 0.

   2. Return this's height, in CSS pixels.

The `ResizeQuality` enumeration is used to express a preference for the interpolation quality to use when scaling images.

The "pixelated" value indicates a preference to scale the image that maximizes the appearance. Scaling algorithms that "smooth" colors are acceptable, such as bilinear interpolation.

The "low" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "medium" value indicates a preference for a medium level of image interpolation quality.

The "high" value indicates a preference for a high level of image interpolation quality. High-
quality image interpolation may be more computationally expensive than lower settings.

Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-scaling algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used unless the value is "pixelated".

Using this API, a sprite sheet can be precut and prepared:

```javascript
var sprites = {};
function loadMySprites() {
    var image = new Image();
    image.src = 'mysprites.png';
    var resolver;
    var promise = new Promise(function (arg) { resolver = arg });
    image.onload = function () {
        resolver(Promise.all([
            createImageBitmap(image, 0, 0, 40, 40).then(function (image) { sprites.tree = image; }),
            createImageBitmap(image, 40, 0, 40, 40).then(function (image) { sprites.knight = image; }),
            createImageBitmap(image, 80, 0, 40, 40).then(function (image) { sprites.tower = image; }),
            createImageBitmap(image, 0, 40, 40, 40).then(function (image) { sprites.tree = image; }),
            createImageBitmap(image, 40, 40, 40, 40).then(function (image) { sprites.knight = image; }),
            createImageBitmap(image, 80, 40, 40, 40).then(function (image) { sprites.tower = image; })
        ]));
    }
    return promise;
}

function runDemo() {
    var canvas = document.querySelector('canvas#demo');
    var context = canvas.getContext('2d');
    context.drawImage(sprites.tree, 30, 10);
    context.drawImage(sprites.snake, 70, 10);
}

loadMySprites().then(runDemo);

8.11 Animation frames

Some objects include the AnimationFrameProvider interface mixin.

callback FrameRequestCallback = undefined (DOMHighResTimeStamp time);

interface mixin AnimationFrameProvider {
    unsigned long requestAnimationFrame(FrameRequestCallback callback);
    undefined cancelAnimationFrame(unsigned long handle);
};
Window includes AnimationFrameProvider;
DedicatedWorkerGlobalScope includes AnimationFrameProvider;

Each AnimationFrameProvider object also has a target object that stores the provider’s internal state. It is defined as follows:

If the AnimationFrameProvider is a Window
   The Window’s associated Document
If the AnimationFrameProvider is a DedicatedWorkerGlobalScope
   The DedicatedWorkerGlobalScope

Each target object has a map of animation frame callbacks, which is an ordered map that must be initially empty, and an animation frame callback identifier, which is a number that must initially be zero.

An AnimationFrameProvider provider is considered supported if any of the following hold:

- provider is a Window.
- provider’s owner set contains a Document object.
- Any of the DedicatedWorkerGlobalScope objects in provider’s owner set are supported.

✔️ MDN

Window/requestAnimationFrame

Support in all current engines.

Firefox 23+Safari 7+Chrome 24+
Opera 15+Edge 79+
Edge (Legacy) 12+Internet Explorer 10+
Firefox Android 23+Safari iOS 7+Chrome Android 25+WebView Android 37+Samsung Internet 1.5+Opera Android 14+

The requestAnimationFrame(callback) method steps are:

1. If this is not supported, then throw a "NotSupportedError" DOMException.
2. Let target be this’s target object.
3. Increment target’s animation frame callback identifier by one, and let handle be the result.
4. Let callbacks be target’s map of animation frame callbacks.
5. Set callbacks[handle] to callback.
6. Return `handle`.

Window/cancelAnimationFrame

Support in all current engines.

<table>
<thead>
<tr>
<th>Engine</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 23+</td>
<td>Safari 7+</td>
</tr>
<tr>
<td>Chrome 24+</td>
<td>Opera 15+</td>
</tr>
<tr>
<td>Edge (Legacy) 12+</td>
<td>Internet Explorer 10+</td>
</tr>
<tr>
<td>Firefox Android 23+</td>
<td>Safari iOS 7+</td>
</tr>
<tr>
<td>Chrome Android 25+</td>
<td>WebView Android 37+</td>
</tr>
<tr>
<td>Samsung Internet 1.5+</td>
<td>Opera Android 14+</td>
</tr>
</tbody>
</table>

The `cancelAnimationFrame(handle)` method steps are:

1. If `this` is not supported, then throw a `"NotAllowedError" DOMException`.
2. Let `callbacks` be `this`’s target object’s map of animation frame callbacks.

To run the animation frame callbacks for a target object `target` with a timestamp `now`:

1. Let `callbacks` be `target`’s map of animation frame callbacks.
2. Let `callbackHandles` be the result of getting the keys of `callbacks`.
3. For each `handle` in `callbackHandles`, if `handle` exists in `callbacks`:
   1. Let `callback` be `callbacks[handle]`.
   2. Remove `callbacks[handle]`.
   3. Invoke `callback`, passing `now` as the only argument, and if an exception is thrown, report the exception.

Inside workers, `requestAnimationFrame()` can be used together with an `OffscreenCanvas` transferred from a `canvas` element. First, in the document, transfer control to the worker:

```javascript
const offscreenCanvas = document.getElementById("c").transferControlToOffscreen;
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker, the following code will draw a rectangle moving from left to right:

```javascript
let ctx, pos = 0;
```
function draw(dt) {
    ctx.clearRect(0, 0, 100, 100);
    ctx.fillRect(pos, 0, 10, 10);
    pos += 10 * dt;
    requestAnimationFrame(draw);
}

self.onmessage = function(ev) {
    const transferredCanvas = ev.data;
    ctx = transferredCanvas.getContext("2d");
    draw();
};

9 Communication

9.1 The MessageEvent interface

MessageEvent

Support in all current engines.

Firefox4+Safari4+Chrome1+
Opera10.6+Edge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS3+Chrome Android18+WebView Android37+Samsung
Internet1.0+Opera Android11+

Messages in server-sent events, web sockets, cross-document messaging, channel messaging,
and broadcast channels use the MessageEvent interface for their message events:

[Exposed=(Window,Worker,AudioWorklet)]
interface MessageEvent : Event {
    constructor(DOMString type, optional MessageEventInit eventInitDict = {});

    readonly attribute any data;
    readonly attribute USVString origin;
    readonly attribute DOMString lastEventId;
    readonly attribute MessageEventSource? source;
    readonly attribute FrozenArray<MessagePort> ports;

    undefined initMessageEvent(DOMString type, optional boolean bubbles = false);
}
dictionary MessageEventInit : EventInit {

any data = null;
USVString origin = "";
DOMString lastEventId = "";
MessageEventSource? source = null;
sequence<MessagePort> ports = [];
};

typedef (WindowProxy or MessagePort or ServiceWorker) MessageEventSource;

event.data

MessageEvent/data

Support in all current engines.

Firefox4+Safari4+Chrome1+
OperaYesEdge79+
Edge (Legacy)12+Internet Explorer9+
Firefox AndroidYesSafari iOS3+Chrome Android18+WebView Android37+Samsung
Internet1.0+Opera AndroidYes

Returns the data of the message.

event.origin

MessageEvent/origin

Support in all current engines.

Firefox4+Safari4+Chrome1+
OperaYesEdge79+
Edge (Legacy)12+Internet Explorer9+
Firefox Android4+Safari iOS3+Chrome Android18+WebView Android37+Samsung
Internet1.0+Opera AndroidYes

Returns the origin of the message, for server-sent events and cross-document messaging.

event.lastEventId

MessageEvent/lastEventId

Support in all current engines.
Returns the last event ID string, for server-sent events.

```js
event.source
``` MDN

**MessageEvent/source**

Support in all current engines.

Firefox55+Safari4+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet ExplorerNo
Firefox Android55+Safari iOS3+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android12.1+

Returns the `WindowProxy` of the source window, for cross-document messaging, and the `MessagePort` being attached, in the `connect` event fired at `SharedWorkerGlobalScope` objects.

```js
event.ports
``` MDN

**MessageEvent/ports**

Support in all current engines.

Firefox4+Safari4+Chrome1+
OperaYesEdge79+
EdgeYesEdge79+
Edge (Legacy)12+Internet Explorer9+
Firefox AndroidYesSafari iOS3+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera AndroidYes

Returns the `MessagePort` array sent with the message, for cross-document messaging and channel messaging.

The `data` attribute must return the value it was initialized to. It represents the message being sent.

The `origin` attribute must return the value it was initialized to. It represents, in server-sent...
events and cross-document messaging, the origin of the document that sent the message (typically the scheme, hostname, and port of the document, but not its path or fragment).

The lastEventId attribute must return the value it was initialized to. It represents, in server-sent events, the last event ID string of the event source.

The source attribute must return the value it was initialized to. It represents, in cross-document messaging, the WindowProxy of the browsing context of the Window object from which the message came; and in the connect events used by shared workers, the newly connecting MessagePort.

The ports attribute must return the value it was initialized to. It represents, in cross-document messaging and channel messaging, the MessagePort array being sent.

The initMessageEvent(type, bubbles, cancelable, data, origin, lastEventId, source, ports) method must initialize the event in a manner analogous to the similarly-named initEvent() method. [DOM]

Various APIs (e.g., WebSocket, EventSource) use the MessageEvent interface for their message event without using the MessagePort API.

9.2 Server-sent events

9.2.1 Introduction

This section is non-normative.

To enable servers to push data to web pages over HTTP or using dedicated server-push protocols, this specification introduces the EventSource interface.

Using this API consists of creating an EventSource object and registering an event listener.

```javascript
var source = new EventSource('updates.cgi');
source.onmessage = function (event) {
```
alert(event.data);
};

On the server-side, the script ("updates.cgi" in this case) sends messages in the following form, with the text/event-stream MIME type:

data: This is the first message.
data: This is the second message, it
data: has two lines.
data: This is the third message.

Authors can separate events by using different event types. Here is a stream that has two event types, "add" and "remove":

```
event: add
data: 73857293

event: remove
data: 2153

event: add
data: 113411
```

The script to handle such a stream would look like this (where addHandler and removeHandler are functions that take one argument, the event):

```javascript
var source = new EventSource('updates.cgi');
source.addEventListener('add', addHandler, false);
source.addEventListener('remove', removeHandler, false);
```

The default event type is "message".

Event streams are always decoded as UTF-8. There is no way to specify another character encoding.

Event stream requests can be redirected using HTTP 301 and 307 redirects as with normal HTTP requests. Clients will reconnect if the connection is closed; a client can be told to stop reconnecting using the HTTP 204 No Content response code.

Using this API rather than emulating it using XMLHttpRequest or an iframe allows the user agent to make better use of network resources in cases where the user agent implementer and the network operator are able to coordinate in advance. Amongst other benefits, this can result in significant savings in battery life on portable devices. This is discussed further in the section
below on connectionless push.

9.2.2 The EventSource interface

EventSource

Support in all current engines.

</tbody>
</table>

[Exposed=(Window,Worker)] interface EventSource : EventTarget {
    constructor(USVString url, optional EventSourceInit eventSourceInitDict = {});

    readonly attribute USVString url;
    readonly attribute boolean withCredentials;

    // ready state
    const unsigned short CONNECTING = 0;
    const unsigned short OPEN = 1;
    const unsigned short CLOSED = 2;
    readonly attribute unsigned short readyState;

    // networking
    attribute EventHandler onopen;
    attribute EventHandler onmessage;
    attribute EventHandler onerror;
    undefined close();
};

dictionary EventSourceInit {
    boolean withCredentials = false;
};

Each EventSource object has the following associated with it:

- A url (a URL record). Set during construction.
- A request. This must initially be null.
A reconnection time, in milliseconds. This must initially be an implementation-defined value, probably in the region of a few seconds.

A last event ID string. This must initially be the empty string.

Apart from url these are not currently exposed on the EventSource object.

```javascript
source = new EventSource( url [, { withCredentials: true } ])
```

EventSource(EventSource)

Support in all current engines.

</table>

Returns the state of this **EventSource** object’s connection. It can have the values described below.

The **EventSource(url, eventSourceInitDict)** constructor, when invoked, must run these steps:
1. Let `ev` be a new `EventSource` object.

2. Let `settings` be `ev`'s relevant settings object.

3. Let `urlRecord` be the result of parsing `url` with `settings`'s API base URL and `settings`'s API URL character encoding.

4. If `urlRecord` is failure, then throw a "SyntaxError" DOMException.

5. Set `ev`'s `url` to `urlRecord`.

7. If the value of `eventSourceInitDict`'s `withCredentials` member is true, then set `corsAttributeState` to Use Credentials and set `ev`'s `withCredentials` attribute to true.

8. Let `request` be the result of creating a potential-CORS request given `urlRecord`, the empty string, and `corsAttributeState`.

9. Set `request`'s `client` to `settings`.

10. User agents may set (`Accept`, `text/event-stream`) in `request`'s header list.

11. Set `request`'s `cache mode` to "no-store".

12. Set `ev`'s `request` to `request`.

13. Run this step in parallel:

   1. Fetch `request`.

The `url` attribute's getter must return the serialization of this `EventSource` object's `url`.

The `withCredentials` attribute must return the value to which it was last initialized. When the object is created, it must be initialized to false.

The `readyState` attribute represents the state of the connection. It can have the following values:

**CONNECTING** (numeric value 0)
The connection has not yet been established, or it was closed and the user agent is reconnecting.

**OPEN** (numeric value 1)
The user agent has an open connection and is dispatching events as it receives them.
**CLOSED** (numeric value 2)

The connection is not open, and the user agent is not trying to reconnect. Either there was a fatal error or the `close()` method was invoked.

When the object is created its `readyState` must be set to `CONNECTING` (0). The rules given below for handling the connection define when the value changes.

The `close()` method must abort any instances of the `fetch` algorithm started for this `EventSource` object, and must set the `readyState` attribute to `CLOSED`.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the `EventSource` interface:

<table>

9.2.3 Processing model

The resource indicated in the argument to the `EventSource` constructor is fetched when the constructor is run.

As data is received, the tasks queued by the networking task source to handle the data must act as follows.

HTTP 200 OK responses with a `Content-Type` header specifying the type `text/event-stream`, ignoring any MIME type parameters, must be processed line by line as described below.

When a successful response with a supported MIME type is received, such that the user agent begins parsing the contents of the stream, the user agent must announce the connection.

The task that the networking task source places on the task queue once fetching for such a resource (with the correct MIME type) has completed must cause the user agent to reestablish the connection in parallel. This applies whether the connection is closed gracefully or unexpectedly (but does not apply when fetching is canceled by the user agent, e.g., in response to `window.stop()`, since in those cases the final task is actually discarded). It doesn’t apply for the error conditions listed below except where explicitly specified.

HTTP 200 OK responses that have a Content-Type specifying an unsupported type, or that have no Content-Type at all, must cause the user agent to fail the connection.

Network errors that prevents the connection from being established in the first place (e.g. DNS errors), should cause the user agent to reestablish the connection in parallel, unless the user agent knows that to be futile, in which case the user agent may fail the connection.

Any other HTTP response code not listed here, as well as the cancelation of the fetch algorithm by the user agent (e.g. in response to `window.stop()` or the user canceling the network connection manually) must cause the user agent to fail the connection.

When a user agent is to announce the connection, the user agent must queue a task which, if
the `readyState` attribute is set to a value other than `CLOSED`, sets the `readyState` attribute to `OPEN` and fires an event named `open` at the `EventSource` object.

When a user agent is to `reestablish the connection`, the user agent must run the following steps. These steps are run in parallel, not as part of a task. (The tasks that it queues, of course, are run like normal tasks and not themselves in parallel.)

1. **Queue a task** to run the following steps:
   1. If the `readyState` attribute is set to `CLOSED`, abort the task.
   2. Set the `readyState` attribute to `CONNECTING`.
   3. Fire an event named `error` at the `EventSource` object.

2. Wait a delay equal to the reconnection time of the event source.

3. Optionally, wait some more. In particular, if the previous attempt failed, then user agents might introduce an exponential backoff delay to avoid overloading a potentially already overloaded server. Alternatively, if the operating system has reported that there is no network connectivity, user agents might wait for the operating system to announce that the network connection has returned before retrying.

4. Wait until the aforementioned task has run, if it has not yet run.

5. **Queue a task** to run the following steps:
   1. If the `EventSource` object’s `readyState` attribute is not set to `CONNECTING`, then return.
   2. Let `request` be the `EventSource` object’s `request`.
   3. If the `EventSource` object’s last event ID string is not the empty string, then:
      1. Let `lastEventIDValue` be the `EventSource` object’s last event ID string, encoded as UTF-8.
      2. Set (`Last-Event-ID`, `lastEventIDValue`) in `request`’s header list.
   4. Fetch `request` and process the response obtained in this fashion, if any, as described earlier in this section.

When a user agent is to `fail the connection`, the user agent must queue a task which, if the `readyState` attribute is set to a value other than `CLOSED`, sets the `readyState` attribute to `CLOSED` and fires an event named `error` at the `EventSource` object. Once the user agent has failed the connection, it does not attempt to reconnect.
The task source for any tasks that are queued by EventSource objects is the remote event task source.

### 9.2.4 Parsing an event stream

This event stream format’s MIME type is text/event-stream.

The event stream format is as described by the stream production of the following ABNF, the character set for which is Unicode. [ABNF]

```abnf
stream = [ bom ] *event
event = *( comment / field ) end-of-line
comment = colon *any-char end-of-line
field = 1*name-char [ colon [ space ] *any-char ] end-of-line
end-of-line = ( cr lf / cr / lf )
```

; characters
lf = %x000A ; U+000A LINE FEED (LF)
cr = %x000D ; U+000D CARRIAGE RETURN (CR)
space = %x0020 ; U+0020 SPACE
colon = %x003A ; U+003A COLON (:)
bom = %xEF%FF ; U+0000-0009 / %x000B-000C / %x000E-0039 / %x003B-10FFFF
    ; a scalar value other than U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR)
name-char = %x0000-0009 / %x000B-000C / %x000E-0039 / %x003B-10FFFF
    ; a scalar value other than U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR)
any-char = %x0000-0009 / %x000B-000C / %x000E-10FFFF
    ; a scalar value other than U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR)
```

Event streams in this format must always be encoded as UTF-8. [ENCODING]

Lines must be separated by either a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character, or a single U+000D CARRIAGE RETURN (CR) character.

Since connections established to remote servers for such resources are expected to be long-lived, UAs should ensure that appropriate buffering is used. In particular, while line buffering with lines are defined to end with a single U+000A LINE FEED (LF) character is safe, block buffering or line buffering with different expected line endings can cause delays in event dispatch.

### 9.2.5 Interpreting an event stream

Streams must be decoded using the UTF-8 decode algorithm.

The UTF-8 decode algorithm strips one leading UTF-8 Byte Order Mark (BOM), if any.

The stream must then be parsed by reading everything line by line, with a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, and a single
U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character being the ways in which a line can end.

When a stream is parsed, a data buffer, an event type buffer, and a last event ID buffer must be associated with it. They must be initialized to the empty string.

Lines must be processed, in the order they are received, as follows:

If the line is empty (a blank line)

Dispatch the event, as defined below.

If the line starts with a U+003A COLON character (:)  

Ignore the line.

If the line contains a U+003A COLON character (:)  

Collect the characters on the line before the first U+003A COLON character (:), and let field be that string.

Collect the characters on the line after the first U+003A COLON character (:), and let value be that string. If value starts with a U+0020 SPACE character, remove it from value.

Process the field using the steps described below, using field as the field name and value as the field value.

Otherwise, the string is not empty but does not contain a U+003A COLON character (:)  

Process the field using the steps described below, using the whole line as the field name, and the empty string as the field value.

Once the end of the file is reached, any pending data must be discarded. (If the file ends in the middle of an event, before the final empty line, the incomplete event is not dispatched.)

The steps to process the field given a field name and a field value depend on the field name, as given in the following list. Field names must be compared literally, with no case folding performed.

If the field name is "event"

Set the event type buffer to field value.

If the field name is "data"

Append the field value to the data buffer, then append a single U+000A LINE FEED (LF) character to the data buffer.
If the field name is “id”

If the field value does not contain U+0000 NULL, then set the last event ID buffer to the field value. Otherwise, ignore the field.

If the field name is “retry”

If the field value consists of only ASCII digits, then interpret the field value as an integer in base ten, and set the event stream’s reconnection time to that integer. Otherwise, ignore the field.

Otherwise

The field is ignored.

When the user agent is required to dispatch the event, the user agent must process the data buffer, the event type buffer, and the last event ID buffer using steps appropriate for the user agent.

For web browsers, the appropriate steps to dispatch the event are as follows:

1. Set the last event ID string of the event source to the value of the last event ID buffer. The buffer does not get reset, so the last event ID string of the event source remains set to this value until the next time it is set by the server.

2. If the data buffer is an empty string, set the data buffer and the event type buffer to the empty string and return.

3. If the data buffer’s last character is a U+000A LINE FEED (LF) character, then remove the last character from the data buffer.

4. Let event be the result of creating an event using MessageEvent, in the relevant Realm of the EventSource object.

5. Initialize event’s type attribute to message, its data attribute to data, its origin attribute to the serialization of the origin of the event stream’s final URL (i.e., the URL after redirects), and its lastEventId attribute to the last event ID string of the event source.

6. If the event type buffer has a value other than the empty string, change the type of the newly created event to equal the value of the event type buffer.

7. Set the data buffer and the event type buffer to the empty string.

8. Queue a task which, if the readyState attribute is set to a value other than CLOSED, dispatches the newly created event at the EventSource object.

If an event doesn’t have an “id” field, but an earlier event did set the event source’s last event ID
string, then the event’s lastEventId field will be set to the value of whatever the last seen “id” field was.

For other user agents, the appropriate steps to dispatch the event are implementation dependent, but at a minimum they must set the data and event type buffers to the empty string before returning.

The following event stream, once followed by a blank line:

data: YHOO
data: +2
data: 10

...would cause an event message with the interface MessageEvent to be dispatched on the EventSource object. The event’s data attribute would contain the string "YHOO\n+2\n10" (where "\n" represents a newline).

This could be used as follows:

```javascript
var stocks = new EventSource("https://stocks.example.com/ticker.php");
stocks.onmessage = function (event) {
    var data = event.data.split('\n');
    updateStocks(data[0], data[1], data[2]);
};
```

...where updateStocks() is a function defined as:

```javascript
function updateStocks(symbol, delta, value) { ... }
```

...or some such.

The following stream contains four blocks. The first block has just a comment, and will fire nothing. The second block has two fields with names “data” and “id” respectively; an event will be fired for this block, with the data “first event”, and will then set the last event ID to “1” so that if the connection died between this block and the next, the server would be sent a ‘Last-Event-ID’ header with the value “1”. The third block fires an event with data “second event”, and also has an “id” field, this time with no value, which resets the last event ID to the empty string (meaning no ‘Last-Event-ID’ header will now be sent in the event of a reconnection being attempted). Finally, the last block just fires an event with the data ” third event” (with a single leading space character). Note that the last still has to end with a blank line, the end of the stream is not enough to trigger the dispatch of the last event.

: test stream

data: first event
id: 1
The following stream fires two events:

data

data

data:

The first block fires events with the data set to the empty string, as would the last block if it was followed by a blank line. The middle block fires an event with the data set to a single newline character. The last block is discarded because it is not followed by a blank line.

The following stream fires two identical events:

data:test

data: test

This is because the space after the colon is ignored if present.

9.2.6 Authoring notes

Legacy proxy servers are known to, in certain cases, drop HTTP connections after a short timeout. To protect against such proxy servers, authors can include a comment line (one starting with a `:` character) every 15 seconds or so.

Authors wishing to relate event source connections to each other or to specific documents previously served might find that relying on IP addresses doesn’t work, as individual clients can have multiple IP addresses (due to having multiple proxy servers) and individual IP addresses can have multiple clients (due to sharing a proxy server). It is better to include a unique identifier in the document when it is served and then pass that identifier as part of the URL when the connection is established.

Authors are also cautioned that HTTP chunking can have unexpected negative effects on the reliability of this protocol, in particular if the chunking is done by a different layer unaware of the timing requirements. If this is a problem, chunking can be disabled for serving event streams.

Clients that support HTTP’s per-server connection limitation might run into trouble when opening multiple pages from a site if each page has an EventSource to the same domain. Authors can avoid this using the relatively complex mechanism of using unique domain names
per connection, or by allowing the user to enable or disable the EventSource functionality on a per-page basis, or by sharing a single EventSource object using a shared worker.

9.2.7 Connectionless push and other features

User agents running in controlled environments, e.g. browsers on mobile handsets tied to specific carriers, may offload the management of the connection to a proxy on the network. In such a situation, the user agent for the purposes of conformance is considered to include both the handset software and the network proxy.

For example, a browser on a mobile device, after having established a connection, might detect that it is on a supporting network and request that a proxy server on the network take over the management of the connection. The timeline for such a situation might be as follows:

1. Browser connects to a remote HTTP server and requests the resource specified by the author in the EventSource constructor.
2. The server sends occasional messages.
3. In between two messages, the browser detects that it is idle except for the network activity involved in keeping the TCP connection alive, and decides to switch to sleep mode to save power.
4. The browser disconnects from the server.
5. The browser contacts a service on the network, and requests that the service, a “push proxy”, maintain the connection instead.
6. The “push proxy” service contacts the remote HTTP server and requests the resource specified by the author in the EventSource constructor (possibly including a Last-Event-ID HTTP header, etc.).
7. The browser allows the mobile device to go to sleep.
8. The server sends another message.
9. The “push proxy” service uses a technology such as OMA push to convey the event to the mobile device, which wakes only enough to process the event and then returns to sleep.

This can reduce the total data usage, and can therefore result in considerable power savings.

As well as implementing the existing API and text/event-stream wire format as defined by this specification and in more distributed ways as described above, formats of event framing defined by other applicable specifications may be supported. This specification does not define how they are to be parsed or processed.

9.2.8 Garbage collection

While an EventSource object’s readyState is CONNECTING, and the object has one or more event listeners registered for open, message or error events, there must be a strong reference from the Window or WorkerGlobalScope object that the EventSource object’s constructor was invoked from to the EventSource object itself.
While an `EventSource` object’s `readyState` is `OPEN`, and the object has one or more event listeners registered for `message` or `error` events, there must be a strong reference from the `Window` or `WorkerGlobalScope` object that the `EventSource` object’s constructor was invoked from to the `EventSource` object itself.

While there is a task queued by an `EventSource` object on the remote event task source, there must be a strong reference from the `Window` or `WorkerGlobalScope` object that the `EventSource` object’s constructor was invoked from to that `EventSource` object.

If a user agent is to forcibly close an `EventSource` object (this happens when a `Document` object goes away permanently), the user agent must abort any instances of the `fetch` algorithm started for this `EventSource` object, and must set the `readyState` attribute to `CLOSED`.

If an `EventSource` object is garbage collected while its connection is still open, the user agent must abort any instance of the `fetch` algorithm opened by this `EventSource`.

### 9.2.9 Implementation advice

*This section is non-normative.*

User agents are strongly urged to provide detailed diagnostic information about `EventSource` objects and their related network connections in their development consoles, to aid authors in debugging code using this API.

For example, a user agent could have a panel displaying all the `EventSource` objects a page has created, each listing the constructor’s arguments, whether there was a network error, what the CORS status of the connection is and what headers were sent by the client and received from the server to lead to that status, the messages that were received and how they were parsed, and so forth.

Implementations are especially encouraged to report detailed information to their development consoles whenever an `error` event is fired, since little to no information can be made available in the events themselves.

### 9.3 Web sockets

#### 9.3.1 Introduction

*This section is non-normative.*

To enable web applications to maintain bidirectional communications with server-side processes, this specification introduces the `WebSocket` interface.

This interface does not allow for raw access to the underlying network. For example, this interface could not be used to implement an IRC client without proxying messages through a custom server.
9.3.2 The WebSocket interface

**MDN**

WebSocket

Support in all current engines.

Creates a new `WebSocket` object, immediately establishing the associated WebSocket connection.

- `url` is a string giving the URL over which the connection is established. Only "ws" or "wss" schemes are allowed; others will cause a "SyntaxError" DOMException. URLs with fragments will also cause such an exception.

- `protocols` is either a string or an array of strings. If it is a string, it is equivalent to an array consisting of just that string; if it is omitted, it is equivalent to the empty array. Each string in the array is a subprotocol name. The connection will only be established if the server reports that it has selected one of these subprotocols. The subprotocol names have to match the requirements for elements that comprise the value of `Sec-WebSocket-Protocol` fields as defined by *The WebSocket protocol*. [WSP]

```javascript
socket.send(data)
```

Transmits `data` using the WebSocket connection. `data` can be a string, a `Blob`, an `ArrayBuffer`, or an `ArrayBufferView`.

```javascript
socket.close([ code ] [, reason ])
```
WebSocket/close

Support in all current engines.

Firefox 7+ Safari 5+ Chrome 4+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 7+ Safari iOS 4.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Closes the WebSocket connection, optionally using code as the WebSocket connection close code and reason as the WebSocket connection close reason.

socket.url

WebSocket/url

Support in all current engines.

Firefox 7+ Safari 6+ Chrome 18+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer No
Firefox Android 7+ Safari iOS 6+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the URL that was used to establish the WebSocket connection.

socket.readyState

WebSocket/readyState

Support in all current engines.

Firefox 7+ Safari 5+ Chrome 4+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 7+ Safari iOS 4.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the state of the WebSocket object’s connection. It can have the values described below.
socket.bufferedAmount

WebSocket/bufferedAmount

Support in all current engines.

Firefox 7+ Safari 5+ Chrome 4+  
Opera 12.1+ Edge 79+  
Edge (Legacy) 12+ Internet Explorer 10+  
Firefox Android 7+ Safari iOS 4.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the number of bytes of application data (UTF-8 text and binary data) that have been queued using send() but not yet been transmitted to the network.

If the WebSocket connection is closed, this attribute’s value will only increase with each call to the send() method. (The number does not reset to zero once the connection closes.)

socket.extensions

WebSocket/extensions

Support in all current engines.

Firefox 8+ Safari 6+ Chrome 16+  
Opera 12.1+ Edge 79+  
Edge (Legacy) 12+ Internet Explorer 10+  
Firefox Android 8+ Safari iOS 6+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

Returns the extensions selected by the server, if any.

socket.protocol

WebSocket/protocol

Support in all current engines.

Firefox 7+ Safari 6+ Chrome 15+  
Opera 12.1+ Edge 79+  
Edge (Legacy) 12+ Internet Explorer No  
Firefox Android 7+ Safari iOS 6+ Chrome Android 18+ WebView Android 37+ Samsung
1. Returns the subprotocol selected by the server, if any. It can be used in conjunction with the array form of the constructor’s second argument to perform subprotocol negotiation.

```javascript
socket.binaryType [ = value ]
```

**WebSocket/binaryType**

Support in all current engines.

Firefox 11+ Safari 6+ Chrome 15+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 14+ Safari iOS 6+ Chrome Android 18+ WebView Android 37+ Samsung
Internet 1.0+ Opera Android 12.1+

Returns a string that indicates how binary data from the WebSocket object is exposed to scripts:

```
"blob"
```

Binary data is returned in Blob form.

```
"arraybuffer"
```

Binary data is returned in ArrayBuffer form.

Can be set, to change how binary data is returned. The default is “blob”.

The `new WebSocket(url, protocols)` constructor steps are:

1. Let `urlRecord` be the result of applying the URL parser to `url`.
2. If `urlRecord` is failure, then throw a “SyntaxError” DOMException.
3. If `urlRecord`’s `scheme` is not “ws” or “wss”, then throw a “SyntaxError” DOMException.
4. If `urlRecord`’s `fragment` is non-null, then throw a “SyntaxError” DOMException.
5. If `protocols` is a string, set `protocols` to a sequence consisting of just that string.
6. If any of the values in `protocols` occur more than once or otherwise fail to match the requirements for elements that comprise the value of Sec-WebSocket-Protocol fields as defined by The WebSocket protocol, then throw a “SyntaxError”
**DOMException** [WSP]

7. Set this’s `url` to `urlRecord`.

8. Let `client` be this’s relevant settings object.

9. Run this step in parallel:

   1. Establish a WebSocket connection given `urlRecord`, `protocols`, and `client`.

If the establish a WebSocket connection algorithm fails, it triggers the fail the WebSocket connection algorithm, which then invokes the close the WebSocket connection algorithm, which then establishes that the WebSocket connection is closed, which fires the close event as described below.

---

The `url` attribute’s getter must return this WebSocket object’s `url`, serialized.

The `readyState` attribute represents the state of the connection. It can have the following values:

- **CONNECTING** (numeric value 0)
  - The connection has not yet been established.

- **OPEN** (numeric value 1)
  - *The WebSocket connection is established* and communication is possible.

- **CLOSING** (numeric value 2)
  - The connection is going through the closing handshake, or the `close()` method has been invoked.

- **CLOSED** (numeric value 3)
  - The connection has been closed or could not be opened.

When the object is created its `readyState` must be set to CONNECTING (0).

The `extensions` attribute must initially return the empty string. After *the WebSocket connection is established*, its value might change, as defined below.

The `protocol` attribute must initially return the empty string. After *the WebSocket connection is established*, its value might change, as defined below.

The `close(code, reason)` method, when invoked, must run these steps:

   1. If `code` is present, but is neither an integer equal to 1000 nor an integer in the range 3000 to 4999, inclusive, throw an “`InvalidAccessError” DOMException.”
2. If `reason` is present, then run these substeps:

   1. Let `reasonBytes` be the result of encoding `reason`.

   2. If `reasonBytes` is longer than 123 bytes, then throw a “`SyntaxError`” `DOMException`.

3. Run the first matching steps from the following list:

   If the `readyState` attribute is in the `CLOSING` (2) or `CLOSED` (3) state

   Do nothing.

   The connection is already closing or is already closed. If it has not already, a `close` event will eventually fire as described below.

   If the WebSocket connection is not yet `established` [WSP]

   *Fail the WebSocket connection* and set the `readyState` attribute’s value to `CLOSING` (2). [WSP]

   The `fail the WebSocket connection` algorithm invokes the `close the WebSocket connection` algorithm, which then establishes that the WebSocket connection is closed, which fires the `close` event as described below.

   If the WebSocket closing handshake has not yet been `started` [WSP]

   *Start the WebSocket closing handshake* and set the `readyState` attribute’s value to `CLOSING` (2). [WSP]

   If neither `code` nor `reason` is present, the WebSocket Close message must not have a body.

   WebSocket Protocol erroneously states that the status code is required for the `start the WebSocket closing handshake` algorithm.

   If `code` is present, then the status code to use in the WebSocket Close message must be the integer given by `close`. [WSP]

   If `reason` is also present, then `reasonBytes` must be provided in the Close message after the status code. [WSP]

   The `start the WebSocket closing handshake` algorithm eventually invokes the `close the WebSocket connection` algorithm, which then establishes that the WebSocket connection is closed, which fires the `close` event as described below.
Otherwise

Set the `readyState` attribute's value to `CLOSING` (2).

The WebSocket closing handshake is started, and will eventually invoke the close the WebSocket connection algorithm, which will establish that the WebSocket connection is closed, and thus the `close` event will fire, as described below.

The `close()` method does not discard previously sent messages before starting the WebSocket closing handshake — even if, in practice, the user agent is still busy sending those messages, the handshake will only start after the messages are sent.

The `bufferedAmount` attribute must return the number of bytes of application data (UTF-8 text and binary data) that have been queued using `send()` but that, as of the last time the event loop reached step 1, had not yet been transmitted to the network. (This thus includes any text sent during the execution of the current task, regardless of whether the user agent is able to transmit text in the background in parallel with script execution.) This does not include framing overhead incurred by the protocol, or buffering done by the operating system or network hardware.

In this simple example, the `bufferedAmount` attribute is used to ensure that updates are sent either at the rate of one update every 50ms, if the network can handle that rate, or at whatever rate the network can handle, if that is too fast.

```javascript
var socket = new WebSocket('ws://game.example.com:12010/updates');
socket.onopen = function () {
  setInterval(function() {
    if (socket.bufferedAmount == 0)
      socket.send(getUpdateData());
  }, 50);
};
```

The `bufferedAmount` attribute can also be used to saturate the network without sending the data at a higher rate than the network can handle, though this requires more careful monitoring of the value of the attribute over time.

When a `WebSocket` object is created, its `binaryType` IDL attribute must be set to the string “blob”. On getting, it must return the last value it was set to. On setting, the user agent must set the IDL attribute to the new value.

User agents can use the `binaryType` attribute as a hint for how to handle incoming binary data: if the attribute is set to “blob”, it is safe to spool it to disk, and if it is set to “arraybuffer”, it is likely more efficient to keep the data in memory. Naturally, user agents are encouraged to use more subtle heuristics to decide whether to keep incoming data in memory or not, e.g. based on how big the data is or how common it is for a script to change the
attribute at the last minute. This latter aspect is important in particular because it is quite possible for the attribute to be changed after the user agent has received the data but before the user agent has fired the event for it.

The send(data) method transmits data using the connection. If the readyState attribute is CONNECTING, it must throw an "InvalidStateError" DOMException. Otherwise, the user agent must run the appropriate set of steps from the following list:

If the argument is a string

If the WebSocket connection is established and the WebSocket closing handshake has not yet started, then the user agent must send a WebSocket Message comprised of the data argument using a text frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full and then close the WebSocket connection. Any invocation of this method with a string argument that does not throw an exception must increase the bufferedAmount attribute by the number of bytes needed to express the argument as UTF-8. [UNICODE] [ENCODING] [WSP]

If the argument is a Blob object

If the WebSocket connection is established, and the WebSocket closing handshake has not yet started, then the user agent must send a WebSocket Message comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full and then close the WebSocket connection. The data to be sent is the raw data represented by the Blob object. Any invocation of this method with a Blob argument that does not throw an exception must increase the bufferedAmount attribute by the size of the Blob object’s raw data, in bytes. [WSP] [FILEAPI]

If the argument is an ArrayBuffer object

If the WebSocket connection is established, and the WebSocket closing handshake has not yet started, then the user agent must send a WebSocket Message comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full and then close the WebSocket connection. The data to be sent is the data stored in the buffer described by the ArrayBuffer object. Any invocation of this method with an ArrayBuffer argument that does not throw an exception must increase the bufferedAmount attribute by the length of the ArrayBuffer in bytes. [WSP]

If the argument is an object that matches the ArrayBufferView type definition

If the WebSocket connection is established, and the WebSocket closing handshake has not yet started, then the user agent must send a WebSocket Message comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full and then close the
**WebSocket connection.** The data to be sent is the data stored in the section of the buffer described by the **ArrayBuffer** object that *data* references. Any invocation of this method with this kind of argument that does not throw an exception must increase the **bufferedAmount** attribute by the length of *data*’s buffer in bytes. [WSP]

The following are the **event handlers** (and their corresponding **event handler event types**) that must be supported, as **event handler IDL attributes**, by all objects implementing the **WebSocket** interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>onopen</strong></td>
<td>open</td>
</tr>
<tr>
<td><strong>onmessage</strong></td>
<td>message</td>
</tr>
<tr>
<td><strong>onerror</strong></td>
<td>error</td>
</tr>
</tbody>
</table>

**WebSocket/onopen**

Support in all current engines.

Firefox 7+ Safari 5+ Chrome 4+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 7+ Safari iOS 4.2+ Chrome Android 18+ WebView
Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

**WebSocket/onmessage**

Support in all current engines.

Firefox 7+ Safari 5+ Chrome 4+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 7+ Safari iOS 4.2+ Chrome Android 18+ WebView
Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

**WebSocket/onerror**

Support in all current engines.

Firefox 7+ Safari 5+ Chrome 5+
Opera 12.1+ Edge 79+
9.3.3 Feedback from the protocol

When the WebSocket connection is established, the user agent must queue a task to run these steps:

1. Change the readyState attribute’s value to OPEN (1).

2. Change the extensions attribute’s value to the extensions in use, if it is not the null value. [WSP]

3. Change the protocol attribute’s value to the subprotocol in use, if it is not the null value. [WSP]

4. Fire an event named open at the WebSocket object.

Since the algorithm above is queued as a task, there is no race condition between the WebSocket connection being established and the script setting up an event listener for the open event.

When a WebSocket message has been received with type type and data data, the user agent must queue a task to follow these steps: [WSP]

1. If the readyState attribute’s value is not OPEN (1), then return.

2. Let dataForEvent be determined by switching on type and binaryType:

   type indicates that the data is Text
   a new DOMString containing data
type indicates that the data is Binary and \texttt{binaryType} is "blob"

a new \texttt{Blob} object, created in the relevant Realm of the \texttt{WebSocket} object, that
represents \texttt{data} as its raw data [FILEAPI]

\begin{itemize}
\item[] \texttt{type} indicates that the data is Binary and \texttt{binaryType} is "arraybuffer"
\item[] a new \texttt{ArrayBuffer} object, created in the relevant Realm of the \texttt{WebSocket} object, whose contents are \texttt{data}
\end{itemize}

3. Fire an event named \texttt{message} at the \texttt{WebSocket} object, using \texttt{MessageEvent}, with
the \texttt{origin} attribute initialized to the serialization of the \texttt{WebSocket} object’s \texttt{url}’s \texttt{origin}, and the \texttt{data} attribute initialized to \texttt{dataForEvent}.

User agents are encouraged to check if they can perform the above steps efficiently before they run the task, picking tasks from other task queues while they prepare the buffers if not. For example, if the \texttt{binaryType} attribute was set to "blob" when the data arrived, and the user agent spooled all the data to disk, but just before running the above task for this particular message the script switched \texttt{binaryType} to "arraybuffer", the user agent would want to page the data back to RAM before running this task so as to avoid stalling the main thread while it created the \texttt{ArrayBuffer} object.

Here is an example of how to define a handler for the \texttt{message} event in the case of text frames:

\begin{verbatim}
mysocket.onmessage = function (event) {
  if (event.data == 'on') {
    turnLampOn();
  } else if (event.data == 'off') {
    turnLampOff();
  }
};
\end{verbatim}

The protocol here is a trivial one, with the server just sending "on" or "off" messages.

---

When the \texttt{WebSocket} closing handshake is started, the user agent must queue a task to change the \texttt{readyState} attribute’s value to \texttt{CLOSING} (2). (If the \texttt{close()} method was called, the \texttt{readyState} attribute’s value will already be set to \texttt{CLOSING} (2) when this task runs.) [WSP]

---

When the \texttt{WebSocket} connection is closed, possibly cleanly, the user agent must queue a task to run the following substeps:

1. Change the \texttt{readyState} attribute’s value to \texttt{CLOSED} (3).

2. If the user agent was required to fail the \texttt{WebSocket} connection, or if the \texttt{WebSocket connection was closed} after being flagged as full, fire an event named \texttt{error} at the \texttt{WebSocket} object. [WSP]
3. **Fire an event** named `close` at the `WebSocket` object, using `CloseEvent`, with the `wasClean` attribute initialized to true if the connection closed *cleanly* and false otherwise, the `code` attribute initialized to *the WebSocket connection close code*, and the `reason` attribute initialized to the result of applying UTF-8 decode without BOM to *the WebSocket connection close reason*. [WSP]

User agents must not convey any failure information to scripts in a way that would allow a script to distinguish the following situations:

- A server whose host name could not be resolved.
- A server to which packets could not successfully be routed.
- A server that refused the connection on the specified port.
- A server that failed to correctly perform a TLS handshake (e.g., the server certificate can’t be verified).
- A server that did not complete the opening handshake (e.g. because it was not a WebSocket server).
- A WebSocket server that sent a correct opening handshake, but that specified options that caused the client to drop the connection (e.g. the server specified a subprotocol that the client did not offer).
- A WebSocket server that abruptly closed the connection after successfully completing the opening handshake.

In all of these cases, *the WebSocket connection close code* would be 1006, as required by *WebSocket Protocol*. [WSP]

Allowing a script to distinguish these cases would allow a script to probe the user’s local network in preparation for an attack.

In particular, this means the code 1015 is not used by the user agent (unless the server erroneously uses it in its close frame, of course).

---

The task source for all tasks queued in this section is the *WebSocket task source*.

### 9.3.4 Ping and Pong frames

*The WebSocket protocol* defines Ping and Pong frames that can be used for keep-alive, heartbeats, network status probing, latency instrumentation, and so forth. These are not currently exposed in the API.

User agents may send ping and unsolicited pong frames as desired, for example in an attempt to maintain local network NAT mappings, to detect failed connections, or to display latency metrics to the user. User agents must not use pings or unsolicited pongs to aid the server; it is assumed that servers will solicit pongs whenever appropriate for the server's needs.
9.3.5 The **CloseEvent** interface

Support in all current engines:

<table>
<thead>
<tr>
<th>Engine</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox8+Safari6+Chrome13+</td>
<td></td>
</tr>
<tr>
<td>Opera12.1+Edge79+</td>
<td></td>
</tr>
<tr>
<td>Edge (Legacy)12+Internet Explorer10+</td>
<td></td>
</tr>
<tr>
<td>Firefox Android8+Safari iOS6+Chrome Android18+WebView Android37+Samsung</td>
<td></td>
</tr>
<tr>
<td>Internet1.0+Opera Android12.1+</td>
<td></td>
</tr>
</tbody>
</table>

**WebSocket** objects use the **CloseEvent** interface for their **close** events:

```javascript
[Exposed=(Window,Worker)]
interface CloseEvent : Event {
    constructor(DOMString type, optional CloseEventInit eventInitDict = {});

    readonly attribute boolean wasClean;
    readonly attribute unsigned short code;
    readonly attribute USVString reason;
};

dictionary CloseEventInit : EventInit {
    boolean wasClean = false;
    unsigned short code = 0;
    USVString reason = "";
};
```

**event.wasClean**

Returns true if the connection closed cleanly; false otherwise.

**event.code**

Returns the WebSocket connection close code provided by the server.

**event.reason**

Returns the WebSocket connection close reason provided by the server.

The **wasClean** attribute must return the value it was initialized to. It represents whether the connection closed cleanly or not.

The **code** attribute must return the value it was initialized to. It represents the WebSocket
connection close code provided by the server.

The `reason` attribute must return the value it was initialized to. It represents the WebSocket connection close reason provided by the server.

9.3.6 Garbage collection

A `WebSocket` object whose `readyState` attribute’s value was set to `CONNECTING` (0) as of the last time the event loop reached step 1 must not be garbage collected if there are any event listeners registered for `open` events, `message` events, `error` events, or `close` events.

A `WebSocket` object whose `readyState` attribute’s value was set to `OPEN` (1) as of the last time the event loop reached step 1 must not be garbage collected if there are any event listeners registered for `message` events, `error`, or `close` events.

A `WebSocket` object whose `readyState` attribute’s value was set to `CLOSING` (2) as of the last time the event loop reached step 1 must not be garbage collected if there are any event listeners registered for `error` or `close` events.

A `WebSocket` object with an established connection that has data queued to be transmitted to the network must not be garbage collected. [WSP]

If a `WebSocket` object is garbage collected while its connection is still open, the user agent must start the WebSocket closing handshake, with no status code for the Close message. [WSP]

If a user agent is to make disappear a `WebSocket` object (this happens when a `Document` object goes away), the user agent must follow the first appropriate set of steps from the following list:

If the WebSocket connection is not yet established [WSP]

   *Fail the WebSocket connection.* [WSP]

If the WebSocket closing handshake has not yet been started [WSP]

   *Start the WebSocket closing handshake*, with the status code to use in the WebSocket Close message being 1001. [WSP]

Otherwise

   Do nothing.

9.4 Cross-document messaging
Window/postMessage

Support in all current engines.

Web browsers, for security and privacy reasons, prevent documents in different domains from affecting each other; that is, cross-site scripting is disallowed.

While this is an important security feature, it prevents pages from different domains from communicating even when those pages are not hostile. This section introduces a messaging system that allows documents to communicate with each other regardless of their source domain, in a way designed to not enable cross-site scripting attacks.

The `postMessage()` API can be used as a tracking vector.

9.4.1 Introduction

This section is non-normative.

For example, if document A contains an iframe element that contains document B, and script in document A calls `postMessage()` on the Window object of document B, then a message event will be fired on that object, marked as originating from the Window of document A. The script in document A might look like:

```javascript
var o = document.getElementsByTagName('iframe')[0];
o.contentWindow.postMessage('Hello world', 'https://b.example.org/');
```

To register an event handler for incoming events, the script would use `addEventListener()` (or similar mechanisms). For example, the script in document B might look like:

```javascript
window.addEventListener('message', receiver, false);
function receiver(e) {
    if (e.origin == 'https://example.com') {
        if (e.data == 'Hello world') {
            e.source.postMessage('Hello', e.origin);
        } else {
            alert(e.data);
        }
    }
}
```

This script first checks the domain is the expected domain, and then looks at the message,
which it either displays to the user, or responds to by sending a message back to the document which sent the message in the first place.

9.4.2 Security

9.4.2.1 Authors

Use of this API requires extra care to protect users from hostile entities abusing a site for their own purposes.

Authors should check the `origin` attribute to ensure that messages are only accepted from domains that they expect to receive messages from. Otherwise, bugs in the author’s message handling code could be exploited by hostile sites.

Furthermore, even after checking the `origin` attribute, authors should also check that the data in question is of the expected format. Otherwise, if the source of the event has been attacked using a cross-site scripting flaw, further unchecked processing of information sent using the `postMessage()` method could result in the attack being propagated into the receiver.

Authors should not use the wildcard keyword (*) in the `targetOrigin` argument in messages that contain any confidential information, as otherwise there is no way to guarantee that the message is only delivered to the recipient to which it was intended.

Authors who accept messages from any origin are encouraged to consider the risks of a denial-of-service attack. An attacker could send a high volume of messages; if the receiving page performs expensive computation or causes network traffic to be sent for each such message, the attacker’s message could be multiplied into a denial-of-service attack. Authors are encouraged to employ rate limiting (only accepting a certain number of messages per minute) to make such attacks impractical.

9.4.2.2 User agents

The integrity of this API is based on the inability for scripts of one `origin` to post arbitrary events (using `dispatchEvent()` or otherwise) to objects in other origins (those that are not the same).

Implementers are urged to take extra care in the implementation of this feature. It allows authors to transmit information from one domain to another domain, which is normally disallowed for security reasons. It also requires that UAs be careful to allow access to certain properties but not others.

User agents are also encouraged to consider rate-limiting message traffic between different `origins`, to protect naïve sites from denial-of-service attacks.
9.4.3 Posting messages

`window.postMessage(message [, options ])`

Window/postMessage

Support in all current engines.

Firefox 8+  Safari 4+  Chrome 1+
Opera 9.5+  Edge 79+
Edge (Legacy)  12+  Internet Explorer 10+
Firefox Android 8+  Safari iOS 3.2+  Chrome Android 18+  WebView Android 37+  Samsung Internet 1.0+  Opera Android 10.1+

Posts a message to the given window. Messages can be structured objects, e.g. nested objects and arrays, can contain JavaScript values (strings, numbers, `Date` objects, etc.), and can contain certain data objects such as `File Blob`, `FileList`, and `ArrayBuffer` objects.

Objects listed in the `transfer` member of `options` are transferred, not just cloned, meaning that they are no longer usable on the sending side.

A target origin can be specified using the `targetOrigin` member of `options`. If not provided, it defaults to "/". This default restricts the message to same-origin targets only.

If the origin of the target window doesn’t match the given target origin, the message is discarded, to avoid information leakage. To send the message to the target regardless of origin, set the target origin to "/*

Throws a “`DataCloneError` DOMException” if `transfer` array contains duplicate objects or if `message` could not be cloned.

`window.postMessage(message, targetOrigin [, transfer ])`

This is an alternate version of `postMessage()` where the target origin is specified as a parameter. Calling `window.postMessage(message, target, transfer)` is equivalent to `window.postMessage(message, {targetOrigin, transfer})`.

When posting a message to a `Window` of a `browsing context` that has just been navigated to a new `Document` is likely to result in the message not receiving its intended recipient: the scripts in the target `browsing context` have to have had time to set up listeners for the messages. Thus, for instance, in situations where a message is to be sent to the `Window` of newly created child `iframe`, authors are advised to have the child `Document` post a message to their parent announcing their readiness to receive messages, and for the parent to wait for this message before beginning posting messages.
The window post message steps, given a targetWindow, message, and options, are as follows:

1. Let targetRealm be targetWindow’s Realm.
2. Let incumbentSettings be the incumbent settings object.
3. Let targetOrigin be options[“targetOrigin”].
4. If targetOrigin is a single U+002F SOLIDUS character (/), then set targetOrigin to incumbentSettings’s origin.
5. Otherwise, if targetOrigin is not a single U+002A ASTERISK character (*), then:
   1. Let parsedURL be the result of running the URL parser on targetOrigin.
   2. If parsedURL is failure, then throw a “SyntaxError” DOMException.
   3. Set targetOrigin to parsedURL’s origin.
6. Let transfer be options[“transfer”].
7. Let serializeWithTransferResult be StructuredSerializeWithTransfer(message, transfer). Rethrow any exceptions.
8. Queue a global task on the posted message task source given targetWindow to run the following steps:
   1. If the targetOrigin argument is not a single literal U+002A ASTERISK character (*) and targetWindow’s associated Document’s origin is not same origin with targetOrigin, then return.
   2. Let origin be the serialization of incumbentSettings’s origin.
   3. Let source be the WindowProxy object corresponding to incumbentSettings’s global object (a Window object).
   4. Let deserializeRecord be StructuredDeserializeWithTransfer(serializeWithTransferResult, targetRealm).
      If this throws an exception, catch it, fire an event named messageerror at targetWindow, using MessageEvent, with the origin attribute initialized to origin and the source attribute initialized to source, and then return.
   5. Let messageClone be deserializeRecord.[[Deserialized]].
   6. Let newPorts be a new frozen array consisting of all MessagePort objects in deserializeRecord.[[TransferredValues]], if any, maintaining their relative order.
7. Fire an event named **message** at `targetWindow`, using `MessageEvent`, with the **origin** attribute initialized to `origin`, the **source** attribute initialized to `source`, the **data** attribute initialized to `messageClone`, and the **ports** attribute initialized to `newPorts`.

The `Window` interface’s `postMessage(message, options)` method steps are to run the **window post message steps** given `this`, `message`, and `options`.

The `Window` interface’s `postMessage(message, targetOrigin, transfer)` method steps are to run the **window post message steps** given `this`, `message`, and «[“targetOrigin” → targetOrigin, “transfer” → transfer]».

### 9.5.1 Introduction

**This section is non-normative.**

To enable independent pieces of code (e.g. running in different **browsing contexts**) to communicate directly, authors can use **channel messaging**.

Communication channels in this mechanism are implemented as two-ways pipes, with a port at each end. Messages sent in one port are delivered at the other port, and vice-versa. Messages are delivered as DOM events, without interrupting or blocking running **tasks**.
To create a connection (two “entangled” ports), the `MessageChannel()` constructor is called:

```javascript
var channel = new MessageChannel();
```

One of the ports is kept as the local port, and the other port is sent to the remote code, e.g. using `postMessage()`:

```javascript
otherWindow.postMessage('hello', 'https://example.com', [channel.port2]);
```

To send messages, the `postMessage()` method on the port is used:

```javascript
channel.port1.postMessage('hello');
```

To receive messages, one listens to `message` events:

```javascript
channel.port1.onmessage = handleMessage;
function handleMessage(event) {
  // message is in event.data
  // ...
}
```

Data sent on a port can be structured data; for example here an array of strings is passed on a `MessagePort`:

```javascript
port1.postMessage(['hello', 'world']);
```

### 9.5.1.1 Examples

This section is non-normative.

In this example, two JavaScript libraries are connected to each other using `MessagePorts`. This allows the libraries to later be hosted in different frames, or in `Worker` objects, without any change to the APIs.

```html
<script src="contacts.js"></script> <!-- exposes a contacts object -->
<script src="compose-mail.js"></script> <!-- exposes a composer object -->

var channel = new MessageChannel();
composer.addContactsProvider(channel.port1);
contacts.registerConsumer(channel.port2);
</script>
```

Here’s what the “addContactsProvider()” function’s implementation could look like:

```javascript
function addContactsProvider(port) {
  port.onmessage = function (event) {
    switch (event.data.messageType) {
```
case 'search-result': handleSearchResult(event.data.results); break;
case 'search-done': handleSearchDone(); break;
case 'search-error': handleSearchError(event.data.message); break;
    // ...
}

Alternatively, it could be implemented as follows:

```javascript
function addContactsProvider(port) {
    port.addEventListener('message', function (event) {
        if (event.data.messageType == 'search-result')
            handleSearchResult(event.data.results);
    });
    port.addEventListener('message', function (event) {
        if (event.data.messageType == 'search-done')
            handleSearchDone();
    });
    port.addEventListener('message', function (event) {
        if (event.data.messageType == 'search-error')
            handleSearchError(event.data.message);
    });
    // ...
    port.start();
}
```

The key difference is that when using `addEventListener()`, the `start()` method must also be invoked. When using `onmessage`, the call to `start()` is implied.

The `start()` method, whether called explicitly or implicitly (by setting `onmessage`), starts the flow of messages: messages posted on message ports are initially paused, so that they don’t get dropped on the floor before the script has had a chance to set up its handlers.

### 9.5.1.2 Ports as the basis of an object-capability model on the web

This section is non-normative.

Ports can be viewed as a way to expose limited capabilities (in the object-capability model sense) to other actors in the system. This can either be a weak capability system, where the ports are merely used as a convenient model within a particular origin, or as a strong capability model, where they are provided by one origin provider as the only mechanism by which another origin consumer can effect change in or obtain information from provider.

For example, consider a situation in which a social web site embeds in one `iframe` the user’s email contacts provider (an address book site, from a second origin), and in a second `iframe` a game (from a third origin). The outer social site and the game in the second `iframe` cannot
access anything inside the first iframe; together they can only:

- **Navigate** the iframe to a new URL, such as the same URL but with a different fragment, causing the Window in the iframe to receive a hashchange event.
- Resize the iframe, causing the Window in the iframe to receive a resize event.
- Send a message event to the Window in the iframe using the window.postMessage() API.

The contacts provider can use these methods, most particularly the third one, to provide an API that can be accessed by other origins to manipulate the user’s address book. For example, it could respond to a message “add-contact Guillaume Tell <tell@pomme.example.net>” by adding the given person and email address to the user’s address book.

To avoid any site on the web being able to manipulate the user’s contacts, the contacts provider might only allow certain trusted sites, such as the social site, to do this.

Now suppose the game wanted to add a contact to the user’s address book, and that the social site was willing to allow it to do so on its behalf, essentially “sharing” the trust that the contacts provider had with the social site. There are several ways it could do this; most simply, it could just proxy messages between the game site and the contacts site. However, this solution has a number of difficulties: it requires the social site to either completely trust the game site not to abuse the privilege, or it requires that the social site verify each request to make sure it’s not a request that it doesn’t want to allow (such as adding multiple contacts, reading the contacts, or deleting them); it also requires some additional complexity if there’s ever the possibility of multiple games simultaneously trying to interact with the contacts provider.

Using message channels and MessagePort objects, however, all of these problems can go away. When the game tells the social site that it wants to add a contact, the social site can ask the contacts provider not for it to add a contact, but for the capability to add a single contact. The contacts provider then creates a pair of MessagePort objects, and sends one of them back to the social site, who forwards it on to the game. The game and the contacts provider then have a direct connection, and the contacts provider knows to only honor a single “add contact” request, nothing else. In other words, the game has been granted the capability to add a single contact.

### 9.5.1.3 Ports as the basis of abstracting out service implementations

*This section is non-normative.*

Continuing the example from the previous section, consider the contacts provider in particular. While an initial implementation might have simply used XMLHttpRequest objects in the service’s iframe, an evolution of the service might instead want to use a shared worker with a single WebSocket connection.

If the initial design used MessagePort objects to grant capabilities, or even just to allow multiple simultaneous independent sessions, the service implementation can switch from the
XMLHttpRequests-in-each-iframe model to the shared-WebSocket model without changing the API at all: the ports on the service provider side can all be forwarded to the shared worker without it affecting the users of the API in the slightest.

9.5.2 Message channels

<MessageChannel>
Support in all current engines.

Firebox41+Safari5+Chrome4+
Opera10.6+Edge79+
Edge (Legacy)12+Internet Explorer10+

Firefox Android41+Safari iOS4.2+Chrome Android18+WebView Android4.4+Samsung
Internet1.0+Opera Android11+

[Exposed=(Window,Worker)]
interface MessageChannel {
  constructor();

    readonly attribute MessagePort port1;
    readonly attribute MessagePort port2;
};

channel = new MessageChannel()

Returns a new MessageChannel object with two new MessagePort objects.

channel.port1

MessageChannel/port1
Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>41+</td>

<td>1.0+</td>
</tr>
<tr>
<td>Opera Android</td>
<td>11+</td>
</tr>
</tbody>
</table>

Returns the first `MessagePort` object.

```javascript
channel. port2
```

Returns the second `MessagePort` object.

A `MessageChannel` object has an associated `port 1` and an associated `port 2`, both `MessagePort` objects.

The `new MessageChannel()` constructor steps are:

1. Set `this`'s `port 1` to a new `MessagePort` in `this`'s relevant Realm.
2. Set `this`'s `port 2` to a new `MessagePort` in `this`'s relevant Realm.
3. Entangle `this`'s `port 1` and `this`'s `port 2`.

The `port1` getter steps are to return `this`'s `port 1`.

The `port2` getter steps are to return `this`'s `port 2`.

9.5.3 Message ports
Support in all current engines.

Firefox 41+ Safari 5+ Chrome 4+
Opera 10.6+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 41+ Safari iOS 4.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

Each channel has two message ports. Data sent through one port is received by the other port, and vice versa.

```javascript
[Exposed=(Window, Worker, AudioWorklet), Transferable]
interface MessagePort : EventTarget {
  undefined postMessage(any message, sequence<object> transfer);
  undefined postMessage(any message, optional StructuredSerializeOptions options optional start());
  undefined close();

  // event handlers
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};

dictionary StructuredSerializeOptions {
  sequence<object> transfer = [];
};

port.postMessage(message [, , transfer])
```

Support in all current engines.

Firefox 41+ Safari 5+ Chrome 4+
Opera 10.6+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 41+ Safari iOS 4.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

`port.postMessage(message [, , { transfer }])`

Posts a message through the channel. Objects listed in `transfer` are transferred, not just cloned, meaning that they are no longer usable on the sending side.

Throws a **DataCloneError** DOMException if `transfer` contains duplicate objects or `port`, or if `message` could not be cloned.
port.start()

**MDN**

**MessagePort/start**

Support in all current engines.

Firefox 41+ Safari 5+ Chrome 4+
Opera 10.6+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 41+ Safari iOS 4.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

Begins dispatching messages received on the port.

port.close()

**MDN**

**MessagePort/close**

Support in all current engines.

Firefox 41+ Safari 5+ Chrome 4+
Opera 10.6+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 41+ Safari iOS 4.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

Disconnects the port, so that it is no longer active.

Each **MessagePort** object can be entangled with another (a symmetric relationship). Each **MessagePort** object also has a task source called the *port message queue*, initially empty. A *port message queue* can be enabled or disabled, and is initially disabled. Once enabled, a port can never be disabled again (though messages in the queue can get moved to another queue or removed altogether, which has much the same effect). A **MessagePort** also has a *has been shipped* flag, which must initially be false.

When a port’s *port message queue* is enabled, the event loop must use it as one of its task sources. When a port’s *relevant global object* is a **Window**, all tasks queued on its *port message queue* must be associated with the port’s *relevant global object’s associated Document*.

If the document is *fully active*, but the event listeners all have scripts whose *settings objects* specify *responsible documents* that are *not fully active*, then the messages will not be received unless and until the documents become *fully active* again.

Each event loop has a task source called the *unshipped port message queue*. This is a virtual
task source: it must act as if it contained the tasks of each port message queue of each MessagePort whose has been shipped flag is false, whose port message queue is enabled, and whose relevant agent’s event loop is that event loop, in the order in which they were added to their respective task source. When a task would be removed from the unshipped port message queue, it must instead be removed from its port message queue.

When a MessagePort’s has been shipped flag is false, its port message queue must be ignored for the purposes of the event loop. (The unshipped port message queue is used instead.)

The has been shipped flag is set to true when a port, its twin, or the object it was cloned from, is or has been transferred. When a MessagePort’s has been shipped flag is true, its port message queue acts as a first-class task source, unaffected to any unshipped port message queue.

When the user agent is to entangle two MessagePort objects, it must run the following steps:

1. If one of the ports is already entangled, then disentangle it and the port that it was entangled with.

   If those two previously entangled ports were the two ports of a MessageChannel object, then that MessageChannel object no longer represents an actual channel: the two ports in that object are no longer entangled.

2. Associate the two ports to be entangled, so that they form the two parts of a new channel. (There is no MessageChannel object that represents this channel.)

   Two ports A and B that have gone through this step are now said to be entangled; one is entangled to the other, and vice versa.

   While this specification describes this process as instantaneous, implementations are more likely to implement it via message passing. As with all algorithms, the key is "merely" that the end result be indistinguishable, in a black-box sense, from the specification.

MessagePort objects are transferable objects. Their transfer steps, given value and dataHolder, are:

1. Set value’s has been shipped flag to true.

2. Set dataHolder.[[PortMessageQueue]] to value’s port message queue.

3. If value is entangled with another port remotePort, then:

   1. Set remotePort’s has been shipped flag to true.

   2. Set dataHolder.[[RemotePort]] to remotePort.

4. Otherwise, set dataHolder.[[RemotePort]] to null.
Their **transfer-receiving steps**, given `dataHolder` and `value`, are:

1. Set `value`'s **has been shipped** flag to true.

2. Move all the **tasks** that are to fire **message** events in `dataHolder.[[PortMessageQueue]]` to the **port message queue** of `value`, if any, leaving `value`'s **port message queue** in its initial disabled state, and, if `value`'s relevant global object is a **Window**, associating the moved **tasks** with `value`'s relevant global object’s associated **Document**.

3. If `dataHolder.[[RemotePort]]` is not null, then **entangle** `dataHolder.[[RemotePort]]` and `value`. (This will disentangle `dataHolder.[[RemotePort]]` from the original port that was transferred.)

---

The **message port post message steps**, given `sourcePart`, `targetPort`, `message` and `options` are as follows:

1. Let `transfer` be `options["transfer"]`.

2. If `transfer` contains `sourcePort`, then throw a **`DataCloneError` DOMException**.

3. Let `doomed` be false.

4. If `targetPort` is not null and `transfer` contains `targetPort`, then set `doomed` to true and optionally report to a developer console that the target port was posted to itself, causing the communication channel to be lost.

5. Let `serializeWithTransferResult` be `StructuredSerializeWithTransfer(message, transfer)`. Rethrow any exceptions.

6. If `targetPort` is null, or if `doomed` is true, then return.

7. Add a **task** that runs the following steps to the **port message queue** of `targetPort`:

   1. Let `finalTargetPort` be the **MessagePort** in whose **port message queue** the task now finds itself.

      This can be different from `targetPort`, if `targetPort` itself was transferred and thus all its tasks moved along with it.

   2. Let `targetRealm` be `finalTargetPort`'s **relevant Realm**.

   3. Let `deserializeRecord` be `StructuredDeserializeWithTransfer(serializeWithTransferResult, targetRealm)`.

      If this throws an exception, catch it, **fire an event named messageerror** at `finalTargetPort`, using **MessageEvent**, and then return.
4. Let `messageClone` be `deserializeRecord`.[[Deserialized]].

5. Let `newPorts` be a new `frozen array` consisting of all `MessagePort` objects in `deserializeRecord`.[[TransferredValues]], if any, maintaining their relative order.

6. Fire an event named `message` at `finalTargetPort`, using `MessageEvent`, with the `data` attribute initialized to `messageClone` and the `ports` attribute initialized to `newPorts`.

The `postMessage(message, options)` method steps are:

1. Let `targetPort` be the port with which `this` is entangled, if any; otherwise let it be null.

2. Run the message port post message steps providing `this`, `targetPort`, `message` and `options`.

The `postMessage(message, transfer)` method steps are:

1. Let `targetPort` be the port with which `this` is entangled, if any; otherwise let it be null.

2. Let `options` be «[“transfer” → `transfer`]».

3. Run the message port post message steps providing `this`, `targetPort`, `message` and `options`.

The `start()` method steps are to enable `this`'s port message queue, if it is not already enabled.

The `close()` method steps are:

1. Set `this`'s [[Detached]] internal slot value to true.

2. If `this` is entangled, disentangle it.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the `MessagePort` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>onmessage</code></td>
<td><code>message</code></td>
</tr>
</tbody>
</table>
Support in all current engines.

Opera47+Edge79+
Edge (Legacy)18Internet ExplorerNo
Firefox Android57+Safari iOSNoChrome Android60+WebView
Android60+Samsung Internet8.0+Opera Android44+

The first time a MessagePort object’s onmessage IDL attribute is set, the port’s port message queue must be enabled, as if the start() method had been called.

9.5.4 Broadcasting to many ports

This section is non-normative.

Broadcasting to many ports is in principle relatively simple: keep an array of MessagePort objects to send messages to, and iterate through the array to send a message. However, this has one rather unfortunate effect: it prevents the ports from being garbage collected, even if the other side has gone away. To avoid this problem, implement a simple protocol whereby the other side acknowledges it still exists. If it doesn’t do so after a certain amount of time, assume it’s gone, close the MessagePort object, and let it be garbage collected.

9.5.5 Ports and garbage collection

When a MessagePort object o is entangled, user agents must either act as if o’s entangled MessagePort object has a strong reference to o, or as if o’s relevant global object has a strong reference to o.

Thus, a message port can be received, given an event listener, and then forgotten, and so long as that event listener could receive a message, the channel will be maintained.

Of course, if this was to occur on both sides of the channel, then both ports could be garbage
collected, since they would not be reachable from live code, despite having a strong reference to
each other.

Furthermore, a MessagePort object must not be garbage collected while there exists an event
referenced by a task in a task queue that is to be dispatched on that MessagePort object, or
while the MessagePort object’s port message queue is enabled and not empty.

Authors are strongly encouraged to explicitly close MessagePort objects to disentangle them,
so that their resources can be recollected. Creating many MessagePort objects and discarding
them without closing them can lead to high transient memory usage since garbage collection is
not necessarily performed promptly, especially for MessagePort objects where garbage collection
can involve cross-process coordination.

9.6 Broadcasting to other browsing contexts

BroadcastChannel

Support in all current engines.

Firefox38+Safari preview+Chrome54+
Opera41+Edge79+
Edge (Legacy)NoInternet ExplorerNo
Firefox Android38+Safari iOSNoChrome Android54+WebView Android54+Samsung
Internet6.0+Opera Android41+

Broadcast_Channel_API

Support in all current engines.

Firefox38+Safari preview+Chrome54+
Opera41+Edge79+
Edge (Legacy)NoInternet ExplorerNo
Firefox Android38+Safari iOSNoChrome Android54+WebView Android54+Samsung
Internet6.0+Opera Android41+

Pages on a single origin opened by the same user in the same user agent but in different
unrelated browsing contexts sometimes need to send notifications to each other, for example
“hey, the user logged in over here, check your credentials again”.

For elaborate cases, e.g. to manage locking of shared state, to manage synchronization of
resources between a server and multiple local clients, to share a WebSocket connection with a
remote host, and so forth, shared workers are the most appropriate solution.

For simple cases, though, where a shared worker would be an unreasonable overhead, authors
can use the simple channel-based broadcast mechanism described in this section.

