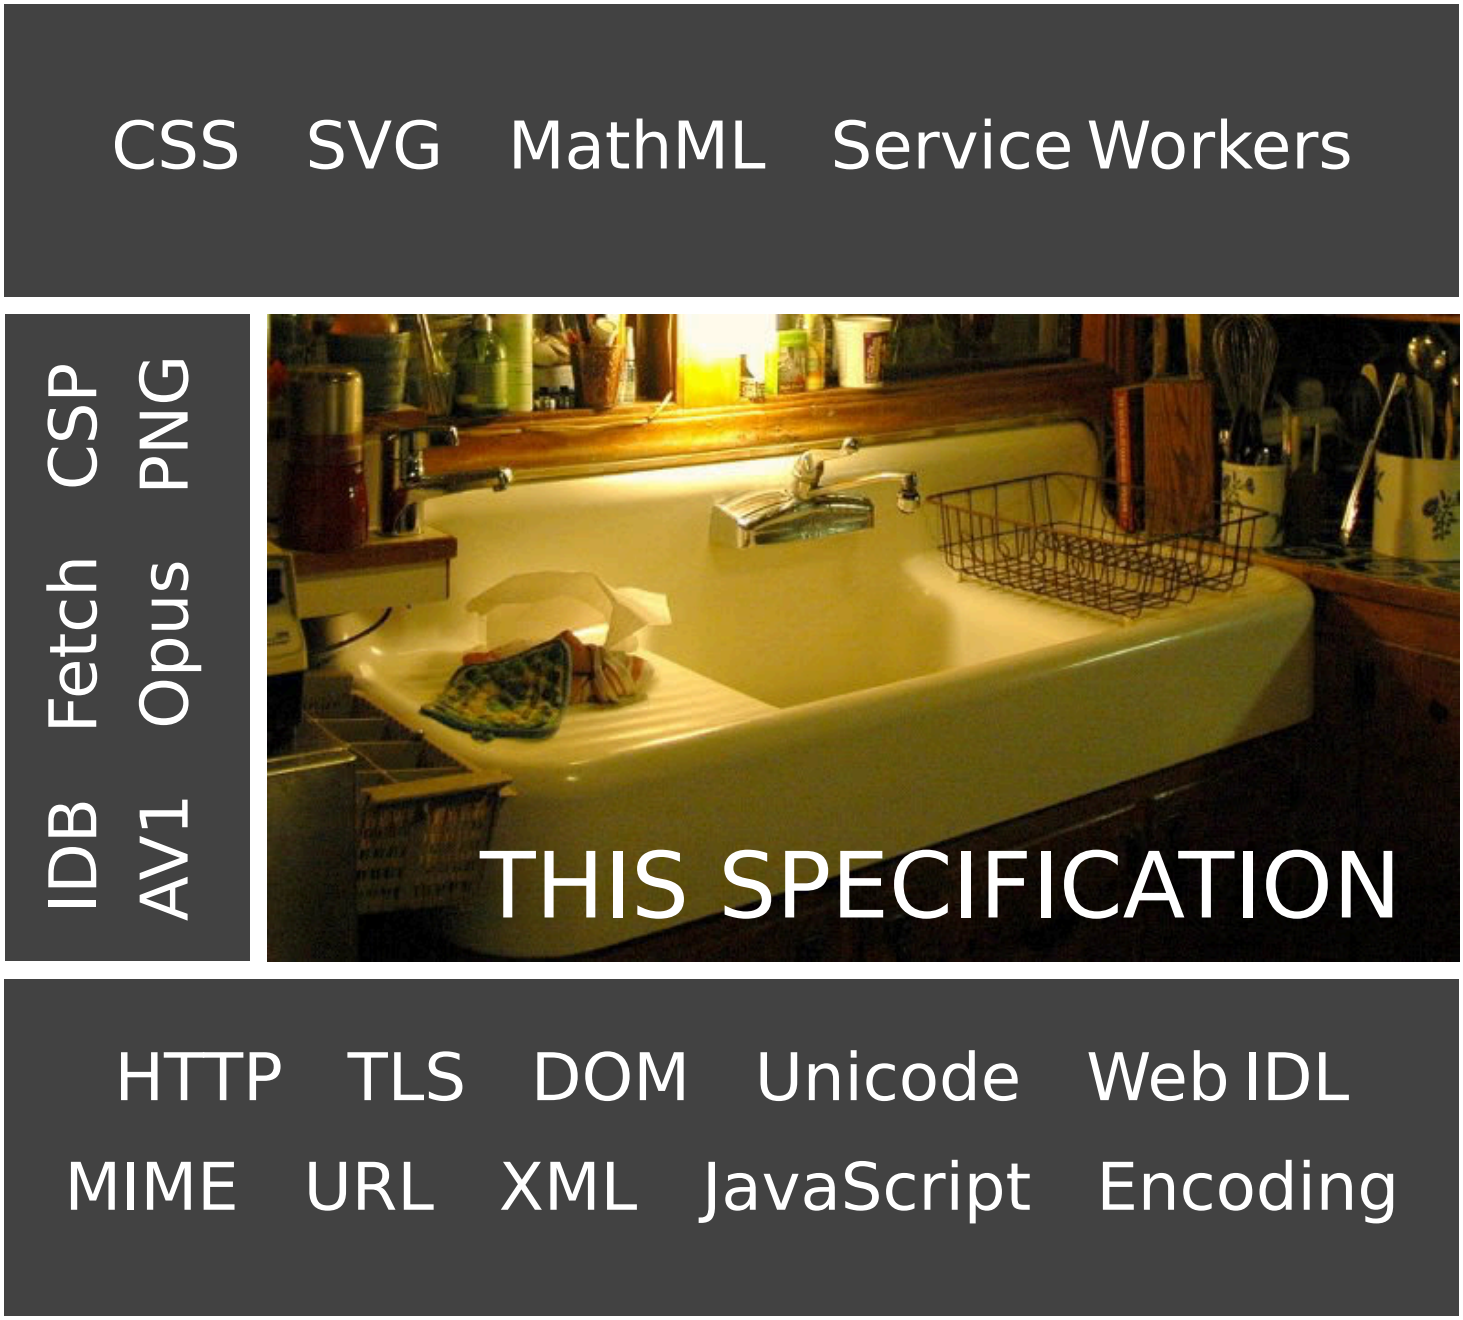
1 Introduction §[p26]

1.1 Where does this specification fit? §[p26]

This specification defines a big part of the web platform, in lots of detail. Its place in the web platform specification stack relative to other specifications can be best summed up as follows:



1.2 Is this HTML5? §[p26]

This section is non-normative.

In short: Yes.

In more length: the term "HTML5" is widely used as a buzzword to refer to modern web technologies, many of which (though by no

means all) are developed at the WHATWG. This document is one such; others are available from the WHATWG Standards overview.

1.3 Background §p27

This section is non-normative.

HTML is the World Wide Web's core markup language. Originally, HTML was primarily designed as a language for semantically describing scientific documents. Its general design, however, has enabled it to be adapted, over the subsequent years, to describe a number of other types of documents and even applications.

1.4 Audience §p27

This section is non-normative.

This specification is intended for authors of documents and scripts that use the features defined in this specification, implementers of tools that operate on pages that use the features defined in this specification, and individuals wishing to establish the correctness of documents or implementations with respect to the requirements of this specification.

This document is probably not suited to readers who do not already have at least a passing familiarity with web technologies, as in places it sacrifices clarity for precision, and brevity for completeness. More approachable tutorials and authoring guides can provide a gentler introduction to the topic.

In particular, familiarity with the basics of DOM is necessary for a complete understanding of some of the more technical parts of this specification. An understanding of Web IDL, HTTP, XML, Unicode, character encodings, JavaScript, and CSS will also be helpful in places but is not essential.

1.5 Scope §p27

This section is non-normative.

This specification is limited to providing a semantic-level markup language and associated semantic-level scripting APIs for authoring accessible pages on the web ranging from static documents to dynamic applications.

The scope of this specification does not include providing mechanisms for media-specific customization of presentation (although default rendering rules for web browsers are included at the end of this specification, and several mechanisms for hooking into CSS are provided as part of the language).

The scope of this specification is not to describe an entire operating system. In particular, hardware configuration software, image manipulation tools, and applications that users would be expected to use with high-end workstations on a daily basis are out of scope. In terms of applications, this specification is targeted specifically at applications that would be expected to be used by users on an occasional basis, or regularly but from disparate locations, with low CPU requirements. Examples of such applications include online purchasing systems, searching systems, games (especially multiplayer online games), public telephone books or address books, communications software (email clients, instant messaging clients, discussion software), document editing software, etc.

1.6 History §p27

This section is non-normative.

For its first five years (1990-1995), HTML went through a number of revisions and experienced a number of extensions, primarily hosted first at CERN, and then at the IETF.

With the creation of the W3C, HTML's development changed venue again. A first abortive attempt at extending HTML in 1995 known as HTML 3.0 then made way to a more pragmatic approach known as HTML 3.2, which was completed in 1997. HTML4 quickly followed

later that same year.

The following year, the W3C membership decided to stop evolving HTML and instead begin work on an XML-based equivalent, called XHTML. This effort started with a reformulation of HTML4 in XML, known as XHTML 1.0, which added no new features except the new serialization, and which was completed in 2000. After XHTML 1.0, the W3C's focus turned to making it easier for other working groups to extend XHTML, under the banner of XHTML Modularization. In parallel with this, the W3C also worked on a new language that was not compatible with the earlier HTML and XHTML languages, calling it XHTML2.

Around the time that HTML's evolution was stopped in 1998, parts of the API for HTML developed by browser vendors were specified and published under the name DOM Level 1 (in 1998) and DOM Level 2 Core and DOM Level 2 HTML (starting in 2000 and culminating in 2003). These efforts then petered out, with some DOM Level 3 specifications published in 2004 but the working group being closed before all the Level 3 drafts were completed.

In 2003, the publication of XForms, a technology which was positioned as the next generation of web forms, sparked a renewed interest in evolving HTML itself, rather than finding replacements for it. This interest was borne from the realization that XML's deployment as a web technology was limited to entirely new technologies (like RSS and later Atom), rather than as a replacement for existing deployed technologies (like HTML).

A proof of concept to show that it was possible to extend HTML4's forms to provide many of the features that XForms 1.0 introduced, without requiring browsers to implement rendering engines that were incompatible with existing HTML web pages, was the first result of this renewed interest. At this early stage, while the draft was already publicly available, and input was already being solicited from all sources, the specification was only under Opera Software's copyright.

The idea that HTML's evolution should be reopened was tested at a W3C workshop in 2004, where some of the principles that underlie the HTML5 work (described below), as well as the aforementioned early draft proposal covering just forms-related features, were presented to the W3C jointly by Mozilla and Opera. The proposal was rejected on the grounds that the proposal conflicted with the previously chosen direction for the web's evolution; the W3C staff and membership voted to continue developing XML-based replacements instead.

Shortly thereafter, Apple, Mozilla, and Opera jointly announced their intent to continue working on the effort under the umbrella of a new venue called the WHATWG. A public mailing list was created, and the draft was moved to the WHATWG site. The copyright was subsequently amended to be jointly owned by all three vendors, and to allow reuse of the specification.

The WHATWG was based on several core principles, in particular that technologies need to be backwards compatible, that specifications and implementations need to match even if this means changing the specification rather than the implementations, and that specifications need to be detailed enough that implementations can achieve complete interoperability without reverse-engineering each other.

The latter requirement in particular required that the scope of the HTML5 specification include what had previously been specified in three separate documents: HTML4, XHTML1, and DOM2 HTML. It also meant including significantly more detail than had previously been considered the norm.

In 2006, the W3C indicated an interest to participate in the development of HTML5 after all, and in 2007 formed a working group chartered to work with the WHATWG on the development of the HTML5 specification. Apple, Mozilla, and Opera allowed the W3C to publish the specification under the W3C copyright, while keeping a version with the less restrictive license on the WHATWG site.

For a number of years, both groups then worked together. In 2011, however, the groups came to the conclusion that they had different goals: the W3C wanted to publish a "finished" version of "HTML5", while the WHATWG wanted to continue working on a Living Standard for HTML, continuously maintaining the specification rather than freezing it in a state with known problems, and adding new features as needed to evolve the platform.

In 2019, the WHATWG and W3C signed an agreement to collaborate on a single version of HTML going forward: this document.

1.7 Design notes §p28

This section is non-normative.

It must be admitted that many aspects of HTML appear at first glance to be nonsensical and inconsistent.

HTML, its supporting DOM APIs, as well as many of its supporting technologies, have been developed over a period of several decades by a wide array of people with different priorities who, in many cases, did not know of each other's existence.

Features have thus arisen from many sources, and have not always been designed in especially consistent ways. Furthermore, because of the unique characteristics of the web, implementation bugs have often become de-facto, and now de-jure, standards, as content is often unintentionally written in ways that rely on them before they can be fixed.

Despite all this, efforts have been made to adhere to certain design goals. These are described in the next few subsections.

1.7.1 Serializability of script execution §p29

This section is non-normative.

To avoid exposing web authors to the complexities of multithreading, the HTML and DOM APIs are designed such that no script can ever detect the simultaneous execution of other scripts. Even with workers[p1254], the intent is that the behavior of implementations can be thought of as completely serializing the execution of all scripts in all globals.

The exception to this general design principle is the JavaScript `SharedArrayBuffer` class. Using `SharedArrayBuffer` objects, it can in fact be observed that scripts in other agents are executing simultaneously. Furthermore, due to the JavaScript memory model, there are situations which not only are un-representable via serialized *script* execution, but also un-representable via serialized *statement* execution among those scripts.

1.7.2 Extensibility §p29

This section is non-normative.

HTML has a wide array of extensibility mechanisms that can be used for adding semantics in a safe manner:

- Authors can use the `class`[p156] attribute to extend elements, effectively creating their own elements, while using the most applicable existing "real" HTML element, so that browsers and other tools that don't know of the extension can still support it somewhat well. This is the tack used by microformats, for example.
- Authors can include data for inline client-side scripts or server-side site-wide scripts to process using the `data-*=""`[p165] attributes. These are guaranteed to never be touched by browsers, and allow scripts to include data on HTML elements that scripts can then look for and process.
- Authors can use the `<meta name="" content="">`[p190] mechanism to include page-wide metadata.
- Authors can use the `rel=""`[p304] mechanism to annotate links with specific meanings by registering extensions to the predefined set of link types[p336]. This is also used by microformats.
- Authors can embed raw data using the `<script type="">`[p660] mechanism with a custom type, for further handling by inline or server-side scripts.
- Authors can extend APIs using the JavaScript prototyping mechanism. This is widely used by script libraries, for instance.
- Authors can use the microdata feature (the `itemscope=""`[p801] and `itemprop=""`[p803] attributes) to embed nested name-value pairs of data to be shared with other applications and sites.
- Authors can define, share, and use custom elements[p766] to extend the vocabulary of HTML. The requirements of valid custom element names[p767] ensure forward compatibility (since no elements will be added to HTML, SVG, or MathML with hyphen-containing local names in the future).

1.8 HTML vs XML syntax §p29

This section is non-normative.

This specification defines an abstract language for describing documents and applications, and some APIs for interacting with in-memory representations of resources that use this language.

The in-memory representation is known as "DOM HTML", or "the DOM" for short.

There are various concrete syntaxes that can be used to transmit resources that use this abstract language, two of which are defined in this specification.

The first such concrete syntax is the HTML syntax. This is the format suggested for most authors. It is compatible with most legacy web browsers. If a document is transmitted with the `text/html` [p1462] MIME type, then it will be processed as an HTML document by web browsers. This specification defines the latest HTML syntax, known simply as "HTML".

The second concrete syntax is XML. When a document is transmitted with an XML MIME type, such as `application/xhtml+xml` [p1464], then it is treated as an XML document by web browsers, to be parsed by an XML processor. Authors are reminded that the processing for XML and HTML differs; in particular, even minor syntax errors will prevent a document labeled as XML from being rendered fully, whereas they would be ignored in the HTML syntax.