```javascript
[Exposed=(Window,Worker)]
interface BroadcastChannel : EventTarget {
    constructor(DOMString name);

    readonly attribute DOMString name;
    undefined postMessage(any message);
    undefined close();
    attribute EventHandler onmessage;
    attribute EventHandler onmessageerror;
};

broadcastChannel = new BroadcastChannel(name)
```
BroadcastChannel/postMessage

Support in all current engines.

Firefox 38+ Safari preview+ Chrome 54+
Opera 41+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 38+ Safari iOS No Chrome Android 54+ WebView Android 54+ Samsung Internet 6.0+ Opera Android 41+

Sends the given message to other BroadcastChannel objects set up for this channel. Messages can be structured objects, e.g. nested objects and arrays.

broadcastChannel.close()

BroadcastChannel/close

Support in all current engines.

Firefox 38+ Safari preview+ Chrome 54+
Opera 41+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 38+ Safari iOS No Chrome Android 54+ WebView Android 54+ Samsung Internet 6.0+ Opera Android 41+

Closes the BroadcastChannel object, opening it up to garbage collection.

A BroadcastChannel object has a channel name and a closed flag.

The new BroadcastChannel(name) constructor steps are:

1. Set this’s channel name to name.
2. Set this’s closed flag to false.

The name getter steps are to return this’s channel name.

A BroadcastChannel object is said to be eligible for messaging when its relevant global object is either:

- a Window object whose associated Document is fully active, or
- a WorkerGlobalScope object whose closing flag is false and whose worker is not a
suspendable worker.

The `postMessage(message)` method steps are:

1. If `this` is not eligible for messaging, then return.
2. If `this`’s closed flag is true, then throw an "InvalidStateError" `DOMException`.
3. Let `serialized` be `StructuredSerialize(message)`. Rethrow any exceptions.
4. Let `sourceOrigin` be `this`’s relevant settings object’s origin.
5. Let `destinations` be a list of `BroadcastChannel` objects that match the following criteria:
   - They are eligible for messaging.
   - Their relevant settings object’s origin is same origin with `sourceOrigin`.
   - Their channel name is `this`’s channel name.
6. Remove `source` from `destinations`.
7. Sort `destinations` such that all `BroadcastChannel` objects whose relevant agents are the same are sorted in creation order, oldest first. (This does not define a complete ordering. Within this constraint, user agents may sort the list in any implementation-defined manner.)
8. For each `destination` in `destinations`, queue a global task on the DOM manipulation task `source` given `destination`’s relevant global object to perform the following steps:
   1. If `destination`’s closed flag is true, then abort these steps.
   2. Let `targetRealm` be `destination`’s relevant Realm.
   3. Let `data` be `StructuredDeserialize(serialized, targetRealm)`. If this throws an exception, catch it, fire an event named `messageerror` at `destination`, using `MessageEvent`, with the origin attribute initialized to the serialization of `sourceOrigin`, and then abort these steps.
   4. Fire an event named `message` at `destination`, using `MessageEvent`, with the data attribute initialized to `data` and the origin attribute initialized to the serialization of `sourceOrigin`.

While a `BroadcastChannel` object whose closed flag is false has an event listener registered for `message` or `messageerror` events, there must be a strong reference from the `BroadcastChannel` object’s relevant global object to the `BroadcastChannel` object itself.
The `close()` method steps are to set this’s closed flag to true.

Authors are strongly encouraged to explicitly close `BroadcastChannel` objects when they are no longer needed, so that they can be garbage collected. Creating many `BroadcastChannel` objects and discarding them while leaving them with an event listener and without closing them can lead to an apparent memory leak, since the objects will continue to live for as long as they have an event listener (or until their page or worker is closed).

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by all objects implementing the `BroadcastChannel` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>onmessage</code></td>
<td>message</td>
</tr>
<tr>
<td><code>onmessageerror</code></td>
<td>messageerror</td>
</tr>
</tbody>
</table>

Suppose a page wants to know when the user logs out, even when the user does so from another tab at the same site:

```javascript
var authChannel = new BroadcastChannel('auth');
authChannel.onmessage = function (event) {
```
if (event.data == 'logout')
    showLogout();
}

function logoutRequested() {
    // called when the user asks us to log them out
    doLogout();
    showLogout();
    authChannel.postMessage('logout');
}

function doLogout() {
    // actually log the user out (e.g. clearing cookies)
    // ...
}

function showLogout() {
    // update the UI to indicate we're logged out
    // ...
}

10 Web workers

Web_Workers_API

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+
Opera 10.6+ Edge 79+

Web_Workers_API/Using_web_workers

10.1 Introduction

10.1.1 Scope

This section is non-normative.

This specification defines an API for running scripts in the background independently of any user interface scripts.
This allows for long-running scripts that are not interrupted by scripts that respond to clicks or other user interactions, and allows long tasks to be executed without yielding to keep the page responsive.

Workers (as these background scripts are called herein) are relatively heavy-weight, and are not intended to be used in large numbers. For example, it would be inappropriate to launch one worker for each pixel of a four megapixel image. The examples below show some appropriate uses of workers.

Generally, workers are expected to be long-lived, have a high start-up performance cost, and a high per-instance memory cost.

### 10.1.2 Examples

*This section is non-normative.*

There are a variety of uses that workers can be put to. The following subsections show various examples of this use.

#### 10.1.2.1 A background number-crunching worker

*This section is non-normative.*

The simplest use of workers is for performing a computationally expensive task without interrupting the user interface.

In this example, the main document spawns a worker to (naïvely) compute prime numbers, and progressively displays the most recently found prime number.

The main page is as follows:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
  <meta charset="utf-8">
  <title>Worker example: One-core computation</title>
</head>
<body>
  <p>The highest prime number discovered so far is: <output id="result"></output></p>
  <script>
    var worker = new Worker('worker.js');
    worker.onmessage = function (event) {
      document.getElementById('result').textContent = event.data;
    };
  </script>
</body>
</html>
```
The `Worker()` constructor call creates a worker and returns a `Worker` object representing that worker, which is used to communicate with the worker. That object’s `onmessage` event handler allows the code to receive messages from the worker.

The worker itself is as follows:

```javascript
var n = 1;
search: while (true) {
  n += 1;
  for (var i = 2; i <= Math.sqrt(n); i += 1)
    if (n % i == 0)
      continue search;
  // found a prime!
  postMessage(n);
}
```

The bulk of this code is simply an unoptimized search for a prime number. The `postMessage()` method is used to send a message back to the page when a prime is found.

View this example online.

10.1.2.2 Using a JavaScript module as a worker

This section is non-normative.

All of our examples so far show workers that run classic scripts. Workers can instead be instantiated using module scripts, which have the usual benefits: the ability to use the JavaScript `import` statement to import other modules; strict mode by default; and top-level declarations not polluting the worker's global scope.

As the `import` statement is available, the `importScripts()` method will automatically fail inside module workers.

In this example, the main document uses a worker to do off-main-thread image manipulation. It imports the filters used from another module.

The main page is as follows:

```html
<!DOCTYPE html>
<html lang="en">
<meta charset="utf-8">
<title>Worker example: image decoding</title>
<p>
  <label type="url" id="image-url" list="image-list">
    Type an image URL to decode
  </label>
</p>
```

<datalist id="image-list">
  <option value="https://html.spec.whatwg.org/images/drawImage.png">
  <option value="https://html.spec.whatwg.org/images/robots.jpeg">
  <option value="https://html.spec.whatwg.org/images/arcTo2.png">
</datalist>

<p>
  Choose a filter to apply
  <select id="filter">
    <option value="none">none</option>
    <option value="grayscale">grayscale</option>
    <option value="brighten">brighten by 20%</option>
  </select>
</p>

<div id="output"></div>

<script type="module">
  const worker = new Worker("worker.js", { type: "module" });
  worker.onmessage = receiveFromWorker;

  const url = document.querySelector("#image-url");
  const filter = document.querySelector("#filter");
  const output = document.querySelector("#output");

  url.oninput = updateImage;
  filter.oninput = sendToWorker;

  let imageData, context;

  function updateImage() {
    const img = new Image();
    img.src = url.value;

    img.onload = () => {
      const canvas = document.createElement("canvas");
      canvas.width = img.width;
      canvas.height = img.height;

      context = canvas.getContext("2d");
      context.drawImage(img, 0, 0);
      imageData = context.getImageData(0, 0, canvas.width, canvas.height);
    }
  }
</script>
sendToWorker();
output.replaceChildren(canvas);
}

function sendToWorker() {
    worker.postMessage({ imageData, filter: filter.value });
}

function receiveFromWorker(e) {
    context.putImageData(e.data, 0, 0);
}
</script>

The worker file is then:

import * as filters from "./filters.js";

self.onmessage = e => {
    const { imageData, filter } = e.data;
    filters[filter](imageData);
    self.postMessage(imageData, [imageData.data.buffer]);
};

Which imports the file filters.js:

export function none() {}

export function grayscale({ data: d }) {
    for (let i = 0; i < d.length; i += 4) {
        const [r, g, b] = [d[i], d[i + 1], d[i + 2]];

        // CIE luminance for the RGB
        // The human eye is bad at seeing red and blue, so we de-emphasize them.
        d[i] = d[i + 1] = d[i + 2] = 0.2126 * r + 0.7152 * g + 0.0722 * b;
    }
}

export function brighten({ data: d }) {
    for (let i = 0; i < d.length; ++i) {
        d[i] *= 1.2;
    }
};

View this example online.
This section is non-normative.

This section introduces shared workers using a Hello World example. Shared workers use slightly different APIs, since each worker can have multiple connections.

This first example shows how you connect to a worker and how a worker can send a message back to the page when it connects to it. Received messages are displayed in a log.

Here is the HTML page:

```html
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 1</title>
<pre id="log">Log:</pre>
<script>
var worker = new SharedWorker('test.js');
var log = document.getElementById('log');
worker.port.onmessage = function(e) {
    log.textContent += '\n' + e.data;
}
</script>
</html>
```

Here is the JavaScript worker:

```javascript
onconnect = function(e) {
    var port = e.ports[0];
    port.postMessage('Hello World!');
}
```

View this example online.

This second example extends the first one by changing two things: first, messages are received using `addEventListener()` instead of an `event handler IDL attribute`, and second, a...
message is sent to the worker, causing the worker to send another message in return. Received messages are again displayed in a log.

Here is the HTML page:

```html
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 2</title>
<pre id="log">Log:</pre>
<script>
var worker = new SharedWorker('test.js');
var log = document.getElementById('log');
worker.port.addEventListener('message', function(e) {
    log.textContent += '\n' + e.data;
}, false);
worker.port.start(); // note: need this when using addEventListener
worker.port.postMessage('ping');
</script>
</html>
```

Here is the JavaScript worker:

```javascript
onconnect = function(e) {
    var port = e.ports[0];
    port.postMessage('Hello World!');
    port.onmessage = function(e) {
        port.postMessage('pong'); // not e.ports[0].postMessage!
        // e.target.postMessage('pong'); would work also
    }
}
```

View this example online.

Finally, the example is extended to show how two pages can connect to the same worker; in this case, the second page is merely in an iframe on the first page, but the same principle would apply to an entirely separate page in a separate top-level browsing context.

Here is the outer HTML page:

```html
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 3</title>
<pre id="log">Log:</pre>
<script>
    var worker = new SharedWorker('test.js');
</script>
```

Here is the inner HTML page:

```html
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 3 inner frame</title>
<pre id=log>Inner log:</pre>
<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.onmessage = function(e) {
    log.textContent += '\n' + e.data;
  }
</script>
</html>
```

Here is the JavaScript worker:

```javascript
var count = 0;
onconnect = function(e) {
  count += 1;
  var port = e.ports[0];
  port.postMessage('Hello World! You are connection #' + count);
  port.onmessage = function(e) {
    port.postMessage('pong');
  }
}
```

View this example online.

10.1.2.4 Shared state using a shared worker

This section is non-normative.

In this example, multiple windows (viewers) can be opened that are all viewing the same map. All the windows share the same map information, with a single worker coordinating all the viewers. Each viewer can move around independently, but if they set any data on the map, all the viewers are updated.
The main page isn’t interesting, it merely provides a way to open the viewers:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
<meta charset="utf-8">
<title>Workers example: Multiviewer</title>
<script>
    function openViewer() {
        window.open('viewer.html');
    }
</script>
</head>
<body>
<p><button type=button onclick="openViewer()">Open a new viewer</button></p>
<p>Each viewer opens in a new window. You can have as many viewers as you like, they all view the same data.</p>
</body>
</html>
```

The viewer is more involved:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
<meta charset="utf-8">
<title>Workers example: Multiviewer viewer</title>
<script>
    var worker = new SharedWorker('worker.js', 'core');

    // CONFIGURATION
    function configure(event) {
        if (event.data.substr(0, 4) != 'cfg ') return;
        var name = event.data.substr(4).split(' ', 1)[0];
        // update display to mention our name is name
        document.getElementsByTagName('h1')[0].textContent += ' ' + name;
        // no longer need this listener
        worker.port.removeEventListener('message', configure, false);
    }
    worker.port.addEventListener('message', configure, false);

    // MAP
    function paintMap(event) {
        if (event.data.substr(0, 4) != 'map ') return;
        var data = event.data.substr(4).split(',');
        // display tiles data[0] .. data[8]
    }
</script>
</head>
<body>
</body>
</html>
```
var canvas = document.getElementById('map');
var context = canvas.getContext('2d');
for (var y = 0; y < 3; y += 1) {
    for (var x = 0; x < 3; x += 1) {
        var tile = data[y * 3 + x];
        if (tile == '0')
            context.fillStyle = 'green';
        else
            context.fillStyle = 'maroon';
        context.fillRect(x * 50, y * 50, 50, 50);
    }
}
worker.port.addEventListener('message', paintMap, false);

// PUBLIC CHAT
function updatePublicChat(event) {
    if (event.data.substr(0, 4) != 'txt ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    var message = event.data.substr(4 + name.length + 1);
    // display "<name> message" in public chat
    var public = document.getElementById('public');
    var p = document.createElement('p');
    var n = document.createElement('button');
    n.textContent = '<' + name + '>';
    n.onclick = function () { worker.port.postMessage('msg ' + name); };
    p.appendChild(n);
    var m = document.createElement('span');
    m.textContent = message;
    p.appendChild(m);
    public.appendChild(p);
}
worker.port.addEventListener('message', updatePublicChat, false);

// PRIVATE CHAT
function startPrivateChat(event) {
    if (event.data.substr(0, 4) != 'msg ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    var port = event.ports[0];
    // display a private chat UI
    var ul = document.getElementById('private');
    var li = document.createElement('li');
    var h3 = document.createElement('h3');
    h3.textContent = 'Private chat with ' + name;
    li.appendChild(h3);
    var div = document.createElement('div');
    var addMessage = function (name, message) {

var p = document.createElement('p');
var n = document.createElement('strong');
n.textContent = '<' + name + '>'; 
p.appendChild(n);
var t = document.createElement('span');
t.textContent = message;
p.appendChild(t);
div.appendChild(p);

port.onmessage = function (event) {
    addMessage(name, event.data);
}
li.appendChild(div);
var form = document.createElement('form');
var p = document.createElement('p');
var input = document.createElement('input');
input.size = 50;
p.appendChild(input);
p.appendChild(document.createTextNode(' '));
var button = document.createElement('button');
button.textContent = 'Post';
p.appendChild(button);
form.onSubmit = function () {
    port.postMessage(input.value);
    addMessage('me', input.value);
    input.value = ''; 
    return false;
};
form.appendChild(p);
li.appendChild(form);
ul.appendChild(li);
worker.port.addEventListener('message', startPrivateChat, false);

worker.port.start();
</script>
</head>
<body>
<h1>Viewer</h1>
<h2>Map</h2>
<p><canvas id="map" height=150 width=150></canvas></p>
<p>
<button type="button" onclick="worker.port.postMessage('mov left')">Left</button>
<button type="button" onclick="worker.port.postMessage('mov up')">Up</button>
<button type="button" onclick="worker.port.postMessage('mov down')">Down</button>
<button type="button" onclick="worker.port.postMessage('mov right')">Right</button>
<button type="button" onclick="worker.port.postMessage('set 0')">Set 0</button>
</p>
<button type=button onclick="worker.port.postMessage('set 1')">Set 1</button>

<p>Public Chat</p>
<div id="public"></div>
<form onsubmit="worker.port.postMessage('txt ' + message.value); message.value = ''; return false;">
  <input type="text" name="message" size="50">
  <button>Post</button>
</form>

<p>Private Chat</p>
<ul id="private"></ul>
</body>
</html>

There are several key things worth noting about the way the viewer is written.

**Multiple listeners.** Instead of a single message processing function, the code here attaches multiple event listeners, each one performing a quick check to see if it is relevant for the message. In this example it doesn’t make much difference, but if multiple authors wanted to collaborate using a single port to communicate with a worker, it would allow for independent code instead of changes having to all be made to a single event handling function.

Registering event listeners in this way also allows you to unregister specific listeners when you are done with them, as is done with the `configure()` method in this example.

Finally, the worker:

```javascript
var nextName = 0;
function getNextName() {
  // this could use more friendly names
  // but for now just return a number
  return nextName++;
}

var map = [
  [0, 0, 0, 0, 0, 0, 0, 0],
  [1, 1, 0, 1, 0, 1, 1],
  [0, 1, 0, 1, 0, 0, 0],
  [0, 1, 0, 1, 0, 1, 1],
  [0, 0, 0, 1, 0, 0, 0],
  [1, 0, 0, 1, 1, 1, 1],
  [1, 1, 0, 1, 1, 0, 1],
];

function wrapX(x) {
  if (x < 0) return wrapX(x + map[0].length);
}```
if (x >= map[0].length) return wrapX(x - map[0].length);
  return x;
}

function wrapY(y) {
  if (y < 0) return wrapY(y + map.length);
  if (y >= map[0].length) return wrapY(y - map.length);
  return y;
}

function wrap(val, min, max) {
  if (val < min)
    return val + (max-min)+1;
  if (val > max)
    return val - (max-min)-1;
  return val;
}

function sendMapData(viewer) {
  var data = '';  
  for (var y = viewer.y-1; y <= viewer.y+1; y += 1) {
    for (var x = viewer.x-1; x <= viewer.x+1; x += 1) {
      if (data != '')
        data += ',',;
      data += map[wrap(y, 0, map[0].length-1)][wrap(x, 0, map.length-1)];
    }
  }
  viewer.port.postMessage('map ' + data);
}

var viewers = {};
onconnect = function (event) {
  var name = getNextName();
  event.ports[0]._data = { port: event.ports[0], name: name, x: 0, y: 0, };
  viewers[name] = event.ports[0]._data;
  event.ports[0].postMessage('cfg ' + name);
  event.ports[0].onmessage = getMessage;
  sendMapData(event.ports[0]._data);
};

function getMessage(event) {
  switch (event.data.substr(0, 4)) {
    case 'mov ':
      var direction = event.data.substr(4);
      var dx = 0;
      var dy = 0;
      switch (direction) {

case 'up': dy = -1; break;
case 'down': dy = 1; break;
case 'left': dx = -1; break;
case 'right': dx = 1; break;
}

event.target._data.x = wrapX(event.target._data.x + dx);
event.target._data.y = wrapY(event.target._data.y + dy);
sendMapData(event.target._data);
break;
case 'set':
    var value = event.data.substr(4);
    map[event.target._data.y][event.target._data.x] = value;
    for (var viewer in viewers)
        sendMapData(viewers[viewer]);
    break;
case 'txt':
    var name = event.target._data.name;
    var message = event.data.substr(4);
    for (var viewer in viewers)
        viewers[viewer].port.postMessage('txt ' + name + ' ' + message);
    break;
case 'msg':
    var party1 = event.target._data;
    var party2 = viewers[event.data.substr(4).split(' ', 1)[0]];
    if (party2) {
        var channel = new MessageChannel();
        party1.port.postMessage('msg ' + party2.name, [channel.port1]);
        party2.port.postMessage('msg ' + party1.name, [channel.port2]);
    }
    break;
}
computationally expensive tasks amongst multiple workers. In this example, a computationally expensive task that is to be performed for every number from 1 to 10,000,000 is farmed out to ten subworkers.

The main page is as follows, it just reports the result:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
  <meta charset="utf-8">
  <title>Worker example: Multicore computation</title>
</head>
<body>
<p>Result: <output id="result"></output></p>
<script>
  var worker = new Worker('worker.js');
  worker.onmessage = function (event) {
    document.getElementById('result').textContent = event.data;
  };
</script>
</body>
</html>
```

The worker itself is as follows:

```javascript
// settings
var num_workers = 10;
var items_per_worker = 1000000;

// start the workers
var result = 0;
var pending_workers = num_workers;
for (var i = 0; i < num_workers; i += 1) {
  var worker = new Worker('core.js');
  worker.postMessage(i * items_per_worker);
  worker.postMessage((i+1) * items_per_worker);
  worker.onmessage = storeResult;
}

// handle the results
function storeResult(event) {
  result += 1*event.data;
  pending_workers -= 1;
  if (pending_workers <= 0)
    postMessage(result); // finished!
}
```
It consists of a loop to start the subworkers, and then a handler that waits for all the
subworkers to respond.

The subworkers are implemented as follows:

```javascript
var start;
onmessage = getStart;
function getStart(event) {
  start = 1*event.data;
onmessage = getEnd;
}

var end;
function getEnd(event) {
  end = 1*event.data;
onmessage = null;
work();
}

function work() {
  var result = 0;
  for (var i = start; i < end; i += 1) {
    // perform some complex calculation here
    result += 1;
  }
  postMessage(result);
close();
}
```

They receive two numbers in two events, perform the computation for the range of numbers
thus specified, and then report the result back to the parent.

View this example online.

10.1.2.6 Providing libraries

This section is non-normative.

Suppose that a cryptography library is made available that provides three tasks:

**Generate a public/private key pair**

  Takes a port, on which it will send two messages, first the public key and then the private
  key.

**Given a plaintext and a public key, return the corresponding ciphertext**

  Takes a port, to which any number of messages can be sent, the first giving the public key,
  and the remainder giving the plaintext, each of which is encrypted and then sent on that
same channel as the ciphertext. The user can close the port when it is done encrypting content.

**Given a ciphertext and a private key, return the corresponding plaintext**

Takes a port, to which any number of messages can be sent, the first giving the private key, and the remainder giving the ciphertext, each of which is decrypted and then sent on that same channel as the plaintext. The user can close the port when it is done decrypting content.

The library itself is as follows:

```javascript
function handleMessage(e) {
    if (e.data == "genkeys")
        genkeys(e.ports[0]);
    else if (e.data == "encrypt")
        encrypt(e.ports[0]);
    else if (e.data == "decrypt")
        decrypt(e.ports[0]);
}

function genkeys(p) {
    var keys = _generateKeyPair();
    p.postMessage(keys[0]);
    p.postMessage(keys[1]);
}

function encrypt(p) {
    var key, state = 0;
    p.onmessage = function (e) {
        if (state == 0) {
            key = e.data;
            state = 1;
        } else {
            p.postMessage(_encrypt(key, e.data));
        }
    };
}

function decrypt(p) {
    var key, state = 0;
    p.onmessage = function (e) {
        if (state == 0) {
            key = e.data;
            state = 1;
        } else {
            p.postMessage(_decrypt(key, e.data));
        }
    };
```
// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
  onmessage = handleMessage;
else // shared worker
  onconnect = function (e) { e.port.onmessage = handleMessage; }

// the "crypto" functions:

function generateKeyPair() {
  return [Math.random(), Math.random()];
}

function encrypt(k, s) {
  return 'encrypted-' + k + ' ' + s;
}

function decrypt(k, s) {
  return s.substr(s.indexOf(' ') + 1);
}

Note that the crypto functions here are just stubs and don’t do real cryptography.

This library could be used as follows:

```html
<!DOCTYPE HTML>
<html lang="en">
<head>
<meta charset="utf-8">
<title>Worker example: Crypto library</title>
<script>
const cryptoLib = new Worker('libcrypto-v1.js'); // or could use 'libcrypto-v2.js'
function startConversation(source, message) {
  const messageChannel = new MessageChannel();
  source.postMessage(message, [messageChannel.port2]);
  return messageChannel.port1;
}
function getKeys() {
  let state = 0;
  startConversation(cryptoLib, "genkeys").onmessage = function (e) {
    if (state === 0)
      document.getElementById('public').value = e.data;
    else if (state === 1)
      document.getElementById('private').value = e.data;
  }
</script>
```
A later version of the API, though, might want to offload all the crypto work onto subworkers. This could be done as follows:

```javascript
function handleMessage(e) {
    if (e.data == "genkeys")
        genkeys(e.ports[0]);
    else if (e.data == "encrypt")
        encrypt(e.ports[0]);
    else if (e.data == "decrypt")
        decrypt(e.ports[0]);
}
```

```html

```
function genkeys(p) {
    var generator = new Worker('libcrypto-v2-generator.js');
    generator.postMessage('', [p]);
}

function encrypt(p) {
    p.onmessage = function (e) {
        var key = e.data;
        var encryptor = new Worker('libcrypto-v2-encryptor.js');
        encryptor.postMessage(key, [p]);
    };
}

function decrypt(p) {
    p.onmessage = function (e) {
        var key = e.data;
        var decryptor = new Worker('libcrypto-v2-decryptor.js');
        decryptor.postMessage(key, [p]);
    };
}

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) { // dedicated worker
    onmessage = handleMessage;
} else { // shared worker
    onconnect = function (e) {
        e.ports[0].onmessage = handleMessage;
    };
}

The little subworkers would then be as follows.

For generating key pairs:

onmessage = function (e) {
    var k = _generateKeyPair();
    e.ports[0].postMessage(k[0]);
    e.ports[0].postMessage(k[1]);
    close();
}

function _generateKeyPair() {
    return [Math.random(), Math.random()];
}

For encrypting:

onmessage = function (e) {
var key = e.data;
e.ports[0].onmessage = function (e) {
  var s = e.data;
  postMessage(_encrypt(key, s));
}
}

function _encrypt(k, s) {
  return 'encrypted-' + k + ' ' + s;
}

For decrypting:

onmessage = function (e) {
  var key = e.data;
e.ports[0].onmessage = function (e) {
  var s = e.data;
  postMessage(_decrypt(key, s));
}
}

function _decrypt(k, s) {
  return s.substr(s.indexOf(' ') + 1);
}

Notice how the users of the API don’t have to even know that this is happening — the API hasn’t changed; the library can delegate to subworkers without changing its API, even though it is accepting data using message channels.

View this example online.

10.1.3 Tutorials

10.1.3.1 Creating a dedicated worker

This section is non-normative.

Creating a worker requires a URL to a JavaScript file. The Worker() constructor is invoked with the URL to that file as its only argument; a worker is then created and returned:

var worker = new Worker('helper.js');

If you want your worker script to be interpreted as a module script instead of the default classic script, you need to use a slightly different signature:

var worker = new Worker('helper.mjs', { type: "module" });
10.1.3.2 Communicating with a dedicated worker

*This section is non-normative.*

Dedicated workers use `MessagePort` objects behind the scenes, and thus support all the same features, such as sending structured data, transferring binary data, and transferring other ports.

To receive messages from a dedicated worker, use the `onmessage` event handler IDL attribute on the `Worker` object:

```javascript
worker.onmessage = function (event) { ... }
```

You can also use the `addEventListener()` method.

The implicit `MessagePort` used by dedicated workers has its `port message queue` implicitly enabled when it is created, so there is no equivalent to the `MessagePort` interface’s `start()` method on the `Worker` interface.

To send data to a worker, use the `postMessage()` method. Structured data can be sent over this communication channel. To send `ArrayBuffer` objects efficiently (by transferring them rather than cloning them), list them in an array in the second argument.

```javascript
worker.postMessage(
  {
    operation: 'find-edges',
    input: buffer, // an ArrayBuffer object
    threshold: 0.6,
  }, [buffer]);
```

To receive a message inside the worker, the `onmessage` event handler IDL attribute is used.

```javascript
onmessage = function (event) { ... }
```

You can again also use the `addEventListener()` method.

In either case, the data is provided in the event object’s `data` attribute.

To send messages back, you again use `postMessage()`. It supports the structured data in the same manner.

```javascript
postMessage(event.data.input, [event.data.input]); // transfer the buffer back
```

10.1.3.3 Shared workers

[MDN](https://developer.mozilla.org/en-US/docs/Web/API/SharedWorker)
This section is non-normative.

Shared workers are identified by the URL of the script used to create it, optionally with an explicit name. The name allows multiple instances of a particular shared worker to be started.

Shared workers are scoped by `origin`. Two different sites using the same names will not collide. However, if a page tries to use the same shared worker name as another page on the same site, but with a different script URL, it will fail.

Creating shared workers is done using the `SharedWorker()` constructor. This constructor takes the URL to the script to use for its first argument, and the name of the worker, if any, as the second argument.

```javascript
var worker = new SharedWorker('service.js');
```

Communicating with shared workers is done with explicit `MessagePort` objects. The object returned by the `SharedWorker()` constructor holds a reference to the port on its `port` attribute.

```javascript
worker.port.onmessage = function (event) { ... };  
worker.port.postMessage('some message');  
worker.port.postMessage({ foo: 'structured', bar: ['data', 'also', 'possible'] });
```

Inside the shared worker, new clients of the worker are announced using the `connect` event. The port for the new client is given by the event object’s `source` attribute.

```javascript
onconnect = function (event) {
    var newPort = event.source;
    // set up a listener
    newPort.onmessage = function (event) { ... };  
    // send a message back to the port
    newPort.postMessage('ready!'); // can also send structured data, of course
};
```

10.2 Infrastructure

This standard defines two kinds of workers: dedicated workers, and shared workers. Dedicated workers, once created, are linked to their creator, but message ports can be used to communicate from a dedicated worker to multiple other browsing contexts or workers. Shared workers, on the other hand, are named, and once created any script running in the same `origin` can obtain a reference to that worker and communicate with it. Service Workers defines a third
kind. [SW]

10.2.1 The global scope

The global scope is the “inside” of a worker.

10.2.1.1 The WorkerGlobalScope common interface

WorkerGlobalScope

Support in all current engines.

[Exposed=Worker]

interface WorkerGlobalScope : EventTarget {
    readonly attribute WorkerGlobalScope self;
    readonly attribute WorkerLocation location;
    readonly attribute WorkerNavigator navigator;
    undefined importScripts (USVString... urls);

    attribute OnErrorEventHandler onerror;
    attribute EventHandler onlanguagechange;
    attribute EventHandler onoffline;
    attribute EventHandler ononline;
    attribute EventHandler onrejectionhandled;
    attribute EventHandler onunhandledrejection;
};

WorkerGlobalScope serves as the base class for specific types of worker global scope objects, including DedicatedWorkerGlobalScope, SharedWorkerGlobalScope, and ServiceWorkerGlobalScope.

A WorkerGlobalScope object has an associated owner set (a set of Document and WorkerGlobalScope objects). It is initially empty and populated when the worker is created or obtained.

It is a set, instead of a single owner, to accommodate SharedWorkerGlobalScope objects.

A WorkerGlobalScope object has an associated type (“classic” or “module”). It is set
A `WorkerGlobalScope` object has an associated `url` (null or a `URL`). It is initially null.

A `WorkerGlobalScope` object has an associated `name` (a string). It is set during creation.

The `name` can have different semantics for each subclass of `WorkerGlobalScope`. For `DedicatedWorkerGlobalScope` instances, it is simply a developer-supplied name, useful mostly for debugging purposes. For `SharedWorkerGlobalScope` instances, it allows obtaining a reference to a common shared worker via the `SharedWorker()` constructor. For `ServiceWorkerGlobalScope` objects, it doesn’t make sense (and as such isn’t exposed through the JavaScript API at all).

A `WorkerGlobalScope` object has an associated `policy container` (a `policy container`). It is initially a new `policy container`.

A `WorkerGlobalScope` object has an associated `embedder policy` (an `embedder policy`).

A `WorkerGlobalScope` object has an associated `module map`. It is a `module map`, initially empty.

A `WorkerGlobalScope` object has an associated `cross-origin isolated capability` boolean. It is initially false.

```javascript
workerGlobal.self
```

Returns `workerGlobal`.

```javascript
workerGlobal.location
```

Returns `workerGlobal.location`.

Support in all current engines.

</tbody>
</table>
Returns `workerGlobal`'s `WorkerLocation` object.

```javascript
workerGlobal.navigator
```

Support in all current engines.

```javascript
WorkerGlobalScope/navigator
```

Fetches each `URL` in `urls`, executes them one-by-one in the order they are passed, and then returns (or throws if something went amiss).

The `self` attribute must return the `WorkerGlobalScope` object itself.

The `location` attribute must return the `WorkerLocation` object whose associated `WorkerGlobalScope` object is the `WorkerGlobalScope` object.

While the `WorkerLocation` object is created after the `WorkerGlobalScope` object, this is not problematic as it cannot be observed from script.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as `event handler IDL attributes`, by objects implementing the
**WorkerGlobalScope** interface:

<table>
<thead>

10.2.1.2 Dedicated workers and the DedicatedWorkerGlobalScope interface

DedicatedWorkerGlobalScope

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+
Opera 10.6+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

[Global=(Worker, DedicatedWorker), Exposed=DedicatedWorker]
interface DedicatedWorkerGlobalScope : WorkerGlobalScope {
  [Replaceable] readonly attribute DOMString name;
  undefined postMessage(any message, sequence<object> transfer);
  undefined postMessage(any message, optional StructuredSerializeOptions options)
  undefined close();
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};

DedicatedWorkerGlobalScope objects act as if they had an implicit MessagePort associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the
**DedicatedWorkerGlobalScope** object.

All messages received by that port must immediately be retargeted at the **DedicatedWorkerGlobalScope** object.

**dedicatedWorkerGlobal.name**

Support in all current engines.

Firefox 55+ Safari 12.1+ Chrome 71+
Opera 58+ Edge 79+
Edge (Legacy) 18+ Internet Explorer No
Firefox Android 55+ Safari iOS 12.2+ Chrome Android 71+ WebView Android 71+ Samsung
Internet 10.0+ Opera Android 50+

Returns **dedicatedWorkerGlobal.name**, i.e. the value given to the **Worker** constructor. Primarily useful for debugging.

**dedicatedWorkerGlobal.postMessage**(message [, transfer ])

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+
Opera 10.6+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung
Internet 1.0+ Opera Android 11+

Clones **message** and transmits it to the **Worker** object associated with **dedicatedWorkerGlobal. transfer** can be passed as a list of objects that are to be transferred rather than cloned.

**dedicatedWorkerGlobal.close()**

Support in all current engines.
Aborts `dedicatedWorkerGlobal`.

The `name` getter steps are to return this's `name`. Its value represents the name given to the worker using the `Worker` constructor, used primarily for debugging purposes.

The `postMessage(message, transfer)` and `postMessage(message, options)` methods on `DedicatedWorkerGlobalScope` objects act as if, when invoked, it immediately invoked the respective `postMessage(message, transfer)` and `postMessage(message, options)` on the port, with the same arguments, and returned the same return value.

To close a worker, given a `workerGlobal`, run these steps:

1. Discard any `tasks` that have been added to `workerGlobal`'s `relevant agent`'s `event loop`'s task queues.

2. Set `workerGlobal`'s `closing` flag to true. (This prevents any further tasks from being queued.)

The `close()` method steps are to close a worker given this.

The following are the `event handlers` (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by objects implementing the `DedicatedWorkerGlobalScope` interface:

```
<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>onmessage</code></td>
<td><code>message</code></td>
</tr>
</tbody>
</table>
```

`DedicatedWorkerGlobalScope/onmessage`

Support in all current engines.
onmessageerror

DedicatedWorkerGlobalScope/onmessageerror

Firefox 57+ Safari No Chrome 60+ 
Opera 47+ Edge 79+ 
Edge (Legacy) 18+ Internet Explorer No 
Firefox Android 57+ Safari iOS No Chrome Android 60+ WebView 
Android 60+ Samsung Internet 8.0+ Opera Android 44+

10.2.1.3 Shared workers and the SharedWorkerGlobalScope interface

A SharedWorkerGlobalScope object has an associated constructor origin, constructor url, and credentials. They are initialized when the SharedWorkerGlobalScope object is created, in the run a worker algorithm.

Shared workers receive message ports through connect events on their SharedWorkerGlobalScope object for each connection.
**SharedWorkerGlobalScope/name**

<table>
<thead>
<tr>
<th>Engine</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 55+</td>
<td>Safari No</td>
</tr>
<tr>
<td>Opera 10.6+</td>
<td>Edge 79+</td>
</tr>
<tr>
<td>Edge (Legacy) No</td>
<td>Internet ExplorerNo</td>
</tr>
<tr>
<td>Firefox Android 55+</td>
<td>Safari iOS No</td>
</tr>
<tr>
<td>Chrome 4+</td>
<td>WebView Android 37+</td>
</tr>
<tr>
<td>Internet 1.0+</td>
<td>Opera Android 11+</td>
</tr>
</tbody>
</table>

Returns `sharedWorkerGlobal`'s name, i.e. the value given to the `SharedWorker` constructor. Multiple `SharedWorker` objects can correspond to the same shared worker (and `SharedWorkerGlobalScope`), by reusing the same name.

**sharedWorkerGlobal.close()**

<table>
<thead>
<tr>
<th>Engine</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 29+</td>
<td>Safari 5+</td>
</tr>
<tr>
<td>Opera 10.6+</td>

<td>WebView Android 37+</td>
</tr>
<tr>
<td>Internet 1.0+</td>
<td>Opera Android 11+</td>
</tr>
</tbody>
</table>

Aborts `sharedWorkerGlobal`.

The `name` getter steps are to return this’s name. Its value represents the name that can be used to obtain a reference to the worker using the `SharedWorker` constructor.

The `close()` method steps are to close a worker given this.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by objects implementing the `SharedWorkerGlobalScope` interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>onconnect</code></td>
<td>connect</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Engine</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox 29+</td>
<td>Safari No</td>
</tr>
<tr>
<td>Chrome 4+</td>
<td></td>
</tr>
</tbody>
</table>
10.2.2 The event loop

A worker event loop’s task queues only have events, callbacks, and networking activity as tasks. These worker event loops are created by the run a worker algorithm.

Each WorkerGlobalScope object has a closing flag, which must be initially false, but which can get set to true by the algorithms in the processing model section below.

Once the WorkerGlobalScope’s closing flag is set to true, the event loop’s task queues must discard any further tasks that would be added to them (tasks already on the queue are unaffected except where otherwise specified). Effectively, once the closing flag is true, timers stop firing, notifications for all pending background operations are dropped, etc.

10.2.3 The worker’s lifetime

Workers communicate with other workers and with browsing contexts through message channels and their MessagePort objects.

Each WorkerGlobalScope object worker global scope has a list of the worker’s ports, which consists of all the MessagePort objects that are entangled with another port and that have one (but only one) port owned by worker global scope. This list includes the implicit MessagePort in the case of dedicated workers.

Given an environment settings object o when creating or obtaining a worker, the relevant owner to add depends on the type of global object specified by o. If o specifies a global object that is a WorkerGlobalScope object (i.e., if we are creating a nested dedicated worker), then the relevant owner is that global object. Otherwise, o specifies a global object that is a Window object, and the relevant owner is the responsible document specified by o.

A worker is said to be a permissible worker if its WorkerGlobalScope’s owner set is not empty or:

- its owner set has been empty for no more than a short implementation-defined timeout value,
- its WorkerGlobalScope object is a SharedWorkerGlobalScope object (i.e., the worker is a shared worker), and
- the user agent has a browsing context whose Document object is not completely loaded.
The second part of this definition allows a shared worker to survive for a short time while a page is loading, in case that page is going to contact the shared worker again. This can be used by user agents as a way to avoid the cost of restarting a shared worker used by a site when the user is navigating from page to page within that site.

A worker is said to be an active needed worker if any its owners are either Document objects that are fully active or active needed workers.

A worker is said to be a protected worker if it is an active needed worker and either it has outstanding timers, database transactions, or network connections, or its list of the worker’s ports is not empty, or its WorkerGlobalScope is actually a SharedWorkerGlobalScope object (i.e., the worker is a shared worker).

A worker is said to be a suspendable worker if it is not an active needed worker but it is a permissible worker.

10.2.4 Processing model

When a user agent is to run a worker for a script with Worker or SharedWorker object worker, URL url, environment settings object outside settings, MessagePort outside port, and a WorkerOptions dictionary options, it must run the following steps.

1. Let is shared be true if worker is a SharedWorker object, and false otherwise.

2. Let owner be the relevant owner to add given outside settings.

3. Let parent worker global scope be null.

4. If owner is a WorkerGlobalScope object (i.e., we are creating a nested dedicated worker), then set parent worker global scope to owner.

5. Let agent be the result of obtaining a dedicated/shared worker agent given outside settings and is shared. Run the rest of these steps in that agent.

   For the purposes of timing APIs, this is the official moment of creation of the worker.

6. Let realm execution context be the result of creating a new JavaScript realm given agent and the following customizations:

   ◦ For the global object, if is shared is true, create a new SharedWorkerGlobalScope object. Otherwise, create a new DedicatedWorkerGlobalScope object.

7. Let worker global scope be the global object of realm execution context’s Realm component.

   This is the DedicatedWorkerGlobalScope or SharedWorkerGlobalScope object
Set up a worker environment settings object with realm execution context and outside settings, and let inside settings be the result.

Set worker global scope's name to the value of options's name member.

Append owner to worker global scope's owner set.

If is shared is true, then:

1. Set worker global scope's constructor origin to outside settings's origin.
2. Set worker global scope's constructor url to url.
3. Set worker global scope's type to the value of options's type member.
4. Set worker global scope's credentials to the value of options's credentials member.

Let destination be "sharedworker" if is shared is true, and "worker" otherwise.

Obtain script by switching on the value of options's type member:

"classic"
Fetch a classic worker script given url, outside settings, destination, and inside settings.

"module"
Fetch a module worker script graph given url, outside settings, destination, the value of the credentials member of options, and inside settings.

In both cases, to perform the fetch given request, perform the following steps if the is top-level flag is set:

1. Set request's reserved client to inside settings.
2. Fetch request, and asynchronously wait to run the remaining steps as part of fetch's process response for the response response.
3. Set worker global scope's url to response's url.
4. Initialize worker global scope's policy container given worker global scope, response, and inside settings.
5. If the Run CSP initialization for a global object algorithm returns "Blocked" when executed upon worker global scope, set response to a network error. [CSP]
6. If worker global scope’s embedder policy’s value is compatible with cross-origin isolation and is shared is true, then set agent’s agent cluster’s cross-origin isolation mode to “logical” or “concrete”. The one chosen is implementation-defined.

This really ought to be set when the agent cluster is created, which requires a redesign of this section.

7. If the result of checking a global object’s embedder policy with worker global scope, outside settings, and response is false, then set response to a network error.

8. Set worker global scope’s cross-origin isolated capability to true if agent’s agent cluster’s cross-origin isolation mode is “concrete”.

9. If is shared is false and owner’s cross-origin isolated capability is false, then set worker global scope’s cross-origin isolated capability to false.

10. If is shared is false and response’s url’s scheme is ”data”, then set worker global scope’s cross-origin isolated capability to false.

This is a conservative default for now, while we figure out how workers in general, and data: URL workers in particular (which are cross-origin from their owner), will be treated in the context of permissions policies. See w3c/webappsec-permissions-policy issue #207 for more details.

11. Asynchronously complete the perform the fetch steps with response.

If the algorithm asynchronously completes with null or with a script whose error to rethrow is non-null, then:

1. Queue a global task on the DOM manipulation task source given worker’s relevant global object to fire an event named error at worker.

2. Run the environment discarding steps for inside settings.

3. Return.

Otherwise, continue the rest of these steps after the algorithm’s asynchronous completion, with script being the asynchronous completion value.

15. Let inside port be a new MessagePort object in inside settings’s Realm.

16. Associate inside port with worker global scope.

17. Entangle outside port and inside port.
18. Create a new `WorkerLocation` object and associate it with `worker global scope`.

19. **Closing orphan workers**: Start monitoring the worker such that no sooner than it stops being a `protected worker`, and no later than it stops being a `permissible worker`, `worker global scope`'s `closing` flag is set to true.

20. **Suspending workers**: Start monitoring the worker, such that whenever `worker global scope`'s `closing` flag is false and the worker is a `suspendable worker`, the user agent suspends execution of script in that worker until such time as either the `closing` flag switches to true or the worker stops being a `suspendable worker`.

22. If `script` is a `classic script`, then run the classic script `script`. Otherwise, it is a `module script`; run the module script `script`.

   In addition to the usual possibilities of returning a value or failing due to an exception, this could be `prematurely aborted` by the `terminate a worker` algorithm defined below.

23. Enable `outside port`'s `port message queue`.

24. If `is shared` is false, enable the `port message queue` of the worker's implicit port.

25. If `is shared` is true, then queue a global task on `DOM manipulation task source` given `worker global scope` to fire an event named `connect` at `worker global scope`, using `MessageEvent`, with the `data` attribute initialized to the empty string, the `ports` attribute initialized to a new `frozen array` containing `inside port`, and the `source` attribute initialized to `inside port`.

26. Enable the `client message queue` of the `ServiceWorkerContainer` object whose associated `service worker client` is `worker global scope`'s `relevant settings object`.

27. **Event loop**: Run the `responsible event loop` specified by `inside settings` until it is destroyed.

   The handling of events or the execution of callbacks by tasks run by the `event loop` might get `prematurely aborted` by the `terminate a worker` algorithm defined below.

   The worker processing model remains on this step until the event loop is destroyed, which happens after the `closing` flag is set to true, as described in the `event loop` processing model.

28. Clear the `worker global scope`'s `map of active timers`.

29. Disentangle all the ports in the list of `the worker's ports`.

30. Empty `worker global scope`'s `owner set`. 
When a user agent is to *terminate a worker* it must run the following steps in parallel with the worker’s main loop (the “run a worker” processing model defined above):

1. Set the worker’s `WorkerGlobalScope` object’s `closing` flag to true.

2. If there are any tasks queued in the `WorkerGlobalScope` object’s relevant agent’s event loop’s task queues, discard them without processing them.

3. *Abort the script* currently running in the worker.

4. If the worker’s `WorkerGlobalScope` object is actually a `DedicatedWorkerGlobalScope` object (i.e. the worker is a dedicated worker), then empty the port message queue of the port that the worker’s implicit port is entangled with.

User agents may invoke the *terminate a worker* algorithm when a worker stops being an active needed worker and the worker continues executing even after its `closing` flag was set to true.

### 10.2.5 Runtime script errors

Whenever an uncaught runtime script error occurs in one of the worker’s scripts, if the error did not occur while handling a previous script error, the user agent must report the error for that script, with the position (line number and column number) where the error occurred, using the `WorkerGlobalScope` object as the target.

For shared workers, if the error is still *not handled* afterwards, the error may be reported to a developer console.

For dedicated workers, if the error is still *not handled* afterwards, the user agent must queue a task to run these steps:

1. Let `notHandled` be the result of firing an event named `error` at the `Worker` object associated with the worker, using `ErrorEvent`, with the `cancelable` attribute initialized to true, the `message`, `filename`, `lineno`, and `colno` attributes initialized appropriately, and the `error` attribute initialized to null.

2. If `notHandled` is true, then the user agent must act as if the uncaught runtime script error had occurred in the global scope that the `Worker` object is in, thus repeating the entire runtime script error reporting process one level up.

If the implicit port connecting the worker to its `Worker` object has been disentangled (i.e. if the parent worker has been terminated), then the user agent must act as if the `Worker` object had no `error` event handler and as if that worker’s `onerror` attribute was null, but must otherwise act as described above.

Thus, error reports propagate up to the chain of dedicated workers up to the original `Document`, even if some of the workers along this chain have been terminated and garbage
collected.

The task source for the task mentioned above is the DOM manipulation task source.

### 10.2.6 Creating workers

#### 10.2.6.1 The AbstractWorker mixin

```javascript
interface mixin AbstractWorker {
  attribute EventHandler onerror;
};
```

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by objects implementing the AbstractWorker interface:

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Event handler event type</th>
</tr>
</thead>
<tbody>
<tr>
<td>onerror</td>
<td>✔</td>
</tr>
</tbody>
</table>

- **ServiceWorker/onerror**
  - Support in all current engines.
    - Firefox 44+ Safari 11.1+ Chrome 40+
    - Opera 27+ Edge 79+
    - Edge (Legacy) 17+ Internet Explorer No
    - Firefox Android 44+ Safari iOS 11.3+ Chrome Android 40+ WebView
    - Android 40+ Samsung Internet 4.0+ Opera Android 27+

- **SharedWorker/onerror**
  - Firefox 29+ Safari 5–7 Chrome 4+
    - Opera 10.6+ Edge 79+
    - Edge (Legacy) No Internet Explorer No
    - Firefox Android 33+ Safari iOS 5–7 Chrome Android No WebView
    - Android No Samsung Internet 4.0–5.0 Opera Android 11–14

- **Worker/onerror**
  - Support in all current engines.
    - Firefox 3.5+ Safari 4+ Chrome 4+
      - Opera 10.6+ Edge 79+
      - Edge (Legacy) 12+ Internet Explorer 10+
10.2.6.2 Script settings for workers

To set up a worker environment settings object, given a JavaScript execution context execution context and environment settings object outside settings:

1. Let inherited origin be outside settings's origin.
2. Let realm be the value of execution context's Realm component.
3. Let worker global scope be realm's global object.
4. Let settings object be a new environment settings object whose algorithms are defined as follows:

   The realm execution context
   
   Return execution context.

   The module map
   
   Return worker global scope's module map.

   The responsible document
   
   Not applicable (the responsible event loop is not a window event loop).

   The API URL character encoding
   
   Return UTF-8.

   The API base URL
   
   Return worker global scope's url.

   The origin
   
   Return a unique opaque origin if worker global scope's url's scheme is "data", and inherited origin otherwise.

   The policy container
   
   Return worker global scope's policy container.
The **cross-origin isolated capability**

Return worker global scope's cross-origin isolated capability.

5. Set settings object's id to a new unique opaque string, creation URL to worker global scope's url, top-level creation URL to null, target browsing context to null, and active service worker to null.

6. If worker global scope is a DedicatedWorkerGlobalScope object, then set settings object's top-level origin to outside settings's top-level origin.

7. Otherwise, set settings object's top-level origin to an implementation-defined value.

   See Client-Side Storage Partitioning for the latest on properly defining this.

8. Set realm's [[HostDefined]] field to settings object.

9. Return settings object.

10.2.6.3 Dedicated workers and the Worker interface

[Exposed=(Window,DedicatedWorker,SharedWorker)]
interface Worker : EventTarget {
    constructor (USVString scriptURL, optional WorkerOptions options = {});

    undefined terminate();

    undefined postMessage (any message, sequence<object> transfer);
    undefined postMessage (any message, optional StructuredSerializeOptions options); attribute EventHandler onmessage;
    attribute EventHandler onmessageerror;
};

dictionary WorkerOptions {
    WorkerType type = "classic";
RequestCredentials credentials = "same-origin"; // credentials is only used if type is "module"

};

enum WorkerType { "classic", "module" };

Worker includes AbstractWorker;

worker = new Worker(scriptURL [, options ])

worker.terminate()

worker.postMessage(message [, transfer ])

Returns a new Worker object. scriptURL will be fetched and executed in the background, creating a new global environment for which worker represents the communication channel. options can be used to define the name of that global environment via the name option, primarily for debugging purposes. It can also ensure this new global environment supports JavaScript modules (specify type: "module"), and if that is specified, can also be used to specify how scriptURL is fetched through the credentials option.

Aborts worker's associated global environment.
**Worker/postMessage**

Support in all current engines.

```javascript
worker.postMessage(message [, { transfer } ])
```

Clones `message` and transmits it to `worker`'s global environment. `transfer` can be passed as a list of objects that are to be transferred rather than cloned.

The `terminate()` method, when invoked, must cause the terminate a worker algorithm to be run on the worker with which the object is associated.

`Worker` objects act as if they had an implicit `MessagePort` associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the `Worker` object.

All messages received by that port must immediately be retargeted at the `Worker` object.

The `postMessage(message, transfer)` and `postMessage(message, options)` methods on `Worker` objects act as if, when invoked, they immediately invoked the respective `postMessage(message, transfer)` and `postMessage(message, options)` on the port, with the same arguments, and returned the same return value.

The `postMessage()` method's first argument can be structured data:

```javascript
worker.postMessage({opcode: 'activate', device: 1938, parameters: [23, 102]})
```

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler IDL attributes, by objects implementing the `Worker` interface:

```javascript
Event handler | Event handler event type
--- | ---
onmessage ✔ | MDN
Worker/onmessage | message
```

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+

Opera 10.6+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 10+

Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 4+ Samsung Internet 1.0+ Opera Android 11+

Support in all current engines.
When the `Worker(scriptURL, options)` constructor is invoked, the user agent must run the following steps:

1. The user agent may throw a `"SecurityError" DOMException` if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start dedicated workers).

2. Let `outside settings` be the `current settings object`.

3. Parse the `scriptURL` argument relative to `outside settings`.

4. If this fails, throw a `"SyntaxError" DOMException`.

5. Let `worker URL` be the `resulting URL record`.

   Any same-origin URL (including `blob:` URLs) can be used. `data:` URLs can also be used, but they create a worker with an opaque origin.

6. Let `worker` be a new `Worker` object.

7. Let `outside port` be a new `MessagePort` in `outside settings`'s Realm.

8. Associate the `outside port` with `worker`.

9. Run this step in parallel:

   1. Run a worker given `worker`, `worker URL`, `outside settings`, `outside port`, and `options`. 
10. Return `worker`.

10.2.6.4 Shared workers and the `SharedWorker` interface

```js
sharedWorker = new SharedWorker(scriptURL [, name ])
```

Returns a new `SharedWorker` object. `scriptURL` will be fetched and executed in the background, creating a new global environment for which `sharedWorker` represents the communication channel. `name` can be used to define the `name` of that global environment.

```js
sharedWorker = new SharedWorker(scriptURL [, options ])
```

Returns a new `SharedWorker` object. `scriptURL` will be fetched and executed in the background, creating a new global environment for which `sharedWorker` represents the communication channel. `options` can be used to define the `name` of that global environment via the `name` option. It can also ensure this new global environment supports JavaScript modules (specify `type: "module"`), and if that is specified, can also be used to specify how `scriptURL` is fetched through the `credentials` option. Note that attempting to
construct a shared worker with `options` whose `type` or `credentials` values mismatch an existing shared worker will cause the returned `sharedWorker` to fire an error event and not connect to the existing shared worker.

**sharedWorker.port**

<table>
<thead>
<tr>
<th>Browser</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox29+</td>
<td>Safari5–7</td>
</tr>
<tr>
<td>Chrome4+</td>
<td>Opera10.6+</td>
</tr>
<tr>
<td>Edge79+</td>
<td>Edge (Legacy)</td>
</tr>
<tr>
<td>Internet Explorer</td>
<td>No</td>
</tr>
<tr>
<td>Firefox Android33+</td>
<td>Safari iOS5–7</td>
</tr>
<tr>
<td>Chrome AndroidNo</td>
<td>WebView AndroidNo</td>
</tr>
<tr>
<td>Samsung</td>
<td>Internet4.0–5.0</td>
</tr>
</tbody>
</table>

Returns `sharedWorker`'s `MessagePort` object which can be used to communicate with the global environment.

The `port` attribute must return the value it was assigned by the object’s constructor. It represents the `MessagePort` for communicating with the shared worker.

A user agent has an associated shared worker manager which is the result of starting a new parallel queue.

Each user agent has a single shared worker manager for simplicity. Implementations could use one per `origin`; that would not be observably different and enables more concurrency.

When the `SharedWorker(scriptURL, options)` constructor is invoked:

1. Optionally, throw a "`SecurityError`" `DOMException` if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start shared workers).

2. If `options` is a `DOMString`, set `options` to a new `WorkerOptions` dictionary whose `name` member is set to the value of `options` and whose other members are set to their default values.

3. Let `outside settings` be the `current settings object`.

4. Parse `scriptURL` relative to `outside settings`.

5. If this fails, throw a "`SyntaxError`" `DOMException`.

6. Otherwise, let `urlRecord` be the `resulting URL record`.

Any same-origin URL (including `blob:` URLs) can be used. `data:` URLs can also be used, but they create a worker with an opaque origin.
7. Let worker be a new `SharedWorker` object.

8. Let outside port be a new `MessagePort` in outside settings's Realm.

9. Assign outside port to the `port` attribute of worker.

10. Let `callerIsSecureContext` be true if outside settings is a secure context; otherwise, false.

11. Enqueue the following steps to the shared worker manager:

   1. Let worker global scope be null.

   2. If there exists a `SharedWorkerGlobalScope` object whose `closing` flag is false, `constructor origin` is same origin with outside settings's origin, `constructor url` equals `urlRecord`, and `name` equals the value of `options`'s `name` member, then set worker global scope to that `SharedWorkerGlobalScope` object.

   **data:** URLs create a worker with an opaque origin. Both the `constructor origin` and `constructor url` are compared so the same `data:` URL can be used within an origin to get to the same `SharedWorkerGlobalScope` object, but cannot be used to bypass the same origin restriction.

   3. If worker global scope is not null, but the user agent has been configured to disallow communication between the worker represented by the worker global scope and the scripts whose `settings object` is outside settings, then set worker global scope to null.

      For example, a user agent could have a development mode that isolates a particular top-level browsing context from all other pages, and scripts in that development mode could be blocked from connecting to shared workers running in the normal browser mode.

   4. If worker global scope is not null, then check if worker global scope's `type` and `credentials` match the `options` values. If not, queue a task to fire an event named `error` and abort these steps.

   5. If worker global scope is not null, then run these subsubsteps:

      1. Let `settings object` be the relevant settings object for worker global scope.

      2. Let `workerIsSecureContext` be true if `settings object` is a secure context; otherwise, false.

      3. If `workerIsSecureContext` is not `callerIsSecureContext`, then queue a task to fire an event named `error` at worker and abort these steps. [SECURE-CONTEXTS]
4. Associate worker with worker global scope.

5. Let inside port be a new MessagePort in settings object’s Realm.

6. Entangle outside port and inside port.

7. Queue a task, using the DOM manipulation task source, to fire an event named connect at worker global scope, using MessageEvent, with the data attribute initialized to the empty string, the ports attribute initialized to a new frozen array containing only inside port, and the source attribute initialized to inside port.

8. Append the relevant owner to add given outside settings to worker global scope’s owner set.

6. Otherwise, in parallel, run a worker given worker, urlRecord, outside settings, outside port, and options.

12. Return worker.

10.2.7 Concurrent hardware capabilities

interface mixin NavigatorConcurrentHardware {
    readonly attribute unsigned long long hardwareConcurrency;
};

self.navigator.hardwareConcurrency

Navigator/hardwareConcurrency

Firefox48+Safari10.1–11Chrome37+
Opera24+Edge79+
Edge (Legacy)15+Internet ExplorerNo
Firefox Android48+Safari iOS10.3–11Chrome Android37+WebView Android37+Samsung Internet3.0+Opera Android24+

Navigator/hardwareConcurrency

Firefox48+Safari10.1–11Chrome37+
Opera24+Edge79+
Edge (Legacy)15+Internet ExplorerNo
Firefox Android48+Safari iOS10.3–11Chrome Android37+WebView Android37+Samsung Internet3.0+Opera Android24+

Returns the number of logical processors potentially available to the user agent.
The `navigator.hardwareConcurrency` attribute’s getter must return a number between 1 and the number of logical processors potentially available to the user agent. If this cannot be determined, the getter must return 1.

User agents should err toward exposing the number of logical processors available, using lower values only in cases where there are user-agent specific limits in place (such as a limitation on the number of workers that can be created) or when the user agent desires to limit fingerprinting possibilities.

10.3 APIs available to workers

10.3.1 Importing scripts and libraries

The `importScripts(...urls)` method steps are to import scripts into worker global scope given `this` and `urls`.

To import scripts into worker global scope, given a `WorkerGlobalScope` object worker global scope and a `sequence<DOMString>` `urls`, run these steps. The algorithm may optionally be customized by supplying custom `perform the fetch` hooks, which if provided will be used when invoking `fetch a classic worker-imported script`.

1. If worker global scope’s `type` is "module", throw a `TypeError` exception.

2. Let `settings object` be the `current settings object`.

3. If `urls` is empty, return.

4. Parse each value in `urls` relative to `settings object`. If any fail, throw a "SyntaxError" `DOMException`.

5. For each `url` in the resulting URL records, run these substeps:

   1. Fetch a classic worker-imported script given `url` and `settings object`, passing along any custom `perform the fetch` steps provided. If this succeeds, let `script` be the result. Otherwise, rethrow the exception.

   2. Run the classic script `script`, with the rethrow errors argument set to true.

      `script` will run until it either returns, fails to parse, fails to catch an exception, or gets prematurely aborted by the `terminate a worker` algorithm defined above.

      If an exception was thrown or if the script was prematurely aborted, then abort all these steps, letting the exception or aborting continue to be processed by the calling `script`. 
Service Workers is an example of a specification that runs this algorithm with its own options for the perform the fetch hook. [SW]

10.3.2 The **WorkerNavigator** interface

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+

Opera Yes Edge 79+

Edge (Legacy) 12+ Internet Explorer 10+

Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android Yes

The **navigator** attribute of the **WorkerGlobalScope** interface must return an instance of the **WorkerNavigator** interface, which represents the identity and state of the user agent (the client):

```javascript
[Exposed=Worker]
interface WorkerNavigator {
}
WorkerNavigator includes NavigatorID;
WorkerNavigator includes NavigatorLanguage;
WorkerNavigator includes NavigatorOnLine;
WorkerNavigator includes NavigatorConcurrentHardware;
```

10.3.3 The **WorkerLocation** interface

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 3+

Opera 12.1+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 10+

Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

WorkerLocation/toString
Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 3+
Opera 15+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 14+

[Exposed=Worker]
interface WorkerLocation {
    stringifier readonly attribute USVString href;
    readonly attribute USVString origin;
    readonly attribute USVString protocol;
    readonly attribute USVString host;
    readonly attribute USVString hostname;
    readonly attribute USVString port;
    readonly attribute USVString pathname;
    readonly attribute USVString search;
    readonly attribute USVString hash;
};

A WorkerLocation object has an associated WorkerGlobalScope object (a WorkerGlobalScope object).

✔✔ MDN

WorkerLocation/href

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 3+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

The href getter steps are to return this’s WorkerGlobalScope object’s url, serialized.

✔✔ MDN

WorkerLocation/origin

Support in all current engines.

Firefox 29+ Safari 10+ Chrome 38+
Opera 25+ Edge 79+
The **origin** getter steps are to return the serialization of this’s `WorkerGlobalScope` object’s `url`’s `origin`.

✔️ MDN

**WorkerLocation/protocol**

Support in all current engines.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Minimum Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>3.5+</td>
</tr>
<tr>
<td>Safari</td>
<td>4+</td>
</tr>

<td>1.0+</td>
</tr>
<tr>
<td>Opera Android</td>
<td>12.1+</td>
</tr>
</tbody>
</table>

The **host** getter steps are:

1. Let `url` be this’s `WorkerGlobalScope` object’s `url`.
2. If `url`’s `host` is null, return the empty string.
3. If `url`’s `port` is null, return `url`’s `host`, serialized.
4. Return `url`’s `host`, serialized, followed by “:” and `url`’s `port`, serialized.

✔️ MDN
**WorkerLocation/hostname**

Support in all current engines.

- Firefox 3.5+
- Safari 4+
- Chrome 3+
- Opera 12.1+
- Edge (Legacy) 12+
- Internet Explorer 10+
- Firefox Android 4+
- Safari iOS 5+
- Chrome Android 18+
- WebView Android 37+
- Samsung Internet 1.0+
- Opera Android 12.1+

The **hostname** getter steps are:

1. Let `host` be this’s `WorkerGlobalScope` object’s `url`’s `host`.
2. If `host` is null, return the empty string.
3. Return `host`, serialized.

**WorkerLocation/port**

Support in all current engines.

- Firefox 3.5+
- Safari 4+
- Chrome 3+
- Opera 12.1+
- Edge (Legacy) 12+
- Internet Explorer 10+
- Firefox Android 4+
- Safari iOS 5+
- Chrome Android 18+
- WebView Android 37+
- Samsung Internet 1.0+
- Opera Android 12.1+

The **port** getter steps are:

1. Let `port` be this’s `WorkerGlobalScope` object’s `url`’s `port`.
2. If `port` is null, return the empty string.
3. Return `port`, serialized.

**WorkerLocation/pathname**

Support in all current engines.

- Firefox 3.5+
- Safari 4+
- Chrome 3+
- Opera 12.1+
- Edge 79+
The `pathname` getter steps are to return the result of URL path serializing this’s `WorkerGlobalScope` object’s `url`.

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 3+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

The `search` getter steps are:

1. Let `query` be this’s `WorkerGlobalScope` object’s `url`’s `query`.
2. If `query` is either null or the empty string, return the empty string.
3. Return `"?"`, followed by `query`.

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 3+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 10+
Firefox Android 4+ Safari iOS 5+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

The `hash` getter steps are:

1. Let `fragment` be this’s `WorkerGlobalScope` object’s `url`’s `fragment`.
2. If `fragment` is either null or the empty string, return the empty string.
3. Return `"#"`, followed by `fragment`.
11 Worklets

11.1 Introduction

*This section is non-normative.*

Worklets are a piece of specification infrastructure which can be used for running scripts independent of the main JavaScript execution environment, while not requiring any particular implementation model.

The worklet infrastructure specified here cannot be used directly by web developers. Instead, other specifications build upon it to create directly-usable worklet types, specialized for running in particular parts of the browser implementation pipeline.

11.1.1 Motivations

*This section is non-normative.*

Allowing extension points to rendering, or other sensitive parts of the implementation pipeline such as audio output, is difficult. If extension points were done with full access to the APIs available on `Window`, engines would need to abandon previously-held assumptions for what could happen in the middle of those phases. For example, during the layout phase, rendering engines assume that no DOM will be modified.

Additionally, defining extension points in the `Window` environment would restrict user agents to performing work in the same thread as the `Window` object. (Unless implementations added complex, high-overhead infrastructure to allow thread-safe APIs, as well as thread-joining guarantees.)

Worklets are designed to allow extension points, while keeping guarantees that user agents currently rely on. This is done through new global environments, based on subclasses of `WorkletGlobalScope`.

Worklets are similar to web workers. However, they:

- Are thread-agnostic. That is, they are not designed to run on a dedicated separate thread, like each worker is. Implementations can run worklets wherever they choose (including on the main thread).

- Are able to have multiple duplicate instances of the global scope created, for the purpose of parallelism.

- Do not use an event-based API. Instead, classes are registered on the global scope, whose methods are invoked by the user agent.

- Have a reduced API surface on the global scope.
- Have a lifetime for their **global object** which is defined by other specifications, often in an **implementation-defined** manner.

As worklets have relatively high overhead, they are best used sparingly. Due to this, a given **WorkletGlobalScope** is expected to be shared between multiple separate scripts. (This is similar to how a single **Window** is shared between multiple separate scripts.)

Worklets are a general technology that serve different use cases. Some worklets, such as those defined in **CSS Painting API**, provide extension points intended for stateless, idempotent, and short-running computations, which have special considerations as described in the next couple of sections. Others, such as those defined in **Web Audio API**, are used for stateful, long-running operations. [CSSPAINT] [WEBAUDIO]

### 11.1.2 Code idempotence

Some specifications which use worklets are intended to allow user agents to parallelize work over multiple threads, or to move work between threads as required. In these specifications, user agents might invoke methods on a web-developer-provided class in an **implementation-defined** order.

As a result of this, to prevent interoperability issues, authors who register classes on such **WorkletGlobalScope**s should make their code idempotent. That is, a method or set of methods on the class should produce the same output given a particular input.

This specification uses the following techniques in order to encourage authors to write code in an idempotent way:

- No reference to the global object is available (i.e., there is no counterpart to **self** on **WorkletGlobalScope**).

  Although this was the intention when worklets were first specified, the introduction of **globalThis** has made it no longer true. See [issue #6059](https://github.com/W3C/worklet/issues/6059) for more discussion.

- Code is loaded as a **module script**, which results in the code being executed in strict mode and with no shared **this** referencing the global proxy.

Together, these restrictions help prevent two different scripts from sharing state using properties of the **global object**.

Additionally, specifications which use worklets and intend to allow **implementation-defined** behavior must obey the following:

- They must require user agents to always have at least two **WorkletGlobalScope** instances per **Worklet**, and randomly assign a method or set of methods on a class to a particular **WorkletGlobalScope** instance. These specifications may provide an opt-out under memory constraints.
These specifications must allow user agents to create and destroy instances of their `WorkletGlobalScope` subclasses at any time.

11.1.3 Speculative evaluation

Some specifications which use worklets can invoke methods on a web-developer-provided class based on the state of the user agent. To increase concurrency between threads, a user agent may invoke a method speculatively, based on potential future states.

In these specifications, user agents might invoke such methods at any time, and with any arguments, not just ones corresponding to the current state of the user agent. The results of such speculative evaluations are not displayed immediately, but can be cached for use if the user agent state matches the speculated state. This can increase the concurrency between the user agent and worklet threads.

As a result of this, to prevent interoperability risks between user agents, authors who register classes on such `WorkletGlobalScope`es should make their code stateless. That is, the only effect of invoking a method should be its result, and not any side effects such as updating mutable state.

The same techniques which encourage code idempotence also encourage authors to write stateless code.

11.2 Examples

*This section is non-normative.*

For these examples, we’ll use a fake worklet. The `Window` object provides two `Worklet` instances, which each run code in their own collection of `FakeWorkletGlobalScope`

```javascript
partial interface Window {
    [SameObject, SecureContext] readonly attribute Worklet fakeWorklet1;
    [SameObject, SecureContext] readonly attribute Worklet fakeWorklet2;
}
```

Each `Window` has two `Worklet` instances, `fake worklet 1` and `fake worklet 2`. Both of these have their worklet global scope type set to `FakeWorkletGlobalScope`, and their worklet destination type set to "fakeworklet". User agents should create at least two `FakeWorkletGlobalScope` instances per worklet.

"fakeworklet" is not actually a valid destination per Fetch. But this illustrates how real worklets would generally have their own worklet-type-specific destination. [FETCH]

The `fakeWorklet1` getter steps are to return this’s fake worklet 1.

The `fakeWorklet2` getter steps are to return this’s fake worklet 2.
[Global=(Worklet,FakeWorklet),
Exposed=FakeWorklet,
SecureContext]

interface FakeWorkletGlobalScope : WorkletGlobalScope {
  undefined registerFake(DOMString type, Function classConstructor);
};

Each FakeWorkletGlobalScope has a registered class constructors map, which is an ordered map, initially empty.

The registerFake(type, classConstructor) method steps are to set this’s registered class constructors map[type] to classConstructor.

11.2.1 Loading scripts

This section is non-normative.

To load scripts into fake worklet 1, a web developer would write:

window.fakeWorklet1.addModule('script1.mjs');
window.fakeWorklet1.addModule('script2.mjs');

Note that which script finishes fetching and runs first is dependent on network timing: it could be either script1.mjs or script2.mjs. This generally won’t matter for well-written scripts intended to be loaded in worklets, if they follow the suggestions about preparing for speculative evaluation.

If a web developer wants to perform a task only after the scripts have successfully run and loaded into some worklets, they could write:

Promise.all([
  window.fakeWorklet1.addModule('script1.mjs'),
  window.fakeWorklet2.addModule('script2.mjs')
]).then(() => {
  // Do something which relies on those scripts being loaded.
});

Another important point about script-loading is that loaded scripts can be run in multiple WorkletGlobalScope as per Worklet, as discussed in the section on code idempotence. In particular, the specification above for fake worklet 1 and fake worklet 2 require this. So, consider a scenario such as the following:

// script.mjs
console.log("Hello from a FakeWorkletGlobalScope!");

// app.mjs
window.fakeWorklet1.addModule("script.mjs");

This could result in output such as the following from a user agent’s console:

```
[fakeWorklet1#1] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#4] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#2] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#3] Hello from a FakeWorkletGlobalScope!
```

If the user agent at some point decided to kill and restart the third instance of `FakeWorkletGlobalScope`, the console would again print `[fakeWorklet1#3] Hello from a FakeWorkletGlobalScope!` when this occurs.

### 11.2.2 Registering a class and invoking its methods

*This section is non-normative.*

Let’s say that one of the intended usages of our fake worklet by web developers is to allow them to customize the highly-complex process of boolean negation. They might register their customization as follows:

```javascript
// script.mjs
registerFake('negation-processor', class {
    process(arg) {
        return !arg;
    }
});

// app.mjs
window.fakeWorklet1.addModule("script.mjs");
```

To make use of such registered classes, the specification for fake worklets could define a *find the opposite of true* algorithm, given a `Worklet` `worklet`:

1. Optionally, create a worklet global scope for `worklet`.
2. Let `workletGlobalScope` be one of `worklet`’s global scopes, chosen in an implementation-defined manner.
3. Let `classConstructor` be `workletGlobalScope`’s registered class constructors map["negation-processor"].
4. Let `classInstance` be the result of constructing `classConstructor`, with no arguments.
5. Let `function` be `Get(classInstance, "process")`. Rethrow any exceptions.
6. Let `callback` be the result of converting `function` to a Web IDL `Function` instance.
7. Return the result of invoking callback with the arguments « true » and with classInstance as the callback this value.

Another, perhaps better, specification architecture would be to extract the “process” property and convert it into a Function at registration time, as part of the registerFake() method steps.

11.3 Infrastructure

11.3.1 The global scope

Subclasses of WorkletGlobalScope are used to create global objects wherein code loaded into a particular Worklet can execute.

```javascript
[Exposed=Worklet, SecureContext]
interface WorkletGlobalScope {};
```

Other specifications are intended to subclass WorkletGlobalScope, adding APIs to register a class, as well as other APIs specific for their worklet type.

Each WorkletGlobalScope has an associated module map. It is a module map, initially empty.

11.3.1.1 Agents and event loops

This section is non-normative.

Each WorkletGlobalScope is contained in its own worklet agent, which has its corresponding event loop. However, in practice, implementation of these agents and event loops is expected to be different from most others.

A worklet agent exists for each WorkletGlobalScope since, in theory, an implementation could use a separate thread for each WorkletGlobalScope instance, and allowing this level of parallelism is best done using agents. However, because their [[CanBlock]] value is false, there is no requirement that agents and threads are one-to-one. This allows implementations the freedom to execute scripts loaded into a worklet on any thread, including one running code from other agents with [[CanBlock]] of false, such as the thread of a similar-origin window agent ("the main thread"). Contrast this with dedicated worker agents, whose true value for [[CanBlock]] effectively requires them to get a dedicated operating system thread.

Worklet event loops are also somewhat special. They are only used for tasks associated with addModule(), tasks wherein the user agent invokes author-defined methods, and microtasks. Thus, even though the event loop processing model specifies that all event loops run continuously, implementations can achieve observably-equivalent results using a simpler strategy, which just invokes author-provided methods and then relies on that process to perform a microtask checkpoint.
11.3.1.2 Creation and termination

To create a worklet global scope for a Worklet worklet:

1. Let outsideSettings be worklet’s relevant settings object.

2. Let agent be the result of obtaining a worklet agent given outsideSettings. Run the rest of these steps in that agent.

3. Let realmExecutionContext be the result of creating a new JavaScript realm given agent and the following customizations:
   ◦ For the global object, create a new object of the type given by worklet’s worklet global scope type.

4. Let workletGlobalScope be the global object of realmExecutionContext’s Realm component.

5. Let insideSettings be the result of setting up a worklet environment settings object given realmExecutionContext and outsideSettings.

6. For each moduleURL of worklet’s added modules list:
   1. Fetch a worklet script graph given moduleURL, insideSettings, worklet’s worklet destination type, what credentials mode?, insideSettings, and worklet’s module responses map. Wait until the algorithm asynchronously completes with script.

      This will not actually perform a network request, as it will just reuse responses from worklet’s module responses map. The main purpose of this step is to create a new workletGlobalScope-specific module script from the response.

2. Assert: script is not null, since the fetch succeeded and the source text was successfully parsed when worklet’s module responses map was initially populated with moduleURL.

3. Run a module script given script.

7. Append workletGlobalScope to outsideSettings’s global object’s associated Document’s worklet global scopes.

8. Append workletGlobalScope to worklet’s global scopes.

9. Run the responsible event loop specified by insideSettings.

To terminate a worklet global scope given a WorkletGlobalScope workletGlobalScope:

1. Let eventLoop be workletGlobalScope’s relevant agent’s event loop.
2. If there are any tasks queued in eventLoop's task queues, discard them without processing them.

3. Wait for eventLoop to complete the currently running task.

4. If the previous step doesn’t complete within an implementation-defined period of time, then abort the script currently running in the worklet.

5. Destroy eventLoop.

6. Remove workletGlobalScope from the global scopes of the Worklet whose global scopes contains workletGlobalScope.

7. Remove workletGlobalScope from the worklet global scopes of the Document whose worklet global scopes contains workletGlobalScope.

11.3.1.3 Script settings for worklets

To set up a worklet environment settings object, given a JavaScript execution context executionContext and an environment settings object outsideSettings:

1. Let origin be a unique opaque origin.

2. Let inheritedAPIBaseURL be outsideSettings's API base URL.

3. Let inheritedPolicyContainer be a clone of outsideSettings's policy container.

4. Let realm be the value of executionContext's Realm component.

5. Let workletGlobalScope be realm's global object.

6. Let settingsObject be a new environment settings object whose algorithms are defined as follows:

   The realm execution context

   Return executionContext.

   The module map

   Return workletGlobalScope's module map.

   The responsible document

   Not applicable (the responsible event loop is not a window event loop).
The API URL character encoding

Return UTF-8.

The API base URL

Return inheritedAPIBaseURL.

Unlike workers or other globals derived from a single resource, worklets have no primary resource; instead, multiple scripts, each with their own URL, are loaded into the global scope via worklet.addModule(). So this API base URL is rather unlike that of other globals. However, so far this doesn’t matter, as no APIs available to worklet code make use of the API base URL.

The origin

Return origin.

The policy container

Return inheritedPolicyContainer.

The cross-origin isolated capability

Return TODO.

7. Set settingsObject's id to a new unique opaque string, creation URL to inheritedAPIBaseURL, top-level creation URL to null, top-level origin to outsideSettings's top-level origin, target browsing context to null, and active service worker to null.

8. Set realm's [[HostDefined]] field to settingsObject.

11.3.2 The Worklet class

✔️ MDN

Worklet

Support in all current engines.

Firefox 76+ Safari 14.1+ Chrome 65+
Opera 52+ Edge 79+
Edge (Legacy) No Internet Explorer No
Firefox Android 79+ Safari iOS 14.5+ Chrome Android 65+ WebView Android 65+ Samsung
The **Worklet** class provides the capability to add module scripts into its associated **WorkletGlobalScope**s. The user agent can then create classes registered on the **WorkletGlobalScope**s and invoke their methods.

```
[Exposed=Window, SecureContext]
interface Worklet {
  [NewObject] Promise<undefined> addModule(USVString moduleURL, optional WorkletOptions);  
};

dictionary WorkletOptions {
  RequestCredentials credentials = "same-origin";
};
```

Specifications that create **Worklet** instances must specify the following for a given instance:

- its **worklet global scope type**, which must be a Web IDL type that **inherits** from **WorkletGlobalScope**; and
- its **worklet destination type**, which must be a **destination**, and is used when fetching scripts.

```
await worklet.addModule(moduleURL[, { credentials }])
```

Loads and executes the **module script** given by **moduleURL** into all of **worklet's global scopes**. It can also create additional global scopes as part of this process, depending on the **worklet type**. The returned promise will fulfill once the script has been successfully loaded and run in all global scopes.

The **credentials** option can be set to a **credentials mode** to modify the script-fetching process. It defaults to "same-origin".

Any failures in **fetching** the script or its dependencies will cause the returned promise to be rejected with an **AbortError** **DOMException**. Any errors in parsing the script or its dependencies will cause the returned promise to be rejected with the exception generated during parsing.
A **Worklet** has a list of global scopes, which contains instances of the **Worklet**’s worklet global scope type. It is initially empty.

A **Worklet** has an *added modules list*, which is a list of URLs, initially empty. Access to this list should be thread-safe.

A **Worklet** has a module responses map, which is an ordered map from URLs to responses, initially empty. Access to this map should be thread-safe.

The added modules list and module responses map exist to ensure that **WorkletGlobalScope**s created at different times get equivalent module scripts run in them, based on the same source text. This allows the creation of additional **WorkletGlobalScope**s to be transparent to the author.

In practice, user agents are not expected to implement these data structures, and the algorithms that consult them, using thread-safe programming techniques. Instead, when `addModule()` is called, user agents can fetch the module graph on the main thread, and send the fetched source text (i.e., the important data contained in the module responses map) to each thread which has a **WorkletGlobalScope**.

Then, when a user agent creates a new **WorkletGlobalScope** for a given **Worklet**, it can simply send the map of fetched source text and the list of entry points from the main thread to the thread containing the new **WorkletGlobalScope**.

The `addModule(moduleURL, options)` method steps are:

1. Let `outsideSettings` be the relevant settings object of this.
2. Parse `moduleURL` relative to `outsideSettings`.
3. If this fails, then return a promise rejected with a "**SyntaxError**" **DOMException**.
4. Let `moduleURLRecord` be the resulting URL record.
5. Let `promise` be a new promise.
6. Run the following steps in parallel:
   1. If this’s global scopes is empty, then:
      1. Create a worklet global scope given this.
      2. Optionally, create additional global scope instances given this, depending on the specific worklet in question and its specification.
      3. Wait for all steps of the creation process(es) — including those taking place within the worklet agents — to complete, before moving on.
2. Let pendingTasks be this’s global scopes’s size.

3. Let addedSuccessfully be false.

4. For each workletGlobalScope of this’s global scopes, queue a global task on the networking task source given workletGlobalScope to perform the following steps:

   1. Fetch a worklet script graph given moduleURLRecord, outsideSettings, this’s worklet destination type, options["credentials"], workletGlobalScope’s relevant settings object, and this’s module responses map. Wait until the algorithm asynchronously completes with script.

      Only the first of these fetches will actually perform a network request; the ones for other WorkletGlobalScope will reuse responses from this’s module responses map.

   2. If script is null, then:

      1. Queue a global task on the networking task source given this’s relevant global object to perform the following steps:

         1. If pendingTasks is not −1, then:

            1. Set pendingTasks to −1.

            2. Reject promise with an "AbortError" DOMException.

         2. Abort these steps.

      3. If script’s error to rethrow is not null, then:

         1. Queue a global task on the networking task source given this’s relevant global object to perform the following steps:

            1. If pendingTasks is not −1, then:

               1. Set pendingTasks to −1.

               2. Reject promise with script’s error to rethrow.

         2. Abort these steps.

   4. If addedSuccessfully is false, then:

      1. Append moduleURLRecord to this’s added modules list.
2. Set `addedSuccessfully` to true.

5. Run a module script given `script`.

6. Queue a global task on the networking task source given this’s relevant global object to perform the following steps:

   1. If `pendingTasks` is not $-1$, then:
      
      1. Set `pendingTasks` to `pendingTasks` $-1$.
      
      2. If `pendingTasks` is 0, then resolve `promise`.

7. Return `promise`.

11.3.3 The worklet’s lifetime

The lifetime of a Worklet has no special considerations; it is tied to the object it belongs to, such as the Window.

Each Document has a worklet global scopes, which is a set of WorkletGlobalScope, initially empty.

The lifetime of a WorkletGlobalScope is, at a minimum, tied to the Document whose worklet global scopes contain it. In particular, discarding the Document will terminate the corresponding WorkletGlobalScope and allow it to be garbage-collected.

Additionally, user agents may, at any time, terminate a given WorkletGlobalScope, unless the specification defining the corresponding worklet type says otherwise. For example, they might terminate them if the worklet agent’s event loop has no tasks queued, or if the user agent has no pending operations planning to make use of the worklet, or if the user agent detects abnormal operations such as infinite loops or callbacks exceeding imposed time limits.

Finally, specifications for specific worklet types can give more specific details on when to create WorkletGlobalScope for a given worklet type. For example, they might create them during specific processes that call upon worklet code, as in the example.

12 Web storage

✔️ MDN

Web_Storage_API

Support in all current engines.

Firefox3.5+Safari4+Chrome4+
12.1 Introduction

This section is non-normative.

This specification introduces two related mechanisms, similar to HTTP session cookies, for storing name-value pairs on the client side. [COOKIES]

The first is designed for scenarios where the user is carrying out a single transaction, but could be carrying out multiple transactions in different windows at the same time.

Cookies don’t really handle this case well. For example, a user could be buying plane tickets in two different windows, using the same site. If the site used cookies to keep track of which ticket the user was buying, then as the user clicked from page to page in both windows, the ticket currently being purchased would “leak” from one window to the other, potentially causing the user to buy two tickets for the same flight without noticing.

To address this, this specification introduces the sessionStorage getter. Sites can add data to the session storage, and it will be accessible to any page from the same site opened in that window.

For example, a page could have a checkbox that the user ticks to indicate that they want insurance:

```html
<label>
  <input type="checkbox" onchange="sessionStorage.insurance = checked ? 'true' : ''"
    I want insurance on this trip.
</label>
```

A later page could then check, from script, whether the user had checked the checkbox or not:

```javascript
if (sessionStorage.insurance) { ... }
```

If the user had multiple windows opened on the site, each one would have its own individual copy of the session storage object.

The second storage mechanism is designed for storage that spans multiple windows, and lasts beyond the current session. In particular, web applications might wish to store megabytes of user data, such as entire user-authored documents or a user’s mailbox, on the client side for performance reasons.
Again, cookies do not handle this case well, because they are transmitted with every request.

The `localStorage` getter is used to access a page’s local storage area.

The site at example.com can display a count of how many times the user has loaded its page by putting the following at the bottom of its page:

```html
<p>You have viewed this page <span id="count">an untold number of</span> time(s).</p>
<script>
  if (!localStorage.pageLoadCount)
    localStorage.pageLoadCount = 0;
  localStorage.pageLoadCount = parseInt(localStorage.pageLoadCount) + 1;
  document.getElementById('count').textContent = localStorage.pageLoadCount;
</script>
```

Each site has its own separate storage area.

The `localStorage` getter provides access to shared state. This specification does not define the interaction with other browsing contexts in a multiprocess user agent, and authors are encouraged to assume that there is no locking mechanism. A site could, for instance, try to read the value of a key, increment its value, then write it back out, using the new value as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same “unique” identifier for both sessions, with potentially disastrous effects.

12.2 The API

Storage

Support in all current engines.

12.2.1 The `Storage` interface

[Exposed=Window]
interface Storage {
  readonly attribute unsigned long length;
  DOMString? key(unsigned long index);
  getter DOMString? getItem(DOMString key);
  setter undefined setItem(DOMString key, DOMString value);
  deleter undefined removeItem(DOMString key);
  undefined clear();
};

storage.length

Storage/length

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+
Opera 10.5+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 8+
Firefox Android 6+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung
Internet 1.0+ Opera Android 11+

Returns the number of key/value pairs.

storage.key (n)

Storage/key

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+
Opera 10.5+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 8+
Firefox Android 6+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung
Internet 1.0+ Opera Android 11+

Returns the name of the nth key, or null if n is greater than or equal to the number of key/value pairs.

value = storage.getItem (key)

Storage/getItem

Support in all current engines.
value = storage[key]

Returns the current value associated with the given key, or null if the given key does not exist.

storage.setItem (key, value)

Sets the value of the pair identified by key to value, creating a new key/value pair if none existed for key previously.

Throws a "QuotaExceededError" DOMException exception if the new value couldn’t be set. (Setting could fail if, e.g., the user has disabled storage for the site, or if the quota has been exceeded.)

Dispatches a storage event on Window objects holding an equivalent Storage object.
storage.removeItem (key)

Storage/removeItem

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+
Opera 10.5+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 8+
Firefox Android 6+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

delete storage[key]

Removes the key/value pair with the given key, if a key/value pair with the given key exists.

Dispatches a storage event on Window objects holding an equivalent Storage object.

storage.clear()

Storage/clear

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+
Opera 10.5+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 8+
Firefox Android 6+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

Removes all key/value pairs, if there are any.

Dispatches a storage event on Window objects holding an equivalent Storage object.

A Storage object has an associated:

map

A storage proxy map.

type

"local" or "session".

To reorder a Storage object storage, reorder storage's map's entries in an implementation-defined manner.
Unfortunate as it is, iteration order is not defined and can change upon most mutations.

To broadcast a Storage object storage, given a key, oldValue, and newValue, run these steps:

1. Let url be storage's relevant global object’s associated Document’s URL.

2. Let remoteStorages be all Storage objects excluding storage whose:
   - type is storage’s type
   - relevant settings object’s origin is same origin with storage’s relevant settings object’s origin.

   and, if type is "session", whose relevant settings object’s browsing session is storage’s relevant settings object’s browsing session.

3. For each remoteStorage of remoteStorages: queue a global task on the DOM manipulation task source given remoteStorage’s relevant global object to fire an event named storage at remoteStorage’s relevant global object, using StorageEvent, with key initialized to key, oldValue initialized to oldValue, newValue initialized to newValue, url initialized to url, and storageArea initialized to remoteStorage.

   The Document object associated with the resulting task is not necessarily fully active, but events fired on such objects are ignored by the event loop until the Document becomes fully active again.

The length getter steps are to return this’s map’s size.

The key(index) method steps are:

1. If index is greater than or equal to this’s map’s size, then return null.

2. Let keys be the result of running get the keys on this’s map.

3. Return keys[index].

The supported property names on a Storage object storage are the result of running get the keys on storage’s map.

The getItem(key) method steps are:

1. If this’s map[key] does not exist, then return null.

2. Return this’s map[key].

The setItem(key, value) method are:
1. Let oldValue be null.

2. Let reorder be true.

3. If this’s map[key] exists:
   1. Set oldValue to this’s map[key].
   2. If oldValue is value, then return.
   3. Set reorder to false.

4. If value cannot be stored, then throw a "QuotaExceededError" DOMException exception.

5. Set this’s map[key] to value.

6. If reorder is true, then reorder this.

7. Broadcast this with key, oldValue, and value.

The removeItem(key) method steps are:

1. If this’s map[key] does not exist, then return null.

2. Set oldValue to this’s map[key].

3. Remove this’s map[key].

4. Reorder this.

5. Broadcast this with key, oldValue, and null.

The clear() method steps are:

1. Clear this’s map.

2. Broadcast this with null, null, and null.

12.2.2 The sessionStorage getter

interface mixin WindowSessionStorage {
  readonly attribute Storage sessionStorage;
};

Window includes WindowSessionStorage;

window.sessionStorage
**Window/sessionStorage**

Support in all current engines.

<table>
<thead>
<tr>
<th>Engine</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>2+</td>
</tr>
<tr>
<td>Safari</td>
<td>4+</td>
</tr>
<tr>
<td>Chrome</td>
<td>5+</td>
</tr>
<tr>
<td>Opera</td>
<td>10.5+</td>
</tr>
<tr>
<td>Edge (Legacy)</td>
<td>12+</td>
</tr>
<tr>
<td>Internet Explorer</td>
<td>8+</td>
</tr>
<tr>
<td>Firefox Android</td>
<td>4+</td>
</tr>
<tr>
<td>Safari iOS</td>
<td>3.2+</td>
</tr>
<tr>
<td>Chrome Android</td>
<td>18+</td>
</tr>
<tr>
<td>WebView Android</td>

</tr>
<tr>
<td>Samsung</td>
<td>Internet 1.0+Opera Android 11+</td>
</tr>
</tbody>
</table>

Returns the `Storage` object associated with that `window`'s origin’s session storage area.

Throws a `SecurityError` `DOMException` if the `Document`'s `origin` is an `opaque origin` or if the request violates a policy decision (e.g., if the user agent is configured to not allow the page to persist data).

A `Document` object has an associated `session storage holder`, which is null or a `Storage` object. It is initially null.

(This is a tracking vector.) The `sessionStorage` getter steps are:

1. If this’s associated `Document`’s session storage holder is non-null, then return this’s associated `Document`’s session storage holder.

2. Let `map` be the result of running `obtain a session storage bottle map` with this’s relevant settings object and “sessionStorage”.

3. If `map` is failure, then throw a “SecurityError” `DOMException`.

4. Let `storage` be a new `Storage` object whose `map` is `map`.

5. Set this’s associated `Document`’s session storage holder to `storage`.

6. Return `storage`.

While creating a new auxiliary browsing context, the session storage is copied over.

12.2.3 The `localStorage` getter

```javascript
interface mixin WindowLocalStorage {
  readonly attribute Storage localStorage;
}
```
Window includes WindowLocalStorage;

window.localStorage
✔ MDN

Window/localStorage

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+
Opera 10.5+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 8+
Firefox Android 4+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

Returns the Storage object associated with window’s origin’s local storage area.

Throws a “SecurityError” DOMException if the Document’s origin is an opaque origin or if the request violates a policy decision (e.g., if the user agent is configured to not allow the page to persist data).

A Document object has an associated local storage holder, which is null or a Storage object. It is initially null.

(This is a tracking vector) The localStorage getter steps are:

1. If this’s associated Document’s local storage holder is non-null, then return this’s associated Document’s local storage holder.

2. Let map be the result of running obtain a local storage bottle map with this’s relevant settings object and “localStorage”.

3. If map is failure, then throw a “SecurityError” DOMException.

4. Let storage be a new Storage object whose map is map.

5. Set this’s associated Document’s local storage holder to storage.

6. Return storage.

12.2.4 The StorageEvent interface

✔ MDN
StorageEvent

Support in all current engines.

Firefox 13+ Safari 4+ Chrome 1+
Opera 12.1+ Edge 79+
Edge (Legacy) 12+ Internet Explorer 9+
Firefox Android 14+ Safari iOS 3+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

[Exposed=Window]
interface StorageEvent : Event {
  constructor(DOMString type, optional StorageEventInit eventInitDict = {});

  readonly attribute DOMString? key;
 readonly attribute DOMString? oldValue;
  readonly attribute DOMString? newValue;
  readonly attribute USVstring url;
  readonly attribute Storage? storageArea;

  undefined initStorageEvent(DOMString type, optional boolean bubbles = false);
};

dictionary StorageEventInit : EventInit {
  DOMString? key = null;
  DOMString? oldValue = null;
  DOMString? newValue = null;
  USVString url = "";
  Storage? storageArea = null;
};

event.key

Returns the key of the storage item being changed.

event.oldValue

Returns the old value of the key of the storage item whose value is being changed.

event.newValue

Returns the new value of the key of the storage item whose value is being changed.

event.url

Returns the URL of the document whose storage item changed.
**event**: `storageArea`

Returns the `Storage` object that was affected.

The `key, oldValue, newValue, url`, and `storageArea` attributes must return the values they were initialized to.

---

**StorageEvent/initStorageEvent**

Support in all current engines.

The `initStorageEvent(type, bubbles, cancelable, key, oldValue, newValue, url, storageArea)` method must initialize the event in a manner analogous to the similarly-named `initEvent()` method. [DOM]

---

### 12.3 Privacy

#### 12.3.1 User tracking

A third-party advertiser (or any entity capable of getting content distributed to multiple sites) could use a unique identifier stored in its local storage area to track a user across multiple sessions, building a profile of the user’s interests to allow for highly targeted advertising. In conjunction with a site that is aware of the user’s real identity (for example an e-commerce site that requires authenticated credentials), this could allow oppressive groups to target individuals with greater accuracy than in a world with purely anonymous web usage.

There are a number of techniques that can be used to mitigate the risk of user tracking:

**Blocking third-party storage**

User agents may restrict access to the `localStorage` objects to scripts originating at the domain of the active document of the top-level browsing context, for instance denying access to the API for pages from other domains running in `iframes`.

**Expiring stored data**

User agents may, possibly in a manner configured by the user, automatically delete stored data after a period of time.
For example, a user agent could be configured to treat third-party local storage areas as session-only storage, deleting the data once the user had closed all the browsing contexts that could access it.

This can restrict the ability of a site to track a user, as the site would then only be able to track the user across multiple sessions when they authenticate with the site itself (e.g. by making a purchase or logging in to a service).

However, this also reduces the usefulness of the API as a long-term storage mechanism. It can also put the user’s data at risk, if the user does not fully understand the implications of data expiration.

**Treating persistent storage as cookies**

If users attempt to protect their privacy by clearing cookies without also clearing data stored in the local storage area, sites can defeat those attempts by using the two features as redundant backup for each other. User agents should present the interfaces for clearing these in a way that helps users to understand this possibility and enables them to delete data in all persistent storage features simultaneously. [COOKIES]

**Site-specific safelisting of access to local storage areas**

User agents may allow sites to access session storage areas in an unrestricted manner, but require the user to authorize access to local storage areas.

**Origin-tracking of stored data**

User agents may record the origins of sites that contained content from third-party origins that caused data to be stored.

If this information is then used to present the view of data currently in persistent storage, it would allow the user to make informed decisions about which parts of the persistent storage to prune. Combined with a blocklist (“delete this data and prevent this domain from ever storing data again”), the user can restrict the use of persistent storage to sites that they trust.

**Shared blocklists**

User agents may allow users to share their persistent storage domain blocklists.

This would allow communities to act together to protect their privacy.

While these suggestions prevent trivial use of this API for user tracking, they do not block it altogether. Within a single domain, a site can continue to track the user during a session, and can then pass all this information to the third party along with any identifying information (names, credit card numbers, addresses) obtained by the site. If a third party cooperates with multiple sites to obtain such information, a profile can still be created.
However, user tracking is to some extent possible even with no cooperation from the user agent whatsoever, for instance by using session identifiers in URLs, a technique already commonly used for innocuous purposes but easily repurposed for user tracking (even retroactively). This information can then be shared with other sites, using visitors’ IP addresses and other user-specific data (e.g. user-agent headers and configuration settings) to combine separate sessions into coherent user profiles.

### 12.3.2 Sensitivity of data

User agents should treat persistently stored data as potentially sensitive; it’s quite possible for emails, calendar appointments, health records, or other confidential documents to be stored in this mechanism.

To this end, user agents should ensure that when deleting data, it is promptly deleted from the underlying storage.

### 12.4 Security

#### 12.4.1 DNS spoofing attacks

Because of the potential for DNS spoofing attacks, one cannot guarantee that a host claiming to be in a certain domain really is from that domain. To mitigate this, pages can use TLS. Pages using TLS can be sure that only the user, software working on behalf of the user, and other pages using TLS that have certificates identifying them as being from the same domain, can access their storage areas.

#### 12.4.2 Cross-directory attacks

Different authors sharing one host name, for example users hosting content on the now defunct geocities.com, all share one local storage object. There is no feature to restrict the access by pathname. Authors on shared hosts are therefore urged to avoid using these features, as it would be trivial for other authors to read the data and overwrite it.

Even if a path-restriction feature was made available, the usual DOM scripting security model would make it trivial to bypass this protection and access the data from any path.

#### 12.4.3 Implementation risks

The two primary risks when implementing these persistent storage features are letting hostile sites read information from other domains, and letting hostile sites write information that is then read from other domains.

Letting third-party sites read data that is not supposed to be read from their domain causes information leakage. For example, a user’s shopping wishlist on one domain could be used by another domain for targeted advertising; or a user’s work-in-progress confidential documents stored by a word-processing site could be examined by the site of a competing company.
Letting third-party sites write data to the persistent storage of other domains can result in information spoofing, which is equally dangerous. For example, a hostile site could add items to a user’s wishlist; or a hostile site could set a user’s session identifier to a known ID that the hostile site can then use to track the user’s actions on the victim site.

Thus, strictly following the origin model described in this specification is important for user security.

13 The HTML syntax

This section only describes the rules for resources labeled with an HTML MIME type. Rules for XML resources are discussed in the section below entitled “The XML syntax”.

13.1 Writing HTML documents

This section only applies to documents, authoring tools, and markup generators. In particular, it does not apply to conformance checkers; conformance checkers must use the requirements given in the next section (“parsing HTML documents”).

Documents must consist of the following parts, in the given order:

1. Optionally, a single U+FEFF BYTE ORDER MARK (BOM) character.
2. Any number of comments and ASCII whitespace.
3. A DOCTYPE.
4. Any number of comments and ASCII whitespace.
5. The document element, in the form of an html element.
6. Any number of comments and ASCII whitespace.

The various types of content mentioned above are described in the next few sections.

In addition, there are some restrictions on how character encoding declarations are to be serialized, as discussed in the section on that topic.

ASCII whitespace before the html element, at the start of the html element and before the head element, will be dropped when the document is parsed; ASCII whitespace after the html element will be parsed as if it were at the end of the body element. Thus, ASCII whitespace around the document element does not round-trip.

It is suggested that newlines be inserted after the DOCTYPE, after any comments that are before the document element, after the html element’s start tag (if it is not omitted), and after any comments that are inside the html element but before the head element.

Many strings in the HTML syntax (e.g. the names of elements and their attributes) are case-insensitive, but only for ASCII upper alphas and ASCII lower alphas. For convenience, in this section this is just referred to as “case-insensitive”.

13.1.1 The DOCTYPE

A DOCTYPE is a required preamble.

DOCTYPEs are required for legacy reasons. When omitted, browsers tend to use a different rendering mode that is incompatible with some specifications. Including the DOCTYPE in a document ensures that the browser makes a best-effort attempt at following the relevant specifications.

A DOCTYPE must consist of the following components, in this order:

1. A string that is an ASCII case-insensitive match for the string "<!DOCTYPE".
2. One or more ASCII whitespace.
3. A string that is an ASCII case-insensitive match for the string "html".
4. Optionally, a DOCTYPE legacy string.
5. Zero or more ASCII whitespace.
6. A U+003E GREATER-THAN SIGN character (>).

In other words, <!DOCTYPE html>, case-insensitively.

For the purposes of HTML generators that cannot output HTML markup with the short DOCTYPE "<!DOCTYPE html>", a DOCTYPE legacy string may be inserted into the DOCTYPE (in the position defined above). This string must consist of:

1. One or more ASCII whitespace.
2. A string that is an ASCII case-insensitive match for the string "SYSTEM".
3. One or more ASCII whitespace.
4. A U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (the quote mark).
5. The literal string "about:legacy-compat".
6. A matching U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (i.e. the same character as in the earlier step labeled quote mark).

In other words, <!DOCTYPE html SYSTEM "about:legacy-compat"> or <!DOCTYPE html SYSTEM 'about:legacy-compat'>, case-insensitively except for the part in single or double quotes.

The DOCTYPE legacy string should not be used unless the document is generated from a system that cannot output the shorter string.

13.1.2 Elements

There are six different kinds of elements: void elements, the template element, raw text elements, escapable raw text elements, foreign elements, and normal elements.

Void elements

area, base, br, col, embed, hr, img, input, link, meta, param, source, track, wbr
The **template** element

```html
template
```

**Raw text elements**

```html
script, style
```

**Escapable raw text elements**

```html
textarea, title
```

**Foreign elements**

Elements from the [MathML namespace](https://www.w3.org/TR/MathML3/) and the [SVG namespace](https://www.w3.org/TR/SVG/).

**Normal elements**

All other allowed [HTML elements](https://developer.mozilla.org/en-US/docs/Web/HTML/Introduction) are normal elements.

Tags are used to delimit the start and end of elements in the markup. **Raw text**, **escapable raw text**, and **normal** elements have a **start tag** to indicate where they begin, and an **end tag** to indicate where they end. The start and end tags of certain **normal elements** can be **omitted**, as described below in the section on **optional tags**. Those that cannot be omitted must not be omitted. **Void elements** only have a start tag; end tags must not be specified for **void elements**. **Foreign elements** must either have a start tag and an end tag, or a start tag that is marked as self-closing, in which case they must not have an end tag.

The **contents** of the element must be placed between just after the start tag (which might be implied, in certain cases) and just before the end tag (which again, might be implied in certain cases). The exact allowed contents of each individual element depend on the **content model** of that element, as described earlier in this specification. Elements must not contain content that their content model disallows. In addition to the restrictions placed on the contents by those content models, however, the five types of elements have additional **syntactic** requirements.

**Void elements** can’t have any contents (since there’s no end tag, no content can be put between the start tag and the end tag).

The **template** element can have **template contents**, but such **template contents** are not children of the **template** element itself. Instead, they are stored in a **DocumentFragment** associated with a different **Document** — without a **browsing context** — so as to avoid the **template** contents interfering with the main **Document**. The markup for the **template contents** of a **template** element is placed just after the **template** element’s start tag and just before **template** element’s end tag (as with other elements), and may consist of any **text**, character references, **elements**, and **comments**, but the text must not contain the character U+003C LESS-THAN SIGN (<) or an **ambiguous ampersand**.

**Raw text elements** can have **text**, though it has **restrictions** described below.

**Escapable raw text elements** can have **text** and **character references**, but the text must not contain an **ambiguous ampersand**. There are also **further restrictions** described below.

**Foreign elements** whose start tag is marked as self-closing can’t have any contents (since, again,
as there’s no end tag, no content can be put between the start tag and the end tag). Foreign elements whose start tag is not marked as self-closing can have text, character references, CDATA sections, other elements, and comments, but the text must not contain the character U+003C LESS-THEAN SIGN (<) or an ambiguous ampersand.

The HTML syntax does not support namespace declarations, even in foreign elements.

For instance, consider the following HTML fragment:

```html
<p>
<svg>
<metadata>
<!-- this is invalid -->
<cdr:license xmlns:cdr="https://www.example.com/cdr/metadata" name="MIT"/>
</metadata>
</svg>
</p>
```

The innermost element, cdr:license, is actually in the SVG namespace, as the "xmlns:cdr" attribute has no effect (unlike in XML). In fact, as the comment in the fragment above says, the fragment is actually non-conforming. This is because SVG 2 does not define any elements called "cdr:license" in the SVG namespace.

Normal elements can have text, character references, other elements, and comments, but the text must not contain the character U+003C LESS-THEAN SIGN (<) or an ambiguous ampersand. Some normal elements also have yet more restrictions on what content they are allowed to hold, beyond the restrictions imposed by the content model and those described in this paragraph. Those restrictions are described below.

Tags contain a tag name, giving the element’s name. HTML elements all have names that only use ASCII alphanumerics. In the HTML syntax, tag names, even those for foreign elements, may be written with any mix of lower- and uppercase letters that, when converted to all-lowercase, matches the element’s tag name; tag names are case-insensitive.

13.1.2.1 Start tags

Start tags must have the following format:

1. The first character of a start tag must be a U+003C LESS-THEAN SIGN character (<).
2. The next few characters of a start tag must be the element’s tag name.
3. If there are to be any attributes in the next step, there must first be one or more ASCII whitespace.
4. Then, the start tag may have a number of attributes, the syntax for which is described below. Attributes must be separated from each other by one or more ASCII whitespace.
5. After the attributes, or after the tag name if there are no attributes, there may be one or more ASCII whitespace. (Some attributes are required to be followed by a space. See the attributes section below.)
6. Then, if the element is one of the void elements, or if the element is a foreign element, then there may be a single U+002F SOLIDUS character (/). This character has no effect on void elements, but on foreign elements it marks the start tag as self-closing.

7. Finally, start tags must be closed by a U+003E GREATER-THAN SIGN character (>).

13.1.2.2 End tags

End tags must have the following format:

1. The first character of an end tag must be a U+003C LESS-THAN SIGN character (<).
2. The second character of an end tag must be a U+002F SOLIDUS character (/).
3. The next few characters of an end tag must be the element’s tag name.
4. After the tag name, there may be one or more ASCII whitespace.
5. Finally, end tags must be closed by a U+003E GREATER-THAN SIGN character (>).

13.1.2.3 Attributes

Attributes for an element are expressed inside the element’s start tag.

Attributes have a name and a value. Attribute names must consist of one or more characters other than controls, U+0020 SPACE, U+0022 ("), U+0027 ('), U+003E (>), U+002F (/), U+003D (=), and noncharacters. In the HTML syntax, attribute names, even those for foreign elements, may be written with any mix of ASCII lower and ASCII upper alphas.

Attribute values are a mixture of text and character references, except with the additional restriction that the text cannot contain an ambiguous ampersand.

Attributes can be specified in four different ways:

Empty attribute syntax

Just the attribute name. The value is implicitly the empty string.

In the following example, the disabled attribute is given with the empty attribute syntax:

<input disabled>

If an attribute using the empty attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

Unquoted attribute value syntax

The attribute name, followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by the attribute value, which, in addition to the requirements given above for attribute values, must not contain any literal ASCII whitespace, any U+0022 QUOTATION MARK.
characters ("), U+0027 APOSTROPHE characters (‘), U+003D EQUALS SIGN characters (=), U+003C LESS-THEAN SIGN characters (<), U+003E GREATER-THEAN SIGN characters (>), or U+0060 GRAVE ACCENT characters (‘), and must not be the empty string.

In the following example, the value attribute is given with the unquoted attribute value syntax:

```html
<input value=yes>
```

If an attribute using the unquoted attribute syntax is to be followed by another attribute or by the optional U+002F SOLIDUS character (/) allowed in step 6 of the start tag syntax above, then there must be ASCII whitespace separating the two.

**Single-quoted attribute value syntax**

The attribute name, followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by a single U+0027 APOSTROPHE character (‘), followed by the attribute value, which, in addition to the requirements given above for attribute values, must not contain any literal U+0027 APOSTROPHE characters (‘), and finally followed by a second single U+0027 APOSTROPHE character (‘).

In the following example, the type attribute is given with the single-quoted attribute value syntax:

```html
<input type='checkbox'>
```

If an attribute using the single-quoted attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

**Double-quoted attribute value syntax**

The attribute name, followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by a single U+0032 QUOTATION MARK character ("), followed by the attribute value, which, in addition to the requirements given above for attribute values, must not contain any literal U+0032 QUOTATION MARK characters ("), and finally followed by a second single U+0032 QUOTATION MARK character (").

In the following example, the name attribute is given with the double-quoted attribute value syntax:

```html
<input name="be evil">
```

If an attribute using the double-quoted attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.
There must never be two or more attributes on the same start tag whose names are an ASCII case-insensitive match for each other.

When a foreign element has one of the namespaced attributes given by the local name and namespace of the first and second cells of a row from the following table, it must be written using the name given by the third cell from the same row.

<table>
<thead>
<tr>
<th>Local name</th>
<th>Namespace</th>
<th>Attribute name</th>
</tr>
</thead>
<tbody>
<tr>
<td>actuate</td>
<td>XLink namespace</td>
<td>xlink:actuate</td>
</tr>
<tr>
<td>arcrole</td>
<td>XLink namespace</td>
<td>xlink:arcrole</td>
</tr>
<tr>
<td>href</td>
<td>XLink namespace</td>
<td>xlink:href</td>
</tr>
<tr>
<td>role</td>
<td>XLink namespace</td>
<td>xlink:role</td>
</tr>
<tr>
<td>show</td>
<td>XLink namespace</td>
<td>xlink:show</td>
</tr>
<tr>
<td>title</td>
<td>XLink namespace</td>
<td>xlink:title</td>
</tr>
<tr>
<td>type</td>
<td>XLink namespace</td>
<td>xlink:type</td>
</tr>
<tr>
<td>lang</td>
<td>XML namespace</td>
<td>xml:lang</td>
</tr>
<tr>
<td>space</td>
<td>XML namespace</td>
<td>xml:space</td>
</tr>
<tr>
<td>xmlns</td>
<td>XMLNS namespace</td>
<td>xmlns</td>
</tr>
<tr>
<td>xlink</td>
<td>XMLNS namespace</td>
<td>xmlns:xlink</td>
</tr>
</tbody>
</table>

No other namespaced attribute can be expressed in the HTML syntax.

Whether the attributes in the table above are conforming or not is defined by other specifications (e.g. SVG 2 and MathML); this section only describes the syntax rules if the attributes are serialized using the HTML syntax.

13.1.2.4 Optional tags

Certain tags can be omitted.

Omitting an element’s start tag in the situations described below does not mean the element is not present; it is implied, but it is still there. For example, an HTML document always has a root html element, even if the string <html> doesn’t appear anywhere in the markup.

An html element’s start tag may be omitted if the first thing inside the html element is not a comment.

For example, in the following case it’s ok to remove the “<html>” tag:

```html
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
```
<body>
   <p>Welcome to this example.</p>
</body>
</html>

Doing so would make the document look like this:

<!DOCTYPE HTML>

<head>
   <title>Hello</title>
</head>
<body>
   <p>Welcome to this example.</p>
</body>
</html>

This has the exact same DOM. In particular, note that whitespace around the document element is ignored by the parser. The following example would also have the exact same DOM:

<!DOCTYPE HTML><head>
   <title>Hello</title>
</head>
<body>
   <p>Welcome to this example.</p>
</body>
</html>

However, in the following example, removing the start tag moves the comment to before the html element:

<!DOCTYPE HTML>
<html>
   <!-- where is this comment in the DOM? -->
   <head>
      <title>Hello</title>
   </head>
   <body>
      <p>Welcome to this example.</p>
   </body>
</html>

With the tag removed, the document actually turns into the same as this:

<!DOCTYPE HTML>
<!-- where is this comment in the DOM? -->
<html>
This is why the tag can only be removed if it is not followed by a comment: removing the tag when there is a comment there changes the document’s resulting parse tree. Of course, if the position of the comment does not matter, then the tag can be omitted, as if the comment had been moved to before the start tag in the first place.

An html element’s end tag may be omitted if the html element is not immediately followed by a comment.

A head element’s start tag may be omitted if the element is empty, or if the first thing inside the head element is an element.

A head element’s end tag may be omitted if the head element is not immediately followed by ASCII whitespace or a comment.

A body element’s start tag may be omitted if the element is empty, or if the first thing inside the body element is not ASCII whitespace or a comment, except if the first thing inside the body element is a meta, link, script, style, or template element.

A body element’s end tag may be omitted if the body element is not immediately followed by a comment.

Note that in the example above, the head element start and end tags, and the body element start tag, can’t be omitted, because they are surrounded by whitespace:

```html
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

(The body and html element end tags could be omitted without trouble; any spaces after those get parsed into the body element anyway.)

Usually, however, whitespace isn’t an issue. If we first remove the whitespace we don’t care about:
<!DOCTYPE HTML> <html> <head> <title>Hello</title> </head> <body> <p>Welcome to this example.</p> </body> </html>

Then we can omit a number of tags without affecting the DOM:

<!DOCTYPE HTML> <title>Hello</title> <p>Welcome to this example.</p>

At that point, we can also add some whitespace back:

<!DOCTYPE HTML>
<title>Hello</title>
<p>Welcome to this example.</p>

This would be equivalent to this document, with the omitted tags shown in their parser-implied positions; the only whitespace text node that results from this is the newline at the end of the head element:

<!DOCTYPE HTML>
<html>
<head>
<title>Hello</title>
</head>
<body>
<p>Welcome to this example.</p>
</body>
</html>

An li element’s end tag may be omitted if the li element is immediately followed by another li element or if there is no more content in the parent element.

A dt element’s end tag may be omitted if the dt element is immediately followed by another dt element or a dd element.

A dd element’s end tag may be omitted if the dd element is immediately followed by another dd element or a dt element, or if there is no more content in the parent element.

A p element’s end tag may be omitted if the p element is immediately followed by an address, article, aside, blockquote, details, div, dl, fieldset, figcaption, figure, footer, form, h1, h2, h3, h4, h5, h6, header, hgroup, hr, main, menu, nav, ol, p, pre, section, table, or ul element, or if there is no more content in the parent element and the parent element is an HTML element that is not an a, audio, del, ins, map, noscript, or video element, or an autonomous custom element.

We can thus simplify the earlier example further:

<!DOCTYPE HTML> <title>Hello</title> <p>Welcome to this example.</p>

An rt element’s end tag may be omitted if the rt element is immediately followed by an rt or rp element, or if there is no more content in the parent element.

An rp element’s end tag may be omitted if the rp element is immediately followed by an rt or rp element, or if there is no more content in the parent element.

An optgroup element’s end tag may be omitted if the optgroup element is immediately
followed by another `optgroup` element, or if there is no more content in the parent element.

An `option` element’s end tag may be omitted if the `option` element is immediately followed by another `option` element, or if it is immediately followed by an `optgroup` element, or if there is no more content in the parent element.

A `colgroup` element’s start tag may be omitted if the first thing inside the `colgroup` element is a `col` element, and if the element is not immediately preceded by another `colgroup` element whose end tag has been omitted. (It can’t be omitted if the element is empty.)

A `colgroup` element’s end tag may be omitted if the `colgroup` element is not immediately followed by ASCII whitespace or a comment.

A `caption` element’s end tag may be omitted if the `caption` element is not immediately followed by ASCII whitespace or a comment.

A `thead` element’s end tag may be omitted if the `thead` element is immediately followed by a `tbody` or `tfoot` element.

A `tbody` element’s start tag may be omitted if the first thing inside the `tbody` element is a `tr` element, and if the element is not immediately preceded by a `tbody`, `thead`, or `tfoot` element whose end tag has been omitted. (It can’t be omitted if the element is empty.)

A `tbody` element’s end tag may be omitted if the `tbody` element is immediately followed by a `tbody` or `tfoot` element, or if there is no more content in the parent element.

A `tfoot` element’s end tag may be omitted if there is no more content in the parent element.

A `tr` element’s end tag may be omitted if the `tr` element is immediately followed by another `tr` element, or if there is no more content in the parent element.

A `td` element’s end tag may be omitted if the `td` element is immediately followed by a `td` or `th` element, or if there is no more content in the parent element.

A `th` element’s end tag may be omitted if the `th` element is immediately followed by a `td` or `th` element, or if there is no more content in the parent element.

The ability to omit all these table-related tags makes table markup much terser.

Take this example:

```html
<table>
  <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
  <colgroup><col><col></colgroup>
  <thead>
    <tr>
      <th>Function</th>
    </tr>
  </thead>
</table>
```
<table>
<thead>
<tr>
<th>Function</th>
<th>Control Unit</th>
<th>Central Station</th>
</tr>
</thead>
<tbody>
<tr>
<td>Headlights</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Interior Lights</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Electric locomotive operating sounds</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Engineer's cab lighting</td>
<td></td>
<td>✔</td>
</tr>
<tr>
<td>Station Announcements - Swiss</td>
<td></td>
<td>✔</td>
</tr>
</tbody>
</table>
Since the cells take up much less room this way, this can be made even terser by having each row on one line:

```
<table>
  <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
  <thead>
    <tr><th>Function</th><th>Control Unit</th><th>Central Station</th></tr>
  </thead>
  <tbody>
    <tr><td>Headlights</td><td>✔</td><td>✔</td></tr>
    <tr><td>Interior Lights</td><td>✔</td><td>✔</td></tr>
    <tr><td>Electric locomotive operating sounds</td><td>✔</td><td>✔</td></tr>
    <tr><td>Engineer's cab lighting</td><td></td><td>✔</td></tr>
    <tr><td>Station Announcements - Swiss</td><td></td><td>✔</td></tr>
  </tbody>
</table>
```

The only differences between these tables, at the DOM level, is with the precise position of the (in any case semantically-neutral) whitespace.

However, a start tag must never be omitted if it has any attributes.

Returning to the earlier example with all the whitespace removed and then all the optional tags removed:

```html
<!DOCTYPE HTML>
<title>Hello</title>
<p>Welcome to this example.</p>
```

If the body element in this example had to have a class attribute and the html element had to have a lang attribute, the markup would have to become:
This section assumes that the document is conforming, in particular, that there are no content model violations. Omitting tags in the fashion described in this section in a document that does not conform to the content models described in this specification is likely to result in unexpected DOM differences (this is, in part, what the content models are designed to avoid).

13.1.2.5 Restrictions on content models

For historical reasons, certain elements have extra restrictions beyond even the restrictions given by their content model.

A `table` element must not contain `tr` elements, even though these elements are technically allowed inside `table` elements according to the content models described in this specification. (If a `tr` element is put inside a `table` in the markup, it will in fact imply a `tbody` start tag before it.)

A single newline may be placed immediately after the start tag of `pre` and `textarea` elements. This does not affect the processing of the element. The otherwise optional newline must be included if the element’s contents themselves start with a newline (because otherwise the leading newline in the contents would be treated like the optional newline, and ignored).

The following two `pre` blocks are equivalent:

```
<pre>Hello</pre>

<pre>Hello</pre>
```

13.1.2.6 Restrictions on the contents of raw text and escapable raw text elements

The text in raw text and escapable raw text elements must not contain any occurrences of the string "" (U+003C LESS-THAN SIGN, U+002F SOLIDUS) followed by characters that case-insensitively match the tag name of the element followed by one of U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), U+0020 SPACE, U+003E GREATER-THEAN SIGN (>), or U+002F SOLIDUS (/).

13.1.3 Text

Text is allowed inside elements, attribute values, and comments. Extra constraints are placed on what is and what is not allowed in text based on where the text is to be put, as described in the other sections.

13.1.3.1 Newlines

Newlines in HTML may be represented either as U+000D CARRIAGE RETURN (CR)
characters, U+000A LINE FEED (LF) characters, or pairs of U+000D CARRIAGE RETURN (CR), U+000A LINE FEED (LF) characters in that order.

Where character references are allowed, a character reference of a U+000A LINE FEED (LF) character (but not a U+000D CARRIAGE RETURN (CR) character) also represents a newline.

13.1.4 Character references

In certain cases described in other sections, text may be mixed with character references. These can be used to escape characters that couldn’t otherwise legally be included in text.

Character references must start with a U+0026 AMPERSAND character (&). Following this, there are three possible kinds of character references:

Named character references

The ampersand must be followed by one of the names given in the named character references section, using the same case. The name must be one that is terminated by a U+003B SEMICOLON character (;).

Decimal numeric character reference

The ampersand must be followed by a U+0023 NUMBER SIGN character (#), followed by one or more ASCII digits, representing a base-ten integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

Hexadecimal numeric character reference

The ampersand must be followed by a U+0023 NUMBER SIGN character (#), which must be followed by either a U+0078 LATIN SMALL LETTER X character (x) or a U+0058 LATIN CAPITAL LETTER X character (X), which must then be followed by one or more ASCII hex digits, representing a hexadecimal integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

The numeric character reference forms described above are allowed to reference any code point excluding U+000D CR, noncharacters, and controls other than ASCII whitespace.

An ambiguous ampersand is a U+0026 AMPERSAND character (&) that is followed by one or more ASCII alphanumerics, followed by a U+003B SEMICOLON character (;), where these characters do not match any of the names given in the named character references section.

13.1.5 CDATA sections

CDATA sections must consist of the following components, in this order:

1. The string “<! [CDATA[”.
2. Optionally, text, with the additional restriction that the text must not contain the string ”]]>”.
3. The string "]]>”.

CDATA sections can only be used in foreign content (MathML or SVG). In this example, a CDATA section is used to escape the contents of a MathML ms element:

```xml
<p>You can add a string to a number, but this stringifies the number:</p>
<math>
  <ms><![CDATA[x<y]]></ms>
  <mo>+</mo>
  <mn>3</mn>
  <mo>=</mo>
  <ms><![CDATA[x<y3]]></ms>
</math>
```

13.1.6 Comments

Comments must have the following format:

1. The string “<!- -”.
2. Optionally, text, with the additional restriction that the text must not start with the string “>”, nor start with the string “->”, nor contain the strings “<! -”, “- ->”, or “- - !>”, nor end with the string “<! -”.
3. The string “- - >”.

The text is allowed to end with the string “<!”, as in <!--My favorite operators are > and <!- -- >.

13.2 Parsing HTML documents

This section only applies to user agents, data mining tools, and conformance checkers.

The rules for parsing XML documents into DOM trees are covered by the next section, entitled “The XML syntax”.

User agents must use the parsing rules described in this section to generate the DOM trees from text/html resources. Together, these rules define what is referred to as the HTML parser.

While the HTML syntax described in this specification bears a close resemblance to SGML and XML, it is a separate language with its own parsing rules.

Some earlier versions of HTML (in particular from HTML2 to HTML4) were based on SGML and used SGML parsing rules. However, few (if any) web browsers ever implemented true SGML parsing for HTML documents; the only user agents to strictly handle HTML as an SGML application have historically been validators. The resulting confusion — with validators claiming documents to have one representation while widely deployed web browsers interoperably implemented a different representation — has wasted decades of productivity. This version of HTML thus returns to a non-SGML basis.
Authors interested in using SGML tools in their authoring pipeline are encouraged to use XML tools and the XML serialization of HTML.

For the purposes of conformance checkers, if a resource is determined to be in the HTML syntax, then it is an HTML document.

As stated in the terminology section, references to element types that do not explicitly specify a namespace always refer to elements in the HTML namespace. For example, if the spec talks about "a menu element", then that is an element with the local name "menu", the namespace "http://www.w3.org/1999/xhtml", and the interface HTMLMenuElement. Where possible, references to such elements are hyperlinked to their definition.

13.2.1 Overview of the parsing model

The input to the HTML parsing process consists of a stream of code points, which is passed through a tokenization stage followed by a tree construction stage. The output is a Document object.
Implementations that do not support scripting do not have to actually create a DOM Document object, but the DOM tree in such cases is still used as the model for the rest of the specification.

In the common case, the data handled by the tokenization stage comes from the network, but it can also come from script running in the user agent, e.g. using the document.write() API.

There is only one set of states for the tokenizer stage and the tree construction stage, but the tree construction stage is reentrant, meaning that while the tree construction stage is handling one token, the tokenizer might be resumed, causing further tokens to be emitted and processed before the first token’s processing is complete.

In the following example, the tree construction stage will be called upon to handle a "p" start tag token while handling the "script" end tag token:

```html
...<script>
document.write(''<p>'');
</script>...
```

To handle these cases, parsers have a script nesting level, which must be initially set to zero, and a parser pause flag, which must be initially set to false.

### 13.2.2 Parse errors

This specification defines the parsing rules for HTML documents, whether they are syntactically correct or not. Certain points in the parsing algorithm are said to be parse errors. The error handling for parse errors is well-defined (that's the processing rules described throughout this specification), but user agents, while parsing an HTML document, may abort the parser at the first parse error that they encounter for which they do not wish to apply the rules described in this specification.

Conformance checkers must report at least one parse error condition to the user if one or more parse error conditions exist in the document and must not report parse error conditions if none exist in the document. Conformance checkers may report more than one parse error condition if more than one parse error condition exists in the document.

Parse errors are only errors with the syntax of HTML. In addition to checking for parse errors, conformance checkers will also verify that the document obeys all the other conformance requirements described in this specification.

Some parse errors have dedicated codes outlined in the table below that should be used by conformance checkers in reports.

*Error descriptions in the table below are non-normative.*
<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abrupt-closing-of-empty-comment</td>
<td>This error occurs if the parser encounters an empty comment that is abruptly closed by a U+003E (&gt;) code point (i.e., &lt;!-- or &lt;!--&gt;-&gt;). The parser behaves as if the comment is closed correctly.</td>
</tr>
<tr>
<td>abrupt-doctype-public-identifier</td>
<td>This error occurs if the parser encounters a U+003E (&gt;) code point in the DOCTYPE public identifier (e.g., &lt;!--DOCTYPE html PUBLIC &quot;foo&quot;&gt;). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document to quirks mode.</td>
</tr>
<tr>
<td>abrupt-doctype-system-identifier</td>
<td>This error occurs if the parser encounters a U+003E (&gt;) code point in the DOCTYPE system identifier (e.g., &lt;!--DOCTYPE html PUBLIC &quot;-//W3C//DTD HTML 4.01//EN&quot; &quot;foo&quot;&gt;). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document to quirks mode.</td>
</tr>
<tr>
<td>absence-of-digits-in-numeric-character-reference</td>
<td>This error occurs if the parser encounters a numeric character reference that doesn’t contain any digits (e.g., &amp;x;). In this case the parser doesn’t resolve the character reference.</td>
</tr>
<tr>
<td>cdata-in-html-content</td>
<td>This error occurs if the parser encounters a CDATA section outside of foreign content (SVG or MathML). The parser treats such CDATA sections (including leading &quot;[CDATA[&quot; and trailing &quot;]&quot;]&quot; strings) as comments.</td>
</tr>
<tr>
<td>character-reference-outside-unicode-range</td>
<td>This error occurs if the parser encounters a numeric character reference that references a code point that is greater than the valid Unicode range. The parser resolves such a character reference to a U+FFFD REPLACEMENT CHARACTER.</td>
</tr>
<tr>
<td>control-character-in-input-stream</td>
<td>This error occurs if the input stream contains a control code point that is not ASCII whitespace or U+0000 NULL. Such code points are parsed as-is and usually, where parsing rules don’t apply any additional restrictions, make their way into the DOM.</td>
</tr>
<tr>
<td>control-character-reference</td>
<td>This error occurs if the parser encounters a numeric character reference that references a control code point that is not ASCII whitespace or is a U+000D CARRIAGE RETURN. The parser resolves such character references as-is except C1 control references that are replaced according to the numeric character reference end state.</td>
</tr>
<tr>
<td>end-tag-with-attributes</td>
<td>This error occurs if the parser encounters an end tag with attributes. Attributes in end tags are ignored and do not make their way into the DOM.</td>
</tr>
<tr>
<td>duplicate-attribute</td>
<td>This error occurs if the parser encounters an attribute in a tag that already has an attribute with the same name. The parser ignores all such duplicate</td>
</tr>
<tr>
<td>Code</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>end-tag-with-trailing-solidus</code></td>
<td>This error occurs if the parser encounters an end tag that has a U+002F (/) code point right before the closing U+003E (&gt;) code point (e.g., <code>&lt;/div/&gt;</code>). Such a tag is treated as a regular end tag.</td>
</tr>
<tr>
<td><code>eof-before-tag-name</code></td>
<td>This error occurs if the parser encounters the end of the input stream where a tag name is expected. In this case the parser treats the beginning of a start tag (i.e., <code>&lt;</code>) or an end tag (i.e., <code>&lt;/</code>) as text content.</td>
</tr>
<tr>
<td><code>eof-in-cdata</code></td>
<td>This error occurs if the parser encounters the end of the input stream in a CDATA section. The parser treats such CDATA sections as if they are closed immediately before the end of the input stream.</td>
</tr>
<tr>
<td><code>eof-in-comment</code></td>
<td>This error occurs if the parser encounters the end of the input stream in a comment. The parser treats such comments as if they are closed immediately before the end of the input stream.</td>
</tr>
<tr>
<td><code>eof-in-doctype</code></td>
<td>This error occurs if the parser encounters the end of the input stream in a DOCTYPE. In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document to quirks mode.</td>
</tr>
<tr>
<td><code>eof-in-script-html-comment-like-text</code></td>
<td>Syntactic structures that resemble HTML comments in script elements are parsed as text content. They can be a part of a scripting language-specific syntactic structure or be treated as an HTML-like comment, if the scripting language supports them (e.g., parsing rules for HTML-like comments can be found in Annex B of the JavaScript specification). The common reason for this error is a violation of the restrictions for contents of script elements. [JAVASCRIPT]</td>
</tr>
<tr>
<td><code>eof-in-tag</code></td>
<td>This error occurs if the parser encounters the end of the input stream in a start tag or an end tag (e.g., <code>&lt;/div id=</code>). Such a tag is ignored.</td>
</tr>
<tr>
<td><code>incorrectly-closed-comment</code></td>
<td>This error occurs if the parser encounters a comment that is closed by the &quot;--&quot; code point sequence. The parser treats such comments as if they are correctly closed by the &quot;- &gt;&quot; code point sequence.</td>
</tr>
</tbody>
</table>
| `incorrectly-opened-comment` | This error occurs if the parser encounters the "<!" code point sequence that is not immediately followed by two U+002D (-) code points and that is not the start of a DOCTYPE or a CDATA section. All content that follows the "<!" code
invalid-character-sequence-after-doctype-name

This error occurs if the parser encounters any code point sequence other than “PUBLIC” and “SYSTEM” keywords after a DOCTYPE name. In such a case, the parser ignores any following public or system identifiers, and if the DOCTYPE is correctly placed as a document preamble, and if the parser cannot change the mode flag is false, sets the Document to quirks mode.

invalid-first-character-of-tag-name

This error occurs if the parser encounters a code point that is not an ASCII alpha where first code point of a start tag name or an end tag name is expected. If a start tag was expected such code point and a preceding U+003C (<) is treated as text content, and all content that follows is treated as markup. Whereas, if an end tag was expected, such code point and all content that follows up to a U+003E (>) code point (if present) or to the end of the input stream is treated as a comment.

For example, consider the following markup:

invalid-first-character-of-tag-name

<42></42>

This will be parsed into:

- html
  - head
  - body
    - #text: <42>
    - #comment: 42

missing-attribute-value

This error occurs if the parser encounters a U+003E (>) code point where an attribute value is expected (e.g., <div id=>). The parser treats the attribute as having an empty value.

missing-doctype-name

This error occurs if the parser encounters a DOCTYPE that is missing a name (e.g., <!DOCTYPE>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document to quirks mode.

missing-doctype-name

This error occurs if the parser encounters a U+003E (>) code point where start
<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>public-identifier</td>
<td>of the <strong>DOCTYPE</strong> public identifier is expected (e.g., <code>&lt;!DOCTYPE html PUBLIC &gt;</code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the <strong>Document</strong> to <strong>quirks mode</strong>.</td>
</tr>
<tr>
<td>missing-doctype-system-identifier</td>
<td>This error occurs if the parser encounters a <code>U+003E (&gt;)</code> code point where start of the <strong>DOCTYPE</strong> system identifier is expected (e.g., <code>&lt;!DOCTYPE html SYSTEM &gt;</code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the <strong>Document</strong> to <strong>quirks mode</strong>.</td>
</tr>
<tr>
<td>missing-end-tag-name</td>
<td>This error occurs if the parser encounters a <code>U+003E (&gt;)</code> code point where an <strong>end tag</strong> name is expected, i.e., <code>&lt;/&gt;</code>. The parser ignores the whole <code>&quot;/&gt;&quot;</code> code point sequence.</td>
</tr>
<tr>
<td>missing-quote-before-doctype-public-identifier</td>
<td>This error occurs if the parser encounters the <strong>DOCTYPE</strong> public identifier that is not preceded by a quote (e.g., <code>&lt;!DOCTYPE html PUBLIC -//W3C//DTD HTML 4.01//EN&quot;&gt;</code>). In such a case, the parser ignores the public identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the <strong>Document</strong> to <strong>quirks mode</strong>.</td>
</tr>
<tr>
<td>missing-quote-before-doctype-system-identifier</td>
<td>This error occurs if the parser encounters the <strong>DOCTYPE</strong> system identifier that is not preceded by a quote (e.g., <code>&lt;!DOCTYPE html SYSTEM http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd&quot;&gt;</code>). In such a case, the parser ignores the system identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the <strong>Document</strong> to <strong>quirks mode</strong>.</td>
</tr>
<tr>
<td>missing-semicolon-after-character-reference</td>
<td>This error occurs if the parser encounters a <strong>character reference</strong> that is not terminated by a <code>U+003B (;)</code> code point. Usually the parser behaves as if character reference is terminated by the <code>U+003B (;)</code> code point; however, there are some ambiguous cases in which the parser includes subsequent code points in the character reference. For example, <code>&amp;not;in</code> will be parsed as <code>&quot;¬in&quot;</code> whereas <code>&amp;notin</code> will be parsed as <code>&quot;∉&quot;</code>.</td>
</tr>
<tr>
<td>missing-whitespace-after-doctype-public-keyword</td>
<td>This error occurs if the parser encounters a <strong>DOCTYPE</strong> whose <strong>&quot;PUBLIC&quot;</strong> keyword and public identifier are not separated by <strong>ASCII whitespace</strong>. In this case the parser behaves as if ASCII whitespace is present.</td>
</tr>
<tr>
<td>missing-whitespace-after-doctype-system-keyword</td>
<td>This error occurs if the parser encounters a <strong>DOCTYPE</strong> whose <strong>&quot;SYSTEM&quot;</strong> keyword and system identifier are not separated by <strong>ASCII whitespace</strong>. In this case the parser behaves as if ASCII whitespace is present.</td>
</tr>
</tbody>
</table>
This error occurs if the parser encounters a DOCTYPE whose "DOCTYPE" keyword and name are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.

This error occurs if the parser encounters attributes that are not separated by ASCII whitespace (e.g., <div id="foo"class="bar">). In this case the parser behaves as if ASCII whitespace is present.

This error occurs if the parser encounters a DOCTYPE whose public and system identifiers are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.

This error occurs if the parser encounters a nested comment (e.g., <!-- <!-- nested --> -->). Such a comment will be closed by the first occurring "-->") code point sequence and everything that follows will be treated as markup.

This error occurs if the parser encounters a numeric character reference that references a noncharacter. The parser resolves such character references as-is.

This error occurs if the input stream contains a noncharacter. Such code points are parsed as-is and usually, where parsing rules don’t apply any additional restrictions, make their way into the DOM.

This error occurs if the parser encounters a start tag for an element that is not in the list of void elements or is not a part of foreign content (i.e., not an SVG or MathML element) that has a U+002F (/) code point right before the closing U+003E (>) code point. The parser behaves as if the U+002F (/) is not present.

For example, consider the following markup:

```html
<div/><span></span><span></span></span>
```

This will be parsed into:

- `html`
  - `head`
  - `body`
    - `div`
    - `span`
<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>null-character-reference</td>
<td>This error occurs if the parser encounters a numeric character reference that references a U+0000 NULL code point. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.</td>
</tr>
<tr>
<td>surrogate-character-reference</td>
<td>This error occurs if the parser encounters a numeric character reference that references a surrogate. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.</td>
</tr>
<tr>
<td>surrogate-in-input-stream</td>
<td>Surrogates can only find their way into the input stream via script APIs such as document.write().</td>
</tr>
<tr>
<td>unexpected-character-after-doctype-system-identifier</td>
<td>This error occurs if the parser encounters any code points other than ASCII whitespace or closing U+003E (&gt;) after the DOCTYPE system identifier. The parser ignores these code points.</td>
</tr>
<tr>
<td>unexpected-character-in-attribute-name</td>
<td>This error occurs if the parser encounters a U+0022 (&quot;), U+0027 (‘), or U+003C (&lt;) code point in an attribute name. The parser includes such code points in the attribute name.</td>
</tr>
<tr>
<td>For example, consider the following markup:</td>
<td>Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute name.</td>
</tr>
<tr>
<td>&lt;div foo&lt;div&gt;</td>
<td>Due to a forgotten U+003E (&gt;) code point after foo the parser treats this markup as a single div element with a “foo&lt;div” attribute.</td>
</tr>
<tr>
<td>As another example of this error, consider the following markup:</td>
<td></td>
</tr>
<tr>
<td>&lt;div id='bar'&gt;</td>
<td></td>
</tr>
</tbody>
</table>
Due to a forgotten U+003D (=) code point between an attribute name and value the parser treats this markup as a `div` element with the attribute "id'bar'" that has an empty value.

This error occurs if the parser encounters a U+0022 ("), U+0027 ('), U+003C (<), U+003D (=), or U+0060 ('`) code point in an unquoted attribute value. The parser includes such code points in the attribute value.

Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute value.

U+0060 ('`) is in the list of code points that trigger this error because certain legacy user agents treat it as a quote.

For example, consider the following markup:

```html
<div foo="b'ar'">
```

Due to a misplaced U+0027 ('') code point the parser sets the value of the "foo" attribute to "b'ar".

This error occurs if the parser encounters a U+003D (=) code point before an attribute name. In this case the parser treats U+003D (=) as the first code point of the attribute name.

The common reason for this error is a forgotten attribute name.

For example, consider the following markup:

```html
<div foo="bar" ="baz">
```

Due to a forgotten attribute name the parser treats this markup as a `div` element with two attributes: a "foo" attribute with a "bar" value and a "=""baz" attribute with an empty value.

This error occurs if the parser encounters a U+0000 NULL code point in the input stream in certain positions. In general, such code points are either ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER.

This error occurs if the parser encounters a U+003F (?) code point where first code point of a start tag name is expected. The U+003F (?) and all content that follows up to a U+003E (>) code point (if present) or to the end of the input stream is treated as a comment.
For example, consider the following markup:

```xml
<?xml-stylesheet type="text/css" href="style.css"?>
```

This will be parsed into:

- `#comment`: `<?xml-stylesheet type="text/css" href="style.css"?>`
- `html`
  - `head`
  - `body`

The common reason for this error is an XML processing instruction (e.g., `<?xml-stylesheet type="text/css" href="style.css"?>`) or an XML declaration (e.g., `<?xml version="1.0" encoding="UTF-8"?>`) being used in HTML.

- **unexpected-solidus-in-tag**: This error occurs if the parser encounters a U+002F (/) code point that is not a part of a quoted attribute value and not immediately followed by a U+003E (>) code point in a tag (e.g., `<div / id="foo">`). In this case the parser behaves as if it encountered ASCII whitespace.

- **unknown-named-character-reference**: This error occurs if the parser encounters an ambiguous ampersand. In this case the parser doesn’t resolve the character reference.

### 13.2.3 The input byte stream

The stream of code points that comprises the input to the tokenization stage will be initially seen by the user agent as a stream of bytes (typically coming over the network or from the local file system). The bytes encode the actual characters according to a particular character encoding, which the user agent uses to decode the bytes into characters.

For XML documents, the algorithm user agents are required to use to determine the character encoding is given by XML. This section does not apply to XML documents. [XML]

Usually, the [encoding sniffing algorithm](#) defined below is used to determine the character encoding.

Given a character encoding, the bytes in the input byte stream must be converted to characters for the tokenizer’s input stream, by passing the input byte stream and character encoding to decode.

A leading Byte Order Mark (BOM) causes the character encoding argument to be ignored and will itself be skipped.
Bytes or sequences of bytes in the original byte stream that did not conform to the Encoding standard (e.g. invalid UTF-8 byte sequences in a UTF-8 input byte stream) are errors that conformance checkers are expected to report.

The decoder algorithms describe how to handle invalid input; for security reasons, it is imperative that those rules be followed precisely. Differences in how invalid byte sequences are handled can result in, amongst other problems, script injection vulnerabilities (“XSS”).

When the HTML parser is decoding an input byte stream, it uses a character encoding and a confidence. The confidence is either tentative, certain, or irrelevant. The encoding used, and whether the confidence in that encoding is tentative or certain, is used during the parsing to determine whether to change the encoding. If no encoding is necessary, e.g. because the parser is operating on a Unicode stream and doesn’t have to use a character encoding at all, then the confidence is irrelevant.

Some algorithms feed the parser by directly adding characters to the input stream rather than adding bytes to the input byte stream.

### 13.2.3.1 Parsing with a known character encoding

When the HTML parser is to operate on an input byte stream that has a known definite encoding, then the character encoding is that encoding and the confidence is certain.

### 13.2.3.2 Determining the character encoding

In some cases, it might be impractical to unambiguously determine the encoding before parsing the document. Because of this, this specification provides for a two-pass mechanism with an optional pre-scan. Implementations are allowed, as described below, to apply a simplified parsing algorithm to whatever bytes they have available before beginning to parse the document. Then, the real parser is started, using a tentative encoding derived from this pre-parse and other out-of-band metadata. If, while the document is being loaded, the user agent discovers a character encoding declaration that conflicts with this information, then the parser can get reinvoked to perform a parse of the document with the real encoding.

User agents must use the following algorithm, called the encoding sniffing algorithm, to determine the character encoding to use when decoding a document in the first pass. This algorithm takes as input any out-of-band metadata available to the user agent (e.g. the Content-Type metadata of the document) and all the bytes available so far, and returns a character encoding and a confidence that is either tentative or certain.

1. If the result of BOM sniffing is an encoding, return that encoding with confidence certain.

   Although the decode algorithm will itself change the encoding to use based on the presence of a byte order mark, this algorithm sniffs the BOM as well in order to set the correct document’s character encoding and confidence.
2. If the user has explicitly instructed the user agent to override the document’s character encoding with a specific encoding, optionally return that encoding with the confidence certain.

Typically, user agents remember such user requests across sessions, and in some cases apply them to documents in iframes as well.

3. The user agent may wait for more bytes of the resource to be available, either in this step or at any later step in this algorithm. For instance, a user agent might wait 500ms or 1024 bytes, whichever came first. In general preparsing the source to find the encoding improves performance, as it reduces the need to throw away the data structures used when parsing upon finding the encoding information. However, if the user agent delays too long to obtain data to determine the encoding, then the cost of the delay could outweigh any performance improvements from the preparse.

The authoring conformance requirements for character encoding declarations limit them to only appearing in the first 1024 bytes. User agents are therefore encouraged to use the prescan algorithm below (as invoked by these steps) on the first 1024 bytes, but not to stall beyond that.

4. If the transport layer specifies a character encoding, and it is supported, return that encoding with the confidence certain.

5. Optionally prescan the byte stream to determine its encoding, with the end condition being when the user agent decides that scanning further bytes would not be efficient. User agents are encouraged to only prescan the first 1024 bytes. User agents may decide that scanning any bytes is not efficient, in which case these substeps are entirely skipped.

The aforementioned algorithm returns either a character encoding or failure. If it returns a character encoding, then return the same encoding, with confidence tentative.

6. If the HTML parser for which this algorithm is being run is associated with a Document d whose browsing context is non-null and a child browsing context, then:

   1. Let parentDocument be d’s browsing context’s container document.

   2. If parentDocument’s origin is same origin with d’s origin and parentDocument’s character encoding is not UTF-16BE/LE, then return parentDocument’s character encoding, with the confidence tentative.

7. Otherwise, if the user agent has information on the likely encoding for this page, e.g. based on the encoding of the page when it was last visited, then return that encoding, with the confidence tentative.

8. The user agent may attempt to autodetect the character encoding from applying frequency analysis or other algorithms to the data stream. Such algorithms may use information about the resource other than the resource’s contents, including the address
of the resource. If autodetection succeeds in determining a character encoding, and that encoding is a supported encoding, then return that encoding, with the confidence tentative. [UNIVCHARDET]

User agents are generally discouraged from attempting to autodetect encodings for resources obtained over the network, since doing so involves inherently non-interoperable heuristics. Attempting to detect encodings based on an HTML document’s preamble is especially tricky since HTML markup typically uses only ASCII characters, and HTML documents tend to begin with a lot of markup rather than with text content.

The UTF-8 encoding has a highly detectable bit pattern. Files from the local file system that contain bytes with values greater than 0x7F which match the UTF-8 pattern are very likely to be UTF-8, while documents with byte sequences that do not match it are very likely not. When a user agent can examine the whole file, rather than just the preamble, detecting for UTF-8 specifically can be especially effective. [PPUTF8] [UTF8DET]

9. Otherwise, return an implementation-defined or user-specified default character encoding, with the confidence tentative.

In controlled environments or in environments where the encoding of documents can be prescribed (for example, for user agents intended for dedicated use in new networks), the comprehensive UTF-8 encoding is suggested.

In other environments, the default encoding is typically dependent on the user’s locale (an approximation of the languages, and thus often encodings, of the pages that the user is likely to frequent). The following table gives suggested defaults based on the user’s locale, for compatibility with legacy content. Locales are identified by BCP 47 language tags. [BCP47] [ENCODING]

The contents of this table are derived from the intersection of Windows, Chrome, and Firefox defaults.

The **document’s character encoding** must immediately be set to the value returned from this algorithm, at the same time as the user agent uses the returned value to select the decoder to use for the input byte stream.

When an algorithm requires a user agent to *prescan a byte stream to determine its encoding*, given some defined *end condition*, then it must run the following steps. If at any point during these steps (including during instances of the *get an attribute* algorithm invoked by this one) the user agent either runs out of bytes (meaning the *position* pointer created in the first step below goes beyond the end of the byte stream obtained so far) or reaches its *end condition*, then abort the *prescan a byte stream to determine its encoding* algorithm and return the result *get an XML encoding* applied to the same bytes that the *prescan a byte stream to determine its encoding* algorithm was applied to. Otherwise, these steps will return a character encoding.

1. Let *fallback encoding* be null.

2. Let *position* be a pointer to a byte in the input byte stream, initially pointing at the first byte.

3. Prescan for UTF-16 XML declarations: If *position* points to:

   A sequence of bytes starting with: 0x3C, 0x0, 0x3F, 0x0, 0x78, 0x0 (case-sensitive
UTF-16 little-endian ‘<?x’

Return UTF-16LE.

A sequence of bytes starting with: 0x0, 0x3C, 0x0, 0x3F, 0x0, 0x78 (case-sensitive UTF-16 big-endian ‘<?x’)

Return UTF-16BE.

For historical reasons, the prefix is two bytes longer than in Appendix F of XML and the encoding name is not checked.

4. Loop: If position points to:

A sequence of bytes starting with: 0x3C 0x21 0x2D 0x2D (`A sequence of bytes starting with: 0x3C 0x21 0x2D 0x2D (`

Advance the position pointer so that it points at the first 0x3E byte which is preceded by two 0x2D bytes (i.e. at the end of an ASCII ‘--’ sequence) and comes after the 0x3C byte that was found. (The two 0x2D bytes can be the same as those in the ‘<!--’ sequence.)

A sequence of bytes starting with: 0x3C, 0x4D or 0x6D, 0x45 or 0x65, 0x54 or 0x74, 0x41 or 0x61, and one of 0x09, 0x0A, 0x0C, 0x0D, 0x20, 0x2F (case-insensitive ASCII ‘<meta’ followed by a space or slash)

1. Advance the position pointer so that it points at the next 0x09, 0x0A, 0x0C, 0x0D, 0x20, or 0x2F byte (the one in sequence of characters matched above).

2. Let attribute list be an empty list of strings.

3. Let got pragma be false.

4. Let need pragma be null.

5. Let charset be the null value (which, for the purposes of this algorithm, is distinct from an unrecognized encoding or the empty string).

6. Attributes: Get an attribute and its value. If no attribute was sniffed, then jump to the processing step below.

7. If the attribute’s name is already in attribute list, then return to the step labeled attributes.

8. Add the attribute’s name to attribute list.

9. Run the appropriate step from the following list, if one applies:
If the attribute's name is "http-equiv"

If the attribute's value is "content-type", then set got pragma to true.

If the attribute's name is "content"

Apply the algorithm for extracting a character encoding from a meta element, giving the attribute's value as the string to parse. If a character encoding is returned, and if charset is still set to null, let charset be the encoding returned, and set need pragma to true.

If the attribute's name is "charset"

Let charset be the result of getting an encoding from the attribute's value, and set need pragma to false.

10. Return to the step labeled attributes.

11. Processing: If need pragma is null, then jump to the step below labeled next byte.

12. If need pragma is true but got pragma is false, then jump to the step below labeled next byte.

13. If charset is failure, then jump to the step below labeled next byte.

14. If charset is UTF-16BE/LE, then set charset to UTF-8.

15. If charset is x-user-defined, then set charset to windows-1252.

16. Return charset.

A sequence of bytes starting with a 0x3C byte (<), optionally a 0x2F byte (/), and finally a byte in the range 0x41-0x5A or 0x61-0x7A (A-Z or a-z)

1. Advance the position pointer so that it points at the next 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (>) byte.

2. Repeatedly get an attribute until no further attributes can be found, then jump to the step below labeled next byte.

A sequence of bytes starting with: 0x3C 0x21 (<!)
A sequence of bytes starting with: 0x3C 0x2F (</)
A sequence of bytes starting with: 0x3C 0x3F (<?)

Advance the position pointer so that it points at the first 0x3E byte (>) that comes after the 0x3C byte that was found.
Any other byte

Do nothing with that byte.

5. **Next byte**: Move *position* so it points at the next byte in the input byte stream, and return to the step above labeled *loop*.

When the **prescan a byte stream to determine its encoding** algorithm says to **get an attribute**, it means doing this:

1. If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x2F (/) then advance *position* to the next byte and redo this step.

2. If the byte at *position* is 0x3E (>), then abort the **get an attribute** algorithm. There isn’t one.

3. Otherwise, the byte at *position* is the start of the attribute name. Let *attribute name* and *attribute value* be the empty string.

4. Process the byte at *position* as follows:

   - **If it is 0x3D (=)**, and the *attribute name* is longer than the empty string
     Advance *position* to the next byte and jump to the step below labeled *value*.

   - **If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP)**
     Jump to the step below labeled *spaces*.

   - **If it is 0x2F (/) or 0x3E (>)**
     Abort the **get an attribute** algorithm. The attribute’s name is the value of *attribute name*, its value is the empty string.

   - **If it is in the range 0x41 (A) to 0x5A (Z)**
     Append the code point \( b + 0x20 \) to *attribute name* (where \( b \) is the value of the byte at *position*). (This converts the input to lowercase.)

   - **Anything else**
     Append the code point with the same value as the byte at *position* to *attribute name*. (It doesn’t actually matter how bytes outside the ASCII range are handled here, since only ASCII bytes can contribute to the detection of a character encoding.)

5. Advance *position* to the next byte and return to the previous step.

6. **Spaces**: If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance *position* to the next byte, then, repeat this step.

7. If the byte at *position* is **not** 0x3D (=), abort the **get an attribute** algorithm. The attribute’s name is the value of *attribute name*, its value is the empty string.
8. Advance position past the 0x3D (=) byte.

9. **Value**: If the byte at position is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance position to the next byte, then, repeat this step.

10. Process the byte at position as follows:

    **If it is 0x22 (") or 0x27 (’)**
    1. Let \( b \) be the value of the byte at position.
    2. **Quote loop**: Advance position to the next byte.
    3. If the value of the byte at position is the value of \( b \), then advance position to the next byte and abort the “get an attribute” algorithm. The attribute’s name is the value of attribute name, and its value is the value of attribute value.
    4. Otherwise, if the value of the byte at position is in the range 0x41 (A) to 0x5A (Z), then append a code point to attribute value whose value is 0x20 more than the value of the byte at position.
    5. Otherwise, append a code point to attribute value whose value is the same as the value of the byte at position.
    6. Return to the step above labeled quote loop.

    **If it is 0x3E (>)**
    Abort the get an attribute algorithm. The attribute’s name is the value of attribute name, its value is the empty string.

    **If it is in the range 0x41 (A) to 0x5A (Z)**
    Append a code point \( b + 0x20 \) to attribute value (where \( b \) is the value of the byte at position). Advance position to the next byte.

    **Anything else**
    Append a code point with the same value as the byte at position to attribute value.
    Advance position to the next byte.

11. Process the byte at position as follows:

    **If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (>)**
    Abort the get an attribute algorithm. The attribute’s name is the value of attribute name and its value is the value of attribute value.

    **If it is in the range 0x41 (A) to 0x5A (Z)**
    Append a code point \( b + 0x20 \) to attribute value (where \( b \) is the value of the byte at position).

    **Anything else**
    Append a code point with the same value as the byte at position to attribute value.

12. Advance position to the next byte and return to the previous step.
When the prescan a byte stream to determine its encoding algorithm is aborted without returning an encoding, get an XML encoding means doing this.

Looking for syntax resembling an XML declaration, even in text/html, is necessary for compatibility with existing content.

1. Let encodingPosition be a pointer to the start of the stream.

2. If encodingPosition does not point to the start of a byte sequence 0x3C, 0x3F, 0x78, 0x6D, 0x6C (`<?xml`), then return failure.

3. Let xmlDeclarationEnd be a pointer to the next byte in the input byte stream which is 0x3E (>). If there is no such byte, then return failure.

4. Set encodingPosition to the position of the first occurrence of the subsequence of bytes 0x65, 0x6E, 0x63, 0x6F, 0x64, 0x69, 0x6E, 0x67 (`encoding`) at or after the current encodingPosition. If there is no such sequence, then return failure.

5. Advance encodingPosition past the 0x67 (g) byte.

6. While the byte at encodingPosition is less than or equal to 0x20 (i.e., it is either an ASCII space or control character), advance encodingPosition to the next byte.

7. If the byte at encodingPosition is not 0x3D (=), then return failure.

8. Advance encodingPosition to the next byte.

9. While the byte at encodingPosition is less than or equal to 0x20 (i.e., it is either an ASCII space or control character), advance encodingPosition to the next byte.

10. Let quoteMark be the byte at encodingPosition.

11. If quoteMark is not either 0x22 (”) or 0x27 (‘), then return failure.

12. Advance encodingPosition to the next byte.

13. Let encodingEndPosition be the position of the next occurrence of quoteMark at or after encodingPosition. If quoteMark does not occur again, then return failure.

14. Let potentialEncoding be the sequence of the bytes between encodingPosition (inclusive) and encodingEndPosition (exclusive).

15. If potentialEncoding contains one or more bytes whose byte value is 0x20 or below, then return failure.

16. Let encoding be the result of getting an encoding given potentialEncoding isomorphic decoded.
17. If the encoding is UTF-16BE/LE, then change it to UTF-8.

18. Return encoding.

For the sake of interoperability, user agents should not use a pre-scan algorithm that returns different results than the one described above. (But, if you do, please at least let us know, so that we can improve this algorithm and benefit everyone...)

13.2.3.3 Character encodings

The above prohibits supporting, for example, CESU-8, UTF-7, BOCU-1, SCSU, EBCDIC, and UTF-32. This specification does not make any attempt to support prohibited encodings in its algorithms; support and use of prohibited encodings would thus lead to unexpected behavior.

13.2.3.4 Changing the encoding while parsing

When the parser requires the user agent to change the encoding, it must run the following steps. This might happen if the encoding sniffing algorithm described above failed to find a character encoding, or if it found a character encoding that was not the actual encoding of the file.

1. If the encoding that is already being used to interpret the input stream is UTF-16BE/LE, then set the confidence to certain and return. The new encoding is ignored; if it was anything but the same encoding, then it would be clearly incorrect.

2. If the new encoding is UTF-16BE/LE, then change it to UTF-8.

3. If the new encoding is x-user-defined, then change it to windows-1252.

4. If the new encoding is identical or equivalent to the encoding that is already being used to interpret the input stream, then set the confidence to certain and return. This happens when the encoding information found in the file matches what the encoding sniffing algorithm determined to be the encoding, and in the second pass through the parser if the first pass found that the encoding sniffing algorithm described in the earlier section failed to find the right encoding.

5. If all the bytes up to the last byte converted by the current decoder have the same Unicode interpretations in both the current encoding and the new encoding, and if the user agent supports changing the converter on the fly, then the user agent may change to the new converter for the encoding on the fly. Set the document’s character encoding
and the encoding used to convert the input stream to the new encoding, set the confidence to certain, and return.

6. Otherwise, navigate to the document again, with historyHandling set to "replace", and using the same source browsing context, but this time skip the encoding sniffing algorithm and instead just set the encoding to the new encoding and the confidence to certain. Whenever possible, this should be done without actually contacting the network layer (the bytes should be re-parsed from memory), even if, e.g., the document is marked as not being cacheable. If this is not possible and contacting the network layer would involve repeating a request that uses a method other than 'GET', then instead set the confidence to certain and ignore the new encoding. The resource will be misinterpreted. User agents may notify the user of the situation, to aid in application development.

This algorithm is only invoked when a new encoding is found declared on a meta element.

13.2.3.5 Preprocessing the input stream

The input stream consists of the characters pushed into it as the input byte stream is decoded or from the various APIs that directly manipulate the input stream.

Any occurrences of surrogates are surrogate-in-input-stream parse errors. Any occurrences of noncharacters are noncharacter-in-input-stream parse errors and any occurrences of controls other than ASCII whitespace and U+0000 NULL characters are control-character-in-input-stream parse errors.

The handling of U+0000 NULL characters varies based on where the characters are found and happens at the later stages of the parsing. They are either ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER. This handling is, by necessity, spread across both the tokenization stage and the tree construction stage.

Before the tokenization stage, the input stream must be preprocessed by normalizing newlines. Thus, newlines in HTML DOMs are represented by U+000A LF characters, and there are never any U+000D CR characters in the input to the tokenization stage.

The next input character is the first character in the input stream that has not yet been consumed or explicitly ignored by the requirements in this section. Initially, the next input character is the first character in the input. The current input character is the last character to have been consumed.

The insertion point is the position (just before a character or just before the end of the input stream) where content inserted using document.write() is actually inserted. The insertion point is relative to the position of the character immediately after it, it is not an absolute offset into the input stream. Initially, the insertion point is undefined.

The "EOF" character in the tables below is a conceptual character representing the end of the input stream. If the parser is a script-created parser, then the end of the input stream is reached.
when an explicit "EOF" character (inserted by the `document.close()` method) is consumed. Otherwise, the "EOF" character is not a real character in the stream, but rather the lack of any further characters.

### 13.2.4 Parse state

#### 13.2.4.1 The insertion mode

The *insertion mode* is a state variable that controls the primary operation of the tree construction stage.

Initially, the insertion mode is "initial". It can change to "before html", "before head", "in head", "in head noscript", "after head", "in body", "text", "in table", "in table text", "in caption", "in column group", "in table body", "in row", "in cell", "in select", "in select in table", "in template", "after body", "in frameset", "after frameset", "after after body", and "after after frameset" during the course of the parsing, as described in the tree construction stage. The insertion mode affects how tokens are processed and whether CDATA sections are supported.

Several of these modes, namely "in head", "in body", "in table", and "in select", are special, in that the other modes defer to them at various times. When the algorithm below says that the user agent is to do something "using the rules for the m insertion mode", where m is one of these modes, the user agent must use the rules described under the m insertion mode's section, but must leave the insertion mode unchanged unless the rules in m themselves switch the insertion mode to a new value.

When the insertion mode is switched to "text" or "in table text", the original insertion mode is also set. This is the insertion mode to which the tree construction stage will return.

Similarly, to parse nested `template` elements, a *stack of template insertion modes* is used. It is initially empty. The current template insertion mode is the insertion mode that was most recently added to the stack of template insertion modes. The algorithms in the sections below will push insertion modes onto this stack, meaning that the specified insertion mode is to be added to the stack, and pop insertion modes from the stack, which means that the most recently added insertion mode must be removed from the stack.

---

When the steps below require the UA to *reset the insertion mode appropriately*, it means the UA must follow these steps:

1. Let `last` be false.

2. Let `node` be the last node in the stack of open elements.

3. **Loop:** If `node` is the first node in the stack of open elements, then set `last` to true, and, if the parser was created as part of the HTML fragment parsing algorithm (fragment case), set `node` to the context element passed to that algorithm.
4. If `node` is a `select` element, run these substeps:

   1. If `last` is true, jump to the step below labeled `done`.
   2. Let `ancestor` be `node`.
   3. **Loop**: If `ancestor` is the first node in the **stack of open elements**, jump to the step below labeled `done`.
   4. Let `ancestor` be the node before `ancestor` in the **stack of open elements**.
   5. If `ancestor` is a `template` node, jump to the step below labeled `done`.
   6. If `ancestor` is a `table` node, switch the **insertion mode** to “in select in table” and return.
   7. Jump back to the step labeled `loop`.
   8. **Done**: Switch the **insertion mode** to ”in select” and return.

5. If `node` is a `td` or `th` element and `last` is false, then switch the **insertion mode** to ”in cell” and return.

6. If `node` is a `tr` element, then switch the **insertion mode** to ”in row” and return.

7. If `node` is a `tbody`, `thead`, or `tfoot` element, then switch the **insertion mode** to ”in table body” and return.

8. If `node` is a `caption` element, then switch the **insertion mode** to ”in caption” and return.

9. If `node` is a `colgroup` element, then switch the **insertion mode** to ”in column group” and return.

10. If `node` is a `table` element, then switch the **insertion mode** to ”in table” and return.

11. If `node` is a `template` element, then switch the **insertion mode** to the current template **insertion mode** and return.

12. If `node` is a `head` element and `last` is false, then switch the **insertion mode** to ”in head” and return.

13. If `node` is a `body` element, then switch the **insertion mode** to ”in body” and return.

14. If `node` is a `frameset` element, then switch the **insertion mode** to ”in frameset” and return. (fragment case)

15. If `node` is an `html` element, run these substeps:
1. If the **head element pointer** is null, switch the **insertion mode** to "before head" and return. (fragment case)

2. Otherwise, the **head element pointer** is not null, switch the **insertion mode** to "after head" and return.

16. If *last* is true, then switch the **insertion mode** to "in body" and return. (fragment case)

17. Let *node* now be the node before *node* in the **stack of open elements**.

18. Return to the step labeled *loop*.

### 13.2.4.2 The stack of open elements

Initially, the *stack of open elements* is empty. The stack grows downwards; the topmost node on the stack is the first one added to the stack, and the bottommost node of the stack is the most recently added node in the stack (notwithstanding when the stack is manipulated in a random access fashion as part of the handling for misnested tags).

The "before html" **insertion mode** creates the **html document element**, which is then added to the stack.

In the fragment case, the *stack of open elements* is initialized to contain an **html element** that is created as part of that algorithm. (The fragment case skips the "before html" **insertion mode**.)

The **html node**, however it is created, is the topmost node of the stack. It only gets popped off the stack when the parser **finishes**.

The **current node** is the bottommost node in this **stack of open elements**.

The **adjusted current node** is the **context element** if the parser was created as part of the HTML fragment parsing algorithm and the **stack of open elements** has only one element in it (fragment case); otherwise, the adjusted current node is the current node.

Elements in the **stack of open elements** fall into the following categories:

**Special**

MathML annotation-xml; and SVG foreignObject, SVG desc, and SVG title.

An image start tag token is handled by the tree builder, but it is not in this list because it is not an element; it gets turned into an img element.

**Formatting**

The following HTML elements are those that end up in the list of active formatting elements: a, b, big, code, em, font, i, nobr, s, small, strike, strong, tt, and u.

**Ordinary**

All other elements found while parsing an HTML document.

Typically, the special elements have the start and end tag tokens handled specifically, while ordinary elements’ tokens fall into “any other start tag” and “any other end tag” clauses, and some parts of the tree builder check if a particular element in the stack of open elements is in the special category. However, some elements (e.g., the option element) have their start or end tag tokens handled specifically, but are still not in the special category, so that they get the ordinary handling elsewhere.

The stack of open elements is said to have an element target node in a specific scope consisting of a list of element types list when the following algorithm terminates in a match state:

1. Initialize node to be the current node (the bottommost node of the stack).
2. If node is the target node, terminate in a match state.
3. Otherwise, if node is one of the element types in list, terminate in a failure state.
4. Otherwise, set node to the previous entry in the stack of open elements and return to step 2. (This will never fail, since the loop will always terminate in the previous step if the top of the stack — an html element — is reached.)

The stack of open elements is said to have a particular element in scope when it has that element in the specific scope consisting of the following element types:

- applet
- caption
- html
- table
- td
- th
- marquee
- object
- template
- MathML mi
The stack of open elements is said to have a particular element in list item scope when it has that element in the specific scope consisting of the following element types:

- All the element types listed above for the has an element in scope algorithm.
- `ol` in the HTML namespace
- `ul` in the HTML namespace

The stack of open elements is said to have a particular element in button scope when it has that element in the specific scope consisting of the following element types:

- All the element types listed above for the has an element in scope algorithm.
- `button` in the HTML namespace

The stack of open elements is said to have a particular element in table scope when it has that element in the specific scope consisting of the following element types:

- `html` in the HTML namespace
- `table` in the HTML namespace
- `template` in the HTML namespace

The stack of open elements is said to have a particular element in select scope when it has that element in the specific scope consisting of all element types except the following:

- `optgroup` in the HTML namespace
- `option` in the HTML namespace

Nothing happens if at any time any of the elements in the stack of open elements are moved to a new location in, or removed from, the Document tree. In particular, the stack is not changed in this situation. This can cause, amongst other strange effects, content to be appended to nodes that are no longer in the DOM.

In some cases (namely, when closing misnested formatting elements), the stack is manipulated in a random-access fashion.

### 13.2.4.3 The list of active formatting elements

Initially, the list of active formatting elements is empty. It is used to handle mis-nested formatting element tags.
The list contains elements in the formatting category, and markers. The markers are inserted when entering applet, object, marquee, template, td, th, and caption elements, and are used to prevent formatting from "leaking" into applet, object, marquee, template, td, th, and caption elements.

In addition, each element in the list of active formatting elements is associated with the token for which it was created, so that further elements can be created for that token if necessary.

When the steps below require the UA to push onto the list of active formatting elements an element element, the UA must perform the following steps:

1. If there are already three elements in the list of active formatting elements after the last marker, if any, or anywhere in the list if there are no markers, that have the same tag name, namespace, and attributes as element, then remove the earliest such element from the list of active formatting elements. For these purposes, the attributes must be compared as they were when the elements were created by the parser; two elements have the same attributes if all their parsed attributes can be paired such that the two attributes in each pair have identical names, namespaces, and values (the order of the attributes does not matter).

   This is the Noah’s Ark clause. But with three per family instead of two.

2. Add element to the list of active formatting elements.

When the steps below require the UA to reconstruct the active formatting elements, the UA must perform the following steps:

1. If there are no entries in the list of active formatting elements, then there is nothing to reconstruct; stop this algorithm.

2. If the last (most recently added) entry in the list of active formatting elements is a marker, or if it is an element that is in the stack of open elements, then there is nothing to reconstruct; stop this algorithm.

3. Let entry be the last (most recently added) element in the list of active formatting elements.

4. Rewind: If there are no entries before entry in the list of active formatting elements, then jump to the step labeled create.

5. Let entry be the entry one earlier than entry in the list of active formatting elements.

6. If entry is neither a marker nor an element that is also in the stack of open elements, go to the step labeled rewind.

7. Advance: Let entry be the element one later than entry in the list of active formatting elements.
8. Create: Insert an HTML element for the token for which the element entry was created, to obtain new element.

9. Replace the entry for entry in the list with an entry for new element.

10. If the entry for new element in the list of active formatting elements is not the last entry in the list, return to the step labeled advance.

This has the effect of reopening all the formatting elements that were opened in the current body, cell, or caption (whichever is youngest) that haven’t been explicitly closed.

The way this specification is written, the list of active formatting elements always consists of elements in chronological order with the least recently added element first and the most recently added element last (except for while steps 7 to 10 of the above algorithm are being executed, of course).

When the steps below require the UA to clear the list of active formatting elements up to the last marker, the UA must perform the following steps:

1. Let entry be the last (most recently added) entry in the list of active formatting elements.

2. Remove entry from the list of active formatting elements.

3. If entry was a marker, then stop the algorithm at this point. The list has been cleared up to the last marker.

4. Go to step 1.

13.2.4.4 The element pointers

Initially, the head element pointer and the form element pointer are both null.

Once a head element has been parsed (whether implicitly or explicitly) the head element pointer gets set to point to this node.

The form element pointer points to the last form element that was opened and whose end tag has not yet been seen. It is used to make form controls associate with forms in the face of dramatically bad markup, for historical reasons. It is ignored inside template elements.

13.2.4.5 Other parsing state flags

The scripting flag is set to "enabled" if scripting was enabled for the Document with which the parser is associated when the parser was created, and "disabled" otherwise.

The scripting flag can be enabled even when the parser was created as part of the HTML fragment parsing algorithm, even though script elements don’t execute in that case.
The *frameset-ok flag* is set to "ok" when the parser is created. It is set to "not ok" after certain tokens are seen.

### 13.2.5 Tokenization

Implementations must act as if they used the following state machine to tokenize HTML. The state machine must start in the *data state*. Most states consume a single character, which may have various side-effects, and either switches the state machine to a new state to *reconsume* the *current input character*, or switches it to a new state to consume the *next character*, or stays in the same state to consume the next character. Some states have more complicated behavior and can consume several characters before switching to another state. In some cases, the tokenizer state is also changed by the tree construction stage.

When a state says to *reconsume* a matched character in a specified state, that means to switch to that state, but when it attempts to consume the *next input character*, provide it with the *current input character* instead.

The exact behavior of certain states depends on the *insertion mode* and the *stack of open elements*. Certain states also use a *temporary buffer* to track progress, and the *character reference state* uses a *return state* to return to the state it was invoked from.

The output of the tokenization step is a series of zero or more of the following tokens: DOCTYPE, start tag, end tag, comment, character, end-of-file. DOCTYPE tokens have a name, a public identifier, a system identifier, and a *force-quirks flag*. When a DOCTYPE token is created, its name, public identifier, and system identifier must be marked as missing (which is a distinct state from the empty string), and the *force-quirks flag* must be set to *off* (its other state is *on*). Start and end tag tokens have a tag name, a *self-closing flag*, and a list of attributes, each of which has a name and a value. When a start or end tag token is created, its *self-closing flag* must be unset (its other state is that it be set), and its attributes list must be empty. Comment and character tokens have data.

When a token is emitted, it must immediately be handled by the *tree construction stage*. The tree construction stage can affect the state of the tokenization stage, and can insert additional characters into the stream. (For example, the *script* element can result in scripts executing and using the *dynamic markup insertion* APIs to insert characters into the stream being tokenized.)

Creating a token and emitting it are distinct actions. It is possible for a token to be created but implicitly abandoned (never emitted), e.g. if the file ends unexpectedly while processing the characters that are being parsed into a start tag token.

When a start tag token is emitted with its *self-closing flag* set, if the flag is not *acknowledged* when it is processed by the tree construction stage, that is a *non-void-html-element-start-tag-with-trailing-solidus parse error*.

When an end tag token is emitted with attributes, that is an *end-tag-with-attributes parse error*. 
When an end tag token is emitted with its `self-closing flag` set, that is an `end-tag-with-trailing-solidus parse error`.

An appropriate end tag token is an end tag token whose tag name matches the tag name of the last start tag to have been emitted from this tokenizer, if any. If no start tag has been emitted from this tokenizer, then no end tag token is appropriate.

A character reference is said to be consumed as part of an attribute if the `return state` is either attribute value (double-quoted) state, attribute value (single-quoted) state or attribute value (unquoted) state.

When a state says to flush code points consumed as a character reference, it means that for each code point in the temporary buffer (in the order they were added to the buffer) user agent must append the code point from the buffer to the current attribute’s value if the character reference was consumed as part of an attribute, or emit the code point as a character token otherwise.

Before each step of the tokenizer, the user agent must first check the `parser pause flag`. If it is true, then the tokenizer must abort the processing of any nested invocations of the tokenizer, yielding control back to the caller.

The tokenizer state machine consists of the states defined in the following subsections.

13.2.5.1 **Data state**

Consume the next input character:

U+0026 AMPERSAND (&)
  Set the `return state` to the `data state`. Switch to the `character reference state`.

U+003C LESS- THAN SIGN (<)
  Switch to the `tag open state`.

U+0000 NULL
  This is an unexpected-null-character parse error. Emit the `current input character` as a character token.

EOF
  Emit an end-of-file token.

Anything else
  Emit the `current input character` as a character token.

13.2.5.2 **RCDATA state**

Consume the next input character:
U+0026 AMPERSAND (&)
   Set the return state to the RCDATA state. Switch to the character reference state.

U+003C LESS-THEAN SIGN (<)
   Switch to the RCDATA less-than sign state.

U+0000 NULL
   This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

EOF
   Emit an end-of-file token.

Anything else
   Emit the current input character as a character token.

13.2.5.3 RAWTEXT state

Consume the next input character:

U+003C LESS-THEAN SIGN (<)
   Switch to the RAWTEXT less-than sign state.

U+0000 NULL
   This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

EOF
   Emit an end-of-file token.

Anything else
   Emit the current input character as a character token.

13.2.5.4 Script data state

Consume the next input character:

U+003C LESS-THEAN SIGN (<)
   Switch to the script data less-than sign state.

U+0000 NULL
   This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

EOF
   Emit an end-of-file token.

Anything else
   Emit the current input character as a character token.
13.2.5.5 PLAINTEXT state

Consume the next input character:

U+0000 NULL
   This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

EOF
   Emit an end-of-file token.

Anything else
   Emit the current input character as a character token.

13.2.5.6 Tag open state

Consume the next input character:

U+0021 EXCLAMATION MARK (!)
   Switch to the markup declaration open state.

U+002F SOLIDUS (/)
   Switch to the end tag open state.

ASCII alpha
   Create a new start tag token, set its tag name to the empty string. Reconsume in the tag name state.

U+003F QUESTION MARK (?)
   This is an unexpected-question-mark-instead-of-tag-name parse error. Create a comment token whose data is the empty string. Reconsume in the bogus comment state.

EOF
   This is an eof-before-tag-name parse error. Emit a U+003C LESS-Tahn SIGN character token and an end-of-file token.

Anything else
   This is an invalid-first-character-of-tag-name parse error. Emit a U+003C LESS-Tahn SIGN character token. Reconsume in the data state.

13.2.5.7 End tag open state

Consume the next input character:

ASCII alpha
   Create a new end tag token, set its tag name to the empty string. Reconsume in the tag name state.
This is a missing-end-tag-name parse error. Switch to the data state.

This is an eof-before-tag-name parse error. Emit a U+003C LESS-TAN SIGN character token, a U+002F SOLIDUS character token and an end-of-file token.

This is an invalid-first-character-of-tag-name parse error. Create a comment token whose data is the empty string. Reconsume in the bogus comment state.

13.2.5.8 Tag name state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE

Switch to the before attribute name state.

U+002F SOLIDUS (/)

Switch to the self-closing start tag state.

U+003E GREATER-TAN SIGN (>

Switch to the data state. Emit the current tag token.

ASCII upper alpha

Append the lowercase version of the current input character (add 0x020 to the character’s code point) to the current tag token’s tag name.

U+0000 NULL

This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current tag token’s tag name.

EOF

This is an eof-in-tag parse error. Emit an end-of-file token.

Anything else

Append the current input character to the current tag token’s tag name.

13.2.5.9 RCDATA less-than sign state

Consume the next input character:

U+002F SOLIDUS (/)

Set the temporary buffer to the empty string. Switch to the RCDATA end tag open state.
Anything else
   Emit a U+003C LESS-THAN SIGN character token. Reconsume in the RCDATA state.

13.2.5.10 RCDATA end tag open state

Consume the next input character:

ASCII alpha
   Create a new end tag token, set its tag name to the empty string. Reconsume in the
   RCDATA end tag name state.

Anything else
   Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character
   token. Reconsume in the RCDATA state.

13.2.5.11 RCDATA end tag name state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
   If the current end tag token is an appropriate end tag token, then switch to the before
   attribute name state. Otherwise, treat it as per the ”anything else” entry below.

U+002F SOLIDUS (/)
   If the current end tag token is an appropriate end tag token, then switch to the self-closing
   start tag state. Otherwise, treat it as per the ”anything else” entry below.

U+003E GREATER-THAN SIGN (>)
   If the current end tag token is an appropriate end tag token, then switch to the data state
   and emit the current tag token. Otherwise, treat it as per the ”anything else” entry below.

ASCII upper alpha
   Append the lowercase version of the current input character (add 0x0020 to the character’s
   code point) to the current tag token’s tag name. Append the current input character to the
   temporary buffer.

ASCII lower alpha
   Append the current input character to the current tag token’s tag name. Append the
   current input character to the temporary buffer.

Anything else
   Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token,
   and a character token for each of the characters in the temporary buffer (in the order they
   were added to the buffer). Reconsume in the RCDATA state.
13.2.5.12 RAWTEXT less-than sign state

Consume the next input character:

U+002F SOLIDUS (/)
    Set the temporary buffer to the empty string. Switch to the RAWTEXT end tag open state.

Anything else
    Emit a U+003C LESS-THAN SIGN character token. Reconsume in the RAWTEXT state.

13.2.5.13 RAWTEXT end tag open state

Consume the next input character:

ASCII alpha
    Create a new end tag token, set its tag name to the empty string. Reconsume in the RAWTEXT end tag name state.

Anything else
    Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Reconsume in the RAWTEXT state.

13.2.5.14 RAWTEXT end tag name state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
    If the current end tag token is an appropriate end tag token, then switch to the before attribute name state. Otherwise, treat it as per the "anything else" entry below.

U+002F SOLIDUS (/)
    If the current end tag token is an appropriate end tag token, then switch to the self-closing start tag state. Otherwise, treat it as per the "anything else" entry below.

U+003E GREATER-THAN SIGN (>)
    If the current end tag token is an appropriate end tag token, then switch to the data state and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

ASCII upper alpha
    Append the lowercase version of the current input character (add 0x0020 to the character’s code point) to the current tag token’s tag name. Append the current input character to the temporary buffer.

ASCII lower alpha
    Append the current input character to the current tag token’s tag name. Append the
current input character to the temporary buffer.

Anything else
  Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the temporary buffer (in the order they were added to the buffer). Reconsume in the RAWTEXT state.

13.2.5.15 Script data less-than sign state

Consume the next input character:

U+002F SOLIDUS (/)
  Set the temporary buffer to the empty string. Switch to the script data end tag open state.

U+0021 EXCLAMATION MARK (!)
  Switch to the script data escape start state. Emit a U+003C LESS-THAN SIGN character token and a U+0021 EXCLAMATION MARK character token.

Anything else
  Emit a U+003C LESS-THAN SIGN character token. Reconsume in the script data state.

13.2.5.16 Script data end tag open state

Consume the next input character:

ASCII alpha
  Create a new end tag token, set its tag name to the empty string. Reconsume in the script data end tag name state.

Anything else
  Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Reconsume in the script data state.

13.2.5.17 Script data end tag name state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
  If the current end tag token is an appropriate end tag token, then switch to the before attribute name state. Otherwise, treat it as per the "anything else" entry below.

U+002F SOLIDUS (/)
  If the current end tag token is an appropriate end tag token, then switch to the self-closing start tag state. Otherwise, treat it as per the "anything else" entry below.
U+003E GREATER-THAN SIGN (>)
If the current end tag token is an appropriate end tag token, then switch to the data state and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

ASCII upper alpha
Append the lowercase version of the current input character (add 0x0020 to the character’s code point) to the current tag token’s tag name. Append the current input character to the temporary buffer.

ASCII lower alpha
Append the current input character to the current tag token’s tag name. Append the current input character to the temporary buffer.

Anything else
Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the temporary buffer (in the order they were added to the buffer). Reconsume in the script data state.

13.2.5.18 Script data escape start state
Consume the next input character:
U+002D HYPHEN-MINUS (-)
Switch to the script data escape start dash state. Emit a U+002D HYPHEN-MINUS character token.

Anything else
Reconsume in the script data state.

13.2.5.19 Script data escape start dash state
Consume the next input character:
U+002D HYPHEN-MINUS (-)
Switch to the script data escaped dash dash state. Emit a U+002D HYPHEN-MINUS character token.

Anything else
Reconsume in the script data state.

13.2.5.20 Script data escaped state
Consume the next input character:
U+002D HYPHEN-MINUS (-)
Switch to the script data escaped dash state. Emit a U+002D HYPHEN-MINUS character token.
U+003C LESS-THAN SIGN (<)  
Switch to the script data escaped less-than sign state.

U+0000 NULL  
This is an unexpected-null-character parse error. Emit a U+FFFD REPLACEMENT CHARACTER character token.

EOF  
This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

Anything else  
Emit the current input character as a character token.

13.2.5.21 Script data escaped dash state

Consume the next input character:

U+002D HYPHEN-MINUS (-)  
Switch to the script data escaped dash dash state. Emit a U+002D HYPHEN-MINUS character token.

U+003C LESS-THAN SIGN (<)  
Switch to the script data escaped less-than sign state.

U+0000 NULL  
This is an unexpected-null-character parse error. Switch to the script data escaped state. Emit a U+FFFD REPLACEMENT CHARACTER character token.

EOF  
This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

Anything else  
Switch to the script data escaped state. Emit the current input character as a character token.

13.2.5.22 Script data escaped dash dash state

Consume the next input character:

U+002D HYPHEN-MINUS (-)  
Emit a U+002D HYPHEN-MINUS character token.

U+003C LESS-THAN SIGN (<)  
Switch to the script data escaped less-than sign state.

U+003E GREATER-THAN SIGN (>)  
Switch to the script data state. Emit a U+003E GREATER-THAN SIGN character token.
This is an unexpected-null-character parse error. Switch to the script data escaped state. Emit a U+FFFD REPLACEMENT CHARACTER character token.

EOF

This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

Anything else

Switch to the script data escaped state. Emit the current input character as a character token.

13.2.5.23 Script data escaped less-than sign state

Consume the next input character:

U+002F SOLIDUS (/)

Set the temporary buffer to the empty string. Switch to the script data escaped end tag open state.

ASCII alpha

Set the temporary buffer to the empty string. Emit a U+003C LESS-THEL SIGN character token. Recomsume in the script data double escape start state.

Anything else

 Emit a U+003C LESS-THEL SIGN character token. Recomsume in the script data escaped state.

13.2.5.24 Script data escaped end tag open state

Consume the next input character:

ASCII alpha

Create a new end tag token, set its tag name to the empty string. Recomsume in the script data escaped end tag name state.

Anything else

 Emit a U+003C LESS-THEL SIGN character token and a U+002F SOLIDUS character token. Recomsume in the script data escaped state.

13.2.5.25 Script data escaped end tag name state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE

If the current end tag token is an appropriate end tag token, then switch to the before
attribute name state. Otherwise, treat it as per the "anything else" entry below.

U+002F SOLIDUS (/)
If the current end tag token is an appropriate end tag token, then switch to the self-closing start tag state. Otherwise, treat it as per the "anything else" entry below.

U+003E GREATER-THEAN SIGN (>)
If the current end tag token is an appropriate end tag token, then switch to the data state and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

**ASCII upper alpha**
Append the lowercase version of the current input character (add 0x0020 to the character’s code point) to the current tag token’s tag name. Append the current input character to the temporary buffer.

**ASCII lower alpha**
Append the current input character to the current tag token’s tag name. Append the current input character to the temporary buffer.

Anything else
Emit a U+003C LESS-THEAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the temporary buffer (in the order they were added to the buffer). Reconsume in the script data escaped state.

13.2.5.26 Script data double escape start state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
U+002F SOLIDUS (/)
U+003E GREATER-THEAN SIGN (>)
If the temporary buffer is the string "script", then switch to the script data double escaped state. Otherwise, switch to the script data escaped state. Emit the current input character as a character token.

**ASCII upper alpha**
Append the lowercase version of the current input character (add 0x0020 to the character’s code point) to the temporary buffer. Emit the current input character as a character token.

**ASCII lower alpha**
Append the current input character to the temporary buffer. Emit the current input character as a character token.

Anything else
Reconsume in the script data escaped state.
13.2.5.27 *Script data double escaped state*

Consume the **next input character**:

**U+002D HYPHEN-MINUS (-)**

Switch to the **script data double escaped dash state**. Emit a U+002D HYPHEN-MINUS character token.

**U+003C LESS-THEAN SIGN (<)**

Switch to the **script data double escaped less-than sign state**. Emit a U+003C LESS-THEAN SIGN character token.

**U+0000 NULL**

This is an **unexpected-null-character parse error**. Emit a U+FFFD REPLACEMENT CHARACTER character token.

**EOF**

This is an **eof-in-script-html-comment-like-text parse error**. Emit an end-of-file token.

Anything else

Emit the **current input character** as a character token.

13.2.5.28 *Script data double escaped dash state*

Consume the **next input character**:

**U+002D HYPHEN-MINUS (-)**

Switch to the **script data double escaped dash dash state**. Emit a U+002D HYPHEN-MINUS character token.

**U+003C LESS-THEAN SIGN (<)**

Switch to the **script data double escaped less-than sign state**. Emit a U+003C LESS-THEAN SIGN character token.

**U+0000 NULL**

This is an **unexpected-null-character parse error**. Switch to the **script data double escaped state**. Emit a U+FFFD REPLACEMENT CHARACTER character token.

**EOF**

This is an **eof-in-script-html-comment-like-text parse error**. Emit an end-of-file token.

Anything else

Switch to the **script data double escaped state**. Emit the **current input character** as a character token.

13.2.5.29 *Script data double escaped dash dash state*

Consume the **next input character**:
U+002D HYPHEN-MINUS (-)
   Emit a U+002D HYPHEN-MINUS character token.

U+003C LESS-THEAN SIGN (<)
   Switch to the script data double escaped less-than sign state. Emit a U+003C LESS-THEAN SIGN character token.

U+003E GREATER-THEAN SIGN (>)
   Switch to the script data state. Emit a U+003E GREATER-THEAN SIGN character token.

U+0000 NULL
   This is an unexpected-null-character parse error. Switch to the script data double escaped state. Emit a U+FFFD REPLACEMENT CHARACTER character token.

EOF
   This is an eof-in-script-html-comment-like-text parse error. Emit an end-of-file token.

Anything else
   Switch to the script data double escaped state. Emit the current input character as a character token.

13.2.5.30 Script data double escaped less-than sign state

Consume the next input character:

U+002F SOLIDUS (/)
   Set the temporary buffer to the empty string. Switch to the script data double escape end state. Emit a U+002F SOLIDUS character token.

Anything else
   Reconsume in the script data double escaped state.

13.2.5.31 Script data double escape end state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
U+002F SOLIDUS (/)
U+003E GREATER-THEAN SIGN (>
   If the temporary buffer is the string "script", then switch to the script data escaped state. Otherwise, switch to the script data double escaped state. Emit the current input character as a character token.

ASCII upper alpha
   Append the lowercase version of the current input character (add 0x0020 to the character’s
code point) to the temporary buffer. Emit the current input character as a character token.

**ASCII lower alpha**
Append the current input character to the temporary buffer. Emit the current input character as a character token.

Anything else
Reconsume in the script data double escaped state.

13.2.5.32 Before attribute name state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
  Ignore the character.

U+002F SOLIDUS (/)
U+003E GREATER-THAN SIGN (>)
EOF
  Reconsume in the after attribute name state.

U+003D EQUALS SIGN (=)
  This is an unexpected-equals-sign-before-attribute-name parse error. Start a new attribute in the current tag token. Set that attribute’s name to the current input character, and its value to the empty string. Switch to the attribute name state.

Anything else
  Start a new attribute in the current tag token. Set that attribute name and value to the empty string. Reconsume in the attribute name state.

13.2.5.33 Attribute name state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
U+002F SOLIDUS (/)
U+003E GREATER-THAN SIGN (>)
EOF
  Reconsume in the after attribute name state.

U+003D EQUALS SIGN (=)
  Switch to the before attribute value state.
ASCII upper alpha

Append the lowercase version of the current input character (add 0x0020 to the character’s code point) to the current attribute’s name.

U+0000 NULL

This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute’s name.

U+0022 QUOTATION MARK ("")
U+0027 APOSTROPHE (’)
U+003C LESS-THAN SIGN (<)

This is an unexpected-character-in-attribute-name parse error. Treat it as per the "anything else" entry below.

Anything else

Append the current input character to the current attribute’s name.

When the user agent leaves the attribute name state (and before emitting the tag token, if appropriate), the complete attribute’s name must be compared to the other attributes on the same token; if there is already an attribute on the token with the exact same name, then this is a duplicate-attribute parse error and the new attribute must be removed from the token.

If an attribute is so removed from a token, it, and the value that gets associated with it, if any, are never subsequently used by the parser, and are therefore effectively discarded. Removing the attribute in this way does not change its status as the "current attribute" for the purposes of the tokenizer, however.

13.2.5.34 After attribute name state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE

Ignore the character.

U+002F SOLIDUS (/)

Switch to the self-closing start tag state.

U+003D EQUALS SIGN (=)

Switch to the before attribute value state.

U+003E GREATER-THAN SIGN (>

Switch to the data state. Emit the current tag token.

EOF

This is an eof-in-tag parse error. Emit an end-of-file token.
Anything else
   Start a new attribute in the current tag token. Set that attribute name and value to the empty string. **Reconsume** in the attribute name state.

13.2.5.35 Before attribute value state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
   Ignore the character.

U+0022 QUOTATION MARK (")
   Switch to the attribute value (double-quoted) state.

U+0027 APOSTROPHE (’)
   Switch to the attribute value (single-quoted) state.

U+003E GREATER-THAN SIGN (>)
   This is a missing-attribute-value parse error. Switch to the data state. Emit the current tag token.

Anything else
   **Reconsume** in the attribute value (unquoted) state.

13.2.5.36 Attribute value (double-quoted) state

Consume the next input character:

U+0022 QUOTATION MARK (")
   Switch to the after attribute value (quoted) state.

U+0026 AMPERSAND (&)
   Set the return state to the attribute value (double-quoted) state. Switch to the character reference state.

U+0000 NULL
   This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute’s value.

EOF
   This is an eof-in-tag parse error. Emit an end-of-file token.

Anything else
   Append the current input character to the current attribute’s value.
13.2.5.37 Attribute value (single-quoted) state

Consume the **next input character**:

U+0027 APOSTROPHE (’)
Switch to the **after attribute value (quoted) state**.

U+0026 AMPERSAND (&)
Set the **return state** to the **attribute value (quoted) state**. Switch to the **character reference state**.

U+0000 NULL
This is an **unexpected-null-character parse error**. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute’s value.

**EOF**
This is an **eof-in-tag parse error**. Emit an end-of-file token.

**Anything else**
Append the **current input character** to the current attribute’s value.

13.2.5.38 Attribute value (unquoted) state

Consume the **next input character**:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
Switch to the **before attribute name state**.

U+0026 AMPERSAND (&)
Set the **return state** to the **attribute value (unquoted) state**. Switch to the **character reference state**.

U+003E GREATER-THAN SIGN (>)
Switch to the **data state**. Emit the current tag token.

U+0000 NULL
This is an **unexpected-null-character parse error**. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute’s value.

U+0022 QUOTATION MARK (")
U+0027 APOSTROPHE (’)
U+003C LESS-THAN SIGN (<)
U+003D EQUALS SIGN (=)
U+0060 GRAVE ACCENT (‘)
This is an **unexpected-character-in-unquoted-attribute-value parse error**. Treat it as per
the “anything else” entry below.

EOF
   This is an [eof-in-tag parse error](#). Emit an end-of-file token.

Anything else
   Append the [current input character](#) to the current attribute’s value.

13.2.5.39 *After attribute value (quoted) state*

Consume the [next input character](#):

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
   Switch to the [before attribute name state](#).

U+002F SOLIDUS (/)
   Switch to the [self-closing start tag state](#).

U+003E GREATER-THEAN SIGN (>)
   Switch to the [data state](#). Emit the current tag token.

EOF
   This is an [eof-in-tag parse error](#). Emit an end-of-file token.

Anything else
   This is a [missing-whitespace-between-attributes parse error](#). Reconsume in the [before attribute name state](#).

13.2.5.40 *Self-closing start tag state*

Consume the [next input character](#):

U+003E GREATER-THEN SIGN (>)
   Set the [self-closing flag](#) of the current tag token. Switch to the [data state](#). Emit the current tag token.

EOF
   This is an [eof-in-tag parse error](#). Emit an end-of-file token.

Anything else
   This is an [unexpected-solidus-in-tag parse error](#). Reconsume in the [before attribute name state](#).
13.2.5.41 *Bogus comment state*

Consume the [next input character](#): 

U+003E GREATER-THEAN SIGN (>)
   
Switch to the [data state](#). Emit the current comment token.

**EOF**

Emit the comment. Emit an end-of-file token.

U+0000 NULL
   
This is an [unexpected-null-character parse error](#). Append a U+FFFD REPLACEMENT CHARACTER character to the comment token’s data.

Anything else
   
Append the [current input character](#) to the comment token’s data.

13.2.5.42 *Markup declaration open state*

If the next few characters are:

Two U+002D HYPHEN-MINUS characters (-)
   
Consume those two characters, create a comment token whose data is the empty string, and switch to the [comment start state](#).

ASCII case-insensitive match for the word "DOCTYPE"
   
Consume those characters and switch to the [DOCTYPE state](#).

The string "[CDATA[" (the five uppercase letters "CDATA" with a U+005B LEFT SQUARE BRACKET character before and after)
   
Consume those characters. If there is an [adjusted current node](#) and it is not an element in the HTML namespace, then switch to the [CDATA section state](#). Otherwise, this is a [cdata-in-html-content parse error](#). Create a comment token whose data is the "[CDATA[" string. Switch to the [bogus comment state](#).

Anything else
   
This is an [incorrectly-opened-comment parse error](#). Create a comment token whose data is the empty string. Switch to the [bogus comment state](#) (don’t consume anything in the current state).

13.2.5.43 *Comment start state*

Consume the [next input character](#):

U+002D HYPHEN-MINUS (-)
   
Switch to the [comment start dash state](#).
U+003E GREATER-THEAN SIGN (>)
This is an abrupt-closing-of-empty-comment parse error. Switch to the data state. Emit the current comment token.

Anything else
Reconsume in the comment state.

13.2.5.44 Comment start dash state

Consume the next input character:

U+0002D HYPHEN-MINUS (-)
Switch to the comment end state.

U+003E GREATER-THEAN SIGN (>)
This is an abrupt-closing-of-empty-comment parse error. Switch to the data state. Emit the current comment token.

EOF
This is an eof-in-comment parse error. Emit the current comment token. Emit an end-of-file token.

Anything else
Append a U+002D HYPHEN-MINUS character (-) to the comment token’s data. Reconsume in the comment state.

13.2.5.45 Comment state

Consume the next input character:

U+003C LESS-THEAN SIGN (<)
Append the current input character to the comment token’s data. Switch to the comment less-than sign state.

U+0002D HYPHEN-MINUS (-)
Switch to the comment end dash state.

U+0000 NULL
This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the comment token’s data.

EOF
This is an eof-in-comment parse error. Emit the current comment token. Emit an end-of-file token.

Anything else
Append the current input character to the comment token’s data.
13.2.5.46 Comment less-than sign state

Consume the next input character:

U+0021 EXCLAMATION MARK (!)
   Append the current input character to the comment token’s data. Switch to the comment less-than sign bang state.

U+003C LESS-THAN SIGN (<)
   Append the current input character to the comment token’s data.

Anything else
   Reconsume in the comment state.

13.2.5.47 Comment less-than sign bang state

Consume the next input character:

U+002D HYPHEN-MINUS (-)
   Switch to the comment less-than sign bang dash state.

Anything else
   Reconsume in the comment state.

13.2.5.48 Comment less-than sign bang dash state

Consume the next input character:

U+002D HYPHEN-MINUS (-)
   Switch to the comment less-than sign bang dash dash state.

Anything else
   Reconsume in the comment end dash state.

13.2.5.49 Comment less-than sign bang dash dash state

Consume the next input character:

U+003E GREATER-THAN SIGN (>)
EOF
   Reconsume in the comment end state.

Anything else
   This is a nested-comment parse error. Reconsume in the comment end state.

13.2.5.50 Comment end dash state

Consume the next input character:
U+002D HYPHEN-MINUS (-)
Switch to the comment end state.

EOF
This is an eof-in-comment parse error. Emit the current comment token. Emit an end-of-file token.

Anything else
Append a U+002D HYPHEN-MINUS character (-) to the comment token’s data.
Reconsume in the comment state.

13.2.5.51 Comment end state

Consume the next input character:

U+003E GREATER-THAN SIGN (>)
Switch to the data state. Emit the current comment token.

U+0021 EXCLAMATION MARK (!)
Switch to the comment end bang state.

U+002D HYPHEN-MINUS (-)
Append a U+002D HYPHEN-MINUS character (-) to the comment token’s data.

EOF
This is an eof-in-comment parse error. Emit the current comment token. Emit an end-of-file token.

Anything else
Append two U+002D HYPHEN-MINUS characters (-) to the comment token’s data.
Reconsume in the comment state.

13.2.5.52 Comment end bang state

Consume the next input character:

U+002D HYPHEN-MINUS (-)
Append two U+002D HYPHEN-MINUS characters (-) and a U+0021 EXCLAMATION MARK character (!) to the comment token’s data. Switch to the comment end dash state.

U+003E GREATER-THAN SIGN (>)
This is an incorrectly-closed-comment parse error. Switch to the data state. Emit the current comment token.

EOF
This is an eof-in-comment parse error. Emit the current comment token. Emit an end-of-file token.
Append two `U+002D HYPHEN-MINUS` characters (`-`) and a `U+0021 EXCLAMATION MARK` character (`!`) to the comment token’s data. **Reconsume** in the **comment state**.

13.2.5.53 **DOCTYPE state**

Consume the **next input character**:

- `U+0009 CHARACTER TABULATION` (tab)
- `U+000A LINE FEED` (LF)
- `U+000C FORM FEED` (FF)
- `U+0020 SPACE`

  Switch to the **before DOCTYPE name state**.

**U+003E GREATER-THAN SIGN (`>`)**

  **Reconsume** in the **before DOCTYPE name state**.

**EOF**

  This is an **eof-in-doctype parse error**. Create a new DOCTYPE token. Set its **force-quirks flag** to on. Emit the current token. Emit an end-of-file token.

Anything else

  This is a **missing-whitespace-before-doctype-name parse error**. **Reconsume** in the **before DOCTYPE name state**.

13.2.5.54 **Before DOCTYPE name state**

Consume the **next input character**:

- `U+0009 CHARACTER TABULATION` (tab)
- `U+000A LINE FEED` (LF)
- `U+000C FORM FEED` (FF)
- `U+0020 SPACE`

  Ignore the character.

**ASCII upper alpha**

  Create a new DOCTYPE token. Set the token’s name to the lowercase version of the **current input character** (add `0x0020` to the character’s code point). Switch to the **DOCTYPE name state**.

**U+0000 NULL**

  This is an **unexpected-null-character parse error**. Create a new DOCTYPE token. Set the token’s name to a `U+FFFD REPLACEMENT CHARACTER` character. Switch to the **DOCTYPE name state**.

**U+003E GREATER-THAN SIGN (`>`)**

  This is a **missing-doctype-name parse error**. Create a new DOCTYPE token. Set its **force-quirks flag** to on. Switch to the **data state**. Emit the current token.
This is an **eof-in-doctype parse error**. Create a new DOCTYPE token. Set its **force-quirks flag** to *on*. Emit the current token. Emit an end-of-file token.

**Anything else**

Create a new DOCTYPE token. Set the token’s name to the **current input character**. Switch to the **DOCTYPE name state**.

13.2.5.55 **DOCTYPE name state**

Consume the **next input character**:

U+0009 CHARACTER TABULATION (tab)  
U+000A LINE FEED (LF)  
U+000C FORM FEED (FF)  
U+0020 SPACE  

Switch to the **after DOCTYPE name state**.

U+003E GREATER-THAN SIGN (>)  
Switch to the **data state**. Emit the current DOCTYPE token.

**ASCII upper alpha**

Append the lowercase version of the **current input character** (add 0x0020 to the character’s code point) to the current DOCTYPE token’s name.

U+0000 NULL  
This is an **unexpected-null-character parse error**. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token’s name.

**EOF**

This is an **eof-in-doctype parse error**. Set the current DOCTYPE token’s **force-quirks flag** to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

**Anything else**

Append the **current input character** to the current DOCTYPE token’s name.

13.2.5.56 **After DOCTYPE name state**

Consume the **next input character**:

U+0009 CHARACTER TABULATION (tab)  
U+000A LINE FEED (LF)  
U+000C FORM FEED (FF)  
U+0020 SPACE  

Ignore the character.

U+003E GREATER-THAN SIGN (>)  
Switch to the **data state**. Emit the current DOCTYPE token.
EOF

This is an **eof-in-doctype parse error**. Set the current DOCTYPE token’s *force-quirks flag* to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

**Anything else**

If the six characters starting from the current input character are an ASCII case-insensitive match for the word "PUBLIC", then consume those characters and switch to the after DOCTYPE public keyword state.

Otherwise, if the six characters starting from the current input character are an ASCII case-insensitive match for the word "SYSTEM", then consume those characters and switch to the after DOCTYPE system keyword state.

Otherwise, this is an **invalid-character-sequence-after-doctype-name parse error**. Set the current DOCTYPE token’s *force-quirks flag* to *on*. Reconsume in the *bogus DOCTYPE* state.

**13.2.5.57 After DOCTYPE public keyword state**

Consume the **next input character**:

U+0009 CHARACTER TABULATION (tab)  
U+000A LINE FEED (LF)  
U+0020 SPACE  
Switch to the before DOCTYPE public identifier state.

U+0022 QUOTATION MARK (")  
This is a **missing-whitespace-after-doctype-public-keyword parse error**. Set the current DOCTYPE token’s public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (double-quoted) state.

U+0027 APOSTROPHE (’)
This is a **missing-whitespace-after-doctype-public-keyword parse error**. Set the current DOCTYPE token’s public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (single-quoted) state.

U+003E GREATER-THAN SIGN (>)
This is a **missing-doctype-public-identifier parse error**. Set the current DOCTYPE token’s *force-quirks flag* to *on*. Switch to the *data state*. Emit the current DOCTYPE token.

EOF

This is an **eof-in-doctype parse error**. Set the current DOCTYPE token’s *force-quirks flag* to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

**Anything else**

This is a **missing-quote-before-doctype-public-identifier parse error**. Set the current
DOCTYPE token’s force-quirks flag to on. Reconsume in the bogus DOCTYPE state.

13.2.5.58 Before DOCTYPE public identifier state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
  Ignore the character.

U+0022 QUOTATION MARK (")
  Set the current DOCTYPE token’s public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (double-quoted) state.

U+0027 APOSTROPHE (’)
  Set the current DOCTYPE token’s public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (single-quoted) state.

U+003E GREATER-THAN SIGN (>)
  This is a missing-doctype-public-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Switch to the data state. Emit the current DOCTYPE token.

EOF
  This is an eof-in-doctype parse error. Set the current DOCTYPE token’s force-quirks flag to on. Emit the current DOCTYPE token. Emit an end-of-file token.

Anything else
  This is a missing-quote-before-doctype-public-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Reconsume in the bogus DOCTYPE state.

13.2.5.59 DOCTYPE public identifier (double-quoted) state

Consume the next input character:

U+0022 QUOTATION MARK (")
  Switch to the after DOCTYPE public identifier state.

U+0000 NULL
  This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token’s public identifier.

U+003E GREATER-THAN SIGN (>)
  This is an abrupt-doctype-public-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Switch to the data state. Emit the current DOCTYPE token.
This is an `eof-in-doctype parse error`. Set the current DOCTYPE token’s `force-quirks flag` to `on`. Emit the current DOCTYPE token. Emit an end-of-file token.

**Anything else**
Append the `current input character` to the current DOCTYPE token’s public identifier.

13.2.5.60 **DOCTYPE public identifier (single-quoted) state**

Consume the `next input character`:

U+0027 **APOSTROPHE (’)**
Switch to the `after DOCTYPE public identifier state`.

U+0000 **NULL**
This is an `unexpected-null-character parse error`. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token’s public identifier.

U+003E **GREATER-THEAN SIGN (>)**
This is an `abrupt-doctype-public-identifier parse error`. Set the current DOCTYPE token’s `force-quirks flag` to `on`. Switch to the `data state`. Emit the current DOCTYPE token.

**EOF**
This is an `eof-in-doctype parse error`. Set the current DOCTYPE token’s `force-quirks flag` to `on`. Emit the current DOCTYPE token. Emit an end-of-file token.

**Anything else**
Append the `current input character` to the current DOCTYPE token’s public identifier.

13.2.5.61 **After DOCTYPE public identifier state**

Consume the `next input character`:

U+0009 **CHARACTER TABULATION (tab)**
U+000A **LINE FEED (LF)**
U+000C **FORM FEED (FF)**
U+0020 **SPACE**
Switch to the `between DOCTYPE public and system identifiers state`.

U+003E **GREATER-THEAN SIGN (>)**
Switch to the `data state`. Emit the current DOCTYPE token.

U+0022 **QUOTATION MARK (”)**
This is a `missing-whitespace-between-doctype-public-and-system-identifiers parse error`. Set the current DOCTYPE token’s system identifier to the empty string (not missing), then switch to the `DOCTYPE system identifier (double-quoted) state`. 
This is a missing-whitespace-between-doctype-public-and-system-identifiers parse error. Set the current DOCTYPE token’s system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state.

EOF

This is an eof-in-doctype parse error. Set the current DOCTYPE token’s force-quirks flag to on. Emit the current DOCTYPE token. Emit an end-of-file token.

Anything else

This is a missing-quote-before-doctype-system-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Recomsume in the bogus DOCTYPE state.

13.2.5.62 Between DOCTYPE public and system identifiers state

Consume the next input character:

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE

Ignore the character.

U+003E GREATER-THAN SIGN (>)

Switch to the data state. Emit the current DOCTYPE token.

U+0022 QUOTATION MARK (”)

Set the current DOCTYPE token’s system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state.

U+0027 APOSTROPHE (‘)

Set the current DOCTYPE token’s system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state.

EOF

This is an eof-in-doctype parse error. Set the current DOCTYPE token’s force-quirks flag to on. Emit the current DOCTYPE token. Emit an end-of-file token.

Anything else

This is a missing-quote-before-doctype-system-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Recomsume in the bogus DOCTYPE state.

13.2.5.63 After DOCTYPE system keyword state

Consume the next input character:
Switch to the before DOCTYPE system identifier state.

This is a missing-whitespace-after-doctype-system-keyword parse error. Set the current DOCTYPE token’s system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state.

This is a missing-whitespace-after-doctype-system-keyword parse error. Set the current DOCTYPE token’s system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state.

This is a missing-doctype-system-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Switch to the data state. Emit the current DOCTYPE token.

This is an eof-in-doctype parse error. Set the current DOCTYPE token’s force-quirks flag to on. Emit the current DOCTYPE token. Emit an end-of-file token.

This is a missing-quote-before-doctype-system-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Reconsume in the bogus DOCTYPE state.

13.2.5.64 Before DOCTYPE system identifier state

Consume the next input character:

Ignore the character.

Set the current DOCTYPE token’s system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state.

Set the current DOCTYPE token’s system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state.

This is a missing-doctype-system-identifier parse error. Set the current DOCTYPE token’s
force-quirks flag to on. Switch to the data state. Emit the current DOCTYPE token.

EOF
This is an eof-in-doctype parse error. Set the current DOCTYPE token’s force-quirks flag to on. Emit the current DOCTYPE token. Emit an end-of-file token.

Anything else
This is a missing-quote-before-doctype-system-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Reconsume in the bogus DOCTYPE state.

13.2.5.65 DOCTYPE system identifier (double-quoted) state

Consume the next input character:

U+0022 QUOTATION MARK (‘)
Switch to the after DOCTYPE system identifier state.

U+0000 NULL
This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token’s system identifier.

U+003E GREATER-THEAN SIGN (>)
This is an abrupt-doctype-system-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Switch to the data state. Emit the current DOCTYPE token.

EOF
This is an eof-in-doctype parse error. Set the current DOCTYPE token’s force-quirks flag to on. Emit the current DOCTYPE token. Emit an end-of-file token.

Anything else
Append the current input character to the current DOCTYPE token’s system identifier.

13.2.5.66 DOCTYPE system identifier (single-quoted) state

Consume the next input character:

U+0027 APOSTROPHE (‘)
Switch to the after DOCTYPE system identifier state.

U+0000 NULL
This is an unexpected-null-character parse error. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token’s system identifier.

U+003E GREATER-THEAN SIGN (>)
This is an abrupt-doctype-system-identifier parse error. Set the current DOCTYPE token’s force-quirks flag to on. Switch to the data state. Emit the current DOCTYPE token.
EOF

This is an **eof-in-doctype parse error**. Set the current DOCTYPE token’s *force-quirks flag* to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

**Anything else**

Append the **current input character** to the current DOCTYPE token’s system identifier.

### 13.2.5.67 *After DOCTYPE system identifier state*

Consume the **next input character**:

- U+0009 CHARACTER TABULATION (tab)
- U+000A LINE FEED (LF)
- U+000C FORM FEED (FF)
- U+0020 SPACE
  
  Ignore the character.

- U+003E GREATER-THAN SIGN (>)
  
  Switch to the **data state**. Emit the current DOCTYPE token.

EOF

This is an **eof-in-doctype parse error**. Set the current DOCTYPE token’s *force-quirks flag* to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

**Anything else**

This is an **unexpected-character-after-doctype-system-identifier parse error**. Reconsume in the **bogus DOCTYPE state**. (This does *not* set the current DOCTYPE token’s *force-quirks flag* to *on*.)

### 13.2.5.68 *Bogus DOCTYPE state*

Consume the **next input character**:

- U+003E GREATER-THAN SIGN (>)
  
  Switch to the **data state**. Emit the DOCTYPE token.

- U+0000 NULL
  
  This is an **unexpected-null-character parse error**. Ignore the character.

EOF

Emit the DOCTYPE token. Emit an end-of-file token.

**Anything else**

Ignore the character.

### 13.2.5.69 *CDATA section state*

Consume the **next input character**:
Switch to the CDATA section bracket state.

This is an eof-in-cdata parse error. Emit an end-of-file token.

Anything else
Emit the current input character as a character token.

U+0000 NULL characters are handled in the tree construction stage, as part of the in foreign content insertion mode, which is the only place where CDATA sections can appear.

13.2.5.70 CDATA section bracket state

Consume the next input character:

Switch to the CDATA section end state.

Anything else
Emit a U+005D RIGHT SQUARE BRACKET character token. Reconsume in the CDATA section state.

13.2.5.71 CDATA section end state

Consume the next input character:

Emit a U+005D RIGHT SQUARE BRACKET character token.

Emit a U+003E GREATER-THAN SIGN character
Switch to the data state.

Anything else
Emit two U+005D RIGHT SQUARE BRACKET character tokens. Reconsume in the CDATA section state.

13.2.5.72 Character reference state

Set the temporary buffer to the empty string. Append a U+0026 AMPERSAND (&) character to the temporary buffer. Consume the next input character:

ASCII alphanumeric
Reconsume in the named character reference state.

U+0023 NUMBER SIGN (#)
Append the current input character to the temporary buffer. Switch to the numeric character reference state.
Anything else

Flush code points consumed as a character reference. Reconsume in the return state.

13.2.5.73 Named character reference state

Consume the maximum number of characters possible, where the consumed characters are one of the identifiers in the first column of the named character references table. Append each character to the temporary buffer when it’s consumed.

If there is a match

If the character reference was consumed as part of an attribute, and the last character matched is not a U+003B SEMICOLON character (;), and the next input character is either a U+003D EQUALS SIGN character (=) or an ASCII alphanumeric, then, for historical reasons, flush code points consumed as a character reference and switch to the return state.

Otherwise:

1. If the last character matched is not a U+003B SEMICOLON character (;), then this is a missing-semicolon-after-character-reference parse error.

2. Set the temporary buffer to the empty string. Append one or two characters corresponding to the character reference name (as given by the second column of the named character references table) to the temporary buffer.

3. Flush code points consumed as a character reference. Switch to the return state.

Otherwise

Flush code points consumed as a character reference. Switch to the ambiguous ampersand state.

If the markup contains (not in an attribute) the string I'm &notit; I tell you, the character reference is parsed as “not”, as in, I'm ¬it; I tell you (and this is a parse error). But if the markup was I'm &notin; I tell you, the character reference would be parsed as “notin;”, resulting in I'm € I tell you (and no parse error).

However, if the markup contains the string I'm &notit; I tell you in an attribute, no character reference is parsed and string remains intact (and there is no parse error).

13.2.5.74 Ambiguous ampersand state

Consume the next input character:

ASCII alphanumeric

If the character reference was consumed as part of an attribute, then append the current input character to the current attribute’s value. Otherwise, emit the current input character as a character token.
U+003B SEMICOLON (;)
This is an unknown-named-character-reference parse error. Reconsume in the return state.

Anything else
Reconsume in the return state.

13.2.5.75 Numeric character reference state

Set the character reference code to zero (0).

Consume the next input character:

U+0078 LATIN SMALL LETTER X
U+0058 LATIN CAPITAL LETTER X
Append the current input character to the temporary buffer. Switch to the hexadecimal character reference start state.

Anything else
Reconsume in the decimal character reference start state.

13.2.5.76 Hexadecimal character reference start state

Consume the next input character:

ASCII hex digit
Reconsume in the hexadecimal character reference state.

Anything else
This is an absence-of-digits-in-numeric-character-reference parse error. Flush code points consumed as a character reference. Reconsume in the return state.

13.2.5.77 Decimal character reference start state

Consume the next input character:

ASCII digit
Reconsume in the decimal character reference state.

Anything else
This is an absence-of-digits-in-numeric-character-reference parse error. Flush code points consumed as a character reference. Reconsume in the return state.

13.2.5.78 Hexadecimal character reference state

Consume the next input character:

ASCII digit
Multiply the character reference code by 16. Add a numeric version of the current input
character (subtract 0x0030 from the character’s code point) to the character reference code.

ASCII upper hex digit
Multiply the character reference code by 16. Add a numeric version of the current input character as a hexadecimal digit (subtract 0x0037 from the character’s code point) to the character reference code.

ASCII lower hex digit
Multiply the character reference code by 16. Add a numeric version of the current input character as a hexadecimal digit (subtract 0x0057 from the character’s code point) to the character reference code.

U+003B SEMICOLON
Switch to the numeric character reference end state.

Anything else
This is a missing-semicolon-after-character-reference parse error. Reconsume in the numeric character reference end state.

13.2.5.79 Decimal character reference state
Consume the next input character:

ASCII digit
Multiply the character reference code by 10. Add a numeric version of the current input character (subtract 0x0030 from the character’s code point) to the character reference code.

U+003B SEMICOLON
Switch to the numeric character reference end state.

Anything else
This is a missing-semicolon-after-character-reference parse error. Reconsume in the numeric character reference end state.

13.2.5.80 Numeric character reference end state
Check the character reference code:

- If the number is 0x00, then this is a null-character-reference parse error. Set the character reference code to 0xFFFD.

- If the number is greater than 0x10FFFF, then this is a character-reference-outside-unicode-range parse error. Set the character reference code to 0xFFFD.

- If the number is a surrogate, then this is a surrogate-character-reference parse error. Set the character reference code to 0xFFFD.

- If the number is a noncharacter, then this is a noncharacter-character-reference parse error.
• If the number is 0x0D, or a control that’s not ASCII whitespace, then this is a control-character-reference parse error. If the number is one of the numbers in the first column of the following table, then find the row with that number in the first column, and set the character reference code to the number in the second column of that row.

<table>
<thead>
<tr>

</tbody>
</table>

Set the temporary buffer to the empty string. Append a code point equal to the character reference code to the temporary buffer. Flush code points consumed as a character reference. Switch to the return state.

13.2.6 Tree construction

The input to the tree construction stage is a sequence of tokens from the tokenization stage. The tree construction stage is associated with a DOM Document object when a parser is
created. The “output” of this stage consists of dynamically modifying or extending that document’s DOM tree.

This specification does not define when an interactive user agent has to render the Document so that it is available to the user, or when it has to begin accepting user input.

As each token is emitted from the tokenizer, the user agent must follow the appropriate steps from the following list, known as the tree construction dispatcher:

If the stack of open elements is empty
If the adjusted current node is an element in the HTML namespace
If the adjusted current node is a MathML text integration point and the token is a start tag whose tag name is neither “mglyph” nor “malignmark”
If the adjusted current node is a MathML text integration point and the token is a character token
If the adjusted current node is a MathML annotation-xml element and the token is a start tag whose tag name is “svg”
If the adjusted current node is an HTML integration point and the token is a start tag
If the adjusted current node is an HTML integration point and the token is a character token
If the token is an end-of-file token

Process the token according to the rules given in the section corresponding to the current insertion mode in HTML content.

Otherwise
Process the token according to the rules given in the section for parsing tokens in foreign content.

The next token is the token that is about to be processed by the tree construction dispatcher (even if the token is subsequently just ignored).

A node is a MathML text integration point if it is one of the following elements:

- A MathML mi element
- A MathML mo element
- A MathML mn element
- A MathML ms element
- A MathML mtext element

A node is an HTML integration point if it is one of the following elements:

- A MathML annotation-xml element whose start tag token had an attribute with the name “encoding” whose value was an ASCII case-insensitive match for the string “text/html”
- A MathML annotation-xml element whose start tag token had an attribute with the name “encoding” whose value was an ASCII case-insensitive match for the string “application/xhtml+xml”
• An SVG foreignObject element
• An SVG desc element
• An SVG title element

If the node in question is the context element passed to the HTML fragment parsing algorithm, then the start tag token for that element is the "fake" token created during by that HTML fragment parsing algorithm.

Not all of the tag names mentioned below are conformant tag names in this specification; many are included to handle legacy content. They still form part of the algorithm that implementations are required to implement to claim conformance.

The algorithm described below places no limit on the depth of the DOM tree generated, or on the length of tag names, attribute names, attribute values, Text nodes, etc. While implementers are encouraged to avoid arbitrary limits, it is recognized that practical concerns will likely force user agents to impose nesting depth constraints.

13.2.6.1 Creating and inserting nodes

While the parser is processing a token, it can enable or disable foster parenting. This affects the following algorithm.

The appropriate place for inserting a node, optionally using a particular override target, is the position in an element returned by running the following steps:

1. If there was an override target specified, then let target be the override target.
   Otherwise, let target be the current node.

2. Determine the adjusted insertion location using the first matching steps from the following list:

   If foster parenting is enabled and target is a table, tbody, tfoot, thead, or tr element

   Foster parenting happens when content is misnested in tables.

   Run these substeps:

   1. Let last template be the last template element in the stack of open elements, if any.

   2. Let last table be the last table element in the stack of open elements, if any.

   3. If there is a last template and either there is no last table, or there is one, but
last template is lower (more recently added) than last table in the stack of open elements, then: let adjusted insertion location be inside last template’s template contents, after its last child (if any), and abort these steps.

4. If there is no last table, then let adjusted insertion location be inside the first element in the stack of open elements (the html element), after its last child (if any), and abort these steps. (fragment case)

5. If last table has a parent node, then let adjusted insertion location be inside last table’s parent node, immediately before last table, and abort these steps.

6. Let previous element be the element immediately above last table in the stack of open elements.

7. Let adjusted insertion location be inside previous element, after its last child (if any).

These steps are involved in part because it’s possible for elements, the table element in this case in particular, to have been moved by a script around in the DOM, or indeed removed from the DOM entirely, after the element was inserted by the parser.

Otherwise

Let adjusted insertion location be inside target, after its last child (if any).

3. If the adjusted insertion location is inside a template element, let it instead be inside the template element’s template contents, after its last child (if any).

4. Return the adjusted insertion location.

When the steps below require the UA to create an element for a token in a particular given namespace and with a particular intended parent, the UA must run the following steps:

1. If the active speculative HTML parser is not null, then return the result of creating a speculative mock element given given namespace, the tag name of the given token, and the attributes of the given token.

2. Otherwise, optionally create a speculative mock element given given namespace, the tag name of the given token, and the attributes of the given token.

The result is not used. This step allows for a speculative fetch to be initiated from non-speculative parsing. The fetch is still speculative at this point, because, for example, by the time the element is inserted, intended parent might have been removed from the document.
3. Let document be intended parent's node document.

4. Let local name be the tag name of the token.

5. Let is be the value of the "is" attribute in the given token, if such an attribute exists, or null otherwise.

6. Let definition be the result of looking up a custom element definition given document, given namespace, local name, and is.

7. If definition is non-null and the parser was not created as part of the HTML fragment parsing algorithm, then let will execute script be true. Otherwise, let it be false.

8. If will execute script is true, then:
   1. Increment document's throw-on-dynamic-markup-insertion counter.
   2. If the JavaScript execution context stack is empty, then perform a microtask checkpoint.
   3. Push a new element queue onto document's relevant agent's custom element reactions stack.

9. Let element be the result of creating an element given document, localName, given namespace, null, and is. If will execute script is true, set the synchronous custom elements flag; otherwise, leave it unset.

   This will cause custom element constructors to run, if will execute script is true. However, since we incremented the throw-on-dynamic-markup-insertion counter, this cannot cause new characters to be inserted into the tokenizer, or the document to be blown away.

10. Append each attribute in the given token to element.

    This can enqueue a custom element callback reaction for the attributeChangedCallback, which might run immediately (in the next step).

    Even though the is attribute governs the creation of a customized built-in element, it is not present during the execution of the relevant custom element constructor; it is appended in this step, along with all other attributes.

11. If will execute script is true, then:
   1. Let queue be the result of popping from document's relevant agent's custom element reactions stack. (This will be the same element queue as was pushed above.)
   2. Invoke custom element reactions in queue.
3. Decrement document’s throw-on-dynamic-markup-insertion counter.

12. If element has an xmlns attribute in the XMLNS namespace whose value is not exactly the same as the element’s namespace, that is a parse error. Similarly, if element has an xmlns:xlink attribute in the XMLNS namespace whose value is not the XLink Namespace, that is a parse error.

13. If element is a resettable element, invoke its reset algorithm. (This initializes the element’s value and checkedness based on the element’s attributes.)

14. If element is a form-associated element and not a form-associated custom element, the form element pointer is not null, there is no template element on the stack of open elements, element is either not listed or doesn’t have a form attribute, and the intended parent is in the same tree as the element pointed to by the form element pointer, then associate element with the form element pointed to by the form element pointer and set element’s parser inserted flag.

15. Return element.

When the steps below require the user agent to insert a foreign element for a token in a given namespace, the user agent must run these steps:

1. Let the adjusted insertion location be the appropriate place for inserting a node.

2. Let element be the result of creating an element for the token in the given namespace, with the intended parent being the element in which the adjusted insertion location finds itself.

3. If it is possible to insert element at the adjusted insertion location, then:
   1. If the parser was not created as part of the HTML fragment parsing algorithm, then push a new element queue onto element’s relevant agent’s custom element reactions stack.
   2. Insert element at the adjusted insertion location.
   3. If the parser was not created as part of the HTML fragment parsing algorithm, then pop the element queue from element’s relevant agent’s custom element reactions stack, and invoke custom element reactions in that queue.

   If the adjusted insertion location cannot accept more elements, e.g. because it’s a Document that already has an element child, then element is dropped on the floor.

4. Push element onto the stack of open elements so that it is the new current node.

5. Return element.
When the steps below require the user agent to *insert an HTML element* for a token, the user agent must *insert a foreign element* for the token, in the *HTML namespace*.

When the steps below require the user agent to *adjust MathML attributes* for a token, then, if the token has an attribute named `definitionurl`, change its name to `definitionURL` (note the case difference).

When the steps below require the user agent to *adjust SVG attributes* for a token, then, for each attribute on the token whose attribute name is one of the ones in the first column of the following table, change the attribute’s name to the name given in the corresponding cell in the second column. (This fixes the case of SVG attributes that are not all lowercase.)

<table>

</tbody>
</table>
When the steps below require the user agent to *adjust foreign attributes* for a token, then, if any of the attributes on the token match the strings given in the first column of the following table, let the attribute be a namespaced attribute, with the prefix being the string given in the corresponding cell in the second column, the local name being the string given in the corresponding cell in the third column, and the namespace being the namespace given in the corresponding cell in the fourth column. (This fixes the use of namespaced attributes, in particular [lang attributes in the XML namespace](https://www.w3.org/TR/REC-xml#sec-xml-names).)

<table>
<thead>
<tr>

<td>actuate</td>
<td>XLink namespace</td>
</tr>
<tr>
<td>xlink:arcrole</td>
<td>xlink</td>
<td>arcrole</td>
<td>XLink namespace</td>
</tr>
</tbody>
</table>
When the steps below require the user agent to insert a character while processing a token, the user agent must run the following steps:

1. Let data be the characters passed to the algorithm, or, if no characters were explicitly specified, the character of the character token being processed.

2. Let the adjusted insertion location be the appropriate place for inserting a node.

3. If the adjusted insertion location is in a Document node, then return.

   The DOM will not let Document nodes have Text node children, so they are dropped on the floor.

4. If there is a Text node immediately before the adjusted insertion location, then append data to that Text node’s data.

   Otherwise, create a new Text node whose data is data and whose node document is the same as that of the element in which the adjusted insertion location finds itself, and insert the newly created node at the adjusted insertion location.

Here are some sample inputs to the parser and the corresponding number of Text nodes that they result in, assuming a user agent that executes scripts.

<table>
<thead>
<tr>
<th>Input</th>
<th>Number of Text nodes</th>
</tr>
</thead>
</table>
| A<script>  
 var script = document.getElementsByTagName('script')[0]; 
 document.body.removeChild(script);  
 </script>B | One Text node in the document, containing "AB". |
A<script>
var text = document.createTextNode('B');
document.body.appendChild(text);
</script>C

A<script>
var text = document.getElementsByTagName('script')[0].firstChild;
text.data = 'B';
document.body.appendChild(text);
</script>C

A<table><tr>C</tr>D</table>

A<table><tr> B</tr> C</table>
Input

One Text node before the table, containing "A BC" (A-space-B-C), and one Text node inside the table (as a child of a tbody) with a single space character.

(Space characters separated from non-space characters by non-character tokens are not affected by foster parenting, even if those other tokens then get ignored.)

When the steps below require the user agent to insert a comment while processing a comment
token, optionally with an explicitly insertion position position, the user agent must run the following steps:

1. Let data be the data given in the comment token being processed.

2. If position was specified, then let the adjusted insertion location be position. Otherwise, let adjusted insertion location be the appropriate place for inserting a node.

3. Create a Comment node whose data attribute is set to data and whose node document is the same as that of the node in which the adjusted insertion location finds itself.

4. Insert the newly created node at the adjusted insertion location.

DOM mutation events must not fire for changes caused by the UA parsing the document. This includes the parsing of any content inserted using document.write() and document.writeln() calls. [UIEVENTS]

However, mutation observers do fire, as required by DOM.

13.2.6.2 Parsing elements that contain only text

The generic raw text element parsing algorithm and the generic RCDATA element parsing algorithm consist of the following steps. These algorithms are always invoked in response to a start tag token.

1. Insert an HTML element for the token.

2. If the algorithm that was invoked is the generic raw text element parsing algorithm, switch the tokenizer to the RAWTEXT state; otherwise the algorithm invoked was the generic RCDATA element parsing algorithm, switch the tokenizer to the RCDATA state.

3. Let the original insertion mode be the current insertion mode.

4. Then, switch the insertion mode to "text".

13.2.6.3 Closing elements that have implied end tags

When the steps below require the UA to generate implied end tags, then, while the current node is a dd element, a dt element, an li element, anoptgroup element, an option element, a p element, an rb element, an rp element, an rt element, or an rtc element, the UA must pop the current node off the stack of open elements.

If a step requires the UA to generate implied end tags but lists an element to exclude from the process, then the UA must perform the above steps as if that element was not in the above list.
When the steps below require the UA to generate all implied end tags thoroughly, then, while the current node is a caption element, a colgroup element, a dd element, a dt element, an li element, an optgroup element, an option element, a p element, an rb element, an rp element, an rt element, an rtc element, a tbody element, a td element, a tfoot element, a th element, a thead element, or a tr element, the UA must pop the current node off the stack of open elements.

13.2.6.4 The rules for parsing tokens in HTML content

13.2.6.4.1 The "initial" insertion mode

A Document object has an associated parser cannot change the mode flag (a boolean). It is initially false.

When the user agent is to apply the rules for the "initial" insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Ignore the token.

A comment token

Insert a comment as the last child of the Document object.

A DOCTYPE token

If the DOCTYPE token’s name is not “html”, or the token’s public identifier is not missing, or the token’s system identifier is neither missing nor “about:legacy-compat”, then there is a parse error.

Append a DocumentType node to the Document node, with the name attribute set to the name given in the DOCTYPE token, or the empty string if the name was missing; the publicId attribute set to the public identifier given in the DOCTYPE token, or the empty string if the public identifier was missing; the systemId attribute set to the system identifier given in the DOCTYPE token, or the empty string if the system identifier was missing; and the other attributes specific to DocumentType objects set to null and empty lists as appropriate. Associate the DocumentType node with the Document object so that it is returned as the value of the doctype attribute of the Document object.

Then, if the document is not an iframe srcdoc document, and the parser cannot change the mode flag is false, and the DOCTYPE token matches one of the conditions in the following list, then set the Document to quirks mode:

• The force-quirks flag is set to on.
• The name is not "html".
• The public identifier is set to: "-//W3O//DTD W3 HTML Strict 3.0//EN//"
• The public identifier is set to: "-//W3C//DTD HTML 4.0 Transitional//EN"
• The public identifier is set to: "HTML"
• The system identifier is set to: "http://www.ibm.com/data/dtd/v11/ibmxhtml1-transitional.dtd"
• The public identifier starts with: "+//Silmaril//dtd html Pro v0r1119970101//"
• The public identifier starts with: "-//AS//DTD HTML 3.0 asWedit + extensions//"
• The public identifier starts with: "-//AdvaSoft Ltd//DTD HTML 3.0 asWedit + extensions//"
• The public identifier starts with: "-//IETF//DTD HTML 2.0 Level 1//"
• The public identifier starts with: "-//IETF//DTD HTML 2.0 Level 2//"
• The public identifier starts with: "-//IETF//DTD HTML 2.0 Strict Level 1//"
• The public identifier starts with: "-//IETF//DTD HTML 2.0 Strict Level 2//"
• The public identifier starts with: "-//IETF//DTD HTML 2.0 Strict//"
• The public identifier starts with: "-//IETF//DTD HTML//"
• The public identifier starts with: "-//Metrius//DTD MetriusPresentational//"
• The public identifier starts with: "-//Microsoft//DTD Internet Explorer 2.0 HTML Strict//"
• The public identifier starts with: "-//Microsoft//DTD Internet Explorer 2.0 HTML//"
• The public identifier starts with: "-//Microsoft//DTD Internet Explorer 2.0 Tables//"
• The public identifier starts with: "-//Microsoft//DTD Internet Explorer 3.0 HTML Strict//"
• The public identifier starts with: "-//Microsoft//DTD Internet Explorer 3.0 HTML//"
• The public identifier starts with: "-//Microsoft//DTD Internet Explorer 3.0 Tables//"
• The public identifier starts with: "-//Netscape Comm. Corp.//DTD HTML//"
• The public identifier starts with: "-//Netscape Comm. Corp.//DTD Strict HTML//"
• The public identifier starts with: "-//O'Reilly and Associates//DTD HTML 2.0//"
• The public identifier starts with: "-//O'Reilly and Associates//DTD HTML Extended 1.0//"
• The public identifier starts with: "-//O'Reilly and Associates//DTD HTML Extended Relaxed 1.0//"
• The public identifier starts with: "-//SQ//DTD HTML 2.0 HoTMetaL + extensions//"
• The public identifier starts with: "-//SoftQuad Software//DTD HoTMetaL PRO 6.0::19990601::extensions to HTML 4.0//"
• The public identifier starts with: "-//SoftQuad//DTD HoTMetaL PRO 4.0::19971010::extensions to HTML 4.0//"
• The public identifier starts with: "-//Spyglass//DTD HTML 2.0 Extended//"
• The public identifier starts with: "-//Sun Microsystems Corp.//DTD HotJava HTML//"
• The public identifier starts with: "-//Sun Microsystems Corp.//DTD HotJava Strict HTML//"
• The public identifier starts with: "-//W3C//DTD HTML 3 1995-03-24//"
• The public identifier starts with: "-//W3C//DTD HTML 3.2 Draft//"
• The public identifier starts with: "-//W3C//DTD HTML 3.2 Final//"
• The public identifier starts with: "-//W3C//DTD HTML 3.2//"
• The public identifier starts with: "-//W3C//DTD HTML 3.2S Draft//"
• The public identifier starts with: "-//W3C//DTD HTML 4.0 Frameset//"
• The public identifier starts with: "-//W3C//DTD HTML 4.0 Transitional//"
• The public identifier starts with: "-//W3C//DTD HTML Experimental 19960712//"
• The public identifier starts with: "-//W3C//DTD HTML Experimental 970421//"
• The public identifier starts with: "-//W3C//DTD W3 HTML//"
• The public identifier starts with: "-//W3O//DTD W3 HTML 3.0//"
• The public identifier starts with: "-//WebTechs//DTD Mozilla HTML 2.0//"
• The public identifier starts with: "-//WebTechs//DTD Mozilla HTML//"
• The system identifier is missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Frameset//"
• The system identifier is missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Transitional//"

Otherwise, if the document is not an iframe srcdoc document, and the parser cannot
change the mode flag is false, and the DOCTYPE token matches one of the conditions in the following list, then set the Document to limited- quirks mode:

- The public identifier starts with: "-//W3C//DTD XHTML 1.0 Frameset//"
- The public identifier starts with: "-//W3C//DTD XHTML 1.0 Transitional//"
- The system identifier is not missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Frameset//"
- The system identifier is not missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Transitional//"

The system identifier and public identifier strings must be compared to the values given in the lists above in an ASCII case-insensitive manner. A system identifier whose value is the empty string is not considered missing for the purposes of the conditions above.

Then, switch the insertion mode to "before html".

Anything else

If the document is not an iframe srcdoc document, then this is a parse error; if the parser cannot change the mode flag is false, set the Document to quirks mode.

In any case, switch the insertion mode to "before html", then reprocess the token.

13.2.6.4.2 The "before html" insertion mode

When the user agent is to apply the rules for the "before html" insertion mode, the user agent must handle the token as follows:

A DOCTYPE token

Parse error. Ignore the token.

A comment token

Insert a comment as the last child of the Document object.

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Ignore the token.

A start tag whose tag name is "html"

Create an element for the token in the HTML namespace, with the Document as the intended parent. Append it to the Document object. Put this element in the stack of open elements.
Switch the **insertion mode** to "before head".

An end tag whose tag name is one of: "head", "body", "html", "br"

Act as described in the "anything else" entry below.

Any other end tag

**Parse error**. Ignore the token.

Anything else

Create an **html** element whose **node document** is the **Document** object. Append it to the **Document** object. Put this element in the **stack of open elements**.

Switch the **insertion mode** to "before head", then reprocess the token.

The **document element** can end up being removed from the **Document** object, e.g. by scripts; nothing in particular happens in such cases, content continues being appended to the nodes as described in the next section.

13.2.6.4.3 The "before head" insertion mode

When the user agent is to apply the rules for the "before head" **insertion mode**, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Ignore the token.

A comment token

**Insert a comment**.

A **DOCTYPE** token

**Parse error**. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" **insertion mode**.

A start tag whose tag name is "head"

**Insert an HTML element** for the token.

Set the **head element pointer** to the newly created **head** element.
Switch the **insertion mode** to "in head".

An end tag whose tag name is one of: "head", "body", "html", "br"

Act as described in the "anything else" entry below.

Any other end tag

Parse error. Ignore the token.

Anything else

Insert an HTML element for a "head" start tag token with no attributes.

Set the head element pointer to the newly created head element.

Switch the **insertion mode** to "in head".

Reprocess the current token.

13.2.6.4.4 The "in head" insertion mode

When the user agent is to apply the rules for the "in head" **insertion mode**, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character.

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" **insertion mode**.

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link"

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token's self-closing flag, if it is set.
A start tag whose tag name is “meta”

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token’s self-closing flag, if it is set.

If the active speculative HTML parser is null, then:

1. If the element has a charset attribute, and getting an encoding from its value results in an encoding, and the confidence is currently tentative, then change the encoding to the resulting encoding.

2. Otherwise, if the element has an http-equiv attribute whose value is an ASCII case-insensitive match for the string “Content-Type”, and the element has a content attribute, and applying the algorithm for extracting a character encoding from a meta element to that attribute’s value returns an encoding, and the confidence is currently tentative, then change the encoding to the extracted encoding.

The speculative HTML parser doesn’t speculatively apply character encoding declarations in order to reduce implementation complexity.

A start tag whose tag name is “title”

Follow the generic RCDATA element parsing algorithm.

A start tag whose tag name is “noscript”, if the scripting flag is enabled

Follow the generic raw text element parsing algorithm.

A start tag whose tag name is “noscript”, if the scripting flag is disabled

Insert an HTML element for the token.

Switch the insertion mode to “in head noscript”.

A start tag whose tag name is “script”

Run these steps:

1. Let the adjusted insertion location be the appropriate place for inserting a node.

2. Create an element for the token in the HTML namespace, with the intended parent being the element in which the adjusted insertion location finds itself.

3. Set the element’s parser document to the Document, and unset the element’s “non-
blocking” flag.

This ensures that, if the script is external, any `document.write()` calls in the script will execute in-line, instead of blowing the document away, as would happen in most other cases. It also prevents the script from executing until the end tag is seen.

4. If the parser was created as part of the HTML fragment parsing algorithm, then mark the script element as "already started". (fragment case)

5. If the parser was invoked via the `document.write()` or `document.writeln()` methods, then optionally mark the script element as “already started”. (For example, the user agent might use this clause to prevent execution of cross-origin scripts inserted via `document.write()` under slow network conditions, or when the page has already taken a long time to load.)

6. Insert the newly created element at the adjusted insertion location.

7. Push the element onto the stack of open elements so that it is the new current node.

8. Switch the tokenizer to the script data state.

9. Let the original insertion mode be the current insertion mode.

10. Switch the insertion mode to "text".

An end tag whose tag name is “head”

Pop the current node (which will be the head element) off the stack of open elements.

Switch the insertion mode to "after head".

An end tag whose tag name is one of: “body”, “html”, “br”

Act as described in the "anything else" entry below.

A start tag whose tag name is “template”

Insert an HTML element for the token.

Insert a marker at the end of the list of active formatting elements.

Set the frameset-ok flag to "not ok".

Switch the insertion mode to "in template".

Push “in template” onto the stack of template insertion modes so that it is the new current template insertion mode.
An end tag whose tag name is "template"

If there is no template element on the stack of open elements, then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate all implied end tags thoroughly.
2. If the current node is not a template element, then this is a parse error.
3. Pop elements from the stack of open elements until a template element has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker.
5. Pop the current template insertion mode off the stack of template insertion modes.
6. Reset the insertion mode appropriately.

A start tag whose tag name is "head"

Any other end tag

Parse error. Ignore the token.

Anything else

Parse error. Ignore the token.

13.2.6.4.5 The "in head noscript" insertion mode

When the user agent is to apply the rules for the "in head noscript" insertion mode, the user agent must handle the token as follows:

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" insertion mode.
An end tag whose tag name is "noscript"

Pop the current node (which will be a noscript element) from the stack of open elements; the new current node will be a head element.

Switch the insertion mode to "in head".

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

A comment token

A start tag whose tag name is one of: "basefont", "bgsound", "link", "meta", "noframes", "style"

Process the token using the rules for the "in head" insertion mode.

An end tag whose tag name is "br"

Act as described in the "anything else" entry below.

A start tag whose tag name is one of: "head", "noscript"

Any other end tag

Parse error. Ignore the token.

Anything else

Parse error.

Pop the current node (which will be a noscript element) from the stack of open elements; the new current node will be a head element.

Switch the insertion mode to "in head".

Reprocess the token.

13.2.6.4.6 The "after head" insertion mode

When the user agent is to apply the rules for the "after head" insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character.

A comment token

Insert a comment.
A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" insertion mode.

A start tag whose tag name is "body"

Insert an HTML element for the token.

Set the frameset-ok flag to "not ok".

Switch the insertion mode to "in body".

A start tag whose tag name is "frameset"

Insert an HTML element for the token.

Switch the insertion mode to "in frameset".

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"

Parse error.

Push the node pointed to by the head element pointer onto the stack of open elements.

Process the token using the rules for the "in head" insertion mode.

Remove the node pointed to by the head element pointer from the stack of open elements. (It might not be the current node at this point.)

The head element pointer cannot be null at this point.

An end tag whose tag name is "template"

Process the token using the rules for the "in head" insertion mode.

An end tag whose tag name is one of: "body", "html", "br"

Act as described in the "anything else" entry below.

A start tag whose tag name is "head"

Any other end tag

Parse error. Ignore the token.
Anything else

Insert an HTML element for a "body" start tag token with no attributes.

Switch the insertion mode to "in body".

Reprocess the current token.

13.2.6.4.7 The "in body" insertion mode

When the user agent is to apply the rules for the "in body" insertion mode, the user agent must handle the token as follows:

A character token that is U+0000 NULL

Parse error. Ignore the token.

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Reconstruct the active formatting elements, if any.

Insert the token's character.

Any other character token

Reconstruct the active formatting elements, if any.

Insert the token’s character.

Set the frameset-ok flag to "not ok".

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Parse error.

If there is a template element on the stack of open elements, then ignore the token.

Otherwise, for each attribute on the token, check to see if the attribute is already present on the top element of the stack of open elements. If it is not, add the attribute and its
corresponding value to that element.

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"

An end tag whose tag name is "template"

Process the token using the rules for the "in head" insertion mode.

A start tag whose tag name is "body"

Parse error.

If the second element on the stack of open elements is not a body element, if the stack of open elements has only one node on it, or if there is a template element on the stack of open elements, then ignore the token. (fragment case)

Otherwise, set the frameset-ok flag to "not ok"; then, for each attribute on the token, check to see if the attribute is already present on the body element (the second element) on the stack of open elements, and if it is not, add the attribute and its corresponding value to that element.

A start tag whose tag name is "frameset"

Parse error.

If the stack of open elements has only one node on it, or if the second element on the stack of open elements is not a body element, then ignore the token. (fragment case)

If the frameset-ok flag is set to "not ok", ignore the token.

Otherwise, run the following steps:

1. Remove the second element on the stack of open elements from its parent node, if it has one.

2. Pop all the nodes from the bottom of the stack of open elements, from the current node up to, but not including, the root html element.

3. Insert an HTML element for the token.

4. Switch the insertion mode to "in frameset".

An end-of-file token

If the stack of template insertion modes is not empty, then process the token using the rules for the "in template" insertion mode.

Otherwise, follow these steps:
1. If there is a node in the stack of open elements that is not either a `dd` element, a `dt` element, an `li` element, an `optgroup` element, an `option` element, a `p` element, an `rb` element, an `rp` element, an `rt` element, an `rtc` element, a `tbody` element, a `td` element, a `tfoot` element, a `th` element, a `thead` element, a `tr` element, the `body` element, or the `html` element, then this is a parse error.

2. Stop parsing.

An end tag whose tag name is "body"

If the stack of open elements does not have a `body` element in scope, this is a parse error; ignore the token.

Otherwise, if there is a node in the stack of open elements that is not either a `dd` element, a `dt` element, an `li` element, an `optgroup` element, an `option` element, a `p` element, an `rb` element, an `rp` element, an `rt` element, an `rtc` element, a `tbody` element, a `td` element, a `tfoot` element, a `th` element, a `thead` element, a `tr` element, the `body` element, or the `html` element, then this is a parse error.

Switch the insertion mode to "after body".

An end tag whose tag name is "html"

If the stack of open elements does not have a `body` element in scope, this is a parse error; ignore the token.

Otherwise, if there is a node in the stack of open elements that is not either a `dd` element, a `dt` element, an `li` element, an `optgroup` element, an `option` element, a `p` element, an `rb` element, an `rp` element, an `rt` element, an `rtc` element, a `tbody` element, a `td` element, a `tfoot` element, a `th` element, a `thead` element, a `tr` element, the `body` element, or the `html` element, then this is a parse error.

Switch the insertion mode to "after body".

Reprocess the token.

A start tag whose tag name is one of: "address", "article", "aside", "blockquote", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "main", "menu", "nav", "ol", "p", "section", "summary", "ul"

   If the stack of open elements has a `p` element in button scope, then close a `p` element.

   Insert an HTML element for the token.

A start tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"

   If the stack of open elements has a `p` element in button scope, then close a `p` element.
If the current node is an HTML element whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a parse error; pop the current node off the stack of open elements.

Insert an HTML element for the token.

A start tag whose tag name is one of: "pre", "listing"

If the stack of open elements has a p element in button scope, then close a p element.

Insert an HTML element for the token.

If the next token is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of pre blocks are ignored as an authoring convenience.)

Set the frameset-ok flag to "not ok".

A start tag whose tag name is "form"

If the form element pointer is not null, and there is no template element on the stack of open elements, then this is a parse error; ignore the token.

Otherwise:

If the stack of open elements has a p element in button scope, then close a p element.

Insert an HTML element for the token, and, if there is no template element on the stack of open elements, set the form element pointer to point to the element created.

A start tag whose tag name is "li"

Run these steps:

1. Set the frameset-ok flag to "not ok".

2. Initialize node to be the current node (the bottommost node of the stack).

3. Loop: If node is an li element, then run these substeps:
   1. Generate implied end tags, except for li elements.
   2. If the current node is not an li element, then this is a parse error.
   3. Pop elements from the stack of open elements until an li element has been popped from the stack.
   4. Jump to the step labeled done below.
4. If \( node \) is in the \texttt{special} category, but is not an \texttt{address}, \texttt{div}, or \texttt{p} element, then jump to the step labeled \textit{done} below.

5. Otherwise, set \( node \) to the previous entry in the \texttt{stack of open elements} and return to the step labeled \textit{loop}.

6. \textit{Done}: If the \texttt{stack of open elements} has a \texttt{p} element in button scope, then close a \texttt{p} element.

7. Finally, insert an \texttt{HTML element} for the token.

\textbf{A start tag whose tag name is one of: "dd", "dt"}

Run these steps:

1. Set the \texttt{frameset-ok flag} to "not ok".

2. Initialize \( node \) to be the \texttt{current node} (the bottommost node of the stack).

3. \textit{Loop}: If \( node \) is a \texttt{dd} element, then run these substeps:

   1. Generate implied end tags, except for \texttt{dd} elements.

   2. If the \texttt{current node} is not a \texttt{dd} element, then this is a \texttt{parse error}.

   3. Pop elements from the \texttt{stack of open elements} until a \texttt{dd} element has been popped from the stack.

   4. Jump to the step labeled \textit{done} below.

4. If \( node \) is a \texttt{dt} element, then run these substeps:

   1. Generate implied end tags, except for \texttt{dt} elements.

   2. If the \texttt{current node} is not a \texttt{dt} element, then this is a \texttt{parse error}.

   3. Pop elements from the \texttt{stack of open elements} until a \texttt{dt} element has been popped from the stack.

   4. Jump to the step labeled \textit{done} below.

5. If \( node \) is in the \texttt{special} category, but is not an \texttt{address}, \texttt{div}, or \texttt{p} element, then jump to the step labeled \textit{done} below.

6. Otherwise, set \( node \) to the previous entry in the \texttt{stack of open elements} and return to the step labeled \textit{loop}.

7. \textit{Done}: If the \texttt{stack of open elements} has a \texttt{p} element in button scope, then close a \texttt{p} element.
8. Finally, **insert an HTML element** for the token.

A start tag whose tag name is "plaintext"

If the stack of open elements has a `p` element in button scope, then **close a `p` element.**

**Insert an HTML element** for the token.

Switch the tokenizer to the **PLAINTEXT state.**

Once a start tag with the tag name "plaintext" has been seen, that will be the last token ever seen other than character tokens (and the end-of-file token), because there is no way to switch out of the **PLAINTEXT state.**

A start tag whose tag name is "button"

1. If the stack of open elements has a `button` element in scope, then run these substeps:
   1. **Parse error.**
   2. **Generate implied end tags.**
   3. Pop elements from the stack of open elements until a `button` element has been popped from the stack.

2. **Reconstruct the active formatting elements,** if any.

3. **Insert an HTML element** for the token.

4. Set the **frameset-ok flag** to "not ok".

An end tag whose tag name is one of: "address", "article", "aside", "blockquote", "button", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "listing", "main", "menu", "nav", "ol", "pre", "section", "summary", "ul"

If the stack of open elements does not have an element in scope that is an HTML element with the same tag name as that of the token, then this is a **parse error**; ignore the token.

Otherwise, run these steps:

1. **Generate implied end tags.**

2. If the current node is not an HTML element with the same tag name as that of the token, then this is a **parse error**.
3. Pop elements from the stack of open elements until an HTML element with the same tag name as the token has been popped from the stack.

An end tag whose tag name is "form"

If there is no template element on the stack of open elements, then run these substeps:

1. Let node be the element that the form element pointer is set to, or null if it is not set to an element.
2. Set the form element pointer to null.
3. If node is null or if the stack of open elements does not have node in scope, then this is a parse error; return and ignore the token.
4. Generate implied end tags.
5. If the current node is not node, then this is a parse error.
6. Remove node from the stack of open elements.

If there is a template element on the stack of open elements, then run these substeps instead:

1. If the stack of open elements does not have a form element in scope, then this is a parse error; return and ignore the token.
2. Generate implied end tags.
3. If the current node is not a form element, then this is a parse error.
4. Pop elements from the stack of open elements until a form element has been popped from the stack.

An end tag whose tag name is "p"

If the stack of open elements does not have a p element in button scope, then this is a parse error; insert an HTML element for a "p" start tag token with no attributes.

Close a p element.

An end tag whose tag name is "li"

If the stack of open elements does not have a li element in list item scope, then this is a parse error; ignore the token.

Otherwise, run these steps:
1. Generate implied end tags, except for li elements.

2. If the current node is not an li element, then this is a parse error.

3. Pop elements from the stack of open elements until an li element has been popped from the stack.

An end tag whose tag name is one of: "dd", "dt"

If the stack of open elements does not have an element in scope that is an HTML element with the same tag name as that of the token, then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags, except for HTML elements with the same tag name as the token.

2. If the current node is not an HTML element with the same tag name as that of the token, then this is a parse error.

3. Pop elements from the stack of open elements until an HTML element with the same tag name as the token has been popped from the stack.

An end tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"

If the stack of open elements does not have an element in scope that is an HTML element and whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags.

2. If the current node is not an HTML element with the same tag name as that of the token, then this is a parse error.

3. Pop elements from the stack of open elements until an HTML element whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6" has been popped from the stack.

An end tag whose tag name is "sarcasm"

Take a deep breath, then act as described in the "any other end tag" entry below.

A start tag whose tag name is "a"

If the list of active formatting elements contains an a element between the end of the list and the last marker on the list (or the start of the list if there is no marker on the list), then this is a parse error; run the adoption agency algorithm for the token, then remove that
element from the list of active formatting elements and the stack of open elements if the adoption agency algorithm didn’t already remove it (it might not have if the element is not in table scope).

In the non-conforming stream `<a href="a">a</a><table><a href="b">b</a></table>x`, the first `a` element would be closed upon seeing the second one, and the “x” character would be inside a link to “b”, not to “a”. This is despite the fact that the outer `a` element is not in table scope (meaning that a regular `</a>` end tag at the start of the table wouldn’t close the outer `a` element). The result is that the two `a` elements are indirectly nested inside each other — non-conforming markup will often result in non-conforming DOMs when parsed.

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

A start tag whose tag name is one of: “b”, “big”, “code”, “em”, “font”, “i”, “s”, “small”, “strike”, “strong”, “tt”, “u”

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

A start tag whose tag name is “nobr”

Reconstruct the active formatting elements, if any.

If the stack of open elements has a nobr element in scope, then this is a parse error; run the adoption agency algorithm for the token, then once again reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

An end tag whose tag name is one of: “a”, “b”, “big”, “code”, “em”, “font”, “i”, “nobr”, “s”, “small”, “strike”, “strong”, “tt”, “u”

Run the adoption agency algorithm for the token.

A start tag whose tag name is one of: “applet”, “marquee”, “object”

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token.

Insert a marker at the end of the list of active formatting elements.
Set the **frameset-ok flag** to “not ok”.

**An end tag token whose tag name is one of: “applet”, “marquee”, “object”**

If the **stack of open elements** does not **have an element in scope** that is an **HTML element** with the same tag name as that of the token, then this is a **parse error**; ignore the token.

Otherwise, run these steps:

1. **Generate implied end tags.**
2. If the **current node** is not an **HTML element** with the same tag name as that of the token, then this is a **parse error**.
3. Pop elements from the **stack of open elements** until an **HTML element** with the same tag name as the token has been popped from the stack.
4. **Clear the list of active formatting elements up to the last marker.**

**A start tag whose tag name is “table”**

If the **Document** is not set to **quirks mode**, and the **stack of open elements** has a **p element in button scope**, then **close a p element**.

**Insert an HTML element** for the token.

Set the **frameset-ok flag** to “not ok”.

Switch the **insertion mode** to “in table”.

**An end tag whose tag name is “br”**

**Parse error.** Drop the attributes from the token, and act as described in the next entry; i.e. act as if this was a “br” start tag token with no attributes, rather than the end tag token that it actually is.

**A start tag whose tag name is one of: “area”, “br”, “embed”, “img”, “keygen”, “wbr”**

**Reconstruct the active formatting elements**, if any.

**Insert an HTML element** for the token. Immediately pop the **current node** off the **stack of open elements**.

**Acknowledge the token’s self-closing flag**, if it is set.

Set the **frameset-ok flag** to “not ok”.
A start tag whose tag name is “input”

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token’s self-closing flag, if it is set.

If the token does not have an attribute with the name “type”, or if it does, but that attribute’s value is not an ASCII case-insensitive match for the string “hidden”, then: set the frameset-ok flag to “not ok”.

A start tag whose tag name is one of: “param”, “source”, “track”

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token’s self-closing flag, if it is set.

A start tag whose tag name is “hr”

If the stack of open elements has a p element in button scope, then close a p element.

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token’s self-closing flag, if it is set.

Set the frameset-ok flag to “not ok”.

A start tag whose tag name is “image”

Parse error. Change the token’s tag name to “img” and reprocess it. (Don’t ask.)

A start tag whose tag name is “textarea”

Run these steps:

1. Insert an HTML element for the token.

2. If the next token is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of textarea elements are ignored as an authoring convenience.)

3. Switch the tokenizer to the RCDATA state.

4. Let the original insertion mode be the current insertion mode.
5. Set the `frameset-ok` flag to "not ok".

6. Switch the insertion mode to "text".

A start tag whose tag name is "xmp"

If the stack of open elements has a `p` element in button scope, then close a `p` element.

Reconstruct the active formatting elements, if any.

Set the `frameset-ok` flag to "not ok".

Follow the generic raw text element parsing algorithm.

A start tag whose tag name is "iframe"

Set the `frameset-ok` flag to "not ok".

Follow the generic raw text element parsing algorithm.

A start tag whose tag name is "noembed"

A start tag whose tag name is "noscript", if the scripting flag is enabled

Follow the generic raw text element parsing algorithm.

A start tag whose tag name is "select"

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token.

Set the `frameset-ok` flag to "not ok".

If the insertion mode is one of "in table", "in caption", "in table body", "in row", or "in cell", then switch the insertion mode to "in select in table". Otherwise, switch the insertion mode to "in select".

A start tag whose tag name is one of: "optgroup", "option"

If the current node is an `option` element, then pop the current node off the stack of open elements.

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token.
A start tag whose tag name is one of: "rb", "rtc"

If the stack of open elements has a ruby element in scope, then generate implied end tags. If the current node is not now a ruby element, this is a parse error.

Insert an HTML element for the token.

A start tag whose tag name is one of: "rp", "rt"

If the stack of open elements has a ruby element in scope, then generate implied end tags, except for rtc elements. If the current node is not now a rtc element or a ruby element, this is a parse error.

Insert an HTML element for the token.

A start tag whose tag name is “math”

Reconstruct the active formatting elements, if any.

Adjust MathML attributes for the token. (This fixes the case of MathML attributes that are not all lowercase.)

Adjust foreign attributes for the token. (This fixes the use of namespaced attributes, in particular XLink.)

Insert a foreign element for the token, in the MathML namespace.

If the token has its self-closing flag set, pop the current node off the stack of open elements and acknowledge the token’s self-closing flag.

A start tag whose tag name is “svg”

Reconstruct the active formatting elements, if any.

Adjust SVG attributes for the token. (This fixes the case of SVG attributes that are not all lowercase.)

Adjust foreign attributes for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)

Insert a foreign element for the token, in the SVG namespace.

If the token has its self-closing flag set, pop the current node off the stack of open elements and acknowledge the token’s self-closing flag.
A start tag whose tag name is one of: "caption", "col", "colgroup", "frame", "head", "tbody", "td", "tfoot", "th", "thead", "tr"

**Parse error.** Ignore the token.

Any other start tag

**Reconstruct the active formatting elements**, if any.

**Insert an HTML element** for the token.

This element will be an **ordinary** element.

Any other end tag

Run these steps:

1. Initialize `node` to be the **current node** (the bottommost node of the stack).

2. **Loop**: If `node` is an **HTML element** with the same tag name as the token, then:
   
   1. **Generate implied end tags**, except for **HTML elements** with the same tag name as the token.
   
   2. If `node` is not the **current node**, then this is a **parse error**.
   
   3. Pop all the nodes from the **current node** up to `node`, including `node`, then stop these steps.

3. Otherwise, if `node` is in the **special** category, then this is a **parse error**; ignore the token, and return.

4. Set `node` to the previous entry in the **stack of open elements**.

5. Return to the step labeled **loop**.

When the steps above say the user agent is to **close a p element**, it means that the user agent must run the following steps:

1. **Generate implied end tags**, except for **p** elements.

2. If the **current node** is not a **p** element, then this is a **parse error**.

3. Pop elements from the **stack of open elements** until a **p** element has been popped from the stack.

The **adoption agency algorithm**, which takes as its only argument a token **token** for which the algorithm is being run, consists of the following steps:
1. Let \textit{subject} be \textit{token}'s tag name.

2. If the \textit{current node} is an \textit{HTML element} whose tag name is \textit{subject}, and the \textit{current node} is not in the \textit{list of active formatting elements}, then pop the \textit{current node} off the \textit{stack of open elements} and return.

3. Let \textit{outer loop counter} be 0.

4. While true:

   1. If \textit{outer loop counter} is greater than or equal to 8, then return.

   2. Increment \textit{outer loop counter} by 1.

   3. Let \textit{formatting element} be the last element in the \textit{list of active formatting elements} that:

      - is between the end of the list and the last \textit{marker} in the list, if any, or the start of the list otherwise, and
      - has the tag name \textit{subject}.

      If there is no such element, then return and instead act as described in the "any other end tag" entry above.

   4. If \textit{formatting element} is not in the \textit{stack of open elements}, then this is a \textit{parse error}; remove the element from the list, and return.

   5. If \textit{formatting element} is in the \textit{stack of open elements}, but the element is not \textit{in scope}, then this is a \textit{parse error}; return.

   6. If \textit{formatting element} is not the \textit{current node}, this is a \textit{parse error}. (But do not return.)

   7. Let \textit{furthest block} be the topmost node in the \textit{stack of open elements} that is lower in the stack than \textit{formatting element}, and is an element in the \textit{special} category. There might not be one.

   8. If there is no \textit{furthest block}, then the UA must first pop all the nodes from the bottom of the \textit{stack of open elements}, from the \textit{current node} up to and including \textit{formatting element}, then remove \textit{formatting element} from the \textit{list of active formatting elements}, and finally return.

   9. Let \textit{common ancestor} be the element immediately above \textit{formatting element} in the \textit{stack of open elements}.

10. Let a bookmark note the position of \textit{formatting element} in the \textit{list of active formatting elements} relative to the elements on either side of it in the list.
11. Let $node$ and $last\ node$ be furthest block.

12. Let $inner\ loop\ counter$ be 0.

13. While true:
   
   1. Increment $inner\ loop\ counter$ by 1.
   
   2. Let $node$ be the element immediately above $node$ in the stack of open elements, or if $node$ is no longer in the stack of open elements (e.g. because it got removed by this algorithm), the element that was immediately above $node$ in the stack of open elements before $node$ was removed.
   
   3. If $node$ is formatting element, then break.
   
   4. If $inner\ loop\ counter$ is greater than 3 and $node$ is in the list of active formatting elements, then remove $node$ from the list of active formatting elements.
   
   5. If $node$ is not in the list of active formatting elements, then remove $node$ from the stack of open elements and continue.
   
   6. Create an element for the token for which the element $node$ was created, in the HTML namespace, with common ancestor as the intended parent; replace the entry for $node$ in the list of active formatting elements with an entry for the new element, replace the entry for $node$ in the stack of open elements with an entry for the new element, and let $node$ be the new element.
   
   7. If $last\ node$ is furthest block, then move the aforementioned bookmark to be immediately after the new $node$ in the list of active formatting elements.
   
   8. Append $last\ node$ to $node$.
   
   9. Set $last\ node$ to $node$.

14. Insert whatever $last\ node$ ended up being in the previous step at the appropriate place for inserting a node, but using common ancestor as the override target.

15. Create an element for the token for which formatting element was created, in the HTML namespace, with furthest block as the intended parent.

16. Take all of the child nodes of furthest block and append them to the element created in the last step.

17. Append that new element to furthest block.
18. Remove *formatting element* from the list of active formatting elements, and insert the new element into the list of active formatting elements at the position of the aforementioned bookmark.

19. Remove *formatting element* from the stack of open elements, and insert the new element into the stack of open elements immediately below the position of *furthest block* in that stack.

This algorithm’s name, the "adoptive agency algorithm", comes from the way it causes elements to change parents, and is in contrast with other possible algorithms for dealing with misnested content.

13.2.6.4.8 The *text* insertion mode

When the user agent is to apply the rules for the "text" insertion mode, the user agent must handle the token as follows:

A character token

Insert the token’s character.

This can never be a U+0000 NULL character; the tokenizer converts those to U+FFFD REPLACEMENT CHARACTER characters.

An end-of-file token

Parse error.

If the current node is a *script* element, mark the *script* element as "already started".

Pop the current node off the stack of open elements.

Switch the insertion mode to the original insertion mode and reprocess the token.

An end tag whose tag name is "script"

If the active speculative HTML parser is null and the JavaScript execution context stack is empty, then perform a microtask checkpoint.

Let *script* be the current node (which will be a *script* element).

Pop the current node off the stack of open elements.

Switch the insertion mode to the original insertion mode.

Let the old insertion point have the same value as the current insertion point. Let the insertion point be just before the next input character.
Increment the parser’s script nesting level by one.

If the active speculative HTML parser is null, then prepare the script. This might cause some script to execute, which might cause new characters to be inserted into the tokenizer, and might cause the tokenizer to output more tokens, resulting in a reentrant invocation of the parser.

Decrement the parser’s script nesting level by one. If the parser’s script nesting level is zero, then set the parser pause flag to false.

Let the insertion point have the value of the old insertion point. (In other words, restore the insertion point to its previous value. This value might be the “undefined” value.)

At this stage, if there is a pending parsing-blocking script, then:

If the script nesting level is not zero:

    Set the parser pause flag to true, and abort the processing of any nested invocations of the tokenizer, yielding control back to the caller. (Tokenization will resume when the caller returns to the “outer” tree construction stage.)

    The tree construction stage of this particular parser is being called reentrantly, say from a call to document.write().

Otherwise:

Run these steps:

1. Let the script be the pending parsing-blocking script. There is no longer a pending parsing-blocking script.

2. Start the speculative HTML parser for this instance of the HTML parser.

3. Block the tokenizer for this instance of the HTML parser, such that the event loop will not run tasks that invoke the tokenizer.

4. If the parser’s Document has a style sheet that is blocking scripts or the script’s “ready to be parser-executed” flag is not set: spin the event loop until the parser’s Document has no style sheet that is blocking scripts and the script’s “ready to be parser-executed” flag is set.

5. If this parser has been aborted in the meantime, return.

    This could happen if, e.g., while the spin the event loop algorithm is running, the browsing context gets closed, or the document.open() method gets invoked on the Document.

6. Stop the speculative HTML parser for this instance of the HTML parser.
7. Unblock the tokenizer for this instance of the HTML parser, such that tasks that invoke the tokenizer can again be run.

8. Let the insertion point be just before the next input character.

9. Increment the parser’s script nesting level by one (it should be zero before this step, so this sets it to one).

10. **Execute the script.**

11. Decrement the parser’s script nesting level by one. If the parser’s script nesting level is zero (which it always should be at this point), then set the parser pause flag to false.

12. Let the insertion point be undefined again.

13. If there is once again a pending parsing-blocking script, then repeat these steps from step 1.

Any other end tag

- Pop the current node off the stack of open elements.
- Switch the insertion mode to the original insertion mode.

13.2.6.4.9 The "in table" insertion mode

When the user agent is to apply the rules for the "in table" insertion mode, the user agent must handle the token as follows:

A character token, if the current node is table, tbody, tfoot, thead, or tr element

- Let the pending table character tokens be an empty list of tokens.
- Let the original insertion mode be the current insertion mode.
- Switch the insertion mode to "in table text" and reprocess the token.

A comment token

- Insert a comment.

A DOCTYPE token

- Parse error. Ignore the token.
A start tag whose tag name is "caption"

Clear the stack back to a table context. (See below.)

Insert a marker at the end of the list of active formatting elements.

Insert an HTML element for the token, then switch the insertion mode to "in caption".

A start tag whose tag name is "colgroup"

Clear the stack back to a table context. (See below.)

Insert an HTML element for the token, then switch the insertion mode to "in column group".

A start tag whose tag name is "col"

Clear the stack back to a table context. (See below.)

Insert an HTML element for a "colgroup" start tag token with no attributes, then switch the insertion mode to "in column group".

Reprocess the current token.

A start tag whose tag name is one of: "tbody", "tfoot", "thead"

Clear the stack back to a table context. (See below.)

Insert an HTML element for the token, then switch the insertion mode to "in table body".

A start tag whose tag name is one of: "td", "th", "tr"

Clear the stack back to a table context. (See below.)

Insert an HTML element for a "tbody" start tag token with no attributes, then switch the insertion mode to "in table body".

Reprocess the current token.

A start tag whose tag name is "table"

Parse error.

If the stack of open elements does not have a table element in table scope, ignore the token.

Otherwise:
Pop elements from this stack until a table element has been popped from the stack.

Reset the insertion mode appropriately.

Reprocess the token.

An end tag whose tag name is "table"

If the stack of open elements does not have a table element in table scope, this is a parse error; ignore the token.

Otherwise:

Pop elements from this stack until a table element has been popped from the stack.

Reset the insertion mode appropriately.

An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"

Parse error. Ignore the token.

A start tag whose tag name is one of: "style", "script", "template"

An end tag whose tag name is "template"

Process the token using the rules for the "in head" insertion mode.

A start tag whose tag name is "input"

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an ASCII case-insensitive match for the string "hidden", then: act as described in the "anything else" entry below.

Otherwise:

Parse error.

Insert an HTML element for the token.

Pop that input element off the stack of open elements.

Acknowledge the token's self-closing flag, if it is set.

A start tag whose tag name is "form"

Parse error.

If there is a template element on the stack of open elements, or if the form element
**pointer** is not null, ignore the token.

Otherwise:

Insert an HTML element for the token, and set the **form element pointer** to point to the element created.

Pop that **form** element off the stack of open elements.

An end-of-file token

Process the token using the rules for the ”in body” insertion mode.

Anything else

Parse error. Enable foster parenting, process the token using the rules for the ”in body” insertion mode, and then disable foster parenting.

When the steps above require the UA to clear the stack back to a table context, it means that the UA must, while the current node is not a **table**, **template**, or **html** element, pop elements from the stack of open elements.

This is the same list of elements as used in the **has an element in table scope** steps.

The current node being an **html** element after this process is a **fragment case**.

13.2.6.4.10 The "in table text" insertion mode

When the user agent is to apply the rules for the "in table text" insertion mode, the user agent must handle the token as follows:

A character token that is U+0000 NULL

Parse error. Ignore the token.

Any other character token

Append the character token to the **pending table character tokens** list.

Anything else

If any of the tokens in the **pending table character tokens** list are character tokens that are not ASCII whitespace, then this is a parse error: reprocess the character tokens in the **pending table character tokens** list using the rules given in the ”anything else” entry in the “in table” insertion mode.

Otherwise, insert the characters given by the **pending table character tokens** list.
Switch the insertion mode to the original insertion mode and reprocess the token.

13.2.6.4.1 The "in caption" insertion mode

When the user agent is to apply the rules for the "in caption" insertion mode, the user agent must handle the token as follows:

An end tag whose tag name is "caption"

If the stack of open elements does not have a caption element in table scope, this is a parse error; ignore the token. (fragment case)

Otherwise:

Generate implied end tags.

Now, if the current node is not a caption element, then this is a parse error.

Pop elements from this stack until a caption element has been popped from the stack.

Clear the list of active formatting elements up to the last marker.

Switch the insertion mode to "in table".

A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"

An end tag whose tag name is "table"

If the stack of open elements does not have a caption element in table scope, this is a parse error; ignore the token. (fragment case)

Otherwise:

Generate implied end tags.

Now, if the current node is not a caption element, then this is a parse error.

Pop elements from this stack until a caption element has been popped from the stack.

Clear the list of active formatting elements up to the last marker.

Switch the insertion mode to "in table".

Reprocess the token.
An end tag whose tag name is one of: "body", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"

Parse error. Ignore the token.

Anything else

Process the token using the rules for the "in body" insertion mode.

13.2.6.4.12 The "in column group" insertion mode

When the user agent is to apply the rules for the "in column group" insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character.

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" insertion mode.

A start tag whose tag name is "col"

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token’s self-closing flag, if it is set.

An end tag whose tag name is "colgroup"

If the current node is not a colgroup element, then this is a parse error; ignore the token.

Otherwise, pop the current node from the stack of open elements. Switch the insertion mode to "in table".

An end tag whose tag name is "col"

Parse error. Ignore the token.
A start tag whose tag name is “template”
An end tag whose tag name is “template”

Process the token using the rules for the “in head” insertion mode.

An end-of-file token

Process the token using the rules for the “in body” insertion mode.

Anything else

If the current node is not a colgroup element, then this is a parse error; ignore the token.
Otherwise, pop the current node from the stack of open elements.
Switch the insertion mode to “in table”.
Reprocess the token.

13.2.6.4.13 The “in table body” insertion mode

When the user agent is to apply the rules for the “in table body” insertion mode, the user agent must handle the token as follows:

A start tag whose tag name is “tr”

Clear the stack back to a table body context. (See below.)

Insert an HTML element for the token, then switch the insertion mode to “in row”.

A start tag whose tag name is one of: “th”, “td”

Parse error.

Clear the stack back to a table body context. (See below.)

Insert an HTML element for a “tr” start tag token with no attributes, then switch the insertion mode to “in row”.
Reprocess the current token.

An end tag whose tag name is one of: “tbody”, “tfoot”, “thead”

If the stack of open elements does not have an element in table scope that is an HTML element with the same tag name as the token, this is a parse error; ignore the token.
Otherwise:
Clear the stack back to a table body context. (See below.)

Pop the current node from the stack of open elements. Switch the insertion mode to "in table".

A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead"
An end tag whose tag name is "table"

If the stack of open elements does not have a tbody, thead, or tfoot element in table scope, this is a parse error; ignore the token.

Otherwise:

Clear the stack back to a table body context. (See below.)

Pop the current node from the stack of open elements. Switch the insertion mode to "in table".

Reprocess the token.

An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th", "tr"

Parse error. Ignore the token.

Anything else

Process the token using the rules for the "in table" insertion mode.

When the steps above require the UA to clear the stack back to a table body context, it means that the UA must, while the current node is not a tbody, tfoot, thead, template, or html element, pop elements from the stack of open elements.

The current node being an html element after this process is a fragment case.

13.2.6.4.14 The "in row" insertion mode

When the user agent is to apply the rules for the "in row" insertion mode, the user agent must handle the token as follows:

A start tag whose tag name is one of: "th", "td"

Clear the stack back to a table row context. (See below.)

Insert an HTML element for the token, then switch the insertion mode to "in cell".

Insert a marker at the end of the list of active formatting elements.
An end tag whose tag name is "tr"

If the stack of open elements does not have a tr element in table scope, this is a parse error; ignore the token.

Otherwise:

Clear the stack back to a table row context. (See below.)

Pop the current node (which will be a tr element) from the stack of open elements. Switch the insertion mode to "in table body".

A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead", "tr"

An end tag whose tag name is "table"

If the stack of open elements does not have a tr element in table scope, this is a parse error; ignore the token.

Otherwise:

Clear the stack back to a table row context. (See below.)

Pop the current node (which will be a tr element) from the stack of open elements. Switch the insertion mode to "in table body".

Reprocess the token.

An end tag whose tag name is one of: "tbody", "tfoot", "thead"

If the stack of open elements does not have an element in table scope that is an HTML element with the same tag name as the token, this is a parse error; ignore the token.

If the stack of open elements does not have a tr element in table scope, ignore the token.

Otherwise:

Clear the stack back to a table row context. (See below.)

Pop the current node (which will be a tr element) from the stack of open elements. Switch the insertion mode to "in table body".

Reprocess the token.

An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th"

Parse error. Ignore the token.
Anything else

Process the token **using the rules for the "in table" insertion mode**.

When the steps above require the UA to **clear the stack back to a table row context**, it means that the UA must, while the current node is not a **tr**, **template**, or **html** element, pop elements from the **stack of open elements**.

The current node being an **html** element after this process is a **fragment case**.

13.2.6.4.15 The "in cell" insertion mode

When the user agent is to apply the rules for the **"in cell" insertion mode**, the user agent must handle the token as follows:

**An end tag whose tag name is one of: "td", "th"**

If the stack of open elements does not have an element in table scope that is an **HTML element** with the same tag name as that of the token, then this is a **parse error**; ignore the token.

Otherwise:

**Generate implied end tags.**

Now, if the current node is not an **HTML element** with the same tag name as the token, then this is a **parse error**.

Pop elements from the stack of open elements stack until an **HTML element** with the same tag name as the token has been popped from the stack.

**Clear the list of active formatting elements up to the last marker.**

Switch the **insertion mode** to "**in row**".

**A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"**

If the stack of open elements does **not** have a **td** or **th** element in table scope, then this is a **parse error**; ignore the token. **(fragment case)**

Otherwise, **close the cell** (see below) and reprocess the token.

**An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html"**

**Parse error.** Ignore the token.
An end tag whose tag name is one of: “table”, “tbody”, “tfoot”, “thead”, “tr”

If the stack of open elements does not have an element in table scope that is an HTML element with the same tag name as that of the token, then this is a parse error; ignore the token.

Otherwise, close the cell (see below) and reprocess the token.

Anything else

Process the token using the rules for the “in body” insertion mode.

Where the steps above say to close the cell, they mean to run the following algorithm:

1. Generate implied end tags.
2. If the current node is not now a td element or a th element, then this is a parse error.
3. Pop elements from the stack of open elements stack until a td element or a th element has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker.
5. Switch the insertion mode to “in row”.

The stack of open elements cannot have both a td and a th element in table scope at the same time, nor can it have neither when the close the cell algorithm is invoked.

13.2.6.4.16 The “in select” insertion mode

When the user agent is to apply the rules for the “in select” insertion mode, the user agent must handle the token as follows:

A character token that is U+0000 NULL

Parse error. Ignore the token.

Any other character token

Insert the token’s character.

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.
A start tag whose tag name is “html”

Process the token using the rules for the "in body" insertion mode.

A start tag whose tag name is “option”

If the current node is an option element, pop that node from the stack of open elements.

Insert an HTML element for the token.

A start tag whose tag name is “optgroup”

If the current node is an option element, pop that node from the stack of open elements.

If the current node is an optgroup element, pop that node from the stack of open elements.

Insert an HTML element for the token.

An end tag whose tag name is “optgroup”

First, if the current node is an option element, and the node immediately before it in the stack of open elements is an optgroup element, then pop the current node from the stack of open elements.

If the current node is an optgroup element, then pop that node from the stack of open elements. Otherwise, this is a parse error; ignore the token.

An end tag whose tag name is “option”

If the current node is an option element, then pop that node from the stack of open elements. Otherwise, this is a parse error; ignore the token.

An end tag whose tag name is “select”

If the stack of open elements does not have a select element in select scope, this is a parse error; ignore the token. (fragment case)

Otherwise:

Pop elements from the stack of open elements until a select element has been popped from the stack.

Reset the insertion mode appropriately.

A start tag whose tag name is “select”

Parse error.
If the stack of open elements does not have a select element in select scope, ignore the token. (fragment case)

Otherwise:

Pop elements from the stack of open elements until a select element has been popped from the stack.

Reset the insertion mode appropriately.

It just gets treated like an end tag.

A start tag whose tag name is one of: “input”, ”keygen”, ”textarea”

Parse error.

If the stack of open elements does not have a select element in select scope, ignore the token. (fragment case)

Otherwise:

Pop elements from the stack of open elements until a select element has been popped from the stack.

Reset the insertion mode appropriately.

Reprocess the token.

A start tag whose tag name is one of: ”script”, ”template”
An end tag whose tag name is ”template”

Process the token using the rules for the “in head” insertion mode.

An end-of-file token

Process the token using the rules for the ”in body” insertion mode.

Anything else

Parse error. Ignore the token.

13.2.6.4.17 The “in select in table” insertion mode

When the user agent is to apply the rules for the ”in select in table” insertion mode, the user agent must handle the token as follows:
A start tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"

Parse error.

Pop elements from the stack of open elements until a select element has been popped from the stack.

Reset the insertion mode appropriately.

Reprocess the token.

An end tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"

Parse error.

If the stack of open elements does not have an element in table scope that is an HTML element with the same tag name as that of the token, then ignore the token.

Otherwise:

Pop elements from the stack of open elements until a select element has been popped from the stack.

Reset the insertion mode appropriately.

Reprocess the token.

Anything else

Process the token using the rules for the "in select" insertion mode.

13.2.6.4.18 The "in template" insertion mode

When the user agent is to apply the rules for the "in template" insertion mode, the user agent must handle the token as follows:

A character token
A comment token
A DOCTYPE token

Process the token using the rules for the "in body" insertion mode.

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"
An end tag whose tag name is "template"

Process the token using the rules for the "in head" insertion mode.
A start tag whose tag name is one of: "caption", "colgroup", "tbody", "tfoot", "thead"

Pop the current template insertion mode off the stack of template insertion modes.

Push “in table” onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to “in table”, and reprocess the token.

A start tag whose tag name is "col"

Pop the current template insertion mode off the stack of template insertion modes.

Push “in column group” onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to “in column group”, and reprocess the token.

A start tag whose tag name is “tr”

Pop the current template insertion mode off the stack of template insertion modes.

Push “in table body” onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to “in table body”, and reprocess the token.

A start tag whose tag name is one of: “td”, “th”

Pop the current template insertion mode off the stack of template insertion modes.

Push “in row” onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to “in row”, and reprocess the token.

Any other start tag

Pop the current template insertion mode off the stack of template insertion modes.

Push “in body” onto the stack of template insertion modes so that it is the new current template insertion mode.

Switch the insertion mode to “in body”, and reprocess the token.

Any other end tag

Parse error. Ignore the token.
An end-of-file token

If there is no template element on the stack of open elements, then stop parsing. (fragment case)

Otherwise, this is a parse error.

Pop elements from the stack of open elements until a template element has been popped from the stack.

Clear the list of active formatting elements up to the last marker.

Pop the current template insertion mode off the stack of template insertion modes.

Reset the insertion mode appropriately.

Reprocess the token.

13.2.6.4.19 The “after body” insertion mode

When the user agent is to apply the rules for the “after body” insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Process the token using the rules for the "in body" insertion mode.

A comment token

Insert a comment as the last child of the first element in the stack of open elements (the html element).

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is “html”

Process the token using the rules for the "in body" insertion mode.

An end tag whose tag name is “html”

If the parser was created as part of the HTML fragment parsing algorithm, this is a parse error; ignore the token. (fragment case)

Otherwise, switch the insertion mode to "after after body".
An end-of-file token

**Stop parsing.**

Anything else

**Parse error.** Switch the **insertion mode** to “in body” and reprocess the token.

13.2.6.4.20 The “in frameset” insertion mode

When the user agent is to apply the rules for the “in frameset” **insertion mode**, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

**Insert the character.**

A comment token

**Insert a comment.**

A DOCTYPE token

**Parse error.** Ignore the token.

A start tag whose tag name is “html”

Process the token using the rules for the “in body” **insertion mode**.

A start tag whose tag name is “frameset”

**Insert an HTML element** for the token.

An end tag whose tag name is “frameset”

If the **current node** is the root **html** element, then this is a **parse error**; ignore the token.  
(fragment case)

Otherwise, pop the **current node** from the **stack of open elements**.

If the parser was not created as part of the HTML fragment parsing algorithm (fragment case), and the **current node** is no longer a **frameset** element, then switch the **insertion mode** to “after frameset”.

A start tag whose tag name is “frame”

**Insert an HTML element** for the token. Immediately pop the **current node** off the stack of
open elements.

Acknowledge the token’s self-closing flag, if it is set.

A start tag whose tag name is "noframes"

Process the token using the rules for the "in head" insertion mode.

An end-of-file token

If the current node is not the root html element, then this is a parse error.

The current node can only be the root html element in the fragment case.

Stop parsing.

Anything else

Parse error. Ignore the token.

13.2.6.4.21 The "after frameset" insertion mode

When the user agent is to apply the rules for the "after frameset" insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character.

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "html"

Process the token using the rules for the "in body" insertion mode.

An end tag whose tag name is "html"

Switch the insertion mode to "after after frameset".
A start tag whose tag name is “noframes”

Process the token using the rules for the “in head” insertion mode.

An end-of-file token

Stop parsing.

Anything else

Parse error. Ignore the token.

13.2.6.4.22 The “after after body” insertion mode

When the user agent is to apply the rules for the “after after body” insertion mode, the user agent must handle the token as follows:

A comment token

Insert a comment as the last child of the Document object.

A DOCTYPE token
A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

A start tag whose tag name is “html”

Process the token using the rules for the “in body” insertion mode.

An end-of-file token

Stop parsing.

Anything else

Parse error. Switch the insertion mode to “in body” and reprocess the token.

13.2.6.4.23 The “after after frameset” insertion mode

When the user agent is to apply the rules for the “after after frameset” insertion mode, the user agent must handle the token as follows:

A comment token

Insert a comment as the last child of the Document object.

A DOCTYPE token
A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED
(LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE
A start tag whose tag name is “html”

Process the token using the rules for the ”in body” insertion mode.

An end-of-file token

Stop parsing.

A start tag whose tag name is “noframes”

Process the token using the rules for the ”in head” insertion mode.

Anything else

Parse error. Ignore the token.

13.2.6.5 The rules for parsing tokens in foreign content

When the user agent is to apply the rules for parsing tokens in foreign content, the user agent must handle the token as follows:

A character token that is U+0000 NULL

Parse error. Insert a U+FFFD REPLACEMENT CHARACTER character.

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the token’s character.

Any other character token

Insert the token’s character.

Set the frameset-ok flag to “not ok”.

A comment token

Insert a comment.

A DOCTYPE token

Parse error. Ignore the token.

A start tag whose tag name is "font", if the token has any attributes named "color", "face", or "size"
An end tag whose tag name is "br", "p"

Parse error.

While the current node is not a MathML text integration point, an HTML integration point, or an element in the HTML namespace, pop elements from the stack of open elements.

Reprocess the token according to the rules given in the section corresponding to the current insertion mode in HTML content.

Any other start tag

If the adjusted current node is an element in the MathML namespace, adjust MathML attributes for the token. (This fixes the case of MathML attributes that are not all lowercase.)

If the adjusted current node is an element in the SVG namespace, and the token’s tag name is one of the ones in the first column of the following table, change the tag name to the name given in the corresponding cell in the second column. (This fixes the case of SVG elements that are not all lowercase.)

<table>
<thead>
<tr>

</table>

If the adjusted current node is an element in the SVG namespace, adjust SVG attributes for the token. (This fixes the case of SVG attributes that are not all lowercase.)

Adjust foreign attributes for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)

Insert a foreign element for the token, in the same namespace as the adjusted current node.

If the token has its self-closing flag set, then run the appropriate steps from the following list:

If the token’s tag name is “script”, and the new current node is in the SVG namespace

Acknowledged token’s self-closing flag, and then act as described in the steps for a “script” end tag below.

Otherwise

Pop the current node off the stack of open elements and acknowledge the token’s self-closing flag.

An end tag whose tag name is “script”, if the current node is an SVG script element

Pop the current node off the stack of open elements.
Let the *old insertion point* have the same value as the current *insertion point*. Let the *insertion point* be just before the *next input character*.

Increment the parser’s *script nesting level* by one. Set the *parser pause flag* to true.

If the *active speculative HTML parser* is null and the user agent supports SVG, then *process the SVG script element* according to the SVG rules. [SVG]

Even if this causes *new characters to be inserted into the tokenizer*, the parser will not be executed reentrantly, since the *parser pause flag* is true.

Decrement the parser’s *script nesting level* by one. If the parser’s *script nesting level* is zero, then set the *parser pause flag* to false.

Let the *insertion point* have the value of the *old insertion point*. (In other words, restore the *insertion point* to its previous value. This value might be the “undefined” value.)

**Any other end tag**

Run these steps:

1. Initialize *node* to be the *current node* (the bottommost node of the stack).
2. If *node*’s tag name, converted to ASCII lowercase, is not the same as the tag name of the token, then this is a *parse error*.
3. *Loop:* If *node* is the topmost element in the *stack of open elements*, then return. (fragment case)
4. If *node*’s tag name, converted to ASCII lowercase, is the same as the tag name of the token, pop elements from the *stack of open elements* until *node* has been popped from the stack, and then return.
5. Set *node* to the previous entry in the *stack of open elements*.
6. If *node* is not an element in the *HTML namespace*, return to the step labeled *loop*.
7. Otherwise, process the token according to the rules given in the section corresponding to the current *insertion mode* in HTML content.

13.2.7 The end

✅MDN

Document/DOMContentLoaded_event

Support in all current engines.
Once the user agent stops parsing the document, the user agent must run the following steps:

✔✔ MDN

Window/load_event

Support in all current engines.

1. If the active speculative HTML parser is not null, then stop the speculative HTML parser and return.
2. Set the insertion point to undefined.
3. Update the current document readiness to "interactive".
4. Pop all the nodes off the stack of open elements.
5. While the list of scripts that will execute when the document has finished parsing is not empty:
   1. Spin the event loop until the first script in the list of scripts that will execute when the document has finished parsing has its "ready to be parser-executed" flag set and the parser's Document has no style sheet that is blocking scripts.
   2. Execute the first script in the list of scripts that will execute when the document has finished parsing.
   3. Remove the first script element from the list of scripts that will execute when the document has finished parsing (i.e. shift out the first entry in the list).
6. Queue a global task on the DOM manipulation task source given the Document’s relevant global object to run the following substeps:
   1. Set the Document’s load timing info’s DOM content loaded event start time to
the current high resolution time given the Document’s relevant global object.

2. Fire an event named DOMContentLoaded at the Document object, with its bubbles attribute initialized to true.

3. Set the Document’s load timing info’s DOM content loaded event end time to the current high resolution time given the Document’s relevant global object.

4. Enable the client message queue of the ServiceWorkerContainer object whose associated service worker client is the Document object’s relevant settings object.

5. Invoke WebDriver BiDi DOM content loaded with the Document’s browsing context, and a new WebDriver BiDi navigation status whose id is the Document object’s navigation id, status is "pending", and url is the Document object’s URL.

7. Spin the event loop until the set of scripts that will execute as soon as possible and the list of scripts that will execute in order as soon as possible are empty.

8. Spin the event loop until there is nothing that delays the load event in the Document.

9. Queue a global task on the DOM manipulation task source given the Document’s relevant global object to run the following steps:
   1. Update the current document readiness to "complete".
   2. If the Document object’s browsing context is null, then abort these steps.
   3. Let window be the Document’s relevant global object.
   4. Set the Document’s load timing info’s load event start time to the current high resolution time given window.
   5. Fire an event named load at window, with legacy target override flag set.
   6. Invoke WebDriver BiDi load complete with the Document’s browsing context, and a new WebDriver BiDi navigation status whose id is the Document object’s navigation id, status is "complete", and url is the Document object’s URL.
   7. Set the Document object’s navigation id to null.
   8. Set the Document’s load timing info’s load event end time to the current high resolution time given window.
   9. Assert: Document’s page showing is false.
10. Set the Document’s page showing flag to true.

11. Fire a page transition event named pageshow at window with false.

10. If the Document’s print when loaded flag is set, then run the printing steps.

11. The Document is now ready for post-load tasks.

When the user agent is to abort a parser, it must run the following steps:

1. Throw away any pending content in the input stream, and discard any future content that would have been added to it.

2. Stop the speculative HTML parser for this HTML parser.

3. Update the current document readiness to "interactive".

4. Pop all the nodes off the stack of open elements.

5. Update the current document readiness to "complete".

13.2.8 Speculative HTML parsing

User agents may implement an optimization, as described in this section, to speculatively fetch resources that are declared in the HTML markup while the HTML parser is waiting for a pending parsing-blocking script to be fetched and executed, or during normal parsing, at the time an element is created for a token. While this optimization is not defined in precise detail, there are some rules to consider for interoperability.

Each HTML parser can have an active speculative HTML parser. It is initially null.

The speculative HTML parser must act like the normal HTML parser (e.g., the tree builder rules apply), with some exceptions:

- The state of the normal HTML parser and the document itself must not be affected.
  
  For example, the next input character or the stack of open elements for the normal HTML parser is not affected by the speculative HTML parser.

- Bytes pushed into the HTML parser’s input byte stream must also be pushed into the speculative HTML parser’s input byte stream. Bytes read from the streams must be independent.

- The result of the speculative parsing is primarily a series of speculative fetches. Which
kinds of resources to speculatively fetch is implementation-defined, but user agents must not speculatively fetch resources that would not be fetched with the normal HTML parser, under the assumption that the script that is blocking the HTML parser does nothing.

It is possible that the same markup is seen multiple times from the speculative HTML parser and then the normal HTML parser. It is expected that duplicated fetches will be prevented by caching rules, which are not yet fully specified.

A speculative fetch for a speculative mock element element must follow these rules:

Should some of these things be applied to the document “for real”, even though they are found speculatively?

- If the speculative HTML parser encounters one of the following elements, then act as if that element is processed for the purpose of its effect of subsequent speculative fetches.
  - A base element.
  - A meta element whose http-equiv attribute is in the Content security policy state.
  - A meta element whose name attribute is an ASCII case-insensitive match for "referrer".
  - A meta element whose name attribute is an ASCII case-insensitive match for "viewport". (This can affect whether a media query list matches the environment.) [CSSDEVICEADAPT]

- Let url be the URL that element would fetch if it was processed normally. If there is no such URL or if it is the empty string, then do nothing. Otherwise, if url is already in the list of speculative fetch URLs, then do nothing. Otherwise, fetch url as if the element was processed normally, and add url to the list of speculative fetch URLs.

Each Document has a list of speculative fetch URLs, which is a list of URLs, initially empty.

To start the speculative HTML parser for an instance of an HTML parser parser:

1. Optionally, return.

   This step allows user agents to opt out of speculative HTML parsing.

2. If parser's active speculative HTML parser is not null, then stop the speculative HTML parser for parser.

   This can happen when document.write() writes another parser-blocking script. For simplicity, this specification always restarts speculative parsing, but user agents can implement a more efficient strategy, so long as the end result is equivalent.

3. Let speculativeParser be a new speculative HTML parser, with the same state as parser.
4. Let speculativeDoc be a new isomorphic representation of parser's Document, where all elements are instead speculative mock elements. Let speculativeParser parse into speculativeDoc.

5. Set parser's active speculative HTML parser to speculativeParser.

6. In parallel, run speculativeParser until it is stopped or until it reaches the end of its input stream.

To stop the speculative HTML parser for an instance of an HTML parser parser:

1. Let speculativeParser be parser's active speculative HTML parser.

2. If speculativeParser is null, then return.

3. Throw away any pending content in speculativeParser's input stream, and discard any future content that would have been added to it.

4. Set parser's active speculative HTML parser to null.

The speculative HTML parser will create speculative mock elements instead of normal elements. DOM operations that the tree builder normally does on elements are expected to work appropriately on speculative mock elements.

A speculative mock element is a struct with the following items:

- A string namespace, corresponding to an element’s namespace.
- A string local name, corresponding to an element’s local name.
- A list attribute list, corresponding to an element’s attribute list.
- A list children, corresponding to an element’s children.

To create a speculative mock element given a namespace, tagName, and attributes:

1. Let element be a new speculative mock element.

2. Set element’s namespace to namespace.

3. Set element’s local name to tagName.

4. Set element’s attribute list to attributes.

5. Set element’s children to a new empty list.

6. Optionally, perform a speculative fetch for element.
7. Return element.

When the tree builder says to insert an element into a template element’s template contents, if that is a speculative mock element, instead do nothing. URLs found speculatively inside template elements might themselves be templates, and must not be speculatively fetched.

13.2.9 Coercing an HTML DOM into an infoset

When an application uses an HTML parser in conjunction with an XML pipeline, it is possible that the constructed DOM is not compatible with the XML tool chain in certain subtle ways. For example, an XML toolchain might not be able to represent attributes with the name xmlns, since they conflict with the Namespaces in XML syntax. There is also some data that the HTML parser generates that isn’t included in the DOM itself. This section specifies some rules for handling these issues.

If the XML API being used doesn’t support DOCTYPEs, the tool may drop DOCTYPEs altogether.

If the XML API doesn’t support attributes in no namespace that are named “xmlns”, attributes whose names start with “xmlns:”, or attributes in the XMLNS namespace, then the tool may drop such attributes.

The tool may annotate the output with any namespace declarations required for proper operation.

If the XML API being used restricts the allowable characters in the local names of elements and attributes, then the tool may map all element and attribute local names that the API wouldn’t support to a set of names that are allowed, by replacing any character that isn’t supported with the uppercase letter U and the six digits of the character’s code point when expressed in hexadecimal, using digits 0-9 and capital letters A-F as the symbols, in increasing numeric order.

For example, the element name foo<bar, which can be output by the HTML parser, though it is neither a legal HTML element name nor a well-formed XML element name, would be converted into fooU00003Cbar, which is a well-formed XML element name (though it’s still not legal in HTML by any means).

As another example, consider the attribute xlink:href. Used on a MathML element, it becomes, after being adjusted, an attribute with a prefix “xlink” and a local name “href”. However, used on an HTML element, it becomes an attribute with no prefix and the local name “xlink:href”, which is not a valid NCName, and thus might not be accepted by an XML API. It could thus get converted, becoming “xlinkU00003Ahref”.

The resulting names from this conversion conveniently can’t clash with any attribute generated by the HTML parser, since those are all either lowercase or those listed in the adjust foreign attributes algorithm’s table.
If the XML API restricts comments from having two consecutive U+002D HYPHEN-MINUS characters (–), the tool may insert a single U+0020 SPACE character between any such offending characters.

If the XML API restricts comments from ending in a U+002D HYPHEN-MINUS character (–), the tool may insert a single U+0020 SPACE character at the end of such comments.

If the XML API restricts allowed characters in character data, attribute values, or comments, the tool may replace any U+000C FORM FEED (FF) character with a U+0020 SPACE character, and any other literal non-XML character with a U+FFFD REPLACEMENT CHARACTER.

If the tool has no way to convey out-of-band information, then the tool may drop the following information:

- Whether the document is set to no-quirks mode, limited-quirks mode, or quirks mode
- The association between form controls and forms that aren’t their nearest form element ancestor (use of the form element pointer in the parser)
- The template contents of any template elements.

The mutations allowed by this section apply after the HTML parser’s rules have been applied. For example, a `<a::>` start tag will be closed by a `</a::>` end tag, and never by a `</aU00003AU00003A>` end tag, even if the user agent is using the rules above to then generate an actual element in the DOM with the name aU00003AU00003A for that start tag.

13.2.10 An introduction to error handling and strange cases in the parser

This section is non-normative.

This section examines some erroneous markup and discusses how the HTML parser handles these cases.

13.2.10.1 Misnested tags: `<b><i></b></i>`

This section is non-normative.

The most-often discussed example of erroneous markup is as follows:

```html
<p>1<b>2<i>3</i></b>4</i>5</p>
```

The parsing of this markup is straightforward up to the “3”. At this point, the DOM looks like this:

- `html`
  - `head`
  - `body`
    - `p`
Here, the stack of open elements has five elements on it: html, body, p, b, and i. The list of active formatting elements just has two: b and i. The insertion mode is “in body”.

Upon receiving the end tag token with the tag name “b”, the adoption agency algorithm is invoked. This is a simple case, in that the formatting element is the b element, and there is no furthest block. Thus, the stack of open elements ends up with just three elements: html, body, and p, while the list of active formatting elements has just one: i. The DOM tree is unmodified at this point.

The next token is a character (“4”), triggers the reconstruction of the active formatting elements, in this case just the i element. A new i element is thus created for the “4” Text node. After the end tag token for the “i” is also received, and the “5” Text node is inserted, the DOM looks as follows:

- html
  - head
  - body
    - p
      - #text: 1
    - b
      - #text: 2
      - i
        - #text: 3
      - i
        - #text: 4
      - #text: 5

13.2.10.2 Misnested tags: <b><p></b></p>

This section is non-normative.

A case similar to the previous one is the following:

<b>1</b><p>2</p></b><b>3</b></p>

Up to the “2” the parsing here is straightforward:

- html
  - head
  - body
The interesting part is when the end tag token with the tag name "b" is parsed.

Before that token is seen, the stack of open elements has four elements on it: html, body, b, and p. The list of active formatting elements just has the one: b. The insertion mode is "in body".

Upon receiving the end tag token with the tag name "b", the "adoption agency algorithm" is invoked, as in the previous example. However, in this case, there is a furthest block, namely the p element. Thus, this time the adoption agency algorithm isn’t skipped over.

The common ancestor is the body element. A conceptual "bookmark" marks the position of the b in the list of active formatting elements, but since that list has only one element in it, the bookmark won’t have much effect.

As the algorithm progresses, node ends up set to the formatting element (b), and last node ends up set to the furthest block (p).

The last node gets appended (moved) to the common ancestor, so that the DOM looks like:

- html
  - head
  - body
    - b
      - #text: 1
    - p
      - #text: 2

A new b element is created, and the children of the p element are moved to it:

- html
  - head
  - body
    - b
      - #text: 1
    - p
  - b
    - #text: 2

Finally, the new b element is appended to the p element, so that the DOM looks like:
The `b` element is removed from the list of active formatting elements and the stack of open elements, so that when the “3” is parsed, it is appended to the `p` element:

```
html
  • head
  • body
    • b
      • #text: 1
    • p
      • b
        • #text: 2
```

13.2.10.3 Unexpected markup in tables

This section is non-normative.

Error handling in tables is, for historical reasons, especially strange. For example, consider the following markup:

```
<table><b><tr><td>aaa</td></tr><b>bbb</b></table>ccc
```

The highlighted `b` element start tag is not allowed directly inside a table like that, and the parser handles this case by placing the element before the table. (This is called foster parenting.) This can be seen by examining the DOM tree as it stands just after the `table` element’s start tag has been seen:

```
html
  • head
  • body
    • table
```

...and then immediately after the `b` element start tag has been seen:

```
html
  • head
  • body
```
At this point, the stack of open elements has on it the elements html, body, table, and b (in that order, despite the resulting DOM tree); the list of active formatting elements just has the b element in it; and the insertion mode is “in table”.

The tr start tag causes the b element to be popped off the stack and a tbody start tag to be implied; the tbody and tr elements are then handled in a rather straight-forward manner, taking the parser through the “in table body” and “in row” insertion modes, after which the DOM looks as follows:

- html
  - head
  - body
    - b
    - table
      - tbody
        - tr

Here, the stack of open elements has on it the elements html, body, table, tbody, and tr; the list of active formatting elements still has the b element in it; and the insertion mode is “in row”.

The td element start tag token, after putting a td element on the tree, puts a marker on the list of active formatting elements (it also switches to the “in cell” insertion mode).

- html
  - head
  - body
    - b
    - table
      - tbody
        - tr
        - td

The marker means that when the “aaa” character tokens are seen, no b element is created to hold the resulting Text node:

- html
  - head
  - body
    - b
    - table
      - tbody
        - tr
The end tags are handled in a straight-forward manner; after handling them, the stack of open elements has on it the elements `html`, `body`, `table`, and `tbody`; the list of active formatting elements still has the `b` element in it (the marker having been removed by the “td” end tag token); and the insertion mode is “in table body”.

Thus it is that the “bbb” character tokens are found. These trigger the “in table text” insertion mode to be used (with the original insertion mode set to “in table body”). The character tokens are collected, and when the next token (the `table` element end tag) is seen, they are processed as a group. Since they are not all spaces, they are handled as per the “anything else” rules in the “in table” insertion mode, which defer to the “in body” insertion mode but with foster parenting.

When the active formatting elements are reconstructed, a `b` element is created and foster parented, and then the “bbb” `Text` node is appended to it:

```
• html
  ◦ head
  ◦ body
    • b
    • b
      • #text: bbb
    • table
      • tbody
        • tr
          • td
            • #text: aaa
```

The stack of open elements has on it the elements `html`, `body`, `table`, `tbody`, and the new `b` (again, note that this doesn’t match the resulting tree!); the list of active formatting elements has the new `b` element in it; and the insertion mode is still “in table body”.

Had the character tokens been only ASCII whitespace instead of “bbb”, then that ASCII whitespace would just be appended to the `tbody` element.

Finally, the `table` is closed by a “table” end tag. This pops all the nodes from the stack of open elements up to and including the `table` element, but it doesn’t affect the list of active formatting elements, so the “ccc” character tokens after the table result in yet another `b` element being created, this time after the table:

```
• html
  ◦ head
  ◦ body
    • b
    • b
```
13.2.10.4 Scripts that modify the page as it is being parsed

This section is non-normative.

Consider the following markup, which for this example we will assume is the document with URL https://example.com/inner, being rendered as the content of an iframe in another document with the URL https://example.com/outer:

```html
<div id="a">
  <script>
    var div = document.getElementById('a');
    parent.document.body.appendChild(div);
  </script>
  <script>
    alert(document.URL);
  </script>
</div>
<script>
  alert(document.URL);
</script>
```

Up to the first "script" end tag, before the script is parsed, the result is relatively straightforward:

- **html**
  - head
  - body
    - **div** id="a"
      - **#text**: var div = document.getElementById('a');
      - parent.document.body.appendChild(div);

After the script is parsed, though, the **div** element and its child **script** element are gone:

- **html**
  - head
They are, at this point, in the Document of the aforementioned outer browsing context. However, the stack of open elements still contains the div element.

Thus, when the second script element is parsed, it is inserted into the outer Document object. Those parsed into different Documents than the one the parser was created for do not execute, so the first alert does not show.

Once the div element’s end tag is parsed, the div element is popped off the stack, and so the next script element is in the inner Document:

- html
  - head
  - body
    - script
      - #text: alert(document.URL);

This script does execute, resulting in an alert that says “https://example.com/inner”.

13.2.10.5 The execution of scripts that are moving across multiple documents

This section is non-normative.

Elaborating on the example in the previous section, consider the case where the second script element is an external script (i.e. one with a src attribute). Since the element was not in the parser’s Document when it was created, that external script is not even downloaded.

In a case where a script element with a src attribute is parsed normally into its parser’s Document, but while the external script is being downloaded, the element is moved to another document, the script continues to download, but does not execute.

In general, moving script elements between Documents is considered a bad practice.

13.2.10.6 Unclosed formatting elements

This section is non-normative.

The following markup shows how nested formatting elements (such as b) get collected and continue to be applied even as the elements they are contained in are closed, but that excessive duplicates are thrown away.

```html
<!DOCTYPE html>
<p><b class=x><b class=x><b><b class=x><b class=x><b>X
</b><p>X
</b><p><b>b class=x><b>X
```
<p></p></b></b></b></b></b><b>X

The resulting DOM tree is as follows:

- **DOCTYPE:** html
  - html
    - head
    - body
      - p
        - b class="x"
          - b class="x"
            - b class="x"
              - b
                - b class="x"
                  - b class="x"
                    - b
                      - #text: X
      - p
        - b class="x"
          - b
            - b class="x"
              - b class="x"
                - b
                  - #text: X
      - p
        - b class="x"
          - b
            - b class="x"
              - b class="x"
                - b
                  - #text: X
      - p
        - #text: X

Note how the second p element in the markup has no explicit b elements, but in the resulting DOM, up to three of each kind of formatting element (in this case three b elements with the class attribute, and two unadorned b elements) get reconstructed before the element’s "X”.

Also note how this means that in the final paragraph only six b end tags are needed to completely clear the list of active formatting elements, even though nine b start tags have been seen up to this point.
13.3 Serializing HTML fragments

For the purposes of the following algorithm, an element serializes as void if its element type is one of the void elements, or is basefont, bgsound, frame, or keygen.

The following steps form the HTML fragment serialization algorithm. The algorithm takes as input a DOM Element, Document, or DocumentFragment referred to as the node, and returns a string.

This algorithm serializes the children of the node being serialized, not the node itself.

1. If the node serializes as void, then return the empty string.
2. Let s be a string, and initialize it to the empty string.
3. If the node is a template element, then let the node instead be the template element’s template contents (a DocumentFragment node).
4. For each child node of the node, in tree order, run the following steps:
   1. Let current node be the child node being processed.
   2. Append the appropriate string from the following list to s:

   If current node is an Element

   If current node is an element in the HTML namespace, the MathML namespace, or the SVG namespace, then let tagname be current node’s local name. Otherwise, let tagname be current node’s qualified name.

   Append a U+003C LESS-THAN SIGN character (<), followed by tagname.

   For HTML elements created by the HTML parser or createElement(), tagname will be lowercase.

   If current node’s is value is not null, and the element does not have an is attribute in its attribute list, then append the string ” is="”, followed by current node’s is value escaped as described below in attribute mode, followed by a U+0022 QUOTATION MARK character (”).

   For each attribute that the element has, append a U+0020 SPACE character, the attribute’s serialized name as described below, a U+003D EQUALS SIGN character (=), a U+0022 QUOTATION MARK character (”), the attribute’s value, escaped as described below in attribute mode, and a second U+0022 QUOTATION MARK character (”).

   An attribute’s serialized name for the purposes of the previous paragraph
must be determined as follows:

**If the attribute has no namespace**

The attribute’s serialized name is the attribute’s local name.

For attributes on HTML elements set by the HTML parser or by `setAttribute()`, the local name will be lowercase.

**If the attribute is in the XML namespace**

The attribute’s serialized name is the string "xml:" followed by the attribute’s local name.

**If the attribute is in the XMLNS namespace and the attribute’s local name is `xmlns`**

The attribute’s serialized name is the string "xmlns".

**If the attribute is in the XMLNS namespace and the attribute’s local name is not `xmlns`**

The attribute’s serialized name is the string "xmlns:" followed by the attribute’s local name.

**If the attribute is in the XLink namespace**

The attribute’s serialized name is the string "xlink:" followed by the attribute’s local name.

**If the attribute is in some other namespace**

The attribute’s serialized name is the attribute’s qualified name.

While the exact order of attributes is implementation-defined, and may depend on factors such as the order that the attributes were given in the original markup, the sort order must be stable, such that consecutive invocations of this algorithm serialize an element’s attributes in the same order.

Append a U+003E GREATER-THEAN SIGN character (>).

If *current node* serializes as void, then continue on to the next child node at this point.

Append the value of running the HTML fragment serialization algorithm on the *current node* element (thus recursing into this algorithm for that element), followed by a U+003C LESS-THEAN SIGN character (<), a U+002F
SOLIDUS character (/), \textit{tagname} again, and finally a U+003E GREATER-THAN SIGN character (>).

If \textit{current node} is a \textbf{Text} node

If the parent of \textit{current node} is a \texttt{style}, \texttt{script}, \texttt{xmp}, \texttt{iframe}, \texttt{noembed}, \texttt{noframes}, or \texttt{plaintext} element, or if the parent of \textit{current node} is a \texttt{noscript} element and \textit{scripting} is enabled for the node, then append the value of \textit{current node}'s \texttt{data} IDL attribute literally.

Otherwise, append the value of \textit{current node}'s \texttt{data} IDL attribute, escaped as described below.

If \textit{current node} is a \textbf{Comment}

Append the literal string "<!--" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS), followed by the value of \textit{current node}'s \texttt{data} IDL attribute, followed by the literal string "-->" (U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS, U+003E GREATER-THAN SIGN).

If \textit{current node} is a \textbf{ProcessingInstruction}

Append the literal string "<?" (U+003C LESS-THAN SIGN, U+003F QUESTION MARK), followed by the value of \textit{current node}'s \texttt{target} IDL attribute, followed by a single U+0020 SPACE character, followed by the value of \textit{current node}'s \texttt{data} IDL attribute, followed by a single U+003E GREATER-THAN SIGN character (>).

If \textit{current node} is a \textbf{DocumentType}

Append the literal string "<!DOCTYPE" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+0044 LATIN CAPITAL LETTER D, U+004F LATIN CAPITAL LETTER O, U+0043 LATIN CAPITAL LETTER C, U+0054 LATIN CAPITAL LETTER T, U+0059 LATIN CAPITAL LETTER Y, U+0050 LATIN CAPITAL LETTER P, U+0045 LATIN CAPITAL LETTER E), followed by a space (U+0020 SPACE), followed by the value of \textit{current node}'s \texttt{name} IDL attribute, followed by the literal string ">" (U+003E GREATER-THAN SIGN).

5. Return \texttt{s}.

It is possible that the output of this algorithm, if parsed with an \texttt{HTML parser}, will not return the original tree structure. Tree structures that do not roundtrip a serialize and reparse step can also be produced by the \texttt{HTML parser} itself, although such cases are typically non-conforming.

For instance, if a \texttt{textarea} element to which a \textbf{Comment} node has been appended is serialized
and the output is then reparsed, the comment will end up being displayed in the text control. Similarly, if, as a result of DOM manipulation, an element contains a comment that contains the literal string "-->", then when the result of serializing the element is parsed, the comment will be truncated at that point and the rest of the comment will be interpreted as markup. More examples would be making a script element contain a Text node with the text string "</script>", or having a p element that contains a ul element (as the ul element’s start tag would imply the end tag for the p).

This can enable cross-site scripting attacks. An example of this would be a page that lets the user enter some font family names that are then inserted into a CSS style block via the DOM and which then uses the innerHTML IDL attribute to get the HTML serialization of that style element: if the user enters "</style><script>attack</script>" as a font family name, innerHTML will return markup that, if parsed in a different context, would contain a script node, even though no script node existed in the original DOM.

For example, consider the following markup:

<form id="outer"><div></form><form id="inner"><input>

This will be parsed into:

- html
  - head
  - body
    - form id="outer"
      - div
        - form id="inner"
          - input

The input element will be associated with the inner form element. Now, if this tree structure is serialized and reparsed, the <form id="inner"> start tag will be ignored, and so the input element will be associated with the outer form element instead.

<html><head></head><body><form id="outer"><div><form id="inner"><input></form></div></form>

- html
  - head
  - body
    - form id="outer"
      - div
        - input

As another example, consider the following markup:

<a><table></table></a>

This will be parsed into:
That is, the `a` elements are nested, because the second `a` element is foster parented. After a serialize-reparse roundtrip, the `a` elements and the `table` element would all be siblings, because the second `<a>` start tag implicitly closes the first `a` element.

```html
<html><head></head><body><a><a></a><table></table></a></body></html>
```

For historical reasons, this algorithm does not round-trip an initial U+000A LINE FEED (LF) character in `pre`, `textarea`, or `listing` elements, even though (in the first two cases) the markup being round-tripped can be conforming. The HTML parser will drop such a character during parsing, but this algorithm does not serialize an extra U+000A LINE FEED (LF) character.

For example, consider the following markup:

```
<pre>
Hello.
</pre>
```

When this document is first parsed, the `pre` element’s child text content starts with a single newline character. After a serialize-reparse roundtrip, the `pre` element’s child text content is simply “Hello.”.

Because of the special role of the `is` attribute in signaling the creation of customized built-in elements, in that it provides a mechanism for parsed HTML to set the element’s `is` value, we special-case its handling during serialization. This ensures that an element’s `is` value is preserved through serialize-parse roundtrips.

When creating a customized built-in element via the parser, a developer uses the `is` attribute directly; in such cases serialize-parse roundtrips work fine.

```typescript
window.SuperP = class extends HTMLParagraphElement {};
customElements.define("super-p", SuperP, { extends: "p" });
```
<div id="container"><p is="super-p">Superb!</p></div>

<script>
console.log(container.innerHTML); // <p is="super-p">
container.innerHTML = container.innerHTML;
console.log(container.innerHTML); // <p is="super-p">
console.assert(container.firstChild instanceof SuperP);
</script>

But when creating a customized built-in element via its constructor or via createElement(),
the is attribute is not added. Instead, the is value (which is what the custom elements
machinery uses) is set without intermediating through an attribute.

<script>
container.innerHTML = "";
const p = document.createElement("p", { is: "super-p" });
container.appendChild(p);

// The is attribute is not present in the DOM:
console.assert(!p.hasAttribute("is"));

// But the element is still a super-p:
console.assert(p instanceof SuperP);
</script>

To ensure that serialize-parse roundtrips still work, the serialization process explicitly writes
out the element's is value as an is attribute:

<script>
console.log(container.innerHTML); // <p is="super-p">
container.innerHTML = container.innerHTML;
console.log(container.innerHTML); // <p is="super-p">
console.assert(container.firstChild instanceof SuperP);
</script>

Escaping a string (for the purposes of the algorithm above) consists of running the following steps:

1. Replace any occurrence of the "&" character by the string "&amp;".

2. Replace any occurrences of the U+00A0 NO-BREAK SPACE character by the string "&nbsp;".

3. If the algorithm was invoked in the attribute mode, replace any occurrences of the "" character by the string "&quot;."
4. If the algorithm was not invoked in the attribute mode, replace any occurrences of the "<" character by the string "\&lt;", and any occurrences of the ">" character by the string "\&gt;".

13.4 Parsing HTML fragments

The following steps form the HTML fragment parsing algorithm. The algorithm takes as input an Element node, referred to as the context element, which gives the context for the parser, as well as input, a string to parse, and returns a list of zero or more nodes.

Parts marked fragment case in algorithms in the parser section are parts that only occur if the parser was created for the purposes of this algorithm. The algorithms have been annotated with such markings for informational purposes only; such markings have no normative weight. If it is possible for a condition described as a fragment case to occur even when the parser wasn’t created for the purposes of handling this algorithm, then that is an error in the specification.

1. Create a new Document node, and mark it as being an HTML document.

2. If the node document of the context element is in quirks mode, then let the Document be in quirks mode. Otherwise, the node document of the context element is in limited-quirks mode, then let the Document be in limited-quirks mode. Otherwise, leave the Document in no-quirks mode.

3. Create a new HTML parser, and associate it with the just created Document node.

4. Set the state of the HTML parser’s tokenization stage as follows, switching on the context element:

   title
   textarea
     Switch the tokenizer to the RCDATA state.

   style
   xmp
   iframe
   noembed
   noframes
     Switch the tokenizer to the RAWTEXT state.

   script
     Switch the tokenizer to the script data state.

   noscript
     If the scripting flag is enabled, switch the tokenizer to the RAWTEXT state. Otherwise, leave the tokenizer in the data state.
**plaintext**

Switch the tokenizer to the **PLAINTEXT state**.

Any other element

Leave the tokenizer in the **data state**.

For performance reasons, an implementation that does not report errors and that uses the actual state machine described in this specification directly could use the **PLAINTEXT state** instead of the **RAWTEXT** and script data states where those are mentioned in the list above. Except for rules regarding parse errors, they are equivalent, since there is no **appropriate end tag token** in the fragment case, yet they involve far fewer state transitions.

5. Let root be a new **html** element with no attributes.

6. Append the element root to the **Document** node created above.

7. Set up the parser’s **stack of open elements** so that it contains just the single element root.

8. If the **context** element is a **template** element, push "in template" onto the **stack of template insertion modes** so that it is the new **current template insertion mode**.

9. Create a start tag token whose name is the local name of **context** and whose attributes are the attributes of **context**.

   Let this start tag token be the start tag token of the **context** node, e.g. for the purposes of determining if it is an **HTML integration point**.

10. **Reset the parser’s insertion mode appropriately**.

    The parser will reference the **context** element as part of that algorithm.

11. Set the parser’s **form element pointer** to the nearest node to the **context** element that is a **form** element (going straight up the ancestor chain, and including the element itself, if it is a **form** element), if any. (If there is no such **form** element, the **form element pointer** keeps its initial value, null.)

12. Place the **input** into the **input stream** for the **HTML parser** just created. The encoding **confidence** is **irrelevant**.

13. Start the parser and let it run until it has consumed all the characters just inserted into the input stream.

14. Return the child nodes of root, in **tree order**.

### 13.5 Named character references

This table lists the character reference names that are supported by HTML, and the code points
to which they refer. It is referenced by the previous sections.

It is intentional, for legacy compatibility, that many code points have multiple character reference names. For example, some appear both with and without the trailing semicolon, or with different capitalizations.

</tbody>
</table>
This data is also available as a JSON file.

The glyphs displayed above are non-normative. Refer to Unicode for formal definitions of the characters listed above.

The character reference names originate from XML Entity Definitions for Characters, though only the above is considered normative. [XMLENTITY]
This list is static and will not be expanded or changed in the future.

14 The XML syntax

This section only describes the rules for XML resources. Rules for text/html resources are discussed in the section above entitled "The HTML syntax".

14.1 Writing documents in the XML syntax

The XML syntax for HTML was formerly referred to as "XHTML", but this specification does not use that term (among other reasons, because no such term is used for the HTML syntaxes of MathML and SVG).

The syntax for XML is defined in XML and Namespaces in XML. [XML] [XMLNS]

This specification does not define any syntax-level requirements beyond those defined for XML proper.

XML documents may contain a DOCTYPE if desired, but this is not required to conform to this specification. This specification does not define a public or system identifier, nor provide a formal DTD.

According to XML, XML processors are not guaranteed to process the external DTD subset referenced in the DOCTYPE. This means, for example, that using entity references for characters in XML documents is unsafe if they are defined in an external file (except for &lt;, &gt;, &amp;, &quot;, and &apos;).

14.2 Parsing XML documents

This section describes the relationship between XML and the DOM, with a particular emphasis on how this interacts with HTML.

An XML parser, for the purposes of this specification, is a construct that follows the rules given in XML to map a string of bytes or characters into a Document object.
At the time of writing, no such rules actually exist.

An XML parser is either associated with a Document object when it is created, or creates one implicitly.

This Document must then be populated with DOM nodes that represent the tree structure of the input passed to the parser, as defined by XML, Namespaces in XML, and DOM. When creating DOM nodes representing elements, the create an element for a token algorithm or some equivalent that operates on appropriate XML data structures must be used, to ensure the proper element interfaces are created and that custom elements are set up correctly.

DOM mutation events must not fire for the operations that the XML parser performs on the Document’s tree, but the user agent must act as if elements and attributes were individually appended and set respectively so as to trigger rules in this specification regarding what happens when an element is inserted into a document or has its attributes set, and DOM's requirements regarding mutation observers mean that mutation observers are fired (unlike mutation events).

Between the time an element’s start tag is parsed and the time either the element’s end tag is parsed or the parser detects a well-formedness error, the user agent must act as if the element was in a stack of open elements.

This is used, e.g. by the object element to avoid instantiating plugins before the param element children have been parsed.

This specification provides the following additional information that user agents should use when retrieving an external entity: the public identifiers given in the following list all correspond to the URL given by this link. (This URL is a DTD containing the entity declarations for the names listed in the named character references section.)

- //W3C//DTD XHTML 1.0 Transitional//EN
- //W3C//DTD XHTML 1.1//EN
- //W3C//DTD XHTML 1.0 Strict//EN
- //W3C//DTD XHTML 1.0 Frameset//EN
- //W3C//DTD XHTML Basic 1.0//EN
- //W3C//DTD XHTML 1.1 plus MathML 2.0//EN
- //W3C//DTD XHTML 1.1 plus MathML 2.0 plus SVG 1.1//EN
- //W3C//DTD MathML 2.0//EN
- //WAPFORUM//DTD XHTML Mobile 1.0//EN

Furthermore, user agents should attempt to retrieve the above external entity’s content when one of the above public identifiers is used, and should not attempt to retrieve any other external entity’s content.

This is not strictly a violation of XML, but it does contradict the spirit of XML’s requirements. This is motivated by a desire for user agents to all handle entities in an interoperable fashion without requiring any network access for handling external subsets.
XML parsers can be invoked with XML scripting support enabled or XML scripting support disabled. Except where otherwise specified, XML parsers are invoked with XML scripting support enabled.

When an XML parser with XML scripting support enabled creates a script element, it must have its parser document set and its “non-blocking” flag must be unset. If the parser was created as part of the XML fragment parsing algorithm, then the element must be marked as “already started” also. When the element’s end tag is subsequently parsed, the user agent must perform a microtask checkpoint, and then prepare the script element. If this causes there to be a pending parsing-blocking script, then the user agent must run the following steps:

1. Block this instance of the XML parser, such that the event loop will not run tasks that invoke it.

2. Spin the event loop until the parser’s Document has no style sheet that is blocking scripts and the pending parsing-blocking script’s “ready to be parser-executed” flag is set.

3. Unblock this instance of the XML parser, such that tasks that invoke it can again be run.

4. Execute the pending parsing-blocking script.

5. There is no longer a pending parsing-blocking script.

Since the document.write() API is not available for XML documents, much of the complexity in the HTML parser is not needed in the XML parser.

When the XML parser has XML scripting support disabled, none of this happens.

When an XML parser would append a node to a template element, it must instead append it to the template element’s template contents (a DocumentFragment node).

This is a willful violation of XML; unfortunately, XML is not formally extensible in the manner that is needed for template processing. [XML]

When an XML parser creates a Node object, its node document must be set to the node document of the node into which the newly created node is to be inserted.

Certain algorithms in this specification spoon-feed the parser characters one string at a time. In such cases, the XML parser must act as it would have if faced with a single string consisting of the concatenation of all those characters.

When an XML parser reaches the end of its input, it must stop parsing, following the same rules as the HTML parser. An XML parser can also be aborted, which must again be done in the same way as for an HTML parser.

For the purposes of conformance checkers, if a resource is determined to be in the XML syntax,
then it is an XML document.

14.3 Serializing XML fragments

The XML fragment serialization algorithm for a Document or Element node either returns a fragment of XML that represents that node or throws an exception.

For Documents, the algorithm must return a string in the form of a document entity, if none of the error cases below apply.

For Elements, the algorithm must return a string in the form of an internal general parsed entity, if none of the error cases below apply.

In both cases, the string returned must be XML namespace-well-formed and must be an isomorphic serialization of all of that node’s relevant child nodes, in tree order. User agents may adjust prefixes and namespace declarations in the serialization (and indeed might be forced to do so in some cases to obtain namespace-well-formed XML). User agents may use a combination of regular text and character references to represent Text nodes in the DOM.

A node’s relevant child nodes are those that apply given the following rules:

For template elements
   The relevant child nodes are the child nodes of the template element’s template contents, if any.

For all other nodes
   The relevant child nodes are the child nodes of node itself, if any.

For Elements, if any of the elements in the serialization are in no namespace, the default namespace in scope for those elements must be explicitly declared as the empty string. (This doesn’t apply in the Document case.) [XML] [XMLNS]

For the purposes of this section, an internal general parsed entity is considered XML namespace-well-formed if a document consisting of an element with no namespace declarations whose contents are the internal general parsed entity would itself be XML namespace-well-formed.

If any of the following error cases are found in the DOM subtree being serialized, then the algorithm must throw an "InvalidStateError" DOMException instead of returning a string:

- A Document node with no child element nodes.
- A DocumentType node that has an external subset public identifier that contains characters that are not matched by the XML PubidChar production. [XML]
- A DocumentType node that has an external subset system identifier that contains both a U+0022 QUOTATION MARK (”) and a U+0027 APOSTROPHE (‘) or that contains characters that are not matched by the XML Char production. [XML]
• A node with a local name containing a U+003A COLON (:).
• A node with a local name that does not match the XML Name production. [XML]
• An Attr node with no namespace whose local name is the lowercase string "xmlns". [XMLNS]
• An Element node with two or more attributes with the same local name and namespace.
• An Attr node, Text node, Comment node, or ProcessingInstruction node whose data contains characters that are not matched by the XML Char production. [XML]
• A Comment node whose data contains two adjacent U+002D HYPHEN-MINUS characters (-) or ends with such a character.
• A ProcessingInstruction node whose target name is an ASCII case-insensitive match for the string "xml".
• A ProcessingInstruction node whose target name contains a U+003A COLON (:).
• A ProcessingInstruction node whose data contains the string "?>".

These are the only ways to make a DOM unserialisable. The DOM enforces all the other XML constraints; for example, trying to append two elements to a Document node will throw a "HierarchyRequestError" DOMException.

14.4 Parsing XML fragments

The XML fragment parsing algorithm either returns a Document or throws a "SyntaxError" DOMException. Given a string input and a context element context, the algorithm is as follows:

1. Create a new XML parser.
2. Feed the parser just created the string corresponding to the start tag of the context element, declaring all the namespace prefixes that are in scope on that element in the DOM, as well as declaring the default namespace (if any) that is in scope on that element in the DOM.

A namespace prefix is in scope if the DOM lookupNamespaceURI() method on the element would return a non-null value for that prefix.

The default namespace is the namespace for which the DOM isDefaultNamespace() method on the element would return true.

No DOCTYPE is passed to the parser, and therefore no external subset is referenced, and therefore no entities will be recognized.

3. Feed the parser just created the string input.
4. Feed the parser just created the string corresponding to the end tag of the context element.
5. If there is an XML well-formedness or XML namespace well-formedness error, then
throw a "SyntaxError" DOMException.

6. If the document element of the resulting Document has any sibling nodes, then throw a "SyntaxError" DOMException.

7. Return the child nodes of the document element of the resulting Document, in tree order.

15 Rendering

User agents are not required to present HTML documents in any particular way. However, this section provides a set of suggestions for rendering HTML documents that, if followed, are likely to lead to a user experience that closely resembles the experience intended by the documents’ authors. So as to avoid confusion regarding the normativity of this section, “must” has not been used. Instead, the term “expected” is used to indicate behavior that will lead to this experience. For the purposes of conformance for user agents designated as supporting the suggested default rendering, the term “expected” in this section has the same conformance implications as “must”.

15.1 Introduction

The suggestions in this section are generally expressed in CSS terms. User agents are expected to either support CSS, or translate from the CSS rules given in this section to approximations for other presentation mechanisms.

In the absence of style-layer rules to the contrary (e.g. author style sheets), user agents are expected to render an element so that it conveys to the user the meaning that the element represents, as described by this specification.

The suggestions in this section generally assume a visual output medium with a resolution of 96dpi or greater, but HTML is intended to apply to multiple media (it is a media-independent language). User agent implementers are encouraged to adapt the suggestions in this section to their target media.

An element is being rendered if it has any associated CSS layout boxes, SVG layout boxes, or some equivalent in other styling languages.

Just being off-screen does not mean the element is not being rendered. The presence of the hidden attribute normally means the element is not being rendered, though this might be overridden by the style sheets.

The fully active state does not affect whether an element is being rendered or not. Even if a document is not fully active and not shown at all to the user, elements within it can still qualify as “being rendered”.

An element is said to intersect the viewport when it is being rendered and its associated CSS layout box intersects the viewport.
Similar to the being rendered state, elements in non-fully active documents can still intersect the viewport. The viewport is not shared between documents and might not always be shown to the user, so an element in a non-fully active document can still intersect the viewport associated with its document.

This specification does not define the precise timing for when the intersection is tested, but it is suggested that the timing match that of the Intersection Observer API.

User agents that do not honor author-level CSS style sheets are nonetheless expected to act as if they applied the CSS rules given in these sections in a manner consistent with this specification and the relevant CSS and Unicode specifications. [CSS] [UNICODE] [BIDI]

This is especially important for issues relating to the ‘display’, ‘unicode-bidi’, and ‘direction’ properties.

15.2 The CSS user agent style sheet and presentational hints

The CSS rules given in these subsections are, except where otherwise specified, expected to be used as part of the user-agent level style sheet defaults for all documents that contain HTML elements.

Some rules are intended for the author-level zero-specificity presentational hints part of the CSS cascade; these are explicitly called out as presentational hints.

When the text below says that an attribute attribute on an element element maps to the pixel length property (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute’s value using the rules for parsing non-negative integers doesn’t generate an error, then the user agent is expected to use the parsed value as a pixel length for a presentational hint for properties.

When the text below says that an attribute attribute on an element element maps to the dimension property (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute’s value using the rules for parsing dimension values doesn’t generate an error, then the user agent is expected to use the parsed dimension as the value for a presentational hint for properties, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When the text below says that an attribute attribute on an element element maps to the dimension property (ignoring zero) (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute’s value using the rules for parsing nonzero dimension values doesn’t generate an error, then the user agent is expected to use the parsed dimension as the value for a presentational hint for properties, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension
was a percentage.

When the text below says that a pair of attributes \( w \) and \( h \) on an element maps to the aspect-ratio property, it means that if the element has both attributes \( w \) and \( h \), and parsing those attributes' values using the rules for parsing non-negative integers doesn't generate an error for either, then the user agent is expected to use the parsed integers as a presentational hint for the 'aspect-ratio' property of the form \( \text{auto } w / h \).

When the text below says that a pair of attributes \( w \) and \( h \) on an element maps to the aspect-ratio property (using dimension rules), it means that if the element has both attributes \( w \) and \( h \), and parsing those attributes' values using the rules for parsing dimension values doesn't generate an error or return a percentage for either, then the user agent is expected to use the parsed dimensions as a presentational hint for the 'aspect-ratio' property of the form \( \text{auto } w / h \).

When a user agent is to align descendants of a node, the user agent is expected to align only those descendants that have both their 'margin-inline-start' and 'margin-inline-end' properties computing to a value other than 'auto', that are over-constrained and that have one of those two margins with a used value forced to a greater value, and that do not themselves have an applicable align attribute. When multiple elements are to align a particular descendant, the most deeply nested such element is expected to override the others. Aligned elements are expected to be aligned by having the used values of their margins on the line-left and line-right sides be set accordingly. [CSSLOGICAL] [CSSWM]

15.3 Non-replaced elements

15.3.1 Hidden elements

@namespace url(http://www.w3.org/1999/xhtml);

[hidden], area, base, basefont, datalist, head, link, meta, noembed, noframes, param, rp, script, style, template, title {
  display: none;
}

embed[hidden] { display: inline; height: 0; width: 0; }

input[type=hidden i] { display: none !important; }

@media (scripting) {
  noscript { display: none !important; }
}

15.3.2 The page

@namespace url(http://www.w3.org/1999/xhtml);
For each property in the table below, given a `body` element, the first attribute that exists maps to the pixel length property on the `body` element. If none of the attributes for a property are found, or if the value of the attribute that was found cannot be parsed successfully, then a default value of 8px is expected to be used for that property instead.

<table>
<thead>
<tr>
<th>Property</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>margin-top</code></td>
<td>The <code>body</code> element’s <code>marginheight</code> attribute</td>
</tr>
<tr>
<td></td>
<td>The <code>body</code> element’s <code>topmargin</code> attribute</td>
</tr>
<tr>
<td></td>
<td>The <code>body</code> element’s container frame element’s <code>marginheight</code> attribute</td>
</tr>
<tr>
<td><code>margin-right</code></td>
<td>The <code>body</code> element’s <code>rightmargin</code> attribute</td>
</tr>
<tr>
<td></td>
<td>The <code>body</code> element’s container frame element’s <code>marginwidth</code> attribute</td>
</tr>
<tr>
<td><code>margin-bottom</code></td>
<td>The <code>body</code> element’s <code>bottommargin</code> attribute</td>
</tr>
<tr>
<td></td>
<td>The <code>body</code> element’s container frame element’s <code>marginheight</code> attribute</td>
</tr>
<tr>
<td><code>margin-left</code></td>
<td>The <code>body</code> element’s <code>leftmargin</code> attribute</td>
</tr>
<tr>
<td></td>
<td>The <code>body</code> element’s container frame element’s <code>marginwidth</code> attribute</td>
</tr>
</tbody>
</table>

If the `body` element’s node document’s browsing context is a child browsing context, and the container of that browsing context is a `frame` or `iframe` element, then the container frame element of the `body` element is that `frame` or `iframe` element. Otherwise, there is no container frame element.

The above requirements imply that a page can change the margins of another page (including one from another origin) using, for example, an `iframe`. This is potentially a security risk, as it might in some cases allow an attack to contrive a situation in which a page is rendered not as the author intended, possibly for the purposes of phishing or otherwise misleading the user.

If a `Document`’s browsing context is a child browsing context, then it is expected to be positioned and sized to fit inside the content box of the container of that browsing context. If the container is not being rendered, the browsing context is expected to have a viewport with zero width and zero height.

If a `Document`’s browsing context is a child browsing context, the container of that browsing context is a `frame` or `iframe` element, that element has a scrolling attribute, and that attribute’s value is an ASCII case-insensitive match for the string “off”, “noscroll”, or “no”, then the user agent is expected to prevent any scrollbars from being shown for the viewport of the `Document`’s browsing context, regardless of the ‘overflow’ property that applies to that viewport.
When a `body` element has a `background` attribute set to a non-empty value, the new value is expected to be parsed relative to the element’s node document, and if this is successful, the user agent is expected to treat the attribute as a presentational hint setting the element’s ‘background-image’ property to the resulting URL string.

When a `body` element has a `bgcolor` attribute set, the new value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s ‘background-color’ property to the resulting color.

When a `body` element has a `text` attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s ‘color’ property to the resulting color.

When a `body` element has a `link` attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the ‘color’ property of any element in the Document matching the :link pseudo-class to the resulting color.

When a `body` element has a `vlink` attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the ‘color’ property of any element in the Document matching the :visited pseudo-class to the resulting color.

When a `body` element has an `alink` attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the ‘color’ property of any element in the Document matching the :active pseudo-class and either the :link pseudo-class or the :visited pseudo-class to the resulting color.

15.3.3 Flow content

@namespace url(http://www.w3.org/1999/xhtml);

address, blockquote, center, dialog, div, figure, figcaption, footer, form, header, hr, legend, listing, main, p, plaintext, pre, xmp {
  display: block;
}

blockquote, figure, listing, p, plaintext, pre, xmp {
  margin-block-start: 1em; margin-block-end: 1em;
}

blockquote, figure { margin-inline-start: 40px; margin-inline-end: 40px; }

address { font-style: italic; }
The following rules are also expected to apply, as presentational hints:

@namespace url(http://www.w3.org/1999/xhtml);

pre[wrap] { white-space: pre-wrap; }

In quirks mode, the following rules are also expected to apply:

@namespace url(http://www.w3.org/1999/xhtml);

form { margin-block-end: 1em; }

The **center** element, and the **div** element when it has an **align** attribute whose value is an ASCII case-insensitive match for either the string “center” or the string “middle”, are expected to center text within themselves, as if they had their ‘text-align’ property set to ‘center’ in a presentational hint, and to align descendants to the center.

The **div** element, when it has an **align** attribute whose value is an ASCII case-insensitive match for the string “left”, is expected to left-align text within itself, as if it had its ‘text-align’ property set to ‘left’ in a presentational hint, and to align descendants to the left.

The **div** element, when it has an **align** attribute whose value is an ASCII case-insensitive
The `div` element, when it has an `align` attribute whose value is an ASCII case-insensitive match for the string "justify", is expected to full-justify text within itself, as if it had its `text-align` property set to 'justify' in a presentational hint, and to align descendants to the left.

The `dialog` element, when its is modal flag is true, is expected to act as if it had a user-agent-level style sheet rule setting the following properties:

- 'position' property to 'fixed'
- 'overflow' property to 'auto'
- 'inset-block-start' property to '0'
- 'inset-block-end' property to '0'
- 'max-width' property to 'calc(100% - 6px - 2em)'
- 'max-height' property to 'calc(100% - 6px - 2em)'

15.3.4 Phrasing content