Note

The XML syntax for HTML was formerly referred to as "XHTML", but this specification does not use that term (among other reasons, because no such term is used for the HTML syntaxes of MathML and SVG).

The DOM, the HTML syntax, and the XML syntax cannot all represent the same content. For example, namespaces cannot be represented using the HTML syntax, but they are supported in the DOM and in the XML syntax. Similarly, documents that use the `noscript` [p677] feature can be represented using the HTML syntax, but cannot be represented with the DOM or in the XML syntax. Comments that contain the string "`-->`" can only be represented in the DOM, not in the HTML and XML syntaxes.

1.9 Structure of this specification §[p30]

This section is non-normative.

This specification is divided into the following major sections:

Introduction [p26]

Non-normative materials providing a context for the HTML standard.

Common infrastructure [p44]

The conformance classes, algorithms, definitions, and the common underpinnings of the rest of the specification.

Semantics, structure, and APIs of HTML documents [p131]

Documents are built from elements. These elements form a tree using the DOM. This section defines the features of this DOM, as well as introducing the features common to all elements, and the concepts used in defining elements.

The elements of HTML [p173]

Each element has a predefined meaning, which is explained in this section. Rules for authors on how to use the element, along with user agent requirements for how to handle each element, are also given. This includes large signature features of HTML such as video playback and subtitles, form controls and form submission, and a 2D graphics API known as the HTML canvas.

Microdata [p796]

This specification introduces a mechanism for adding machine-readable annotations to documents, so that tools can extract trees of name-value pairs from the document. This section describes this mechanism and some algorithms that can be used to convert HTML documents into other formats. This section also defines some sample Microdata vocabularies for contact information, calendar events, and licensing works.

User interaction [p832]

HTML documents can provide a number of mechanisms for users to interact with and modify content, which are described in this section, such as how focus works, and drag-and-drop.

Loading web pages [p909]

HTML documents do not exist in a vacuum — this section defines many of the features that affect environments that deal with multiple pages, such as web browsers.

Web application APIs [p1087]

This section introduces basic features for scripting of applications in HTML.

Web workers [p1230]

This section defines an API for background threads in JavaScript.

Worklets p1260

This section defines infrastructure for APIs that need to run JavaScript separately from the main JavaScript execution environment.

The communication APIs p1207

This section describes some mechanisms that applications written in HTML can use to communicate with other applications from different domains running on the same client. It also introduces a server-push event stream mechanism known as Server Sent Events or `EventSource` p1209, and a two-way full-duplex socket protocol for scripts known as Web Sockets.

Web storage p1269

This section defines a client-side storage mechanism based on name-value pairs.

The HTML syntax p1277

The XML syntax p1402

All of these features would be for naught if they couldn't be represented in a serialized form and sent to other people, and so these sections define the syntaxes of HTML and XML, along with rules for how to parse content using those syntaxes.

Rendering p1406

This section defines the default rendering rules for web browsers.

There are also some appendices, listing obsolete features p1443 and IANA considerations p1462, and several indices.

1.9.1 How to read this specification §p31

This specification should be read like all other specifications. First, it should be read cover-to-cover, multiple times. Then, it should be read backwards at least once. Then it should be read by picking random sections from the contents list and following all the cross-references.

As described in the conformance requirements section below, this specification describes conformance criteria for a variety of conformance classes. In particular, there are conformance requirements that apply to *producers*, for example authors and the documents they create, and there are conformance requirements that apply to *consumers*, for example web browsers. They can be distinguished by what they are requiring: a requirement on a producer states what is allowed, while a requirement on a consumer states how software is to act.

Example

For example, "the `foo` attribute's value must be a valid integer p78" is a requirement on producers, as it lays out the allowed values; in contrast, the requirement "the `foo` attribute's value must be parsed using the rules for parsing integers p78" is a requirement on consumers, as it describes how to process the content.

Requirements on producers have no bearing whatsoever on consumers.

Example

Continuing the above example, a requirement stating that a particular attribute's value is constrained to being a valid integer p78 emphatically does *not* imply anything about the requirements on consumers. It might be that the consumers are in fact required to treat the attribute as an opaque string, completely unaffected by whether the value conforms to the requirements or not. It might be (as in the previous example) that the consumers are required to parse the value using specific rules that define how invalid (non-numeric in this case) values are to be processed.

1.9.2 Typographic conventions §p31

This is a definition, requirement, or explanation.

Note

This is a note.

Example

This is an example.

This is an open issue.

⚠Warning!

This is a warning.

IDL

```
[Exposed=Window]
interface Example {
  // this is an IDL definition
};
```

For web developers (non-normative)

***variable* = *object*.*method*[p32](*[optionalArgument]*)**

This is a note to authors describing the usage of an interface.

CSS

```
/* this is a CSS fragment */
```

The defining instance of a term is marked up like **this**. Uses of that term are marked up like this[p32] or like *this*[p32].

The defining instance of an element, attribute, or API is marked up like **`this`**. References to that element, attribute, or API are marked up like `this`[p32].

Other code fragments are marked up `like this`.

Variables are marked up like *this*.

In an algorithm, steps in synchronous sections[p1146] are marked with ⌛.

In some cases, requirements are given in the form of lists with conditions and corresponding requirements. In such cases, the requirements that apply to a condition are always the first set of requirements that follow the condition, even in the case of there being multiple sets of conditions for those requirements. Such cases are presented as follows:

↪ **This is a condition**

↪ **This is another condition**

This is the requirement that applies to the conditions above.

↪ **This is a third condition**

This is the requirement that applies to the third condition.

1.10 A quick introduction to HTML §[p32]

This section is non-normative.

A basic HTML document looks like this:

```
<!DOCTYPE html>
<html lang="en">
 <head>
  <title>Sample page</title>
 </head>
 <body>
  <h1>Sample page</h1>
  <p>This is a <a href="demo.html">simple</a> sample.</p>
  <!-- this is a comment -->
 </body>
</html>
```

HTML documents consist of a tree of elements and text. Each element is denoted in the source by a start tag[p1279], such as "<body>", and an end tag[p1280], such as "</body>". (Certain start tags and end tags can in certain cases be omitted[p1281] and are implied by other tags.)

Tags have to be nested such that elements are all completely within each other, without overlapping:

```
<p>This is <em>very <strong>wrong</em>!</strong></p>
```

```
<p>This <em>is <strong>correct</strong>.</em></p>
```

This specification defines a set of elements that can be used in HTML, along with rules about the ways in which the elements can be nested.

Elements can have attributes, which control how the elements work. In the example below, there is a hyperlink[p303], formed using the a[p258] element and its href[p304] attribute:

```
<a href="demo.html">simple</a>
```

Attributes[p1280] are placed inside the start tag, and consist of a name[p1280] and a value[p1280], separated by an "=" character. The attribute value can remain unquoted[p1280] if it doesn't contain ASCII whitespace or any of " ' ` = < or >. Otherwise, it has to be quoted using either single or double quotes. The value, along with the "=" character, can be omitted altogether if the value is the empty string.

```
<!-- empty attributes -->
<input name=address disabled>
<input name=address disabled="">

<!-- attributes with a value -->
<input name=address maxlength=200>
<input name=address maxlength='200'>
<input name=address maxlength="200">
```

HTML user agents (e.g., web browsers) then *parse* this markup, turning it into a DOM (Document Object Model) tree. A DOM tree is an in-memory representation of a document.

DOM trees contain several kinds of nodes, in particular a DocumentType node, Element nodes, Text nodes, Comment nodes, and in some cases ProcessingInstruction nodes.

The markup snippet at the top of this section[p32] would be turned into the following DOM tree:

- DOCTYPE: html
- **html**[p173] **lang**[p159]="en"
  - **head**[p174]
    - #text: ↵␣␣
    - **title**[p175]
      - #text: *Sample page*
    - #text: ↵␣
  - #text: ↵␣
  - **body**[p206]
    - #text: ↵␣␣
    - **h1**[p217]
      - #text: *Sample page*
    - #text: ↵␣␣
    - **p**[p230]
      - #text: *This is a*
      - **a**[p258] **href**[p304]="demo.html"
        - #text: *simple*
      - #text: *sample.*
    - #text: ↵␣␣
    - #comment: *this is a comment*
    - #text: ↵␣↵

The document element of this tree is the html[p173] element, which is the element always found in that position in HTML documents. It

contains two elements, head[p174] and body[p206], as well as a Text node between them.

There are many more Text nodes in the DOM tree than one would initially expect, because the source contains a number of spaces (represented here by "␣") and line breaks ("⏎") that all end up as Text nodes in the DOM. However, for historical reasons not all of the spaces and line breaks in the original markup appear in the DOM. In particular, all the whitespace before head[p174] start tag ends up being dropped silently, and all the whitespace after the body[p206] end tag ends up placed at the end of the body[p206].

The head[p174] element contains a title[p175] element, which itself contains a Text node with the text "Sample page". Similarly, the body[p206] element contains an h1[p217] element, a p[p230] element, and a comment.

This DOM tree can be manipulated from scripts in the page. Scripts (typically in JavaScript) are small programs that can be embedded using the script[p660] element or using event handler content attributes[p1152]. For example, here is a form with a script that sets the value of the form's output[p588] element to say "Hello World":

```
<form name="main">
 Result: <output name="result"></output>
 <script>
  document.forms.main.elements.result.value = 'Hello World';
 </script>
</form>
```

Each element in the DOM tree is represented by an object, and these objects have APIs so that they can be manipulated. For instance, a link (e.g. the a[p258] element in the tree above) can have its "href[p304]" attribute changed in several ways:

```
var a = document.links[0]; // obtain the first link in the document
a.href = 'sample.html'; // change the destination URL of the link
a.protocol = 'https'; // change just the scheme part of the URL
a.setAttribute('href', 'https://example.com/'); // change the content attribute directly
```

Since DOM trees are used as the way to represent HTML documents when they are processed and presented by implementations (especially interactive implementations like web browsers), this specification is mostly phrased in terms of DOM trees, instead of the markup described above.

HTML documents represent a media-independent description of interactive content. HTML documents might be rendered to a screen, or through a speech synthesizer, or on a braille display. To influence exactly how such rendering takes place, authors can use a styling language such as CSS.

In the following example, the page has been made yellow-on-blue using CSS.

```
<!DOCTYPE html>
<html lang="en">
 <head>
  <title>Sample styled page</title>
  <style>
   body { background: navy; color: yellow; }
  </style>
 </head>
 <body>
  <h1>Sample styled page</h1>
  <p>This page is just a demo.</p>
 </body>
</html>
```

For more details on how to use HTML, authors are encouraged to consult tutorials and guides. Some of the examples included in this specification might also be of use, but the novice author is cautioned that this specification, by necessity, defines the language with a level of detail that might be difficult to understand at first.

1.10.1 Writing secure applications with HTML §[p35]

This section is non-normative.

When HTML is used to create interactive sites, care needs to be taken to avoid introducing vulnerabilities through which attackers can compromise the integrity of the site itself or of the site's users.

A comprehensive study of this matter is beyond the scope of this document, and authors are strongly encouraged to study the matter in more detail. However, this section attempts to provide a quick introduction to some common pitfalls in HTML application development.

The security model of the web is based on the concept of "origins", and correspondingly many of the potential attacks on the web involve cross-origin actions. [ORIGIN][p1498]

Not validating user input

Cross-site scripting (XSS)

SQL injection

When accepting untrusted input, e.g. user-generated content such as text comments, values in URL parameters, messages from third-party sites, etc, it is imperative that the data be validated before use, and properly escaped when displayed. Failing to do this can allow a hostile user to perform a variety of attacks, ranging from the potentially benign, such as providing bogus user information like a negative age, to the serious, such as running scripts every time a user looks at a page that includes the information, potentially propagating the attack in the process, to the catastrophic, such as deleting all data in the server.

When writing filters to validate user input, it is imperative that filters always be safelist-based, allowing known-safe constructs and disallowing all other input. Blocklist-based filters that disallow known-bad inputs and allow everything else are not secure, as not everything that is bad is yet known (for example, because it might be invented in the future).

Example

For example, suppose a page looked at its URL's query string to determine what to display, and the site then redirected the user to that page to display a message, as in:

```
<ul>
 <li><a href="message.cgi?say=Hello">Say Hello</a>
 <li><a href="message.cgi?say=Welcome">Say Welcome</a>
 <li><a href="message.cgi?say=Kittens">Say Kittens</a>
</ul>
```

If the message was just displayed to the user without escaping, a hostile attacker could then craft a URL that contained a script element:

```
https://example.com/message.cgi?say=%3Cscript%3Ealert%28%27Oh%20no%21%27%29%3C/script%3E
```

If the attacker then convinced a victim user to visit this page, a script of the attacker's choosing would run on the page. Such a script could do any number of hostile actions, limited only by what the site offers: if the site is an e-commerce shop, for instance, such a script could cause the user to unknowingly make arbitrarily many unwanted purchases.

This is called a cross-site scripting attack.

There are many constructs that can be used to try to trick a site into executing code. Here are some that authors are encouraged to consider when writing safelist filters:

- When allowing harmless-seeming elements like `img`[p347], it is important to safelist any provided attributes as well. If one allowed all attributes then an attacker could, for instance, use the `onload`[p1160] attribute to run arbitrary script.
- When allowing URLs to be provided (e.g. for links), the scheme of each URL also needs to be explicitly safelisted, as there are many schemes that can be abused. The most prominent example is "`javascript:`[p1033]", but user agents can implement (and indeed, have historically implemented) others.
- Allowing a `base`[p176] element to be inserted means any `script`[p660] elements in the page with relative links can be hijacked, and similarly that any form submissions can get redirected to a hostile site.

Cross-site request forgery (CSRF)

If a site allows a user to make form submissions with user-specific side-effects, for example posting messages on a forum under the user's name, making purchases, or applying for a passport, it is important to verify that the request was made by the user

intentionally, rather than by another site tricking the user into making the request unknowingly.

This problem exists because HTML forms can be submitted to other origins.

Sites can prevent such attacks by populating forms with user-specific hidden tokens, or by checking `Origin` headers on all requests.

Clickjacking

A page that provides users with an interface to perform actions that the user might not wish to perform needs to be designed so as to avoid the possibility that users can be tricked into activating the interface.

One way that a user could be so tricked is if a hostile site places the victim site in a small iframe[p391] and then convinces the user to click, for instance by having the user play a reaction game. Once the user is playing the game, the hostile site can quickly position the iframe under the mouse cursor just as the user is about to click, thus tricking the user into clicking the victim site's interface.

To avoid this, sites that do not expect to be used in frames are encouraged to only enable their interface if they detect that they are not in a frame (e.g. by comparing the window[p935] object to the value of the top[p942] attribute).

1.10.2 Common pitfalls to avoid when using the scripting APIs §[p36]

This section is non-normative.

Scripts in HTML have "run-to-completion" semantics, meaning that the browser will generally run the script uninterrupted before doing anything else, such as firing further events or continuing to parse the document.

On the other hand, parsing of HTML files happens incrementally, meaning that the parser can pause at any point to let scripts run. This is generally a good thing, but it does mean that authors need to be careful to avoid hooking event handlers after the events could have possibly fired.

There are two techniques for doing this reliably: use event handler content attributes[p1152], or create the element and add the event handlers in the same script. The latter is safe because, as mentioned earlier, scripts are run to completion before further events can fire.

Example

One way this could manifest itself is with img[p347] elements and the load[p1490] event. The event could fire as soon as the element has been parsed, especially if the image has already been cached (which is common).