```xhtml
@namespace url(http://www.w3.org/1999/xhtml);

cite, dfn, em, i, var { font-style: italic; }
b, strong { font-weight: bolder; }
code, kbd, samp, tt { font-family: monospace; }
big { font-size: larger; }
small { font-size: smaller; }

sub { vertical-align: sub; }
sup { vertical-align: super; }
sub, sup { line-height: normal; font-size: smaller; }

ruby { display: ruby; }
rt { display: ruby-text; }

:link { color: #0000EE; }
:visited { color: #551A8B; }
:link:active, :visited:active { color: #FF0000; }
:link, :visited { text-decoration: underline; cursor: pointer; }

:focus-visible { outline: auto; }

mark { background: yellow; color: black; } /* this color is just a suggestion */

abbr[title], acronym[title] { text-decoration: dotted underline; }
ins, u { text-decoration: underline; }
del, s, strike { text-decoration: line-through; }
```
The following rules are also expected to apply, as presentational hints:

```css
q::before { content: open-quote; }
q::after { content: close-quote; }

br { display-outside: newline; } /* this also has bidi implications */
nobr { white-space: nowrap; }
wbr { display-outside: break-opportunity; } /* this also has bidi implications */
nobr wbr { white-space: normal; }
```

The following rules are also expected to apply, as presentational hints:

```css
@namespace url(http://www.w3.org/1999/xhtml);

br[clear=left i] { clear: left; }
br[clear=right i] { clear: right; }
br[clear=all i], br[clear=both i] { clear: both; }
```

For the purposes of the CSS ruby model, runs of children of `ruby` elements that are not `rt` or `rp` elements are expected to be wrapped in anonymous boxes whose `display` property has the value `ruby-base`. [CSSRUBY]

When a particular part of a ruby has more than one annotation, the annotations should be distributed on both sides of the base text so as to minimize the stacking of ruby annotations on one side.

When it becomes possible to do so, the preceding requirement will be updated to be expressed in terms of CSS ruby. (Currently, CSS ruby does not handle nested `ruby` elements or multiple sequential `rt` elements, which is how this semantic is expressed.)

User agents that do not support correct ruby rendering are expected to render parentheses around the text of `rt` elements in the absence of `rp` elements.

User agents are expected to support the `clear` property on inline elements (in order to render `br` elements with `clear` attributes) in the manner described in the non-normative note to this effect in CSS.

The initial value for the `color` property is expected to be black. The initial value for the `background-color` property is expected to be `transparent`. The canvas's background is expected to be white.

When a `font` element has a `color` attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element's `color` property to the resulting color.

The `font` element is expected to override the color of any text decoration that spans the text of
the element to the **used value** of the element’s ‘color’ property.

When a **font** element has a **face** attribute, the user agent is expected to treat the attribute as a **presentational hint** setting the element’s ‘font-family’ property to the attribute’s value.

When a **font** element has a **size** attribute, the user agent is expected to use the following steps, known as the **rules for parsing a legacy font size**, to treat the attribute as a **presentational hint** setting the element’s ‘font-size’ property:

1. Let **input** be the attribute’s value.
2. Let **position** be a pointer into **input**, initially pointing at the start of the string.
3. **Skip ASCII whitespace** within **input** given **position**.
4. If **position** is past the end of **input**, there is no **presentational hint**. Return.
5. If the character at **position** is a U+002B PLUS SIGN character (+), then let **mode** be **relative-plus**, and advance **position** to the next character. Otherwise, if the character at **position** is a U+002D HYPHEN-MINUS character (-), then let **mode** be **relative-minus**, and advance **position** to the next character. Otherwise, let **mode** be **absolute**.
6. **Collect a sequence of code points** that are **ASCII digits** from **input** given **position**, and let the resulting sequence be **digits**.
7. If **digits** is the empty string, there is no **presentational hint**. Return.
8. Interpret **digits** as a base-ten integer. Let **value** be the resulting number.
9. If **mode** is **relative-plus**, then increment **value** by 3. If **mode** is **relative-minus**, then let **value** be the result of subtracting **value** from 3.
10. If **value** is greater than 7, let it be 7.
11. If **value** is less than 1, let it be 1.
12. Set ‘**font-size**’ to the keyword corresponding to the value of **value** according to the following table:

<table>
<thead>
<tr>
<th>value</th>
<th>‘font-size’ keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>‘x-small’</td>
</tr>
<tr>
<td>2</td>
<td>‘small’</td>
</tr>
<tr>
<td>3</td>
<td>‘medium’</td>
</tr>
<tr>
<td>4</td>
<td>‘large’</td>
</tr>
<tr>
<td>5</td>
<td>‘x-large’</td>
</tr>
<tr>
<td>6</td>
<td>‘xx-large’</td>
</tr>
<tr>
<td>7</td>
<td>‘xxx-large’</td>
</tr>
</tbody>
</table>
15.3.5 Bidirectional text

@namespace url(http://www.w3.org/1999/xhtml);

[dir]:dir(ltr), bdi:dir(ltr), input[type=tel]:dir(ltr) { direction: ltr; }
[dir]:dir(rtl), bdi:dir(rtl) { direction: rtl; }

address, blockquote, center, div, figure, figcaption, footer, form, header, hgroup, legend, listing, main, p, plaintext, pre, summary, xmp, article, aside, h1, h2, h3, h4, h5, h6, hgroup, nav, section, table, caption, colgroup, col, thead, tbody, tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, bdi, output,
[dir=ltr], [dir=rtl], [dir=auto] {
    unicode-bidi: isolate;
}

bdo, bdo[dir] { unicode-bidi: isolate-override; }

input[dir=auto]:is([type=search], [type=tel], [type=url], [type=email]), textarea[dir=auto], pre[dir=auto] {
    unicode-bidi: plaintext;
}

/* see prose for input elements whose type attribute is in the Text state */

/* the rules setting the 'content' property on br and wbr elements also has bidi */

When an input element’s dir attribute is in the auto state and its type attribute is in the Text state, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the ‘unicode-bidi’ property to ‘plaintext’.

Input fields (i.e. textarea elements, and input elements when their type attribute is in the Text, Search, Telephone, URL, or Email state) are expected to present an editing user interface with a directionality that matches the element’s direction property.

When the document’s character encoding is ISO-8859-8, the following rules are additionally expected to apply, following those above: [ENCODING]

@namespace url(http://www.w3.org/1999/xhtml);

address, blockquote, center, div, figure, figcaption, footer, form, header, hgroup, legend, listing, main, p, plaintext, pre, summary, xmp, article, aside, h1, h2, h3, h4, h5, h6, hgroup, nav, section, table, caption, colgroup, col, thead, tbody, tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, [dir=ltr], [dir=rtl], [dir=auto], *{*} {
    unicode-bidi: bidi-override;
}

input:not([type=submit]):not([type=reset]):not([type=button]), textarea {
In the following CSS block, `x` is shorthand for the following selector: `:is(article, aside, nav, section)`

```css
@namespace url(http://www.w3.org/1999/xhtml);

x h1 { margin-block-start: 0.83em; margin-block-end: 0.83em; font-size: 1.50em; }
x x h1 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; }
x x x h1 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; }
x x x x h1 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x x x x h1 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }

The shorthand is used to keep this block at least mildly readable.
15.3.7 Lists

@namespace url(http://www.w3.org/1999/xhtml);

dir, dd, dl, dt, menu, ol, ul { display: block; }
li { display: list-item; text-align: match-parent; }

dir, dl, menu, ol, ul { margin-block-start: 1em; margin-block-end: 1em; }
:is(dir, dl, menu, ol, ul) :is(dir, dl, menu, ol, ul) {
  margin-block-start: 0; margin-block-end: 0;
}

dd { margin-inline-start: 40px; }
dir, menu, ol, ul { padding-inline-start: 40px; }

ol, ul, menu { counter-reset: list-item; }
ol { list-style-type: decimal; }

dir, menu, ul {
  list-style-type: disc;
}
:is(dir, menu, ol, ul) :is(dir, menu, ul) {
  list-style-type: circle;
}
:is(dir, menu, ol, ul) :is(dir, menu, ol, ul) :is(dir, menu, ul) {
  list-style-type: square;
}

The following rules are also expected to apply, as presentational hints:

@namespace url(http://www.w3.org/1999/xhtml);

ol[type="1"], li[type="1"] { list-style-type: decimal; }
ol[type=a s], li[type=a s] { list-style-type: lower-alpha; }
ol[type=A s], li[type=A s] { list-style-type: upper-alpha; }
ol[type=i s], li[type=i s] { list-style-type: lower-roman; }
ol[type=I s], li[type=I s] { list-style-type: upper-roman; }
ul[type=none i], li[type=none i] { list-style-type: none; }
ul[type=disc i], li[type=disc i] { list-style-type: disc; }
ul[type=circle i], li[type=circle i] { list-style-type: circle; }
ul[type=square i], li[type=square i] { list-style-type: square; }

When rendering li elements, non-CSS user agents are expected to use the ordinal value of the li element to render the counter in the list item marker.

For CSS user agents, some aspects of rendering list items are defined by the CSS Lists
specification. Additionally, the following attribute mappings are expected to apply: [CSSLISTS]

When an li element has a value attribute, and parsing that attribute’s value using the rules for parsing integers doesn’t generate an error, the user agent is expected to use the parsed value value as a presentational hint for the ‘counter-set’ property of the form list-item value.

When an ol element has a start attribute or a reversed attribute, or both, the user agent is expected to use the following steps to treat the attributes as a presentational hint for the ‘counter-reset’ property:

1. Let value be null.
2. If the element has a start attribute, then set value to the result of parsing the attribute’s value using the rules for parsing integers.
3. If the element has a reversed attribute, then:
   1. If value is an integer, then increment value by 1 and return reversed(list-item) value.
   2. Otherwise, return reversed(list-item).

   Either the start attribute was absent, or parsing its value resulted in an error.
4. Otherwise:
   1. If value is an integer, then decrement value by 1 and return list-item value.
   2. Otherwise, there is no presentational hint.

15.3.8 Tables

@namespace url(http://www.w3.org/1999/xhtml);

table { display: table; }
caption { display: table-caption; }
colgroup, colgroup[hidden] { display: table-column-group; }
col, col[hidden] { display: table-column; }
thead, thead[hidden] { display: table-header-group; }
tbody, tbody[hidden] { display: table-row-group; }
tfoot, tfoot[hidden] { display: table-footer-group; }
tr, tr[hidden] { display: table-row; }

colgroup[hidden], col[hidden], thead[hidden], tbody[hidden],
tfoot[hidden], tr[hidden] {
The following rules are also expected to apply, as *presentational hints*:
@namespace url(http://www.w3.org/1999/xhtml);

table[align=left i] { float: left; }
table[align=right i] { float: right; }
table[align=center i] { margin-inline-start: auto; margin-inline-end: auto; }
thead[align=absmiddle i], tbody[align=absmiddle i], tfoot[align=absmiddle i],
tr[align=absmiddle i], td[align=absmiddle i], th[align=absmiddle i] {
  text-align: center;
}
caption[align=bottom i] { caption-side: bottom; }
p[align=left i], h1[align=left i], h2[align=left i], h3[align=left i],
h4[align=left i], h5[align=left i], h6[align=left i] {
  text-align: left;
}
p[align=right i], h1[align=right i], h2[align=right i], h3[align=right i],
h4[align=right i], h5[align=right i], h6[align=right i] {
  text-align: right;
}
p[align=center i], h1[align=center i], h2[align=center i], h3[align=center i],
h4[align=center i], h5[align=center i], h6[align=center i] {
  text-align: center;
}
p[align=justify i], h1[align=justify i], h2[align=justify i], h3[align=justify i],
h4[align=justify i], h5[align=justify i], h6[align=justify i] {
  text-align: justify;
}
thead[valign=top i], tbody[valign=top i], tfoot[valign=top i],
tr[valign=top i], td[valign=top i], th[valign=top i] {
  vertical-align: top;
}
thead[valign=middle i], tbody[valign=middle i], tfoot[valign=middle i],
tr[valign=middle i], td[valign=middle i], th[valign=middle i] {
  vertical-align: middle;
}
thead[valign=bottom i], tbody[valign=bottom i], tfoot[valign=bottom i],
tr[valign=bottom i], td[valign=bottom i], th[valign=bottom i] {
  vertical-align: bottom;
}
thead[valign=baseline i], tbody[valign=baseline i], tfoot[valign=baseline i],
tr[valign=baseline i], td[valign=baseline i], th[valign=baseline i] {
  vertical-align: baseline;
}

td[nowrap], th[nowrap] { white-space: nowrap; }

table[rules=none i], table[rules=groups i], table[rules=rows i],
table[rules=cols i], table[rules=all i] {
  border-style: hidden;
  border-collapse: collapse;
}
table[border] { border-style: outset; } /* only if border is not equivalent to zero */
table[frame=void i] { border-style: hidden; }
table[frame=above i] { border-style: outset hidden hidden hidden hidden; }
table[frame=below i] { border-style: hidden hidden outset hidden hidden; }
table[frame=lhs i] { border-style: outset hidden hidden outset hidden; }
table[frame=rhs i] { border-style: hidden hidden outset hidden Hidden; }
table[frame=box i], table[frame=border i] { border-style: outset; }
table[border] > tr > td, table[border] > tr > th,
table[border] > thead > tr > td, table[border] > thead > tr > th,
table[border] > tbody > tr > td, table[border] > tbody > tr > th,
table[border] > tfoot > tr > td, table[border] > tfoot > tr > th {
  /* only if border is not equivalent to zero */
  border-width: 1px;
  border-style: inset;
}
table[rules=none i] > tr > td, table[rules=none i] > tr > th,
table[rules=none i] > thead > tr > td, table[rules=none i] > thead > tr > th,
table[rules=none i] > tbody > tr > td, table[rules=none i] > tbody > tr > th,
table[rules=none i] > tfoot > tr > td, table[rules=none i] > tfoot > tr > th,
table[rules=groups i] > tr > td, table[rules=groups i] > tr > th,
table[rules=groups i] > thead > tr > td, table[rules=groups i] > thead > tr > th,
table[rules=groups i] > tbody > tr > td, table[rules=groups i] > tbody > tr > th,
table[rules=groups i] > tfoot > tr > td, table[rules=groups i] > tfoot > tr > th,
table[rules=rows i] > tr > td, table[rules=rows i] > tr > th,
table[rules=rows i] > thead > tr > td, table[rules=rows i] > thead > tr > th,
table[rules=rows i] > tbody > tr > td, table[rules=rows i] > tbody > tr > th,
table[rules=rows i] > tfoot > tr > td, table[rules=rows i] > tfoot > tr > th {
  border-width: 1px;
  border-style: none;
}
table[rules=cols i] > tr > td, table[rules=cols i] > tr > th,
table[rules=cols i] > thead > tr > td, table[rules=cols i] > thead > tr > th,
table[rules=cols i] > tbody > tr > td, table[rules=cols i] > tbody > tr > th,
table[rules=cols i] > tfoot > tr > td, table[rules=cols i] > tfoot > tr > th {
  border-width: 1px;
  border-block-start-style: none;
  border-inline-end-style: solid;
  border-block-end-style: none;
  border-inline-start-style: solid;
}
In quirks mode, the following rules are also expected to apply:

@namespace url(http://www.w3.org/1999/xhtml);

For the purposes of the CSS table model, the **col** element is expected to be treated as if it was
present as many times as its **span** attribute specifies.

For the purposes of the CSS table model, the **colgroup** element, if it contains no **col** element, is expected to be treated as if it had as many such children as its **span** attribute specifies.

For the purposes of the CSS table model, the **colspan** and **rowspan** attributes on **td** and **th** elements are expected to **provide** the special knowledge regarding cells spanning rows and columns.

In **HTML documents**, the following rules are also expected to apply:

```html
@namespace url(http://www.w3.org/1999/xhtml);
:is(table, thead, tbody, tfoot, tr) > form { display: none !important; }
```

The **table** element’s **cellspacing** attribute maps to the pixel length property ‘border-spacing’ on the element.

The **table** element’s **cellpadding** attribute maps to the pixel length properties ‘padding-top’, ‘padding-right’, ‘padding-bottom’, and ‘padding-left’ of any **td** and **th** elements that have corresponding cells in the **table** corresponding to the **table** element.

The **table** element’s **height** attribute maps to the dimension property (ignoring zero) ‘height’ on the **table** element.

The **table** element’s **width** attribute maps to the dimension property (ignoring zero) ‘width’ on the **table** element.

The **col** element’s **width** attribute maps to the dimension property ‘width’ on the **col** element.

The **thead**, **tbody**, and **tfoot** elements’ **height** attribute maps to the dimension property ‘height’ on the element.

The **tr** element’s **height** attribute maps to the dimension property ‘height’ on the **tr** element.

The **td** and **th** elements’ **height** attributes map to the dimension property (ignoring zero) ‘height’ on the element.

The **td** and **th** elements’ **width** attributes map to the dimension property (ignoring zero) ‘width’ on the element.

The **thead**, **tbody**, **tfoot**, **tr**, **td**, and **th** elements, when they have an **align** attribute whose value is an ASCII case-insensitive match for either the string “center” or the string “middle”, are expected to center text within themselves, as if they had their ‘text-align’
property set to ‘center’ in a presentational hint, and to align descendants to the center.

The \texttt{thead}, \texttt{tbody}, \texttt{tfoot}, \texttt{tr}, \texttt{td}, and \texttt{th} elements, when they have an \texttt{align} attribute whose value is an ASCII case-insensitive match for the string "left", are expected to left-align text within themselves, as if they had their \texttt{‘text-align’} property set to ‘left’ in a presentational hint, and to align descendants to the left.

The \texttt{thead}, \texttt{tbody}, \texttt{tfoot}, \texttt{tr}, \texttt{td}, and \texttt{th} elements, when they have an \texttt{align} attribute whose value is an ASCII case-insensitive match for the string "right", are expected to right-align text within themselves, as if they had their \texttt{‘text-align’} property set to ‘right’ in a presentational hint, and to align descendants to the right.

The \texttt{thead}, \texttt{tbody}, \texttt{tfoot}, \texttt{tr}, \texttt{td}, and \texttt{th} elements, when they have an \texttt{align} attribute whose value is an ASCII case-insensitive match for the string "justify", are expected to full-justify text within themselves, as if they had their \texttt{‘text-align’} property set to ‘justify’ in a presentational hint, and to align descendants to the left.

User agents are expected to have a rule in their user agent style sheet that matches \texttt{th} elements that have a parent node whose computed value for the \texttt{‘text-align’} property is its initial value, whose declaration block consists of just a single declaration that sets the \texttt{‘text-align’} property to the value ‘center’.

When a \texttt{table}, \texttt{thead}, \texttt{tbody}, \texttt{tfoot}, \texttt{tr}, \texttt{td}, or \texttt{th} element has a \texttt{background} attribute set to a non-empty value, the new value is expected to be parsed relative to the element’s node document, and if this is successful, the user agent is expected to treat the attribute as a presentational hint setting the element’s \texttt{‘background-image’} property to the resulting URL string.

When a \texttt{table}, \texttt{thead}, \texttt{tbody}, \texttt{tfoot}, \texttt{tr}, \texttt{td}, or \texttt{th} element has a \texttt{bgcolor} attribute set, the new value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s \texttt{‘background-color’} property to the resulting color.

When a \texttt{table} element has a \texttt{bordercolor} attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s \texttt{‘border-top-color’}, \texttt{‘border-right-color’}, \texttt{‘border-bottom-color’}, and \texttt{‘border-left-color’} properties to the resulting color.

The \texttt{table} element’s \texttt{border} attribute maps to the pixel length properties \texttt{‘border-top-width’}, \texttt{‘border-right-width’}, \texttt{‘border-bottom-width’}, \texttt{‘border-left-width’} on the element. If the attribute is present but parsing the attribute’s value using the rules for parsing non-negative integers generates an error, a default value of 1px is expected to be used for that property instead.

Rules marked “only if border is not equivalent to zero” in the CSS block above is expected to
only be applied if the `border` attribute mentioned in the selectors for the rule is not only present but, when parsed using the rules for parsing non-negative integers, is also found to have a value other than zero or to generate an error.

In **quirks mode**, a `td` element or a `th` element that has a `nowrap` attribute but also has a `width` attribute whose value, when parsed using the rules for parsing nonzero dimension values, is found to be a length (not an error or a number classified as a percentage), is expected to have a presentational hint setting the element’s ‘white-space’ property to ‘normal’, overriding the rule in the CSS block above that sets it to ‘nowrap’.

### 15.3.9 Margin collapsing quirks

A node is *substantial* if it is a text node that is not inter-element whitespace, or if it is an element node.

A node is *blank* if it is an element that contains no substantial nodes.

The elements with default margins are the following elements: `blockquote`, `dir`, `dl`, `h1`, `h2`, `h3`, `h4`, `h5`, `h6`, `listing`, `menu`, `ol`, `p`, `plaintext`, `pre`, `ul`, `xmp`

In **quirks mode**, any element with default margins that is the child of a `body`, `td`, or `th` element and has no substantial previous siblings is expected to have a user-agent level style sheet rule that sets its ‘margin-block-start’ property to zero.

In **quirks mode**, any element with default margins that is the child of a `body`, `td`, or `th` element, has no substantial previous siblings, and is blank, is expected to have a user-agent level style sheet rule that sets its ‘margin-block-end’ property to zero also.

In **quirks mode**, any element with default margins that is the child of a `td` or `th` element, has no substantial following siblings, and is blank, is expected to have a user-agent level style sheet rule that sets its ‘margin-block-start’ property to zero.

In **quirks mode**, any `p` element that is the child of a `td` or `th` element and has no substantial following siblings, is expected to have a user-agent level style sheet rule that sets its ‘margin-block-end’ property to zero.

### 15.3.10 Form controls

```
@namespace url(http://www.w3.org/1999/xhtml);

input, select, button, textarea {
  letter-spacing: initial;
  word-spacing: initial;
  line-height: initial;
  text-transform: initial;
  text-indent: initial;
```
```css
text-shadow: initial;
}
input, select, textarea {
  text-align: initial;
}
input:is([type=reset i], [type=button i], [type=submit i]), button {
  text-align: center;
}
input, button {
  display: inline-block;
}
input:is([type=radio i], [type=checkbox i], [type=reset i], [type=button i], [type=submit i], [type=color i], [type=search i]), select, button {
  box-sizing: border-box;
}
textarea { white-space: pre-wrap; }
```
In quirks mode, the following rules are also expected to apply:

```css
@namespace url(http://www.w3.org/1999/xhtml);
hr {
  color: gray;
  border-style: inset;
}
```
Each kind of form control is also described in the Widgets section, which describes the look and feel of the control.

For input elements where the type attribute is not in the Hidden state or the Image Button state, and that are being rendered, are expected to act as follows:

- The inner display type is always 'flow-root'.
- The 'overflow' property is ignored, and always behaves as 'visible' for the purpose of interaction with other CSS features (in particular, the 'vertical-align' property), but still clips any overflow at the border edge, and no scrolling mechanism is displayed.

15.3.11 The hr element

```css
@namespace url(http://www.w3.org/1999/xhtml);
hr {
  color: gray;
  border-style: inset;
```

border-width: 1px;
margin-block-start: 0.5em;
margin-inline-end: auto;
margin-block-end: 0.5em;
margin-inline-start: auto;
overflow: hidden;
}

The following rules are also expected to apply, as presentational hints:

@namespace url(http://www.w3.org/1999/xhtml);

hr[align=left i] { margin-left: 0; margin-right: auto; }
hr[align=right i] { margin-left: auto; margin-right: 0; }
hr[align=center i] { margin-left: auto; margin-right: auto; }  
hr[color], hr[noshade] { border-style: solid; }

If an hr element has either a color attribute or a noshade attribute, and furthermore also has a size attribute, and parsing that attribute’s value using the rules for parsing non-negative integers doesn’t generate an error, then the user agent is expected to use the parsed value divided by two as a pixel length for presentational hints for the properties ‘border-top-width’, ‘border-right-width’, ‘border-bottom-width’, and ‘border-left-width’ on the element.

Otherwise, if an hr element has neither a color attribute nor a noshade attribute, but does have a size attribute, and parsing that attribute’s value using the rules for parsing non-negative integers doesn’t generate an error, then: if the parsed value is one, then the user agent is expected to use the attribute as a presentational hint setting the element’s ‘border-bottom-width’ to 0; otherwise, if the parsed value is greater than one, then the user agent is expected to use the parsed value minus two as a pixel length for presentational hints for the ‘height’ property on the element.

The width attribute on an hr element maps to the dimension property ‘width’ on the element.

When an hr element has a color attribute, its value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s ‘color’ property to the resulting color.

15.3.12 The fieldset and legend elements

@namespace url(http://www.w3.org/1999/xhtml);

fieldset {
  display: block;
  margin-inline-start: 2px;
  margin-inline-end: 2px;
  border: groove 2px ThreeDFace;
The `fieldset` element, when it generates a CSS box, is expected to act as follows:

- The element is expected to establish a new block formatting context.

- The `display` property is expected to act as follows:
  - If the computed value of `display` is a value such that the outer display type is `inline`, then behave as `inline-block`.
  - Otherwise, behave as `flow-root`.

  This does not change the computed value.

- If the element’s box has a child box that matches the conditions in the list below, then the first such child box is the `fieldset` element’s rendered legend:
  - The child is a `legend` element.
  - The child’s used value of `float` is `none`.
  - The child’s used value of `position` is not `absolute` or `fixed`.

- If the element has a rendered legend, then the border is expected to not be painted behind the rectangle defined as follows, using the writing mode of the fieldset:

  1. The block-start edge of the rectangle is the smaller of the block-start edge of the rendered legend’s margin rectangle at its static position (ignoring transforms),
and the block-start outer edge of the fieldset’s border.

2. The block-end edge of the rectangle is the larger of the block-end edge of the rendered legend’s margin rectangle at its static position (ignoring transforms), and the block-end outer edge of the fieldset’s border.

3. The inline-start edge of the rectangle is the smaller of the inline-start edge of the rendered legend’s border rectangle at its static position (ignoring transforms), and the inline-start outer edge of the fieldset’s border.

4. The inline-end edge of the rectangle is the larger of the inline-end edge of the rendered legend’s border rectangle at its static position (ignoring transforms), and the inline-end outer edge of the fieldset’s border.

- The space allocated for the element’s border on the block-start side is expected to be the element’s ‘border-block-start-width’ or the rendered legend’s margin box size in the fieldset’s block-flow direction, whichever is greater.

- For the purpose of calculating the used ‘block-size’, if the computed ‘block-size’ is not ‘auto’, the space allocated for the rendered legend’s margin box that spills out past the border, if any, is expected to be subtracted from the ‘block-size’. If the content box’s block-size would be negative, then let the content box’s block-size be zero instead.

- If the element has a rendered legend, then that element is expected to be the first child box.

- The anonymous fieldset content box is expected to appear after the rendered legend and is expected to contain the content (including the ‘::before’ and ‘::after’ pseudo-elements) of the fieldset element except for the rendered legend, if there is one.

- The used value of the ‘padding-top’, ‘padding-right’, ‘padding-bottom’, and ‘padding-left’ properties are expected to be zero.

- For the purpose of calculating the min-content inline size, use the greater of the min-content inline size of the rendered legend and the min-content inline size of the anonymous fieldset content box.

- For the purpose of calculating the max-content inline size, use the greater of the max-content inline size of the rendered legend and the max-content inline size of the anonymous fieldset content box.

A fieldset element’s rendered legend, if any, is expected to act as follows:

- The element is expected to establish a new formatting context for its contents. The type of this formatting context is determined by its ‘display’ value, as usual.

- The ‘display’ property is expected to behave as if its computed value was blockified.
This does not change the computed value.

- If the **computed value** of 'inline-size' is 'auto', then the **used value** is the **fit-content inline size**.

- The element is expected to be positioned in the inline direction as is normal for blocks (e.g., taking into account margins and the 'justify-self' property).

- The element’s box is expected to be constrained in the inline direction by the inline content size of the **fieldset** as if it had used its computed inline padding.

  For example, if the **fieldset** has a specified padding of 50px, then the **rendered legend** will be positioned 50px in from the **fieldset**’s border. The padding will further apply to the **anonymous fieldset content box** instead of the **fieldset** element itself.

- The element is expected to be positioned in the block-flow direction such that its border box is centered over the border on the block-start side of the **fieldset** element.

A **fieldset** element’s **anonymous fieldset content box** is expected to act as follows:

- The **display** property is expected to act as follows:
  - If the computed value of 'display' on the **fieldset** element is 'grid' or 'inline-grid', then set the used value to 'grid'.
  - If the computed value of 'display' on the **fieldset** element is 'flex' or 'inline-flex', then set the used value to 'flex'.
  - Otherwise, set the used value to 'flow-root'.

- The following properties are expected to inherit from the **fieldset** element:
  - ‘align-content’
  - ‘align-items’
  - ‘border-radius’
  - ‘column-count’
  - ‘column-fill’
  - ‘column-gap’
  - ‘column-rule’
  - ‘column-width’
  - ‘flex-direction’
  - ‘flex-wrap’
  - ‘grid-auto-columns’
  - ‘grid-auto-flow’
  - ‘grid-auto-rows’
  - ‘grid-column-gap’
  - ‘grid-row-gap’
- ‘grid-template-areas’
- ‘grid-template-columns’
- ‘grid-template-rows’
- ‘justify-content’
- ‘justify-items’
- ‘overflow’
- ‘padding-bottom’
- ‘padding-left’
- ‘padding-right’
- ‘padding-top’
- ‘text-overflow’
- ‘unicode-bidi’

- The ‘block-size’ property is expected to be set to ‘100%’.

- For the purpose of calculating percentage padding, act as if the padding was calculated for the fieldset element.

The legend is rendered over the top border, and the top border area reserves vertical space for the legend. The fieldset’s top margin starts at the top margin edge of the legend. The legend’s horizontal margins, or the ‘justify-self’ property, gives its horizontal position. The anonymous fieldset content box appears below the legend.

15.4 Replaced elements

The following elements can be replaced elements: audio, canvas, embed, iframe, img, input, object, and video.
15.4.1 Embedded content

The embed, iframe, and video elements are expected to be treated as replaced elements.

A canvas element that represents embedded content is expected to be treated as a replaced element; the contents of such elements are the element’s bitmap, if any, or else a transparent black bitmap with the same intrinsic dimensions as the element. Other canvas elements are expected to be treated as ordinary elements in the rendering model.

An object element that represents an image, plugin, or its nested browsing context is expected to be treated as a replaced element. Other object elements are expected to be treated as ordinary elements in the rendering model.

The audio element, when it is exposing a user interface, is expected to be treated as a replaced element about one line high, as wide as is necessary to expose the user agent’s user interface features. When an audio element is not exposing a user interface, the user agent is expected to force its ‘display’ property to compute to ‘none’, irrespective of CSS rules.

Whether a video element is exposing a user interface is not expected to affect the size of the rendering; controls are expected to be overlaid above the page content without causing any layout changes, and are expected to disappear when the user does not need them.

When a video element represents a poster frame or frame of video, the poster frame or frame of video is expected to be rendered at the largest size that maintains the aspect ratio of that poster frame or frame of video without being taller or wider than the video element itself, and is expected to be centered in the video element.

Any subtitles or captions are expected to be overlayed directly on top of their video element, as defined by the relevant rendering rules; for WebVTT, those are the rules for updating the display of WebVTT text tracks. [WEBVTT]

When the user agent starts exposing a user interface for a video element, the user agent should run the rules for updating the text track rendering of each of the text tracks in the video element’s list of text tracks that are showing and whose text track kind is one of subtitles or captions (e.g., for text tracks based on WebVTT, the rules for updating the display of WebVTT text tracks). [WEBVTT]

Resizing video and canvas elements does not interrupt video playback or clear the canvas.

The following CSS rules are expected to apply:

```
@namespace url(http://www.w3.org/1999/xhtml);

iframe { border: 2px inset; }
video { object-fit: contain; }
```
15.4.2 Images

User agents are expected to render `img` elements and `input` elements whose `type` attributes are in the `Image Button` state, according to the first applicable rules from the following list:

If the element represents an image

The user agent is expected to treat the element as a `replaced element` and render the image according to the rules for doing so defined in CSS.

If the element does not represent an image and either:

- the user agent has reason to believe that the image will become `available` and be rendered in due course, or
- the element has no `alt` attribute, or
- the `Document` is in quirks mode, and the element already has `intrinsic dimensions` (e.g., from the `dimension attributes` or CSS rules)

The user agent is expected to treat the element as a `replaced element` whose content is the text that the element represents, if any, optionally alongside an icon indicating that the image is being obtained (if applicable). For `input` elements, the element is expected to appear button-like to indicate that the element is a `button`.

If the element is an `img` element that represents some text and the user agent does not expect this to change

The user agent is expected to treat the element as a non-replaced phrasing element whose content is the text, optionally with an icon indicating that an image is missing, so that the user can request the image be displayed or investigate why it is not rendering. In non-graphical contexts, such an icon should be omitted.

If the element is an `img` element that represents nothing and the user agent does not expect this to change

The user agent is expected to treat the element as a `replaced element` whose `intrinsic dimensions` are 0. (In the absence of further styles, this will cause the element to essentially not be rendered.)

If the element is an `input` element that does not represent an image and the user agent does not expect this to change

The user agent is expected to treat the element as a `replaced element` consisting of a button whose content is the element’s alternative text. The `intrinsic dimensions` of the button are expected to be about one line in height and whatever width is necessary to render the text on one line.

The icons mentioned above are expected to be relatively small so as not to disrupt most text but be easily clickable. In a visual environment, for instance, icons could be 16 pixels by 16 pixels square, or 1em by 1em if the images are scalable. In an audio environment, the icon could be a short bleep. The icons are intended to indicate to the user that they can be used to get to whatever options the UA provides for images, and, where appropriate, are expected to provide access to the context menu that would have come up if the user interacted with the actual image.
All animated images with the same absolute URL and the same image data are expected to be rendered synchronized to the same timeline as a group, with the timeline starting at the time of the least recent addition to the group.

In other words, when a second image with the same absolute URL and animated image data is inserted into a document, it jumps to the point in the animation cycle that is currently being displayed by the first image.

When a user agent is to restart the animation for an img element showing an animated image, all animated images with the same absolute URL and the same image data in that img element’s node document are expected to restart their animation from the beginning.

The following CSS rules are expected to apply when the Document is in quirks mode:

```css
@namespace url(http://www.w3.org/1999/xhtml);

img[align=left i] { margin-right: 3px; }
img[align=right i] { margin-left: 3px; }
```

15.4.3 Attributes for embedded content and images

The following CSS rules are expected to apply as presentational hints:

```css
@namespace url(http://www.w3.org/1999/xhtml);

iframe[frameborder='0'], iframe[frameborder=no i] { border: none; }
embed[align=left i], iframe[align=left i], img[align=left i],
input[type=image i][align=left i], object[align=left i] {
  float: left;
}
embed[align=right i], iframe[align=right i], img[align=right i],
input[type=image i][align=right i], object[align=right i] {
  float: right;
}
embed[align=top i], iframe[align=top i], img[align=top i],
input[type=image i][align=top i], object[align=top i] {
  vertical-align: top;
}
embed[align=baseline i], iframe[align=baseline i], img[align=baseline i],
input[type=image i][align=baseline i], object[align=baseline i] {
  vertical-align: baseline;
}```
When an `embed`, `iframe`, `img`, or `object` element, or an `input` element whose `type` attribute is in the Image Button state, has an `align` attribute whose value is an ASCII case-insensitive match for the string "center" or the string "middle", the user agent is expected to act as if the element’s `vertical-align` property was set to a value that aligns the vertical middle of the element with the parent element’s baseline.

The `hspace` attribute of `embed`, `img`, or `object` elements, and `input` elements with a `type` attribute in the Image Button state, maps to the dimension properties ‘margin-left’ and ‘margin-right’ on the element.

The `vspace` attribute of `embed`, `img`, or `object` elements, and `input` elements with a `type` attribute in the Image Button state, maps to the dimension properties ‘margin-top’ and ‘margin-bottom’ on the element.

When an `img` element, `object` element, or `input` element with a `type` attribute in the Image Button state has a `border` attribute whose value, when parsed using the rules for parsing non-negative integers, is found to be a number greater than zero, the user agent is expected to use the parsed value for eight presentational hints: four setting the parsed value as a pixel length for the element’s `border-top-width`, `border-right-width`, `border-bottom-width`, and `border-left-width` properties, and four setting the element’s `border-top-style`, `border-right-style`, `border-bottom-style`, and `border-left-style` properties to the value ‘solid’.

The `width` and `height` attributes on an `img` element’s dimension attribute source map to the dimension properties ‘width’ and ‘height’ on the `img` element respectively. They similarly map to the aspect-ratio property (using dimension rules) of the `img` element.

The `width` and `height` attributes on `embed`, `iframe`, `object`, and `video` elements, and `input` elements with a `type` attribute in the Image Button state and that either represents an
image or that the user expects will eventually represent an image, map to the dimension properties ‘width’ and ‘height’ on the element respectively.

The `width` and `height` attributes map to the aspect-ratio property (using dimension rules) on `img` and `video` elements, and `input` elements with a `type` attribute in the Image Button state.

The `width` and `height` attributes map to the aspect-ratio property on `canvas` elements.

15.4.4 Image maps

Shapes on an image map are expected to act, for the purpose of the CSS cascade, as elements independent of the original `area` element that happen to match the same style rules but inherit from the `img` or `object` element.

For the purposes of the rendering, only the ‘cursor’ property is expected to have any effect on the shape.

Thus, for example, if an `area` element has a `style` attribute that sets the ‘cursor’ property to ‘help’, then when the user designates that shape, the cursor would change to a Help cursor.

Similarly, if an `area` element had a CSS rule that set its ‘cursor’ property to ‘inherit’ (or if no rule setting the ‘cursor’ property matched the element at all), the shape’s cursor would be inherited from the `img` or `object` element of the image map, not from the parent of the `area` element.

15.5 Widgets

15.5.1 Introduction

The elements defined in this section can be rendered in a variety of manners, within the guidelines provided below. User agents are encouraged to set the ‘appearance’ CSS property appropriately to achieve platform-native appearances for widgets, and are expected to implement any relevant animations, etc, that are appropriate for the platform.

15.5.2 Button layout

*Button layout* is as follows:

- If the element is a `button` element, then the ‘display’ property is expected to act as follows:
  - If the computed value of ‘display’ is ‘inline-grid’, ‘grid’, ‘inline-flex’, or ‘flex’, then behave as the computed value.
  - Otherwise, if the computed value of ‘display’ is a value such that the outer
**display type** is ‘inline’, then behave as ‘inline-block’.

- Otherwise, behave as ‘flow-root’.

- The element is expected to establish a new **formatting context** for its contents. The type of this formatting context is determined by its **display** value, as usual.

- If the element is **absolutely-positioned**, then for the purpose of the **CSS visual formatting model**, act as if the element is a replaced element. [CSS]

- If the computed value of **inline-size** is ‘auto’, then the used value is the **fit-content inline size**.

- For the purpose of the ‘normal’ keyword of the **align-self** property, act as if the element is a replaced element.

- If the element is an **input** element, or if it is a **button** element and its computed value for **display** is not ‘inline-grid’, ‘grid’, ‘inline-flex’, or ‘flex’, then the element’s box has a child **anonymous button content box** with the following behaviors:
  
  - The box is a **block-level block container** that establishes a new **block formatting context** (i.e., **display** is ‘flow-root’).
  
  - If the box does not overflow in the horizontal axis, then it is centered horizontally.
  
  - If the box does not overflow in the vertical axis, then it is centered vertically.

- Otherwise, there is no **anonymous button content box**.

15.5.3 The **button** element

The **button** element, when it generates a **CSS box**, is expected to depict a button and to use **button layout** whose **anonymous button content box**’s contents (if there is an **anonymous button content box**) are the child boxes the element’s box would otherwise have.

15.5.4 The **details** and **summary** elements

```xml
@namespace url(http://www.w3.org/1999/xhtml);

summary {
  display: list-item;
  counter-increment: list-item 0;
  list-style: disclosure-closed inside;
}

details[open] > summary {
  list-style-type: disclosure-open;
```
The `details` element is expected to render as a block box. The element is also expected to have an internal shadow tree with two slots. The first slot is expected to take the `details` element’s first `summary` element child, if any. The second slot is expected to take the `details` element’s remaining descendants, if any.

The `details` element’s first `summary` element child, if any, is expected to allow the user to request the details be shown or hidden.

The `details` element’s second slot is expected to have its `style` attribute set to “display: block; content-visibility: hidden;” when the `details` element does not have an `open` attribute. When it does have the `open` attribute, the `style` attribute is expected to be removed from the second slot.

Because the slots are hidden inside a shadow tree, this `style` attribute is not directly visible to author code. Its impacts, however, are visible. Notably, the choice of `content-visibility: hidden` instead of, e.g., `display: none`, impacts the results of various APIs that query layout information.

15.5.5 The `input` element as a text entry widget

An `input` element whose `type` attribute is in the Text, Search, Telephone, URL, or Email state, is expected to render as an ‘inline-block’ box depicting a text control. Additionally, the ‘line-height’ property, if it has a computed value equivalent to a value that is less than 1.0, must have a used value of 1.0.

An `input` element whose `type` attribute is in the Password state is expected to render as an ‘inline-block’ box depicting a text control that obscures data entry.

If these text controls provide a text selection, then, when the user changes the current selection, the user agent is expected to queue an element task on the user interaction task source given the `input` element to fire an event named `select` at the element, with the `bubbles` attribute initialized to true.

If an `input` element whose `type` attribute is in one of the above states has a `size` attribute, and parsing that attribute’s value using the rules for parsing non-negative integers doesn’t generate an error, then the user agent is expected to use the attribute as a presentational hint for the ‘width’ property on the element, with the value obtained from applying the converting a character width to pixels algorithm to the value of the attribute.

If an `input` element whose `type` attribute is in one of the above states does not have a `size` attribute, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the ‘width’ property on the element to the value obtained from applying the converting a character width to pixels algorithm to the number 20.

The converting a character width to pixels algorithm returns \((\text{size}-1) \times \text{avg} + \text{max}\), where size is
the character width to convert, \( \text{avg} \) is the average character width of the primary font for the element for which the algorithm is being run, in pixels, and \( \text{max} \) is the maximum character width of that same font, also in pixels. (The element’s ‘\text{letter-spacing}’ property does not affect the result.)

These text controls are expected to be \text{scroll containers} and support scrolling in the \text{inline axis}, but not the \text{block axis}.

**15.5.6 The \textit{input} element as domain-specific widgets**

An \textit{input} element whose \textit{type} attribute is in the \texttt{Date} state is expected to render as an ‘\textit{inline-block}’ box depicting a date control.

An \textit{input} element whose \textit{type} attribute is in the \texttt{Month} state is expected to render as an ‘\textit{inline-block}’ box depicting a month control.

An \textit{input} element whose \textit{type} attribute is in the \texttt{Week} state is expected to render as an ‘\textit{inline-block}’ box depicting a week control.

An \textit{input} element whose \textit{type} attribute is in the \texttt{Time} state is expected to render as an ‘\textit{inline-block}’ box depicting a time control.

An \textit{input} element whose \textit{type} attribute is in the \texttt{Local Date and Time} state is expected to render as an ‘\textit{inline-block}’ box depicting a local date and time control.

An \textit{input} element whose \textit{type} attribute is in the \texttt{Number} state is expected to render as an ‘\textit{inline-block}’ box depicting a number control.

These controls are all expected to be about one line high, and about as wide as necessary to show the widest possible value.

**15.5.7 The \textit{input} element as a range control**

An \textit{input} element whose \textit{type} attribute is in the \texttt{Range} state is expected to render as an ‘\textit{inline-block}’ box depicting a slider control.

When the control is wider than it is tall (or square), the control is expected to be a horizontal slider, with the lowest value on the right if the ‘\texttt{direction}’ property on this element has a \textit{computed value} of ‘\texttt{rtl}’, and on the left otherwise. When the control is taller than it is wide, it is expected to be a vertical slider, with the lowest value on the bottom.

Predefined suggested values (provided by the \texttt{list} attribute) are expected to be shown as tick marks on the slider, which the slider can snap to.

User agents are expected to use the \textit{used value} of the ‘\texttt{direction}’ property on the element to determine the direction in which the slider operates. Typically, a left-to-right (‘\texttt{ltr}’) horizontal control would have the lowest value on the left and the highest value on the right, and vice
versa.

15.5.8 The **input** element as a color well

An **input** element whose **type** attribute is in the Color state is expected to depict a color well, which, when activated, provides the user with a color picker (e.g. a color wheel or color palette) from which the color can be changed. The element, when it generates a **CSS box**, is expected to use button layout, that has no child boxes of the **anonymous button content box**. The **anonymous button content box** is expected to have a presentational hint setting the ‘background-color’ property to the element’s **value**.

Predefined suggested values (provided by the **list** attribute) are expected to be shown in the color picker interface, not on the color well itself.

15.5.9 The **input** element as a checkbox and radio button widgets

An **input** element whose **type** attribute is in the Checkbox state is expected to render as an ‘inline-block’ box containing a single checkbox control, with no label.

An **input** element whose **type** attribute is in the Radio Button state is expected to render as an ‘inline-block’ box containing a single radio button control, with no label.

15.5.10 The **input** element as a file upload control

An **input** element whose **type** attribute is in the File Upload state, when it generates a **CSS box**, is expected to render as an ‘inline-block’ box containing a span of text giving the filename(s) of the selected files, if any, followed by a button that, when activated, provides the user with a file picker from which the selection can be changed. The button is expected to use button layout and match the ‘::file-selector-button’ pseudo-element. The contents of its **anonymous button content box** are expected to be implementation-defined (and possibly locale-specific) text, for example “Choose file”.

15.5.11 The **input** element as a button

An **input** element whose **type** attribute is in the Submit Button, Reset Button, or Button state, when it generates a **CSS box**, is expected to depict a button and use button layout and the contents of the **anonymous button content box** are expected to be the text of the element’s **value** attribute, if any, or text derived from the element’s **type** attribute in an implementation-defined (and probably locale-specific) fashion, if not.

15.5.12 The **marquee** element

```html
@namespace url(http://www.w3.org/1999/xhtml);

marquee {
```
The **marquee** element, while **turned on**, is expected to render in an animated fashion according to its attributes as follows:

If the element’s **behavior** attribute is in the **scroll** state

Slide the contents of the element in the direction described by the **direction** attribute as defined below, such that it begins off the start side of the **marquee**, and ends flush with the inner end side.

For example, if the **direction** attribute is **left** (the default), then the contents would start such that their left edge are off the side of the right edge of the **marquee**’s content area, and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the **marquee**’s content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index. If the element is still **turned on** after this, then the user agent is expected to restart the animation.

If the element’s **behavior** attribute is in the **slide** state

Slide the contents of the element in the direction described by the **direction** attribute as defined below, such that it begins off the start side of the **marquee**, and ends off the end side of the **marquee**.

For example, if the **direction** attribute is **left** (the default), then the contents would start such that their left edge are off the side of the right edge of the **marquee**’s content area, and the contents would then slide up to the point where the **right** edge of the contents are flush with the left inner edge of the **marquee**’s content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index. If the element is still **turned on** after this, then the user agent is expected to restart the animation.

If the element’s **behavior** attribute is in the **alternate** state

When the **marquee current loop index** is even (or zero), slide the contents of the element in the direction described by the **direction** attribute as defined below, such that it begins flush with the start side of the **marquee**, and ends flush with the end side of the **marquee**.

When the **marquee current loop index** is odd, slide the contents of the element in the opposite direction than that described by the **direction** attribute as defined below, such that it begins flush with the end side of the **marquee**, and ends flush with the start side of the **marquee**.
For example, if the `direction` attribute is `left` (the default), then the contents would with their right edge flush with the right inner edge of the marquee’s content area, and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the marquee’s content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index. If the element is still turned on after this, then the user agent is expected to continue the animation.

The `direction` attribute has the meanings described in the following table:

<table>
<thead>
<tr>
<th><code>direction</code> attribute</th>
<th>Direction of animation</th>
<th>Start edge</th>
<th>End edge</th>
<th>Opposite direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>← Right to Left</td>
<td>Right</td>
<td>Left</td>
<td>→ Left to Right</td>
</tr>
<tr>
<td>right</td>
<td>→ Left to Right</td>
<td>Left</td>
<td>Right</td>
<td>← Right to left</td>
</tr>
<tr>
<td>up</td>
<td>↑ Up (Bottom to Top)</td>
<td>Bottom</td>
<td>Top</td>
<td>↓ Down (Top to Bottom)</td>
</tr>
<tr>
<td>down</td>
<td>↓ Down (Top to Bottom)</td>
<td>Top</td>
<td>Bottom</td>
<td>↑ Up (Bottom to Top)</td>
</tr>
</tbody>
</table>

In any case, the animation should proceed such that there is a delay given by the marquee scroll interval between each frame, and such that the content moves at most the distance given by the marquee scroll distance with each frame.

When a `marquee` element has a `bgcolor` attribute set, the value is expected to be parsed using the rules for parsing a legacy color value, and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint setting the element’s `background-color` property to the resulting color.

The `width` and `height` attributes on a `marquee` element map to the dimension properties `width` and `height` on the element respectively.

The intrinsic height of a `marquee` element with its `direction` attribute in the `up` or `down` states is 200 CSS pixels.

The `vspace` attribute of a `marquee` element maps to the dimension properties `margin-top` and `margin-bottom` on the element. The `hspace` attribute of a `marquee` element maps to the dimension properties `margin-left` and `margin-right` on the element.

The `overflow` property on the `marquee` element is expected to be ignored; overflow is expected to always be hidden.

15.5.13 The `meter` element

The `meter` element is expected to render as an `inline-block` box with a `height` of `1em` and a `width` of `5em`, a `vertical-align` of `-0.2em`, and with its contents depicting a gauge.
When the element is wider than it is tall (or square), the depiction is expected to be of a horizontal gauge, with the minimum value on the right if the `direction` property on this element has a computed value of ‘rtl’, and on the left otherwise. When the element is taller than it is wide, it is expected to depict a vertical gauge, with the minimum value on the bottom.

User agents are expected to use a presentation consistent with platform conventions for gauges, if any.

Requirements for what must be depicted in the gauge are included in the definition of the `meter` element.

15.5.14 The `progress` element

The `progress` element is expected to render as an `inline-block` box with a `height` of ‘1em’ and a `width` of ‘10em’, and a `vertical-align` of ‘-0.2em’.

![Progress Bars](image)

When the element is wider than it is tall, the element is expected to be depicted as a horizontal progress bar, with the start on the right and the end on the left if the `direction` property on this element has a computed value of ‘rtl’, and with the start on the left and the end on the right otherwise. When the element is taller than it is wide, it is expected to be depicted as a vertical progress bar, with the lowest value on the bottom. When the element is square, it is expected to be depicted as a direction-independent progress widget (e.g. a circular progress ring).

User agents are expected to use a presentation consistent with platform conventions for progress bars. In particular, user agents are expected to use different presentations for determinate and indeterminate progress bars. User agents are also expected to vary the presentation based on the dimensions of the element.

For example, on some platforms for showing indeterminate progress there is a "spinner" progress indicator with square dimensions, which could be used when the element is square, and an indeterminate progress bar, which could be used when the element is wide.

Requirements for how to determine if the progress bar is determinate or indeterminate, and what progress a determinate progress bar is to show, are included in the definition of the `progress` element.

15.5.15 The `select` element

A `select` element is either a `list box` or a `drop-down box`, depending on its attributes.

A `select` element whose `multiple` attribute is present is expected to render as a multi-select
A **select** element whose `multiple` attribute is absent, and whose `display size` is greater than 1, is expected to render as a single-select **list box**.

When the element renders as a **list box**, it is expected to render as an ‘**inline-block**’ box whose ‘**height**’ is the height necessary to contain as many rows for items as given by the element’s `display size`, or four rows if the attribute is absent, and whose ‘**width**’ is the **width of the select’s labels** plus the width of a scrollbar.

A **select** element whose `multiple` attribute is absent, and whose `display size` is 1, is expected to render as an ‘**inline-block**’ one-line **drop-down box** whose width is the **width of the select’s labels**.

In either case (**list box** or **drop-down box**), the element’s items are expected to be the element’s **list of options**, with the element’s **optgroup** element **children** providing headers for groups of options where applicable.

An **optgroup** element is expected to be rendered by displaying the element’s `label` attribute.

An **option** element is expected to be rendered by displaying the element’s `label`, indented under its **optgroup** element if it has one.

The **width of the select’s labels** is the wider of the width necessary to render the widest **optgroup**, and the width necessary to render the widest **option** element in the element’s **list of options** (including its indent, if any).

If a **select** element contains a **placeholder label option**, the user agent is expected to render that **option** in a manner that conveys that it is a label, rather than a valid option of the control. This can include preventing the **placeholder label option** from being explicitly selected by the user. When the **placeholder label option**’s `selectedness` is true, the control is expected to be displayed in a fashion that indicates that no valid option is currently selected.

User agents are expected to render the labels in a **select** in such a manner that any alignment remains consistent whether the label is being displayed as part of the page or in a menu control.

15.5.16 The **textarea** element

The **textarea** element is expected to render as an ‘**inline-block**’ box depicting a multiline text control. If this multiline text control provides a selection, then, when the user changes the current selection, the user agent is expected to queue an element task on the **user interaction task source** given the **textarea** element to **fire an event** named **select** at the element, with the **bubbles** attribute initialized to true.

If the element has a `cols` attribute, and parsing that attribute’s value using the rules for parsing non-negative integers doesn’t generate an error, then the user agent is expected to use the attribute as a **presentational hint** for the ‘**width**’ property on the element, with the value
being the `textarea effective width` (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the `width` property on the element to the `textarea effective width`.

The `textarea effective width` of a `textarea` element is \( \text{size} \times \text{avg} + \text{sbw} \), where \( \text{size} \) is the element’s character width, \( \text{avg} \) is the average character width of the primary font of the element, in CSS pixels, and \( \text{sbw} \) is the width of a scrollbar, in CSS pixels. (The element’s `letter-spacing` property does not affect the result.)

If the element has a `rows` attribute, and parsing that attribute’s value using the rules for parsing non-negative integers doesn’t generate an error, then the user agent is expected to use the attribute as a presentational hint for the `height` property on the element, with the value being the `textarea effective height` (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the `height` property on the element to the `textarea effective height`.

The `textarea effective height` of a `textarea` element is the height in CSS pixels of the number of lines specified the element’s character height, plus the height of a scrollbar in CSS pixels.

User agents are expected to apply the `white-space` CSS property to `textarea` elements. For historical reasons, if the element has a `wrap` attribute whose value is an ASCII case-insensitive match for the string “off”, then the user agent is expected to treat the attribute as a presentational hint setting the element’s `white-space` property to `pre`.

### 15.6 Frames and framesets

User agent are expected to render `frameset` elements as a box with the height and width of the viewport, with a surface rendered according to the following layout algorithm:

1. The `cols` and `rows` variables are lists of zero or more pairs consisting of a number and a unit, the unit being one of `percentage`, `relative`, and `absolute`.

   Use the rules for parsing a list of dimensions to parse the value of the element’s `cols` attribute, if there is one. Let `cols` be the result, or an empty list if there is no such attribute.

   Use the rules for parsing a list of dimensions to parse the value of the element’s `rows` attribute, if there is one. Let `rows` be the result, or an empty list if there is no such attribute.

2. For any of the entries in `cols` or `rows` that have the number zero and the unit `relative`, change the entry’s number to one.

3. If `cols` has no entries, then add a single entry consisting of the value 1 and the unit `relative to cols`.

   If `rows` has no entries, then add a single entry consisting of the value 1 and the unit
relative to rows.

4. Invoke the algorithm defined below to convert a list of dimensions to a list of pixel values using cols as the input list, and the width of the surface that the frameset is being rendered into, in CSS pixels, as the input dimension. Let sized cols be the resulting list.

Invoke the algorithm defined below to convert a list of dimensions to a list of pixel values using rows as the input list, and the height of the surface that the frameset is being rendered into, in CSS pixels, as the input dimension. Let sized rows be the resulting list.

5. Split the surface into a grid of $w \times h$ rectangles, where $w$ is the number of entries in sized cols and $h$ is the number of entries in sized rows.

Size the columns so that each column in the grid is as many CSS pixels wide as the corresponding entry in the sized cols list.

Size the rows so that each row in the grid is as many CSS pixels high as the corresponding entry in the sized rows list.

6. Let children be the list of frame and frameset elements that are children of the frameset element for which the algorithm was invoked.

7. For each row of the grid of rectangles created in the previous step, from top to bottom, run these substeps:

   1. For each rectangle in the row, from left to right, run these substeps:

      1. If there are any elements left in children, take the first element in the list, and assign it to the rectangle.

         If this is a frameset element, then recurse the entire frameset layout algorithm for that frameset element, with the rectangle as the surface.

         Otherwise, it is a frame element; render its nested browsing context, positioned and sized to fit the rectangle.

      2. If there are any elements left in children, remove the first element from children.

8. If the frameset element has a border, draw an outer set of borders around the rectangles, using the element’s frame border color.

   For each rectangle, if there is an element assigned to that rectangle, and that element has a border, draw an inner set of borders around that rectangle, using the element’s frame border color.
For each (visible) border that does not abut a rectangle that is assigned a frame element with a noresize attribute (including rectangles in further nested frameset elements), the user agent is expected to allow the user to move the border, resizing the rectangles within, keeping the proportions of any nested frameset grids.

A frameset or frame element has a border if the following algorithm returns true:

1. If the element has a frameborder attribute whose value is not the empty string and whose first character is either a U+0031 DIGIT ONE (1) character, a U+0079 LATIN SMALL LETTER Y character (y), or a U+0059 LATIN CAPITAL LETTER Y character (Y), then return true.

2. Otherwise, if the element has a frameborder attribute, return false.

3. Otherwise, if the element has a parent element that is a frameset element, then return true if that element has a border, and false if it does not.

4. Otherwise, return true.

The frame border color of a frameset or frame element is the color obtained from the following algorithm:

1. If the element has a bordercolor attribute, and applying the rules for parsing a legacy color value to that attribute’s value does not result in an error, then return the color so obtained.

2. Otherwise, if the element has a parent element that is a frameset element, then return the frame border color of that element.

3. Otherwise, return gray.

The algorithm to convert a list of dimensions to a list of pixel values consists of the following steps:

1. Let input list be the list of numbers and units passed to the algorithm.

   Let output list be a list of numbers the same length as input list, all zero.

   Entries in output list correspond to the entries in input list that have the same position.

2. Let input dimension be the size passed to the algorithm.

3. Let count percentage be the number of entries in input list whose unit is percentage.

   Let total percentage be the sum of all the numbers in input list whose unit is percentage.

   Let count relative be the number of entries in input list whose unit is relative.
Let \textit{total relative} be the sum of all the numbers in \textit{input list} whose unit is \textit{relative}.

Let \textit{count absolute} be the number of entries in \textit{input list} whose unit is \textit{absolute}.

Let \textit{total absolute} be the sum of all the numbers in \textit{input list} whose unit is \textit{absolute}.

Let \textit{remaining space} be the value of \textit{input dimension}.

4. If \textit{total absolute} is greater than \textit{remaining space}, then for each entry in \textit{input list} whose unit is \textit{absolute}, set the corresponding value in \textit{output list} to the number of the entry in \textit{input list} multiplied by \textit{remaining space} and divided by \textit{total absolute}. Then, set \textit{remaining space} to zero.

Otherwise, for each entry in \textit{input list} whose unit is \textit{absolute}, set the corresponding value in \textit{output list} to the number of the entry in \textit{input list}. Then, decrement \textit{remaining space} by \textit{total absolute}.

5. If \textit{total percentage} multiplied by the \textit{input dimension} and divided by 100 is greater than \textit{remaining space}, then for each entry in \textit{input list} whose unit is \textit{percentage}, set the corresponding value in \textit{output list} to the number of the entry in \textit{input list} multiplied by \textit{remaining space} and divided by \textit{total percentage}. Then, set \textit{remaining space} to zero.

Otherwise, for each entry in \textit{input list} whose unit is \textit{percentage}, set the corresponding value in \textit{output list} to the number of the entry in \textit{input list} multiplied by the \textit{input dimension} and divided by 100. Then, decrement \textit{remaining space} by \textit{total percentage} multiplied by the \textit{input dimension} and divided by 100.

6. For each entry in \textit{input list} whose unit is \textit{relative}, set the corresponding value in \textit{output list} to the number of the entry in \textit{input list} multiplied by \textit{remaining space} and divided by \textit{total relative}.

7. Return \textit{output list}.

User agents working with integer values for frame widths (as opposed to user agents that can lay frames out with subpixel accuracy) are expected to distribute the remainder first to the last entry whose unit is \textit{relative}, then equally (not proportionally) to each entry whose unit is \textit{percentage}, then equally (not proportionally) to each entry whose unit is \textit{absolute}, and finally, failing all else, to the last entry.

The contents of a \texttt{frame} element that does not have a \texttt{frameset} parent are expected to be rendered as \texttt{transparent black}; the user agent is expected to not render its \texttt{nested browsing context} in this case, and its \texttt{nested browsing context} is expected to have a \texttt{viewport} with zero width and zero height.
15.7 Interactive media

15.7.1 Links, forms, and navigation

User agents are expected to allow the user to control aspects of hyperlink activation and form submission, such as which browsing context is to be used for the subsequent navigation.

User agents are expected to allow users to discover the destination of hyperlinks and of forms before triggering their navigation.

User agents are expected to inform the user of whether a hyperlink includes hyperlink auditing, and to let them know at a minimum which domains will be contacted as part of such auditing.

User agents may allow users to navigate browsing contexts to the URLs indicated by the cite attributes on q, blockquote, ins, and del elements.

User agents may surface hyperlinks created by link elements in their user interface, as discussed previously.

15.7.2 The title attribute

User agents are expected to expose the advisory information of elements upon user request, and to make the user aware of the presence of such information.

On interactive graphical systems where the user can use a pointing device, this could take the form of a tooltip. When the user is unable to use a pointing device, then the user agent is expected to make the content available in some other fashion, e.g. by making the element a focusable area and always displaying the advisory information of the currently focused element, or by showing the advisory information of the elements under the user’s finger on a touch device as the user pans around the screen.

U+000A LINE FEED (LF) characters are expected to cause line breaks in the tooltip; U+0009 CHARACTER TABULATION (tab) characters are expected to render as a nonzero horizontal shift that lines up the next glyph with the next tab stop, with tab stops occurring at points that are multiples of 8 times the width of a U+0020 SPACE character.

For example, a visual user agent could make elements with a title attribute focusable, and could make any focused element with a title attribute show its tooltip under the element while the element has focus. This would allow a user to tab around the document to find all the advisory text.

As another example, a screen reader could provide an audio cue when reading an element with a tooltip, with an associated key to read the last tooltip for which a cue was played.
15.7.3 Editing hosts

The current text editing caret (i.e. the active range, if it is empty and in an editing host), if any, is expected to act like an inline replaced element with the vertical dimensions of the caret and with zero width for the purposes of the CSS rendering model.

This means that even an empty block can have the caret inside it, and that when the caret is in such an element, it prevents margins from collapsing through the element.

15.7.4 Text rendered in native user interfaces

User agents are expected to honor the Unicode semantics of text that is exposed in user interfaces, for example supporting the bidirectional algorithm in text shown in dialogs, title bars, popup menus, and tooltips. Text from the contents of elements is expected to be rendered in a manner that honors the directionality of the element from which the text was obtained. Text from attributes is expected to be rendered in a manner that honours the directionality of the attribute.

Consider the following markup, which has Hebrew text asking for a programming language, the languages being text for which a left-to-right direction is important given the punctuation in some of their names:

```html
<p dir="rtl" lang="he">
  <label>
    ?????? ??? ???
  </label>
  <select>
    <option dir="ltr">C++</option>
    <option dir="ltr">C#</option>
    <option dir="ltr">FreePascal</option>
    <option dir="ltr">F#</option>
  </select>
</p>
```

If the select element was rendered as a drop down box, a correct rendering would ensure that the punctuation was the same both in the drop down, and in the box showing the current selection.

The directionality of attributes depends on the attribute and on the element’s dir attribute, as the following example demonstrates. Consider this markup:

```
<select>
  <option dir="ltr">C++</option>
  <option dir="ltr">C#</option>
  <option dir="ltr">FreePascal</option>
  <option dir="ltr">F#</option>
</select>
```
If the `abbr` attributes are rendered, e.g. in a tooltip or other user interface, the first will have a left parenthesis (because the direction is `ltr`), the second will have a right parenthesis (because the direction is `rtl`), and the third will have a right parenthesis (because the direction is determined from the attribute value to be `rtl`).

However, if instead the attribute was not a directionality-capable attribute, the results would be different:

```html
<table>
  <tr>
    <th data-abbr="(?" dir=ltr>A
    <th data-abbr="(?" dir=rtl>A
    <th data-abbr="(?" dir=auto>A
  </table>
```

In this case, if the user agent were to expose the `data-abbr` attribute in the user interface (e.g. in a debugging environment), the last case would be rendered with a left parenthesis, because the direction would be determined from the element’s contents.

A string provided by a script (e.g. the argument to `window.alert()`) is expected to be treated as an independent set of one or more bidirectional algorithm paragraphs when displayed, as defined by the bidirectional algorithm, including, for instance, supporting the paragraph-breaking behavior of U+000A LINE FEED (LF) characters. For the purposes of determining the paragraph level of such text in the bidirectional algorithm, this specification does not provide a higher-level override of rules P2 and P3. [BIDI]

When necessary, authors can enforce a particular direction for a given paragraph by starting it with the Unicode U+200E LEFT-TO-RIGHT MARK or U+200F RIGHT-TO-LEFT MARK characters.

Thus, the following script:

```javascript
alert('\u05DC\u05DE\u05D3 HTML \u05D4\u05D9\u05D5\u05DD!')
```

...would always result in a message reading "???? HTML ???" (not "??? HTML ???!"), regardless of the language of the user agent interface or the direction of the page or any of its elements.

For a more complex example, consider the following script:

```javascript
/* Warning: this script does not handle right-to-left scripts correctly */
var s;
```
if (s = prompt('What is your name?')) {
  alert(s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');}

When the user enters "Kitty", the user agent would alert “Kitty! Ok, Fred, Kitty, and Wilma will get the car.". However, if the user enters "أفهم لا", then the bidirectional algorithm will determine that the direction of the paragraph is right-to-left, and so the output will be the following unintended mess: ".and Wilma will get the car أفهم لا Ok, Fred أفهم لا"

To force an alert that starts with user-provided text (or other text of unknown directionality) to render left-to-right, the string can be prefixed with a U+200E LEFT-TO-RIGHT MARK character:

```javascript
var s;
if (s = prompt('What is your name?')) {
  alert('\u200E' + s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');}
```

15.8 Print media

User agents are expected to allow the user to request the opportunity to obtain a physical form (or a representation of a physical form) of a Document. For example, selecting the option to print a page or convert it to PDF format. [PDF]

When the user actually obtains a physical form (or a representation of a physical form) of a Document, the user agent is expected to create a new rendering of the Document for the print media.

15.9 Unstyled XML documents

HTML user agents may, in certain circumstances, find themselves rendering non-HTML documents that use vocabularies for which they lack any built-in knowledge. This section provides for a way for user agents to handle such documents in a somewhat useful manner.

While a Document is an unstyled document, the user agent is expected to render an unstyled document view.

A Document is an unstyled document while it matches the following conditions:

- The Document has no author style sheets (whether referenced by HTTP headers, processing instructions, elements like link, inline elements like style, or any other mechanism).
- None of the elements in the Document have any presentational hints.
- None of the elements in the Document have any style attributes.
- None of the elements in the Document are in any of the following namespaces: HTML namespace, SVG namespace, MathML namespace.
• The Document has no focusable area (e.g. from XLink) other than the viewport.
• The Document has no hyperlinks (e.g. from XLink).
• There exists no script whose settings object specifies this Document as the responsible document.
• None of the elements in the Document have any registered event listeners.

An unstyled document view is one where the DOM is not rendered according to CSS (which would, since there are no applicable styles in this context, just result in a wall of text), but is instead rendered in a manner that is useful for a developer. This could consist of just showing the Document object’s source, maybe with syntax highlighting, or it could consist of displaying just the DOM tree, or simply a message saying that the page is not a styled document.

If a Document stops being an unstyled document, then the conditions above stop applying, and thus a user agent following these requirements will switch to using the regular CSS rendering.

16 Obsolete features

16.1 Obsolete but conforming features

Features listed in this section will trigger warnings in conformance checkers.

Authors should not specify a border attribute on an img element. If the attribute is present, its value must be the string "0". CSS should be used instead.

Authors should not specify a charset attribute on a script element. If the attribute is present, its value must be an ASCII case-insensitive match for "utf-8". (This has no effect in a document that conforms to the requirements elsewhere in this standard of being encoded as UTF-8.)

Authors should not specify a language attribute on a script element. If the attribute is present, its value must be an ASCII case-insensitive match for the string "JavaScript" and either the type attribute must be omitted or its value must be an ASCII case-insensitive match for the string "text/javascript". The attribute should be entirely omitted instead (with the value "JavaScript", it has no effect), or replaced with use of the type attribute.

Authors should not specify a value for the type attribute on script elements that is the empty string or a JavaScript MIME type essence match. Instead, they should omit the attribute, which has the same effect.

Authors should not specify a type attribute on a style element. If the attribute is present, its value must be an ASCII case-insensitive match for "text/css".

Authors should not specify the name attribute on a elements. If the attribute is present, its value must not be the empty string and must neither be equal to the value of any of the IDs in the element’s tree other than the element’s own ID, if any, nor be equal to the value of any of the other name attributes on a elements in the element’s tree. If this attribute is present and the
element has an ID, then the attribute’s value must be equal to the element’s ID. In earlier versions of the language, this attribute was intended as a way to specify possible targets for fragments in URLs. The id attribute should be used instead.

Authors should not, but may despite requirements to the contrary elsewhere in this specification, specify the maxlength and size attributes on input elements whose type attributes are in the Number state. One valid reason for using these attributes regardless is to help legacy user agents that do not support input elements with type="number" to still render the text control with a useful width.

16.1.1 Warnings for obsolete but conforming features

To ease the transition from HTML4 Transitional documents to the language defined in this specification, and to discourage certain features that are only allowed in very few circumstances, conformance checkers must warn the user when the following features are used in a document. These are generally old obsolete features that have no effect, and are allowed only to distinguish between likely mistakes (regular conformance errors) and mere vestigial markup or unusual and discouraged practices (these warnings).

The following features must be categorized as described above:

- The presence of a border attribute on an img element if its value is the string "0".
- The presence of a charset attribute on a script element if its value is an ASCII case-insensitive match for "utf-8".
- The presence of a language attribute on a script element if its value is an ASCII case-insensitive match for the string “JavaScript” and if there is no type attribute or there is and its value is an ASCII case-insensitive match for the string “text/javascript”.
- The presence of a type attribute on a script element if its value is a JavaScript MIME type essence match.
- The presence of a type attribute on a style element if its value is an ASCII case-insensitive match for “text/css”.
- The presence of a name attribute on an a element, if its value is not the empty string.
- The presence of a maxlength attribute on an input element whose type attribute is in the Number state.
- The presence of a size attribute on an input element whose type attribute is in the Number state.

Conformance checkers must distinguish between pages that have no conformance errors and have none of these obsolete features, and pages that have no conformance errors but do have
some of these obsolete features.

For example, a validator could report some pages as "Valid HTML" and others as "Valid HTML with warnings".

16.2 Non-conforming features

Elements in the following list are entirely obsolete, and must not be used by authors:

**applet**

Use **embed** or **object** instead.

**acronym**

Use **abbr** instead.

**bgsound**

Use **audio** instead.

**dir**

Use **ul** instead.

**frame**

**frameset**

**noframes**

Either use **iframe** and CSS instead, or use server-side includes to generate complete pages with the various invariant parts merged in.

**isindex**

Use an explicit **form** and **text control** combination instead.

**keygen**

For enterprise device management use cases, use native on-device management capabilities.

For certificate enrollment use cases, use the Web Cryptography API to generate a keypair for the certificate, and then export the certificate and key to allow the user to install them manually. [WEBCRYPTO]
listing

Use pre and code instead.

menuitem

To implement a custom context menu, use script to handle the contextmenu event.

nextid

Use GUIDs instead.

noembed

Use object instead of embed when fallback is necessary.

plaintext

Use the "text/plain" MIME type instead.

rb
rtc

Providing the ruby base directly inside the ruby element or using nested ruby elements is sufficient.

strike

Use del instead if the element is marking an edit, otherwise use s instead.

xmp

Use pre and code instead, and escape "<" and "&" characters as "&lt;" and "&amp;" respectively.

basefont
big
blink
center
font
marquee
multicol
nobr
spacer
tt

Use appropriate elements or CSS instead.
Where the `tt` element would have been used for marking up keyboard input, consider the `kbd` element; for variables, consider the `var` element; for computer code, consider the `code` element; and for computer output, consider the `samp` element.

Similarly, if the `big` element is being used to denote a heading, consider using the `h1` element; if it is being used for marking up important passages, consider the `strong` element; and if it is being used for highlighting text for reference purposes, consider the `mark` element.

See also the [text-level semantics usage summary](#) for more suggestions with examples.

The following attributes are obsolete (though the elements are still part of the language), and must not be used by authors:

- `charset` on `a` elements
- `charset` on `link` elements
  
  Use an HTTP `Content-Type` header on the linked resource instead.

- `charset` on `script` elements (except as noted in the previous section)
  
  Omit the attribute. Both documents and scripts are required to use UTF-8, so it is redundant to specify it on the `script` element since it inherits from the document.

- `coords` on `a` elements
- `shape` on `a` elements
  
  Use `area` instead of `a` for image maps.

- `methods` on `a` elements
- `methods` on `link` elements
  
  Use the HTTP OPTIONS feature instead.

- `name` on `a` elements (except as noted in the previous section)
- `name` on `embed` elements
- `name` on `img` elements
- `name` on `option` elements
  
  Use the `id` attribute instead.

- `rev` on `a` elements
- `rev` on `link` elements
  
  Use the `rel` attribute instead, with an opposite term. (For example, instead of `rev="made"`, use `rel="author"`.)
urn on a elements
urn on link elements

Specify the preferred persistent identifier using the href attribute instead.

accept on form elements

Use the accept attribute directly on the input elements instead.

hreflang on area elements
type on area elements

These attributes do not do anything useful, and for historical reasons there are no corresponding IDL attributes on area elements. Omit them altogether.

nohref on area elements

Omitting the href attribute is sufficient; the nohref attribute is unnecessary. Omit it altogether.

profile on head elements

Unnecessary. Omit it altogether.

manifest on html elements

Use service workers instead. [SW]

version on html elements

Unnecessary. Omit it altogether.

ismap on input elements

Unnecessary. Omit it altogether. All input elements with a type attribute in the Image Button state are processed as server-side image maps.

usemap on input elements
usemap on object elements

Use the img element for image maps.

longdesc on iframe elements
longdesc on img elements

Use a regular a element to link to the description, or (in the case of images) use an imagemap to provide a link from the image to the image’s description.
**lowsrc** on **img** elements

Use a progressive JPEG image (given in the **src** attribute), instead of using two separate images.

**target** on **link** elements

Unnecessary. Omit it altogether.

**type** on **menu** elements

To implement a custom context menu, use script to handle the **contextmenu** event. For toolbar menus, omit the attribute.

**label** on **menu** elements

**contextmenu** on all elements

**onshow** on all elements

To implement a custom context menu, use script to handle the **contextmenu** event.

**scheme** on **meta** elements

Use only one scheme per field, or make the scheme declaration part of the value.

**archive** on **object** elements

**classid** on **object** elements

**code** on **object** elements

**codebase** on **object** elements

**codetype** on **object** elements

Use the **data** and **type** attributes to invoke plugins. To set parameters with these names in particular, the **param** element can be used.

**declare** on **object** elements

Repeat the **object** element completely each time the resource is to be reused.

**standby** on **object** elements

Optimize the linked resource so that it loads quickly or, at least, incrementally.

**typemustmatch** on **object** elements

Avoid using **object** elements with untrusted resources.
**type** on **param** elements
**valuetype** on **param** elements

Use the **name** and **value** attributes without declaring value types.

**language** on **script** elements (except as noted in the previous section)

Omit the attribute for JavaScript; for **data blocks**, use the **type** attribute instead.

**event** on **script** elements
**for** on **script** elements

Use DOM events mechanisms to register event listeners. [DOM]

**type** on **style** elements (except as noted in the previous section)

Omit the attribute for CSS; for **data blocks**, use **script** as the container instead of **style**.

**datapagesize** on **table** elements

Unnecessary. Omit it altogether.

**summary** on **table** elements

Use one of the techniques for describing tables given in the **table** section instead.

**abbr** on **td** elements

Use text that begins in an unambiguous and terse manner, and include any more elaborate text after that. The **title** attribute can also be useful in including more detailed text, so that the cell’s contents can be made terse. If it’s a heading, use **th** (which has an **abbr** attribute).

**axis** on **td** and **th** elements

Use the **scope** attribute on the relevant **th**.

**scope** on **td** elements

Use **th** elements for heading cells.

**dataformatas** on **button**, **div**, **input**, **label**, **legend**, **marquee**, **object**, **option**, **select**, **span**, and **table** elements

Use script and a mechanism such as [XMLHttpRequest](https://xhr) to populate the page dynamically.

**dropzone** on all elements

Use script to handle the **dragenter** and **dragover** events instead.
align on body elements
bghcolor on body elements

compact on ul elements
type on ul elements
background on body, table, thead, tbody, tfoot, tr, td, and th elements

Use CSS instead.
16.3 Requirements for implementations

16.3.1 The marquee element

The marquee element is a presentational element that animates content. CSS transitions and animations are a more appropriate mechanism. [CSSANIMATIONS] [CSSTRANSITIONS]

The marquee element must implement the HTMLMarqueeElement interface.

[Exposed=Window]
interface HTMLMarqueeElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute DOMString behavior;
    [CEReactions] attribute DOMString bgColor;
    [CEReactions] attribute DOMString direction;
    [CEReactions] attribute DOMString height;
    [CEReactions] attribute unsigned long hspace;
    [CEReactions] attribute long loop;
    [CEReactions] attribute unsigned long scrollAmount;
    [CEReactions] attribute unsigned long scrollDelay;
    [CEReactions] attribute boolean trueSpeed;
    [CEReactions] attribute unsigned long vspace;
    [CEReactions] attribute DOMString width;

    undefined start();
    undefined stop();
};

A marquee element can be turned on or turned off. When it is created, it is turned on.

When the start() method is called, the marquee element must be turned on.

When the stop() method is called, the marquee element must be turned off.

The behavior content attribute on marquee elements is an enumerated attribute with the following keywords (all non-conforming):

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>scroll</td>
<td>scroll</td>
</tr>
<tr>
<td>slide</td>
<td>slide</td>
</tr>
<tr>
<td>alternate</td>
<td>alternate</td>
</tr>
</tbody>
</table>

The missing value default and invalid value default are the scroll state.
The *direction* content attribute on *marquee* elements is an enumerated attribute with the following keywords (all non-conforming):

<table>
<thead>
<tr>
<th>Keyword</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>left</td>
</tr>
<tr>
<td>right</td>
<td>right</td>
</tr>
<tr>
<td>up</td>
<td>up</td>
</tr>
<tr>
<td>down</td>
<td>down</td>
</tr>
</tbody>
</table>

The *missing value default* and *invalid value default* are the *left* state.

The *truespeed* content attribute on *marquee* elements is a boolean attribute.

A *marquee* element has a *marquee scroll interval*, which is obtained as follows:

1. If the element has a *scrolldelay* attribute, and parsing its value using the rules for parsing non-negative integers does not return an error, then let *delay* be the parsed value. Otherwise, let *delay* be 85.

2. If the element does not have a *truespeed* attribute, and the *delay* value is less than 60, then let *delay* be 60 instead.

3. The *marquee scroll interval* is *delay*, interpreted in milliseconds.

A *marquee* element has a *marquee scroll distance*, which, if the element has a *scrollamount* attribute, and parsing its value using the rules for parsing non-negative integers does not return an error, is the parsed value interpreted in CSS pixels, and otherwise is 6 CSS pixels.

A *marquee* element has a *marquee loop count*, which, if the element has a *loop* attribute, and parsing its value using the rules for parsing integers does not return an error or a number less than 1, is the parsed value, and otherwise is −1.

The *loop* IDL attribute, on getting, must return the element’s *marquee loop count*; and on setting, if the new value is different than the element’s *marquee loop count* and either greater than zero or equal to −1, must set the element’s *loop* content attribute (adding it if necessary) to the valid integer that represents the new value. (Other values are ignored.)

A *marquee* element also has a *marquee current loop index*, which is zero when the element is created.

The rendering layer will occasionally increment the *marquee current loop index*, which must cause the following steps to be run:
1. If the [marquee loop count] is −1, then return.

2. Increment the [marquee current loop index] by one.

3. If the [marquee current loop index] is now equal to or greater than the element’s [marquee loop count], turn off the [marquee] element.

The `behavior`, `direction`, `height`, `hspace`, `vspace`, and `width` IDL attributes must reflect the respective content attributes of the same name.

The `bgColor` IDL attribute must reflect the `bgcolor` content attribute.

The `scrollAmount` IDL attribute must reflect the `scrollamount` content attribute. The default value is 6.

The `scrollDelay` IDL attribute must reflect the `scrolldelay` content attribute. The default value is 85.

The `trueSpeed` IDL attribute must reflect the `truespeed` content attribute.

16.3.2 Frames

The `frameset` element acts as the body element in documents that use frames.

The `frameset` element must implement the `HTMLFrameSetElement` interface.

```javascript
[Exposed=Window]
interface HTMLFrameSetElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute DOMString cols;
    [CEReactions] attribute DOMString rows;
};

HTMLFrameSetElement includes WindowEventHandlers;
```

The `cols` and `rows` IDL attributes of the `frameset` element must reflect the respective content attributes of the same name.

The `frameset` element exposes as event handler content attributes a number of the event handlers of the `Window` object. It also mirrors their event handler IDL attributes.

The event handlers of the `Window` object named by the `Window-reflecting body element event handler set`, exposed on the `frameset` element, replace the generic event handlers with the same names normally supported by `HTML elements`. 
The *frame* element has a nested browsing context similar to the *iframe* element, but rendered within a *frameset* element.

A *frame* element is said to be an active frame element when it is in a document.

When a *frame* element element is created as an active frame element, or becomes an active frame element after not having been one, the user agent must run these steps:

1. Create a new nested browsing context for element.
2. Process the frame attributes for element, with initialInsertion set to true.

When a *frame* element stops being an active frame element, the user agent must discard the element’s nested browsing context, and then set the element’s nested browsing context to null.

Whenever a *frame* element with a non-null nested browsing context has its *src* attribute set, changed, or removed, the user agent must process the frame attributes.

To process the frame attributes for an element element, with an optional boolean initialInsertion:

1. If element has a *src* attribute specified, or initialInsertion is false, then run the shared attribute processing steps for *iframe* and *frame* elements given element and initialInsertion.

The *frame* element potentially delays the load event.

The *frame* element must implement the *HTMLFrameElement* interface.

```javascript
[Exposed=Window]
interface HTMLFrameElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute DOMString name;
    [CEReactions] attribute DOMString scrolling;
    [CEReactions] attribute USVString src;
    [CEReactions] attribute DOMString frameBorder;
    [CEReactions] attribute USVString LongDesc;
    [CEReactions] attribute boolean noResize;
    readonly attribute Document? contentDocument;
    readonly attribute WindowProxy? contentWindow;

    [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginHeight;
    [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginWidth;
};
```

The *name*, *scrolling*, and *src* IDL attributes of the *frame* element must reflect the
respective content attributes of the same name. For the purposes of reflection, the `frame` element’s `src` content attribute is defined as containing a URL.

The `frameBorder` IDL attribute of the `frame` element must reflect the element’s `frameborder` content attribute.

The `longDesc` IDL attribute of the `frame` element must reflect the element’s `longdesc` content attribute, which for the purposes of reflection is defined as containing a URL.

The `noResize` IDL attribute of the `frame` element must reflect the element’s `noresize` content attribute.

The `contentDocument` IDL attribute, on getting, must return the `frame` element’s `content` document.

The `contentWindow` IDL attribute must return the `WindowProxy` object of the `frame` element’s `nested browsing context`, if the element’s `nested browsing context` is non-null, or return null otherwise.

The `marginHeight` IDL attribute of the `frame` element must reflect the element’s `marginheight` content attribute.

The `marginWidth` IDL attribute of the `frame` element must reflect the element’s `marginwidth` content attribute.

16.3.3 Other elements, attributes and APIs

User agents must treat `acronym` elements in a manner equivalent to `abbr` elements in terms of semantics and for purposes of rendering.

---

```javascript
partial interface HTMLAnchorElement {
    [CEReactions] attribute DOMString coords;
    [CEReactions] attribute DOMString charset;
    [CEReactions] attribute DOMString name;
    [CEReactions] attribute DOMString rev;
    [CEReactions] attribute DOMString shape;
};
```

The `coords`, `charset`, `name`, `rev`, and `shape` IDL attributes of the `a` element must reflect the respective content attributes of the same name.

---

```javascript
partial interface HTMLAreaElement {
    [CEReactions] attribute boolean noHref;
};
```
The **noHref** IDL attribute of the **area** element must **reflect** the element’s **nohref** content attribute.

partial interface **HTMLBodyElement** {
    [CEReactions] attribute [LegacyNullToEmptyString] DOMString **text**;
    [CEReactions] attribute [LegacyNullToEmptyString] DOMString **link**;
    [CEReactions] attribute [LegacyNullToEmptyString] DOMString **vLink**;
    [CEReactions] attribute [LegacyNullToEmptyString] DOMString **aLink**;
    [CEReactions] attribute [LegacyNullToEmptyString] DOMString **bgColor**;
    [CEReactions] attribute DOMString **background**;
};

The **text** IDL attribute of the **body** element must **reflect** the element’s **text** content attribute.

The **link** IDL attribute of the **body** element must **reflect** the element’s **link** content attribute.

The **aLink** IDL attribute of the **body** element must **reflect** the element’s **alink** content attribute.

The **vLink** IDL attribute of the **body** element must **reflect** the element’s **vlink** content attribute.

The **bgColor** IDL attribute of the **body** element must **reflect** the element’s **bgcolor** content attribute.

The **background** IDL attribute of the **body** element must **reflect** the element’s **background** content attribute. (The **background** content is not defined to contain a **URL**, despite rules regarding its handling in the Rendering section above.)

partial interface **HTMLBRElement** {
    [CEReactions] attribute DOMString **clear**;
};

The **clear** IDL attribute of the **br** element must **reflect** the content attribute of the same name.

partial interface **HTMLTableCaptionElement** {
    [CEReactions] attribute DOMString **align**;
};

The **align** IDL attribute of the **caption** element must **reflect** the content attribute of the same name.
partial interface HTMLTableColElement {
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString ch;
    [CEReactions] attribute DOMString chOff;
    [CEReactions] attribute DOMString vAlign;
    [CEReactions] attribute DOMString width;
};

The `align` and `width` IDL attributes of the `col` element must `reflect` the respective content attributes of the same name.

The `ch` IDL attribute of the `col` element must `reflect` the element’s `char` content attribute.

The `chOff` IDL attribute of the `col` element must `reflect` the element’s `charoff` content attribute.

The `vAlign` IDL attribute of the `col` element must `reflect` the element’s `valign` content attribute.

User agents must treat `dir` elements in a manner equivalent to `ul` elements in terms of semantics and for purposes of rendering.

The `dir` element must implement the `HTMLDirectoryElement` interface.

[Exposed=Window]
interface HTMLDirectoryElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute boolean compact;
};

The `compact` IDL attribute of the `dir` element must `reflect` the content attribute of the same name.

partial interface HTMLDivElement {
    [CEReactions] attribute DOMString align;
};

The `align` IDL attribute of the `div` element must `reflect` the content attribute of the same name.

partial interface HTMLListElement {
    [CEReactions] attribute boolean compact;
};
The *compact* IDL attribute of the `dl` element must *reflect* the content attribute of the same name.

```plaintext
partial interface HTMLEmbedElement {
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString name;
};
```

The `name` and `align` IDL attributes of the `embed` element must *reflect* the respective content attributes of the same name.

The *font* element must implement the `HTMLFontElement` interface.

```plaintext
[Exposed=Window]
interface HTMLFontElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute [LegacyNullToEmptyString] DOMString color;
    [CEReactions] attribute DOMString face;
    [CEReactions] attribute DOMString size;
};
```

The `color`, `face`, and `size` IDL attributes of the `font` element must *reflect* the respective content attributes of the same name.

```plaintext
partial interface HTMLHeadingElement {
    [CEReactions] attribute DOMString align;
};
```

The `align` IDL attribute of the `h1–h6` elements must *reflect* the content attribute of the same name.

The *profile* IDL attribute on `head` elements (with the `HTMLHeadElement` interface) is intentionally omitted. Unless so required by another applicable specification, implementations would therefore not support this attribute. (It is mentioned here as it was defined in a previous version of *DOM*.)

```plaintext
partial interface HTMLHRElement {
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString color;
    [CEReactions] attribute boolean noShade;
    [CEReactions] attribute DOMString size;
};
```
The `align`, `color`, `size`, and `width` IDL attributes of the `hr` element must reflect the respective content attributes of the same name.

The `noShade` IDL attribute of the `hr` element must reflect the element’s `noshade` content attribute.

```javascript
partial interface HTMLHtmlElement {
    [CEReactions] attribute DOMString version;
};
```

The `version` IDL attribute of the `html` element must reflect the content attribute of the same name.

```javascript
partial interface HTMLIFrameElement {
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString scrolling;
    [CEReactions] attribute DOMString frameborder;
    [CEReactions] attribute USVString longDesc;
    [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginHeight;
    [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginWidth;
};
```

The `align` and `scrolling` IDL attributes of the `iframe` element must reflect the respective content attributes of the same name.

The `frameBorder` IDL attribute of the `iframe` element must reflect the element’s `frameborder` content attribute.

The `longDesc` IDL attribute of the `iframe` element must reflect the element’s `longdesc` content attribute, which for the purposes of reflection is defined as containing a URL.

The `marginHeight` IDL attribute of the `iframe` element must reflect the element’s `marginheight` content attribute.

The `marginWidth` IDL attribute of the `iframe` element must reflect the element’s `marginwidth` content attribute.

```javascript
partial interface HTMLImageElement {
    [CEReactions] attribute DOMString name;
    [CEReactions] attribute USVString lowsrc;
};
```
The `name`, `align`, `border`, `hspace`, and `vspace` IDL attributes of the `img` element must reflect the respective content attributes of the same name.

The `longDesc` IDL attribute of the `img` element must reflect the element’s `longdesc` content attribute, which for the purposes of reflection is defined as containing a URL.

The `lowsrc` IDL attribute of the `img` element must reflect the element’s `lowsrc` content attribute, which for the purposes of reflection is defined as containing a URL.

---

```
partial interface HTMLInputElement {
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString useMap;
};
```

The `align` IDL attribute of the `input` element must reflect the content attribute of the same name.

The `useMap` IDL attribute of the `input` element must reflect the element’s `usemap` content attribute.

---

```
partial interface HTMLLegendElement {
    [CEReactions] attribute DOMString align;
};
```

The `align` IDL attribute of the `legend` element must reflect the content attribute of the same name.

---

```
partial interface HTMLLIElement {
    [CEReactions] attribute DOMString type;
};
```

The `type` IDL attribute of the `li` element must reflect the content attribute of the same name.

---

```
partial interface HTMLLinkElement {
    [CEReactions] attribute DOMString charset;
};
```
The `charset`, `rev`, and `target` IDL attributes of the `link` element must reflect the respective content attributes of the same name.

User agents must treat `listing` elements in a manner equivalent to `pre` elements in terms of semantics and for purposes of rendering.

Partial interface `HTMLMenuElement` {
    [CEReactions] attribute boolean `compact`;
};

The `compact` IDL attribute of the `menu` element must reflect the content attribute of the same name.

Partial interface `HTMLMetaElement` {
    [CEReactions] attribute DOMString `scheme`;
};

User agents may treat the `scheme` content attribute on the `meta` element as an extension of the element’s `name` content attribute when processing a `meta` element with a `name` attribute whose value is one that the user agent recognizes as supporting the `scheme` attribute.

User agents are encouraged to ignore the `scheme` attribute and instead process the value given to the metadata name as if it had been specified for each expected value of the `scheme` attribute.

For example, if the user agent acts on `meta` elements with `name` attributes having the value “eGMS.subject.keyword”, and knows that the `scheme` attribute is used with this metadata name, then it could take the `scheme` attribute into account, acting as if it was an extension of the `name` attribute. Thus the following two `meta` elements could be treated as two elements giving values for two different metadata names, one consisting of a combination of “eGMS.subject.keyword” and “LGCL”, and the other consisting of a combination of “eGMS.subject.keyword” and “ORLY”:

<!-- this markup is invalid -->
<meta name="eGMS.subject.keyword" scheme="LGCL" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" scheme="ORLY" content="Mah car: kthxbye">

The suggested processing of this markup, however, would be equivalent to the following:

<meta name="eGMS.subject.keyword" content="Abandoned vehicles">
The scheme IDL attribute of the meta element must reflect the content attribute of the same name.

```plaintext
partial interface HTMLElement {
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString archive;
    [CEReactions] attribute DOMString code;
    [CEReactions] attribute boolean declare;
    [CEReactions] attribute unsigned long hspace;
    [CEReactions] attribute DOMString standby;
    [CEReactions] attribute unsigned long vspace;
    [CEReactions] attribute DOMString codeBase;
    [CEReactions] attribute DOMString codeType;
    [CEReactions] attribute DOMString useMap;
}
```

The `align`, `archive`, `border`, `code`, `declare`, `hspace`, `standby`, and `vspace` IDL attributes of the object element must reflect the respective content attributes of the same name.

The `codeBase` IDL attribute of the object element must reflect the element’s `codebase` content attribute, which for the purposes of reflection is defined as containing a URL.

The `codeType` IDL attribute of the object element must reflect the element’s `codetype` content attribute.

MDN HTMLObjectElement/useMap

Support in all current engines.

Firefox1+Safari3+Chrome1+
Opera12.1+Edge79+
Edge (Legacy)12+Internet Explorer6+
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android12.1+

The `useMap` IDL attribute must reflect the `usemap` content attribute.
The **compact** IDL attribute of the **ol** element must reflect the content attribute of the same name.

The **align** IDL attribute of the **p** element must reflect the content attribute of the same name.

The **type** IDL attribute of the **param** element must reflect the content attribute of the same name.

The **valueType** IDL attribute of the **param** element must reflect the element’s **valuetype** content attribute.

User agents must treat **plaintext** elements in a manner equivalent to **pre** elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element, though.)

The **width** IDL attribute of the **pre** element must reflect the content attribute of the same name.

The **type** IDL attribute of the **style** element must reflect the element’s **type** content attribute.
The `charset` and `event` IDL attributes of the `script` element must reflect the respective content attributes of the same name.

The `htmlFor` IDL attribute of the `script` element must reflect the element’s `for` content attribute.

The `align`, `border`, `frame`, `summary`, `rules`, and `width`, IDL attributes of the `table` element must reflect the respective content attributes of the same name.

The `bgColor` IDL attribute of the `table` element must reflect the element’s `bgcolor` content attribute.

The `cellPadding` IDL attribute of the `table` element must reflect the element’s `cellpadding` content attribute.

The `cellSpacing` IDL attribute of the `table` element must reflect the element’s `cellspacing` content attribute.

The `align` IDL attribute of the `tbody`, `thead`, and `tfoot` elements must reflect the content
attribute of the same name.

The \textit{ch} IDL attribute of the \texttt{tbody}, \texttt{thead}, and \texttt{tfoot} elements must \textit{reflect} the elements’ \texttt{char} content attributes.

The \textit{chOff} IDL attribute of the \texttt{tbody}, \texttt{thead}, and \texttt{tfoot} elements must \textit{reflect} the elements’ \texttt{charoff} content attributes.

The \textit{vAlign} IDL attribute of the \texttt{tbody}, \texttt{thead}, and \texttt{tfoot} element must \textit{reflect} the elements’ \texttt{valign} content attributes.

\begin{verbatim}
partial interface HTMLTableCellElement {
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString axis;
    [CEReactions] attribute DOMString height;
    [CEReactions] attribute DOMString width;

    [CEReactions] attribute DOMString ch;
    [CEReactions] attribute DOMString chOff;
    [CEReactions] attribute boolean nowrap;
    [CEReactions] attribute DOMString vAlign;

    [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
}
\end{verbatim}

The \texttt{align}, \texttt{axis}, \texttt{height}, and \texttt{width} IDL attributes of the \texttt{td} and \texttt{th} elements must \textit{reflect} the respective content attributes of the same name.

The \textit{ch} IDL attribute of the \texttt{td} and \texttt{th} elements must \textit{reflect} the elements’ \texttt{char} content attributes.

The \textit{chOff} IDL attribute of the \texttt{td} and \texttt{th} elements must \textit{reflect} the elements’ \texttt{charoff} content attributes.

The \textit{nowrap} IDL attribute of the \texttt{td} and \texttt{th} elements must \textit{reflect} the elements’ \texttt{nowrap} content attributes.

The \textit{vAlign} IDL attribute of the \texttt{td} and \texttt{th} elements must \textit{reflect} the elements’ \texttt{valign} content attributes.

The \textit{bgColor} IDL attribute of the \texttt{td} and \texttt{th} elements must \textit{reflect} the elements’ \texttt{bgcolor} content attributes.

\begin{verbatim}
partial interface HTMLTableRowElement {
    [CEReactions] attribute DOMString align;

    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString axis;
    [CEReactions] attribute DOMString height;
    [CEReactions] attribute DOMString width;

    [CEReactions] attribute DOMString ch;
    [CEReactions] attribute DOMString chOff;
    [CEReactions] attribute boolean nowrap;
    [CEReactions] attribute DOMString vAlign;

    [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
}
\end{verbatim}
[CEReactions] attribute DOMString ch;
[CEReactions] attribute DOMString chOff;
[CEReactions] attribute DOMString vAlign;

[CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
}

The align IDL attribute of the tr element must reflect the content attribute of the same name.

The ch IDL attribute of the tr element must reflect the element’s char content attribute.

The chOff IDL attribute of the tr element must reflect the element’s charoff content attribute.

The vAlign IDL attribute of the tr element must reflect the element’s valign content attribute.

The bgColor IDL attribute of the tr element must reflect the element’s bgcolor content attribute.

---

partial interface HTMLUListElement {
  [CEReactions] attribute boolean compact;
  [CEReactions] attribute DOMString type;
};

The compact and type IDL attributes of the ul element must reflect the respective content attributes of the same name.

---

User agents must treat xmp elements in a manner equivalent to pre elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element though.)

---

partial interface Document {
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString fgColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString linkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString vlinkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString alinkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;

  [SameObject] readonly attribute HTMLCollection anchors;
  [SameObject] readonly attribute HTMLCollection applets;

  undefined clear();
The attributes of the `Document` object listed in the first column of the following table must reflect the content attribute on the body element with the name given in the corresponding cell in the second column on the same row, if the body element is a body element (as opposed to a frameset element). When there is no body element or if it is a frameset element, the attributes must instead return the empty string on getting and do nothing on setting.

<table>
<thead>
<tr>
<th>IDL attribute</th>
<th>Content attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>fgColor</td>
<td>text</td>
</tr>
<tr>
<td>linkColor</td>
<td>link</td>
</tr>
<tr>
<td>vlinkColor</td>
<td>vlink</td>
</tr>
<tr>
<td>alinkColor</td>
<td>alink</td>
</tr>
<tr>
<td>bgColor</td>
<td>bgcolor</td>
</tr>
</tbody>
</table>

The `anchors` attribute must return an `HTMLCollection` rooted at the `Document` node, whose filter matches only `a` elements with `name` attributes.

The `applets` attribute must return an `HTMLCollection` rooted at the `Document` node, whose filter matches nothing. (It exists for historical reasons.)

The `clear()`, `captureEvents()`, and `releaseEvents()` methods must do nothing.

The `all` attribute must return an `HTMLAllCollection` rooted at the `Document` node, whose filter matches all elements.

```javascript
undefined captureEvents();
undefined releaseEvents();

[SameObject] readonly attribute HTMLAllCollection all;
};
```

The `captureEvents()` and `releaseEvents()` methods must do nothing.

The `external` attribute of the `Window` interface must return an instance of the `External` interface:

```javascript
[Exposed=Window]
interface External {
```
The `AddSearchProvider()` and `IsSearchProviderInstalled()` methods must do nothing.

### 17 IANA considerations

#### 17.1 `text/html`

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

**Type name:**
- `text`

**Subtype name:**
- `html`

**Required parameters:**
- No required parameters

**Optional parameters:**
- `charset`
  
  The `charset` parameter may be provided to specify the document's character encoding, overriding any character encoding declarations in the document other than a Byte Order Mark (BOM). The parameter's value must be an ASCII case-insensitive match for the string "utf-8". [ENCODING]

**Encoding considerations:**
- 8bit (see the section on character encoding declarations)

**Security considerations:**

Entire novels have been written about the security considerations that apply to HTML documents. Many are listed in this document, to which the reader is referred for more details. Some general concerns bear mentioning here, however:

HTML is scripted language, and has a large number of APIs (some of which are described in this document). Script can expose the user to potential risks of information leakage, credential leakage, cross-site scripting attacks, cross-site request forgeries, and a host of other problems. While the designs in this specification are intended to be safe if implemented correctly, a full implementation is a massive undertaking and, as with any software, user agents are likely to have security bugs.
Even without scripting, there are specific features in HTML which, for historical reasons, are required for broad compatibility with legacy content but that expose the user to unfortunate security problems. In particular, the `<img>` element can be used in conjunction with some other features as a way to effect a port scan from the user’s location on the Internet. This can expose local network topologies that the attacker would otherwise not be able to determine.

HTML relies on a compartmentalization scheme sometimes known as the *same-origin policy*. An origin in most cases consists of all the pages served from the same host, on the same port, using the same protocol.

It is critical, therefore, to ensure that any untrusted content that forms part of a site be hosted on a different origin than any sensitive content on that site. Untrusted content can easily spoof any other page on the same origin, read data from that origin, cause scripts in that origin to execute, submit forms to and from that origin even if they are protected from cross-site request forgery attacks by unique tokens, and make use of any third-party resources exposed to or rights granted to that origin.

**Interoperability considerations:**
Rules for processing both conforming and non-conforming content are defined in this specification.

**Published specification:**
This document is the relevant specification. Labeling a resource with the `text/html` type asserts that the resource is an *HTML document* using the *HTML syntax*.

**Applications that use this media type:**
Web browsers, tools for processing web content, HTML authoring tools, search engines, validators.

**Additional information:**
**Magic number(s):**
No sequence of bytes can uniquely identify an HTML document. More information on detecting HTML documents is available in *MIME Sniffing*. [MIMESNIFF]

**File extension(s):**
“html” and “htm” are commonly, but certainly not exclusively, used as the extension for HTML documents.

**Macintosh file type code(s):**
TEXT

**Person & email address to contact for further information:**
Ian Hickson <ian@hixie.ch>

**Intended usage:**
Common
Restrictions on usage:
   No restrictions apply.

Author:
   Ian Hickson <ian@hixie.ch>

Change controller:
   W3C

Fragments used with text/html resources either refer to the indicated part of the document or provide state information for in-page scripts.

17.2 multipart/x-mixed-replace

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
   multipart

Subtype name:
   x-mixed-replace

Required parameters:
   • boundary (defined in RFC2046) [RFC2046]

Optional parameters:
   No optional parameters.

Encoding considerations:
   binary

Security considerations:
   Subresources of a multipart/x-mixed-replace resource can be of any type, including types with non-trivial security implications such as text/html.

Interoperability considerations:
   None.

Published specification:
   This specification describes processing rules for web browsers. Conformance requirements for generating resources with this type are the same as for multipart/mixed. [RFC2046]

Applications that use this media type:
   This type is intended to be used in resources generated by web servers, for consumption by web browsers.
17.3 application/xhtml+xml

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name: application

Subtype name: xhtml+xml

Required parameters: Same as for application/xml [RFC7303]

Optional parameters: Same as for application/xml [RFC7303]

Encoding considerations: Same as for application/xml [RFC7303]
Security considerations:
Same as for application/xml [RFC7303]

Interoperability considerations:
Same as for application/xml [RFC7303]

Published specification:
Labeling a resource with the application/xhtml+xml type asserts that the resource is an XML document that likely has a document element from the HTML namespace. Thus, the relevant specifications are XML, Namespaces in XML, and this specification. [XML] [XMLNS]

Applications that use this media type:
Same as for application/xml [RFC7303]

Additional information:
Magic number(s):
Same as for application/xml [RFC7303]

File extension(s):
"xhtml" and "xht" are sometimes used as extensions for XML resources that have a document element from the HTML namespace.

Macintosh file type code(s):
TEXT

Change controller:
W3C

Fragments used with application/xhtml+xml resources have the same semantics as with any XML MIME type. [RFC7303]

17.4 text/ping

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.
Type name:
  text

Subtype name:
  ping

Required parameters:
  No parameters

Optional parameters:
  
  charset

  The charset parameter may be provided. The parameter’s value must be “utf-8”. This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:
  Not applicable.

Security considerations:
  If used exclusively in the fashion described in the context of hyperlink auditing, this type introduces no new security concerns.

Interoperability considerations:
  Rules applicable to this type are defined in this specification.

Published specification:
  This document is the relevant specification.

Applications that use this media type:
  Web browsers.

Additional information:
  Magic number(s):
    text/ping resources always consist of the four bytes 0x50 0x49 0x4E 0x47 (‘PING’).

  File extension(s):
    No specific file extension is recommended for this type.

  Macintosh file type code(s):
    No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:
  Ian Hickson <ian@hixie.ch>

Intended usage:
  Common
Restrictions on usage:
Only intended for use with HTTP POST requests generated as part of a web browser’s processing of the ping attribute.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments have no meaning with text/ping resources.

17.5 application/microdata+json

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
application

Subtype name:
microdata+json

Required parameters:
Same as for application/json [JSON]

Optional parameters:
Same as for application/json [JSON]

Encoding considerations:
8bit (always UTF-8)

Security considerations:
Same as for application/json [JSON]

Interoperability considerations:
Same as for application/json [JSON]

Published specification:
Labeling a resource with the application/microdata+json type asserts that the resource is a JSON text that consists of an object with a single entry called "items" consisting of an array of entries, each of which consists of an object with an entry called "id" whose value is a string, an entry called "type" whose value is another string, and an entry called "properties" whose value is an object whose entries each have a value consisting of an array of either objects or strings, the objects being of the same form as the objects in the aforementioned "items" entry. Thus, the relevant specifications are JSON and this specification. [JSON]
Applications that use this media type:

Applications that transfer data intended for use with HTML's microdata feature, especially in the context of drag-and-drop, are the primary application class for this type.

Additional information:

Magic number(s):
  Same as for application/json [JSON]

File extension(s):
  Same as for application/json [JSON]

Macintosh file type code(s):
  Same as for application/json [JSON]

Person & email address to contact for further information:
  Ian Hickson <ian@hixie.ch>

Intended usage:
  Common

Restrictions on usage:
  No restrictions apply.

Author:
  Ian Hickson <ian@hixie.ch>

Change controller:
  W3C

Fragments used with application/microdata+json resources have the same semantics as when used with application/json (namely, at the time of writing, no semantics at all). [JSON]

17.6 text/event-stream

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
  text

Subtype name:
  event-stream

Required parameters:
  No parameters
Optional parameters:

**charset**

The `charset` parameter may be provided. The parameter’s value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

**Encoding considerations:**

8bit (always UTF-8)

**Security considerations:**

An event stream from an origin distinct from the origin of the content consuming the event stream can result in information leakage. To avoid this, user agents are required to apply CORS semantics. [FETCH]

Event streams can overwhelm a user agent; a user agent is expected to apply suitable restrictions to avoid depleting local resources because of an overabundance of information from an event stream.

Servers can be overwhelmed if a situation develops in which the server is causing clients to reconnect rapidly. Servers should use a 5xx status code to indicate capacity problems, as this will prevent conforming clients from reconnecting automatically.

**Interoperability considerations:**

Rules for processing both conforming and non-conforming content are defined in this specification.

**Published specification:**

This document is the relevant specification.

**Applications that use this media type:**

Web browsers and tools using web services.

**Additional information:**

**Magic number(s):**

No sequence of bytes can uniquely identify an event stream.

**File extension(s):**

No specific file extensions are recommended for this type.

**Macintosh file type code(s):**

No specific Macintosh file type codes are recommended for this type.

**Person & email address to contact for further information:**

Ian Hickson <ian@hixie.ch>

**Intended usage:**

Common
Restrictions on usage:
This format is only expected to be used by dynamic open-ended streams served using HTTP or a similar protocol. Finite resources are not expected to be labeled with this type.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments have no meaning with text/event-stream resources.

17.7 `Cross-Origin-Embedder-Policy`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
Cross-Origin-Embedder-Policy

Applicable protocol:
http

Status:
standard

Author/Change controller:
WHATWG

Specification document(s):
This document is the relevant specification.

Related information:
None.

17.8 `Cross-Origin-Embedder-Policy-Report-Only`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
Cross-Origin-Embedder-Policy-Report-Only

Applicable protocol:
http

Status:
standard
17.9 `Cross-Origin-Opener-Policy`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
Cross-Origin-Opener-Policy

Applicable protocol:
http

Status:
standard

Author/Change controller:
WHATWG

Specification document(s):
This document is the relevant specification.

Related information:
None.

17.10 `Cross-Origin-Opener-Policy-Report-Only`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
Cross-Origin-Opener-Policy-Report-Only

Applicable protocol:
http

Status:
standard

Author/Change controller:
WHATWG

Specification document(s):
This document is the relevant specification.

Related information:
None.
17.11 `Origin-Agent-Cluster`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
Origin-Agent-Cluster

Applicable protocol:
http

Status:
standard

Author/Change controller:
WHATWG

Specification document(s):
This document is the relevant specification.

Related information:
None.

17.12 `Ping-From`

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
Ping-From

Applicable protocol:
http

Status:
standard

Author/Change controller:
W3C

Specification document(s):
This document is the relevant specification.
Related information:
None.

17.13 `Ping-To`
This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name: Ping-To
Applicable protocol: http
Status: standard
Author/Change controller: W3C
Specification document(s):
This document is the relevant specification.
Related information:
None.

17.14 `Refresh`
This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name: Refresh
Applicable protocol: http
Status: standard
Author/Change controller: WHATWG
Specification document(s):
This document is the relevant specification.
Related information:
None.
17.15 'Last-Event-ID'

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
    Last-Event-ID

Applicable protocol:
    http

Status:
    standard

Author/Change controller:
    W3C

Specification document(s):
    This document is the relevant specification.

Related information:
    None.

17.16 'X-Frame-Options'

This section describes a header for registration in the Permanent Message Header Field Registry. [RFC3864]

Header field name:
    X-Frame-Options

Applicable protocol:
    http

Status:
    standard

Author/Change controller:
    WHATWG

Specification document(s):
    This document is the relevant specification.

Related information:
    None.
17.17 **web+ scheme prefix**

This section describes a convention for use with the IANA URI scheme registry. It does not itself register a specific scheme. [RFC7595]

**Scheme name:**
Schemes starting with the four characters “web+” followed by one or more letters in the range a-z.

**Status:**
Permanent

**Scheme syntax:**
Scheme-specific.

**Scheme semantics:**
Scheme-specific.

**Encoding considerations:**
All “web+” schemes should use UTF-8 encodings where relevant.

**Applications/protocols that use this scheme name:**
Scheme-specific.

**Interoperability considerations:**
The scheme is expected to be used in the context of web applications.

**Security considerations:**
Any web page is able to register a handler for all “web+” schemes. As such, these schemes must not be used for features intended to be core platform features (e.g., HTTP). Similarly, such schemes must not store confidential information in their URLs, such as usernames, passwords, personal information, or confidential project names.

**Contact:**
Ian Hickson <ian@hixie.ch>

**Change controller:**
Ian Hickson <ian@hixie.ch>

**References:**
*Custom scheme handlers*, HTML Living Standard: https://html.spec.whatwg.org/#custom-handlers

**Index**

The following sections only cover conforming elements and features.
## Elements

*This section is non-normative.*

</tbody>
</table>

An asterisk (*) in a cell indicates that the actual rules are more complicated than indicated in the table above.

† Categories in the "Parents" column refer to parents that list the given categories in their content model, not to elements that themselves are in those categories. For example, the `a` element’s "Parents" column says "phrasing", so any element whose content model contains the "phrasing" category could be a parent of an `a` element. Since the "flow" category includes all the "phrasing" elements, that means the `th` element could be a parent to an `a` element.

**Element content categories**

MIME Types

*This section is non-normative.*

The following MIME types are mentioned in this specification:

- `application/atom+xml`
  - Atom [ATOM]

- `application/ecmascript`
  - JavaScript (legacy type) [JAVASCRIPT]

- `application/javascript`
  - JavaScript (legacy type) [JAVASCRIPT]

- `application/json`
  - JSON [JSON]

- `application/x-ecmascript`
  - JavaScript (legacy type) [JAVASCRIPT]

- `application/x-javascript`
  - JavaScript (legacy type) [JAVASCRIPT]

- `application/octet-stream`
  - Generic binary data [RFC2046]

- `application/microdata+json`
  - Microdata as JSON
application/rss+xml
  RSS

application/x-www-form-urlencoded
  Form submission

application/xhtml+xml
  HTML

application/xml
  XML [XML] [RFC7303]

image/gif
  GIF images [GIF]

image/jpeg
  JPEG images [JPEG]

image/png
  PNG images [PNG]

image/svg+xml
  SVG images [SVG]

multipart/form-data
  Form submission [RFC7578]

multipart/mixed
  Generic mixed content [RFC2046]

multipart/x-mixed-replace
  Streaming server push

text/css
  CSS [CSS]

text/ecmascript
  JavaScript (legacy type) [JAVASCRIPT]

text/event-stream
  Server-sent event streams

text/javascript
  JavaScript [JAVASCRIPT]

text/javascript1.0
  JavaScript (legacy type) [JAVASCRIPT]
text/javascript1.1
JavaScript (legacy type) [JAVASCRIPT]

text/javascript1.2
JavaScript (legacy type) [JAVASCRIPT]

text/javascript1.3
JavaScript (legacy type) [JAVASCRIPT]

text/javascript1.4
JavaScript (legacy type) [JAVASCRIPT]

text/javascript1.5
JavaScript (legacy type) [JAVASCRIPT]

text/jscript
JavaScript (legacy type) [JAVASCRIPT]

text/json
JSON (legacy type)

text/livescript
JavaScript (legacy type) [JAVASCRIPT]

text/plain
Generic plain text [RFC2046] [RFC3676]

text/html
HTML

text/ping
Hyperlink auditing

text/uri-list
List of URLs [RFC2483]

text/vcard
vCard [RFC6350]

text/vtt
WebVTT [WEBVTT]

text/x-ecmascript
JavaScript (legacy type) [JAVASCRIPT]

text/x-javascript
JavaScript (legacy type) [JAVASCRIPT]
References

[COOKIES]
HTTP State Management Mechanism, A. Barth. IETF.

[CSP]
Content Security Policy, M. West, D. Veditz. W3C.

[CSS]
Cascading Style Sheets Level 2 Revision 2, B. Bos, T. Çelik, I. Hickson, H. Lie. W3C.

[CSSALIGN]
CSS Box Alignment, E. Etemad, T. Atkins. W3C.

[CSSANIMATIONS]

[CSSATTR]
CSS Style Attributes, T. Çelik, E. Etemad. W3C.

[CSSBG]
CSS Backgrounds and Borders, B. Bos, E. Etemad, B. Kemper. W3C.

[CSSBOX]
CSS Box Model, E. Etemad. W3C.

[CSSCASCADE]
CSS Cascading and Inheritance, E. Etemad, T. Atkins. W3C.
[CSSCONTAIN]
CSS Containment, T. Atkins, F. Rivoal, V. Levin. W3C.

[CSSCOLOR]
CSS Color Module, T. Çelik, C. Lilley, L. Baron. W3C.

[CSSCOLORADJUST]
CSS Color Adjustment Module, E. Etemad, R. Atanassov, R. Lillesveen, T. Atkins. W3C.

[CSSDEVICEADAPT]
CSS Device Adaption, F. Rivoal, M. Rakow. W3C.

[CSSDISPLAY]
CSS Display, T. Atkins, E. Etemad. W3C.

[CSSFONTLOAD]
CSS Font Loading, T. Atkins, J. Daggett. W3C.

[CSSFONTS]
CSS Fonts, J. Daggett. W3C.

[CSSFLEXBOX]
CSS Flexible Box Layout, T. Atkins, E. Etemad, R. Atanassov. W3C.

[CSSGC]
CSS Generated Content, H. Lie, E. Etemad, I. Hickson. W3C.

[CSSGRID]
CSS Grid Layout, T. Atkins, E. Etemad, R. Atanassov. W3C.

[CSSIMAGES]
CSS Images Module, E. Etemad, T. Atkins, L. Verou. W3C.

[CSSIMAGES4]
CSS Images Module Level 4, E. Etemad, T. Atkins, L. Verou. W3C.

[CSSINLINE]
CSS Inline Layout, D. Cramer, E. Etemad. W3C.

[CSSLISTS]
CSS Lists and Counters, T. Atkins. W3C.

[CSSLOGICAL]
CSS Logical Properties, R. Atanassov, E. Etemad. W3C.

[CSSMULTICOL]
CSS Multi-column Layout, H. Lie, F. Rivoal, R. Andrew. W3C.

[CSSOM]
Cascading Style Sheets Object Model (CSSOM), S. Pieters, G. Adams. W3C.
[CSSOMVIEW]
  CSSOM View Module, S. Pieters, G. Adams. W3C.

[CSSOVERFLOW]
  CSS Overflow Module, L. Baron, F. Rivoal. W3C.

[CSSPAINT]
  (Non-normative) CSS Painting API, I. Kilpatrick, D. Jackson. W3C.

[CSSPOSITION]
  CSS Positioned Layout, R. Atanassov, A. Eicholz. W3C.

[CSSPSEUDO]
  CSS Pseudo-Elements, D. Glazman, E. Etemad, A. Stearns. W3C.

[CSSRUBY]
  CSS3 Ruby Module, R. Ishida. W3C.

[CSSSCOPING]
  CSS Scoping Module, T. Atkins. W3C.

[CSSSIZING]
  CSS Intrinsic & Extrinsic Sizing Module, T. Atkins, E. Etemad. W3C.

[CSSTRANSITIONS]
  (Non-normative) CSS Transitions, D. Jackson, D. Hyatt, C. Marrin, L. Baron. W3C.

[CSSUI]
  CSS3 Basic User Interface Module, T. Çelik. W3C.

[CSSSYNTAX]
  CSS Syntax, T. Atkins, S. Sapin. W3C.

[CSSTABLE]
  CSS Table, F. Remy, G. Whitworth. W3C.

[CSSTEXT]
  CSS Text, E. Etemad, K. Ishii. W3C.

[CSSVALUES]
  CSS3 Values and Units, H. Lie, T. Atkins, E. Etemad. W3C.

[CSSWM]
  CSS Writing Modes, E. Etemad, K. Ishii. W3C.

[DASH]
  Dynamic adaptive streaming over HTTP (DASH), ISO.

[DEVICEPOSTURE]
  (Non-normative) Device Posture API, D. Gonzalez-Zuniga, K. Christiansen. W3C.
[DOM]

DOM, A. van Kesteren, A. Gregor, Ms2ger. WHATWG.

[DOMPARSING]

DOM Parsing and Serialization, T. Leithead. W3C.

[DOT]

(Non-normative) The DOT Language, Graphviz.

[E163]

[ENCODING]

Encoding, A. van Kesteren, J. Bell. WHATWG.

[EXECCOMMAND]

execCommand, J. Wilm, A. Gregor. W3C Editing APIs CG.

[EXIF]

(Non-normative) Exchangeable image file format, JEITA.

[FETCH]

Fetch, A. van Kesteren. WHATWG.

[FILEAPI]

File API, A. Ranganathan. W3C.

[FILTERS]

[FULLSCREEN]

Fullscreen, A. van Kesteren, T. Çelik. WHATWG.

[GEOMETRY]

Geometry Interfaces, S. Pieters, D. Schulze, R. Cabanier. W3C.

Extensible Markup Language, T. Bray, J. Paoli, C. Sperberg-McQueen, E. Maler, F. Yergeau. W3C.

[XMLENTITY]  
(Non-normative) XML Entity Definitions for Characters, D. Carlisle, P. Ion. W3C.

[XMLNS]  
Namespaces in XML, T. Bray, D. Hollander, A. Layman, R. Tobin. W3C.
Acknowledgments

Thanks to Tim Berners-Lee for inventing HTML, without which none of this would exist.

Thanks also to everyone who has ever posted about HTML to their blogs, public mailing lists, or forums, including all the contributors to the various W3C HTML WG lists and the various WHATWG lists.

Special thanks to Richard Williamson for creating the first implementation of canvas in Safari, from which the canvas feature was designed.

Special thanks also to the Microsoft employees who first implemented the event-based drag-and-drop mechanism, contenteditable, and other features first widely deployed by the Windows Internet Explorer browser.

Special thanks and $10,000 to David Hyatt who came up with a broken implementation of the adoption agency algorithm that the editor had to reverse engineer and fix before using it in the parsing section.

Thanks to the participants of the microdata usability study for allowing us to use their mistakes as a guide for designing the microdata feature.

Thanks to the many sources that provided inspiration for the examples used in the specification.

Thanks also to the Microsoft blogging community for some ideas, to the attendees of the W3C Workshop on Web Applications and Compound Documents for inspiration, to the #mrt crew, the #mrt.no crew, and the #whatwg crew, and to Pillar and Hedral for their ideas and support.

Thanks to Igor Zhbanov for generating PDF versions of the specification.

Special thanks to the RICG for developing the picture element and related features; in particular thanks to Adrian Bateman, Bruce Lawson, David Newton, Ilya Grigorik, John Schoenick, Leon de Rijke, Mat Marquis, Marcos Cáceres, Tab Atkins, Theresa O’Connor, and
Yoav Weiss for their contributions.

Special thanks to the WPWG for incubating the custom elements feature. In particular, thanks to David Hyatt and Ian Hickson for their influence through the XBL specifications, Dimitri Glazkov for the first draft of the custom elements specification, and to Alex Komoroske, Alex Russell, Andres Rios, Boris Zbarsky, Brian Kardell, Daniel Buchner, Dominic Cooney, Erik Arvidsson, Elliott Sprehn, Hajime Morrita, Hayato Ito, Jan Miksovsky, Jonas Sicking, Olli Pettay, Rafael Weinstein, Roland Steiner, Ryosuke Niwa, Scott Miles, Steve Faulkner, Steve Orvell, Tab Atkins, Theresa O’Connor, Tim Perry, and William Chen for their contributions.

Special thanks to the CSSWG for developing the worklets. In particular, thanks to Ian Kilpatrik for his work as editor of the original worklets specification.

For about ten years starting in 2003, this standard was almost entirely written by Ian Hickson (Google, ian@hixie.ch). More recently, Simon Pieters (Bocoup, zcorpan@gmail.com), Anne van Kesteren (Mozilla, annevk@annevk.nl), Philip Jägenstedt (Google, philip@foolip.org), and Domenic Denicola (Google, d@domic.me), all previously long-time contributors, have joined Ian in editing the text directly.