Here, the author uses the onload[p1160] handler on an img[p347] element to catch the load[p1490] event:

```
<img src="games.png" alt="Games" onload="gamesLogoHasLoaded(event)">
```

If the element is being added by script, then so long as the event handlers are added in the same script, the event will still not be missed:

```
<script>
 var img = new Image();
 img.src = 'games.png';
 img.alt = 'Games';
 img.onload = gamesLogoHasLoaded;
 // img.addEventListener('load', gamesLogoHasLoaded, false); // would work also
</script>
```

However, if the author first created the img[p347] element and then in a separate script added the event listeners, there's a chance that the load[p1490] event would be fired in between, leading it to be missed:

```
<!-- Do not use this style, it has a race condition! -->
 <img id="games" src="games.png" alt="Games">
 <!-- the 'load' event might fire here while the parser is taking a
      break, in which case you will not see it! -->
```

```
<script>
 var img = document.getElementById('games');
 img.onload = gamesLogoHasLoaded; // might never fire!
</script>
```

1.10.3 How to catch mistakes when writing HTML: validators and conformance checkers §p37

This section is non-normative.

Authors are encouraged to make use of conformance checkers (also known as *validators*) to catch common mistakes. The WHATWG maintains a list of such tools at: https://whatwg.org/validator/

1.11 Conformance requirements for authors §p37

This section is non-normative.

Unlike previous versions of the HTML specification, this specification defines in some detail the required processing for invalid documents as well as valid documents.

However, even though the processing of invalid content is in most cases well-defined, conformance requirements for documents are still important: in practice, interoperability (the situation in which all implementations process particular content in a reliable and identical or equivalent way) is not the only goal of document conformance requirements. This section details some of the more common reasons for still distinguishing between a conforming document and one with errors.

1.11.1 Presentational markup §p37

This section is non-normative.

The majority of presentational features from previous versions of HTML are no longer allowed. Presentational markup in general has been found to have a number of problems:

The use of presentational elements leads to poorer accessibility

While it is possible to use presentational markup in a way that provides users of assistive technologies (ATs) with an acceptable experience (e.g. using ARIA), doing so is significantly more difficult than doing so when using semantically-appropriate markup. Furthermore, even using such techniques doesn't help make pages accessible for non-AT non-graphical users, such as users of text-mode browsers.

Using media-independent markup, on the other hand, provides an easy way for documents to be authored in such a way that they work for more users (e.g. users of text browsers).

Higher cost of maintenance

It is significantly easier to maintain a site written in such a way that the markup is style-independent. For example, changing the color of a site that uses `<font color="">` throughout requires changes across the entire site, whereas a similar change to a site based on CSS can be done by changing a single file.

Larger document sizes

Presentational markup tends to be much more redundant, and thus results in larger document sizes.

For those reasons, presentational markup has been removed from HTML in this version. This change should not come as a surprise; HTML4 deprecated presentational markup many years ago and provided a mode (HTML4 Transitional) to help authors move away from presentational markup; later, XHTML 1.1 went further and obsoleted those features altogether.

The only remaining presentational markup features in HTML are the `style`p164 attribute and the `style`p201 element. Use of the `style`p164 attribute is somewhat discouraged in production environments, but it can be useful for rapid prototyping (where its rules can be

directly moved into a separate style sheet later) and for providing specific styles in unusual cases where a separate style sheet would be inconvenient. Similarly, the style[p201] element can be useful in syndication or for page-specific styles, but in general an external style sheet is likely to be more convenient when the styles apply to multiple pages.

It is also worth noting that some elements that were previously presentational have been redefined in this specification to be media-independent: b[p293], i[p292], hr[p232], s[p265], small[p263], and u[p295].

1.11.2 Syntax errors §[p38]

This section is non-normative.

The syntax of HTML is constrained to avoid a wide variety of problems.

Unintuitive error-handling behavior

Certain invalid syntax constructs, when parsed, result in DOM trees that are highly unintuitive.

Example

For example, the following markup fragment results in a DOM with an hr[p232] element that is an *earlier* sibling of the corresponding table[p479] element:

```
<table><hr>...
```

Errors with optional error recovery

To allow user agents to be used in controlled environments without having to implement the more bizarre and convoluted error handling rules, user agents are permitted to fail whenever encountering a parse error[p1291].

Errors where the error-handling behavior is not compatible with streaming user agents

Some error-handling behavior, such as the behavior for the `<table><hr>...` example mentioned above, are incompatible with streaming user agents (user agents that process HTML files in one pass, without storing state). To avoid interoperability problems with such user agents, any syntax resulting in such behavior is considered invalid.

Errors that can result in infoset coercion

When a user agent based on XML is connected to an HTML parser, it is possible that certain invariants that XML enforces, such as element or attribute names never contain multiple colons, will be violated by an HTML file. Handling this can require that the parser coerce the HTML DOM into an XML-compatible infoset. Most syntax constructs that require such handling are considered invalid. (Comments containing two consecutive hyphens, or ending with a hyphen, are exceptions that are allowed in the HTML syntax.)

Errors that result in disproportionately poor performance

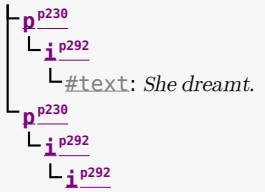
Certain syntax constructs can result in disproportionately poor performance. To discourage the use of such constructs, they are typically made non-conforming.

Example

For example, the following markup results in poor performance, since all the unclosed i[p292] elements have to be reconstructed in each paragraph, resulting in progressively more elements in each paragraph:

```
<p><i>She dreamt.
<p><i>She dreamt that she ate breakfast.
<p><i>Then lunch.
<p><i>And finally dinner.
```

The resulting DOM for this fragment would be:



```
    └#text: She dreamt that she ate breakfast.
└p p230
  └i p292
    └i p292
      └i p292
        └#text: Then lunch.
└p p230
  └i p292
    └i p292
      └i p292
        └i p292
          └#text: And finally dinner.
```

Errors involving fragile syntax constructs

There are syntax constructs that, for historical reasons, are relatively fragile. To help reduce the number of users who accidentally run into such problems, they are made non-conforming.

Example

For example, the parsing of certain named character references in attributes happens even with the closing semicolon being omitted. It is safe to include an ampersand followed by letters that do not form a named character reference, but if the letters are changed to a string that *does* form a named character reference, they will be interpreted as that character instead.

In this fragment, the attribute's value is "?bill&ted":

```
<a href="?bill&ted">Bill and Ted</a>
```

In the following fragment, however, the attribute's value is actually "?art©", *not* the intended "?art&copy", because even without the final semicolon, "&copy" is handled the same as "©" and thus gets interpreted as "©":

```
<a href="?art&copy">Art and Copy</a>
```

To avoid this problem, all named character references are required to end with a semicolon, and uses of named character references without a semicolon are flagged as errors.

Thus, the correct way to express the above cases is as follows:

```
<a href="?bill&ted">Bill and Ted</a> <!-- &ted is ok, since it's not a named character reference
-->
```

```
<a href="?art&amp;copy">Art and Copy</a> <!-- the & has to be escaped, since &copy is a named
character reference -->
```

Errors involving known interoperability problems in legacy user agents

Certain syntax constructs are known to cause especially subtle or serious problems in legacy user agents, and are therefore marked as non-conforming to help authors avoid them.

Example

For example, this is why the U+0060 GRAVE ACCENT character (`) is not allowed in unquoted attributes. In certain legacy user agents, it is sometimes treated as a quote character.

Example

Another example of this is the DOCTYPE, which is required to trigger no-quirks mode, because the behavior of legacy user agents in quirks mode is often largely undocumented.

Errors that risk exposing authors to security attacks

Certain restrictions exist purely to avoid known security problems.

Example

For example, the restriction on using UTF-7 exists purely to avoid authors falling prey to a known cross-site-scripting attack using UTF-7. [UTF7]p1501

Cases where the author's intent is unclear

Markup where the author's intent is very unclear is often made non-conforming. Correcting these errors early makes later maintenance easier.

Example

For example, it is unclear whether the author intended the following to be an h1p217 heading or an h2p217 heading:

```
<h1>Contact details</h2>
```

Cases that are likely to be typos

When a user makes a simple typo, it is helpful if the error can be caught early, as this can save the author a lot of debugging time. This specification therefore usually considers it an error to use element names, attribute names, and so forth, that do not match the names defined in this specification.

Example

For example, if the author typed `<capton>` instead of `<caption>`, this would be flagged as an error and the author could correct the typo immediately.

Errors that could interfere with new syntax in the future

In order to allow the language syntax to be extended in the future, certain otherwise harmless features are disallowed.

Example

For example, "attributes" in end tags are ignored currently, but they are invalid, in case a future change to the language makes use of that syntax feature without conflicting with already-deployed (and valid!) content.

Some authors find it helpful to be in the practice of always quoting all attributes and always including all optional tags, preferring the consistency derived from such custom over the minor benefits of terseness afforded by making use of the flexibility of the HTML syntax. To aid such authors, conformance checkers can provide modes of operation wherein such conventions are enforced.

1.11.3 Restrictions on content models and on attribute values §p40

This section is non-normative.

Beyond the syntax of the language, this specification also places restrictions on how elements and attributes can be specified. These restrictions are present for similar reasons:

Errors involving content with dubious semantics

To avoid misuse of elements with defined meanings, content models are defined that restrict how elements can be nested when such nestings would be of dubious value.

Example

For example, this specification disallows nesting a `section`p210 element inside a `kbd`p290 element, since it is highly unlikely for an author to indicate that an entire section should be keyed in.

Errors that involve a conflict in expressed semantics

Similarly, to draw the author's attention to mistakes in the use of elements, clear contradictions in the semantics expressed are also considered conformance errors.

Example

In the fragments below, for example, the semantics are nonsensical: a separator cannot simultaneously be a cell, nor can a

radio button be a progress bar.

```
<hr role="cell">
```

```
<input type=radio role=progressbar>
```

Example

Another example is the restrictions on the content models of the ul element, which only allows li element children. Lists by definition consist just of zero or more list items, so if a ul element contains something other than an li element, it's not clear what was meant.

Cases where the default styles are likely to lead to confusion

Certain elements have default styles or behaviors that make certain combinations likely to lead to confusion. Where these have equivalent alternatives without this problem, the confusing combinations are disallowed.

Example

For example, div elements are rendered as block boxes, and span elements as inline boxes. Putting a block box in an inline box is unnecessarily confusing; since either nesting just div elements, or nesting just span elements, or nesting span elements inside div elements all serve the same purpose as nesting a div element in a span element, but only the latter involves a block box in an inline box, the latter combination is disallowed.

Example

Another example would be the way interactive content cannot be nested. For example, a button element cannot contain a textarea element. This is because the default behavior of such nesting interactive elements would be highly confusing to users. Instead of nesting these elements, they can be placed side by side.

Errors that indicate a likely misunderstanding of the specification

Sometimes, something is disallowed because allowing it would likely cause author confusion.

Example

For example, setting the disabled attribute to the value "`false`" is disallowed, because despite the appearance of meaning that the element is enabled, it in fact means that the element is *disabled* (what matters for implementations is the presence of the attribute, not its value).

Errors involving limits that have been imposed merely to simplify the language

Some conformance errors simplify the language that authors need to learn.

Example

For example, the area element's shape attribute, despite accepting both circ and circle values in practice as synonyms, disallows the use of the circ value, so as to simplify tutorials and other learning aids. There would be no benefit to allowing both, but it would cause extra confusion when teaching the language.

Errors that involve peculiarities of the parser

Certain elements are parsed in somewhat eccentric ways (typically for historical reasons), and their content model restrictions are intended to avoid exposing the author to these issues.

Example

For example, a form element isn't allowed inside phrasing content, because when parsed as HTML, a form element's start tag will imply a p element's end tag. Thus, the following markup results in two paragraphs, not one:

```
<p>Welcome. <form><label>Name:</label> <input></form>
```

It is parsed exactly like the following:

```
<p>Welcome. </p><form><label>Name:</label> <input></form>
```

Errors that would likely result in scripts failing in hard-to-debug ways

Some errors are intended to help prevent script problems that would be hard to debug.

Example

This is why, for instance, it is non-conforming to have two `id`[p156] attributes with the same value. Duplicate IDs lead to the wrong element being selected, with sometimes disastrous effects whose cause is hard to determine.

Errors that waste authoring time

Some constructs are disallowed because historically they have been the cause of a lot of wasted authoring time, and by encouraging authors to avoid making them, authors can save time in future efforts.

Example

For example, a `script`[p660] element's `src`[p661] attribute causes the element's contents to be ignored. However, this isn't obvious, especially if the element's contents appear to be executable script — which can lead to authors spending a lot of time trying to debug the inline script without realizing that it is not executing. To reduce this problem, this specification makes it non-conforming to have executable script in a `script`[p660] element when the `src`[p661] attribute is present. This means that authors who are validating their documents are less likely to waste time with this kind of mistake.

Errors that involve areas that affect authors migrating between the HTML and XML syntaxes

Some authors like to write files that can be interpreted as both XML and HTML with similar results. Though this practice is discouraged in general due to the myriad of subtle complications involved (especially when involving scripting, styling, or any kind of automated serialization), this specification has a few restrictions intended to at least somewhat mitigate the difficulties. This makes it easier for authors to use this as a transitionary step when migrating between the HTML and XML syntaxes.

Example

For example, there are somewhat complicated rules surrounding the `lang`[p159] and `xml:lang` attributes intended to keep the two synchronized.

Example

Another example would be the restrictions on the values of `xmlns` attributes in the HTML serialization, which are intended to ensure that elements in conforming documents end up in the same namespaces whether processed as HTML or XML.

Errors that involve areas reserved for future expansion

As with the restrictions on the syntax intended to allow for new syntax in future revisions of the language, some restrictions on the content models of elements and values of attributes are intended to allow for future expansion of the HTML vocabulary.

Example

For example, limiting the values of the `target`[p304] attribute that start with an U+005F LOW LINE character (_) to only specific predefined values allows new predefined values to be introduced at a future time without conflicting with author-defined values.

Errors that indicate a mis-use of other specifications

Certain restrictions are intended to support the restrictions made by other specifications.

Example

For example, requiring that attributes that take media query lists use only *valid* media query lists reinforces the importance of following the conformance rules of that specification.

1.12 Suggested reading §[p42]

This section is non-normative.

The following documents might be of interest to readers of this specification.

Character Model for the World Wide Web 1.0: Fundamentals **[CHARMOD]**[p1493]

This Architectural Specification provides authors of specifications, software developers, and content developers with a common

reference for interoperable text manipulation on the World Wide Web, building on the Universal Character Set, defined jointly by the Unicode Standard and ISO/IEC 10646. Topics addressed include use of the terms 'character', 'encoding' and 'string', a reference processing model, choice and identification of character encodings, character escaping, and string indexing.

Unicode Security Considerations **[UTR36]**[p1501]

Because Unicode contains such a large number of characters and incorporates the varied writing systems of the world, incorrect usage can expose programs or systems to possible security attacks. This is especially important as more and more products are internationalized. This document describes some of the security considerations that programmers, system analysts, standards developers, and users should take into account, and provides specific recommendations to reduce the risk of problems.

Web Content Accessibility Guidelines (WCAG) **[WCAG]**[p1501]

Web Content Accessibility Guidelines (WCAG) covers a wide range of recommendations for making web content more accessible. Following these guidelines will make content accessible to a wider range of people with disabilities, including blindness and low vision, deafness and hearing loss, learning disabilities, cognitive limitations, limited movement, speech disabilities, photosensitivity and combinations of these. Following these guidelines will also often make your web content more usable to users in general.

Authoring Tool Accessibility Guidelines (ATAG) 2.0 **[ATAG]**[p1493]

This specification provides guidelines for designing web content authoring tools that are more accessible for people with disabilities. An authoring tool that conforms to these guidelines will promote accessibility by providing an accessible user interface to authors with disabilities as well as by enabling, supporting, and promoting the production of accessible web content by all authors.

User Agent Accessibility Guidelines (UAAG) 2.0 **[UAAG]**[p1500]

This document provides guidelines for designing user agents that lower barriers to web accessibility for people with disabilities. User agents include browsers and other types of software that retrieve and render web content. A user agent that conforms to these guidelines will promote accessibility through its own user interface and through other internal facilities, including its ability to communicate with other technologies (especially assistive technologies). Furthermore, all users, not just users with disabilities, should find conforming user agents to be more usable.

2 Common infrastructure §p44

This specification depends on *Infra*. [INFRA]p1497

2.1 Terminology §p44

This specification refers to both HTML and XML attributes and IDL attributes, often in the same context. When it is not clear which is being referred to, they are referred to as **content attributes** for HTML and XML attributes, and **IDL attributes** for those defined on IDL interfaces. Similarly, the term "properties" is used for both JavaScript object properties and CSS properties. When these are ambiguous they are qualified as **object properties** and **CSS properties** respectively.

Generally, when the specification states that a feature applies to the HTML syntaxp1277 or the XML syntaxp1402, it also includes the other. When a feature specifically only applies to one of the two languages, it is called out by explicitly stating that it does not apply to the other format, as in "for HTML, ... (this does not apply to XML)".

This specification uses the term **document** to refer to any use of HTML, ranging from short static documents to long essays or reports with rich multimedia, as well as to fully-fledged interactive applications. The term is used to refer both to `Document`p131 objects and their descendant DOM trees, and to serialized byte streams using the HTML syntaxp1277 or the XML syntaxp1402, depending on context.

In the context of the DOM structures, the terms HTML document and XML document are used as defined in *DOM*, and refer specifically to two different modes that `Document`p131 objects can find themselves in. [DOM]p1496 (Such uses are always hyperlinked to their definition.)

In the context of byte streams, the term HTML document refers to resources labeled as `text/html`p1462, and the term XML document refers to resources labeled with an XML MIME type.

For simplicity, terms such as **shown**, **displayed**, and **visible** might sometimes be used when referring to the way a document is rendered to the user. These terms are not meant to imply a visual medium; they must be considered to apply to other media in equivalent ways.

2.1.1 Parallelism §p44

To run steps **in parallel** means those steps are to be run, one after another, at the same time as other logic in the standard (e.g., at the same time as the event loopp1138). This standard does not define the precise mechanism by which this is achieved, be it time-sharing cooperative multitasking, fibers, threads, processes, using different hyperthreads, cores, CPUs, machines, etc. By contrast, an operation that is to run **immediately** must interrupt the currently running task, run itself, and then resume the previously running task.

Note

For guidance on writing specifications that leverage parallelism, see Dealing with the event loop from other specificationsp1149.

To avoid race conditions between different in parallelp44 algorithms that operate on the same data, a parallel queuep44 can be used.

A **parallel queue** represents a queue of algorithm steps that must be run in series.

A parallel queuep44 has an **algorithm queue** (a queue), initially empty.

To **enqueue steps** to a parallel queuep44, enqueue the algorithm steps to the parallel queuep44's algorithm queuep44.

To **start a new parallel queue**, run the following steps:

1. Let *parallelQueue* be a new parallel queuep44.
2. Run the following steps in parallelp44:

1. While true:

    1. Let *steps* be the result of dequeuing from *parallelQueue*'s algorithm queue[p44].

    2. If *steps* is not nothing, then run *steps*.

    3. Assert: running *steps* did not throw an exception, as steps running in parallel[p44] are not allowed to throw.

    Note

    Implementations are not expected to implement this as a continuously running loop. Algorithms in standards are to be easy to understand and are not necessarily great for battery life or performance.

3. Return *parallelQueue*.

Note

Steps running in parallel[p44] can themselves run other steps in in parallel[p44]. E.g., inside a parallel queue[p44] it can be useful to run a series of steps in parallel with the queue.

Example

Imagine a standard defined *nameList* (a list), along with a method to add a *name* to *nameList*, unless *nameList* already contains *name*, in which case it rejects.

The following solution suffers from race conditions:

1. Let *p* be a new promise created in this's relevant realm[p1098].
2. Let *global* be this's relevant global object[p1098].
3. Run the following steps in parallel[p44]:

    1. If *nameList* contains *name*, then queue a global task[p1140] on the DOM manipulation task source[p1149] given *global* to reject *p* with a `TypeError`, and abort these steps.

    2. Do some potentially lengthy work.

    3. Append *name* to *nameList*.

    4. Queue a global task[p1140] on the DOM manipulation task source[p1149] given *global* to resolve *p* with undefined.

4. Return *p*.

Two invocations of the above could run simultaneously, meaning *name* isn't in *nameList* during step 3.1, but it *might be added* before step 3.3 runs, meaning *name* ends up in *nameList* twice.

Parallel queues solve this. The standard would let *nameListQueue* be the result of starting a new parallel queue[p44], then:

1. Let *p* be a new promise created in this's relevant realm[p1098].
2. Let *global* be this's relevant global object[p1098].
3. Enqueue the following steps[p44] to *nameListQueue*:

    1. If *nameList* contains *name*, then queue a global task[p1140] on the DOM manipulation task source[p1149] given *global* to reject *p* with a `TypeError`, and abort these steps.

    2. Do some potentially lengthy work.

    3. Append *name* to *nameList*.

    4. Queue a global task[p1140] on the DOM manipulation task source[p1149] given *global* to resolve *p* with undefined.

4. Return *p*.

The steps would now queue and the race is avoided.

2.1.2 Resources §p46

The specification uses the term **supported** when referring to whether a user agent has an implementation capable of decoding the semantics of an external resource. A format or type is said to be *supported* if the implementation can process an external resource of that format or type without critical aspects of the resource being ignored. Whether a specific resource is *supported* can depend on what features of the resource's format are in use.

Example

For example, a PNG image would be considered to be in a supported format if its pixel data could be decoded and rendered, even if, unbeknownst to the implementation, the image also contained animation data.

Example

An MPEG-4 video file would not be considered to be in a supported format if the compression format used was not supported, even if the implementation could determine the dimensions of the movie from the file's metadata.

What some specifications, in particular the HTTP specifications, refer to as a *representation* is referred to in this specification as a **resource**. [HTTP]p1496

A resource's **critical subresources** are those that the resource needs to have available to be correctly processed. Which resources are considered critical or not is defined by the specification that defines the resource's format.

For CSS style sheets, we tentatively define here that their critical subresources are other style sheets imported via `@import` rules, including those indirectly imported by other imported style sheets.

This definition is not fully interoperable; furthermore, some user agents seem to count resources like background images or web fonts as critical subresources. Ideally, the CSS Working Group would define this; see w3c/csswg-drafts issue #1088 to track progress on that front.

2.1.3 XML compatibility §p46

To ease migration from HTML to XML, user agents conforming to this specification will place elements in HTML in the `http://www.w3.org/1999/xhtml` namespace, at least for the purposes of the DOM and CSS. The term "**HTML elements**" refers to any element in that namespace, even in XML documents.

Except where otherwise stated, all elements defined or mentioned in this specification are in the HTML namespace ("`http://www.w3.org/1999/xhtml`"), and all attributes defined or mentioned in this specification have no namespace.

The term **element type** is used to refer to the set of elements that have a given local name and namespace. For example, `button`p567 elements are elements with the element type `button`p567, meaning they have the local name "`button`" and (implicitly as defined above) the HTML namespace.

Attribute names are said to be **XML-compatible** if they match the `Name` production defined in XML and they contain no U+003A COLON characters (:). [XML]p1502

2.1.4 DOM trees §p46

When it is stated that some element or attribute is **ignored**, or treated as some other value, or handled as if it was something else, this refers only to the processing of the node after it is in the DOM. A user agent must not mutate the DOM in such situations.

A content attribute is said to **change** value only if its new value is different than its previous value; setting an attribute to a value it already has does not change it.

The term **empty**, when used for an attribute value, `Text` node, or string, means that the length of the text is zero (i.e., not even containing controls or U+0020 SPACE).

An HTML element can have specific **HTML element insertion steps**, **HTML element post-connection steps**, **HTML element removing steps**, and **HTML element moving steps** all defined for the element's local name.

The insertion steps for the HTML Standard, given *insertedNode*, are defined as the following:

1. If *insertedNode* is an element whose namespace is the HTML namespace, and this standard defines HTML element insertion steps[p46] for *insertedNode*'s local name, then run the corresponding HTML element insertion steps[p46] given *insertedNode*.

2. If *insertedNode* is a form-associated element[p514] or the ancestor of a form-associated element[p514], then:

    1. If the form-associated element[p514]'s parser inserted flag[p601] is set, then return.

    2. Reset the form owner[p602] of the form-associated element[p514].

3. If *insertedNode* is an `Element` that is not on the stack of open elements[p1304] of an HTML parser[p1289], then process internal resource links[p320] given *insertedNode*'s node document.

The post-connection steps for the HTML Standard, given *insertedNode*, are defined as the following:

1. If *insertedNode* is an element whose namespace is the HTML namespace, and this standard defines HTML element post-connection steps[p46] for *insertedNode*'s local name, then run the corresponding HTML element post-connection steps[p46] given *insertedNode*.

The removing steps for the HTML Standard, given *removedNode* and *oldParent*, are defined as the following:

1. Let *document* be *removedNode*'s node document.

2. If *document*'s focused area[p845] is *removedNode*, then set *document*'s focused area[p845] to *document*'s viewport, and set *document*'s relevant global object[p1098]'s navigation API[p964]'s focus changed during ongoing navigation[p976] to false.

    Note

    This does not *perform the unfocusing steps[p851], focusing steps[p851], or focus update steps[p851], and thus no* `blur`[p1489] *or* `change`[p1489] *events are fired.*

3. If *removedNode* is an element whose namespace is the HTML namespace, and this standard defines HTML element removing steps[p46] for *removedNode*'s local name, then run the corresponding HTML element removing steps[p46] given *removedNode* and *oldParent*.

4. If *removedNode* is a form-associated element[p514] with a non-null form owner[p601] and *removedNode* and its form owner[p601] are no longer in the same tree, then reset the form owner[p602] of *removedNode*.

5. If *removedNode*'s `popover`[p895] attribute is not in the No Popover[p896] state, then run the hide popover algorithm[p900] given *removedNode*, false, false, false, and null.

The moving steps for the HTML Standard, given *movedNode*, are defined as the following:

1. If *movedNode* is an element whose namespace is the HTML namespace, and this standard defines HTML element moving steps[p46] for *movedNode*'s local name, then run the corresponding HTML element moving steps[p46] given *movedNode*.

2. If *movedNode* is a form-associated element[p514] with a non-null form owner[p601] and *movedNode* and its form owner[p601] are no longer in the same tree, then reset the form owner[p602] of *movedNode*.

A **node is inserted into a document** when the insertion steps are invoked with it as the argument and it is now in a document tree. Analogously, a **node is removed from a document** when the removing steps are invoked with it as the argument and it is now no longer in a document tree.

A node **becomes connected** when the insertion steps are invoked with it as the argument and it is now connected. Analogously, a node **becomes disconnected** when the removing steps are invoked with it as the argument and it is now no longer connected.

A node is **browsing-context connected** when it is connected and its shadow-including root's browsing context[p1012] is non-null. A node **becomes browsing-context connected** when the insertion steps are invoked with it as the argument and it is now browsing-context connected[p47]. A node **becomes browsing-context disconnected** either when the removing steps are invoked with it as the argument and it is now no longer browsing-context connected[p47], or when its shadow-including root's browsing context[p1012] becomes null.

2.1.5 Scripting §p48

The construction "a Foo object", where Foo is actually an interface, is sometimes used instead of the more accurate "an object implementing the interface Foo".

An IDL attribute is said to be **getting** when its value is being retrieved (e.g. by author script), and is said to be **setting** when a new value is assigned to it.

If a DOM object is said to be **live**, then the attributes and methods on that object must operate on the actual underlying data, not a snapshot of the data.

2.1.6 Plugins §p48

The term **plugin** refers to an implementation-defined set of content handlers used by the user agent that can take part in the user agent's rendering of a Document p131 object, but that neither act as child navigables p1004 of the Document p131 nor introduce any Node objects to the Document p131's DOM.

Typically such content handlers are provided by third parties, though a user agent can also designate built-in content handlers as plugins.

A user agent must not consider the types text/plain and application/octet-stream as having a registered plugin p48.

Example

One example of a plugin would be a PDF viewer that is instantiated in a navigable p1001 when the user navigates to a PDF file. This would count as a plugin regardless of whether the party that implemented the PDF viewer component was the same as that which implemented the user agent itself. However, a PDF viewer application that launches separate from the user agent (as opposed to using the same interface) is not a plugin by this definition.

Note

This specification does not define a mechanism for interacting with plugins, as it is expected to be user-agent- and platform-specific. Some UAs might opt to support a plugin mechanism such as the Netscape Plugin API; others might use remote content converters or have built-in support for certain types. Indeed, this specification doesn't require user agents to support plugins at all. [NPAPI] p1498

⚠Warning!

Browsers should take extreme care when interacting with external content intended for plugins p48. When third-party software is run with the same privileges as the user agent itself, vulnerabilities in the third-party software become as dangerous as those in the user agent.

Since different users having different sets of plugins p48 provides a tracking vector that increases the chances of users being uniquely identified, user agents are encouraged to support the exact same set of plugins p48 for each user.

2.1.7 Character encodings §p48

A **character encoding**, or just *encoding* where that is not ambiguous, is a defined way to convert between byte streams and Unicode strings, as defined in *Encoding*. An encoding has an **encoding name** and one or more **encoding labels**, referred to as the encoding's *name* and *labels* in the Encoding standard. [ENCODING] p1496

2.1.8 Conformance classes §p48

This specification describes the conformance criteria for user agents (relevant to implementers) and documents (relevant to authors and authoring tool implementers).

Conforming documents are those that comply with all the conformance criteria for documents. For readability, some of these conformance requirements are phrased as conformance requirements on authors; such requirements are implicitly requirements on

documents: by definition, all documents are assumed to have had an author. (In some cases, that author may itself be a user agent — such user agents are subject to additional rules, as explained below.)

Example

For example, if a requirement states that "authors must not use the `foobar` element", it would imply that documents are not allowed to contain elements named `foobar`.

Note

There is no implied relationship between document conformance requirements and implementation conformance requirements. User agents are not free to handle non-conformant documents as they please; the processing model described in this specification applies to implementations regardless of the conformity of the input documents.

User agents fall into several (overlapping) categories with different conformance requirements.

Web browsers and other interactive user agents

Web browsers that support the XML syntax[p1402] must process elements and attributes from the HTML namespace found in XML documents as described in this specification, so that users can interact with them, unless the semantics of those elements have been overridden by other specifications.

Example

A conforming web browser would, upon finding a `script`[p660] element in an XML document, execute the script contained in that element. However, if the element is found within a transformation expressed in XSLT (assuming the user agent also supports XSLT), then the processor would instead treat the `script`[p660] element as an opaque element that forms part of the transform.

Web browsers that support the HTML syntax[p1277] must process documents labeled with an HTML MIME type as described in this specification, so that users can interact with them.

User agents that support scripting must also be conforming implementations of the IDL fragments in this specification, as described in *Web IDL*. [WEBIDL][p1501]

Note

Unless explicitly stated, specifications that override the semantics of HTML elements do not override the requirements on DOM objects representing those elements. For example, the `script`[p660] element in the example above would still implement the `HTMLScriptElement`[p660] interface.

Non-interactive presentation user agents

User agents that process HTML and XML documents purely to render non-interactive versions of them must comply to the same conformance criteria as web browsers, except that they are exempt from requirements regarding user interaction.

Note

Typical examples of non-interactive presentation user agents are printers (static UAs) and overhead displays (dynamic UAs). It is expected that most static non-interactive presentation user agents will also opt to lack scripting support[p50].

Example

A non-interactive but dynamic presentation UA would still execute scripts, allowing forms to be dynamically submitted, and so forth. However, since the concept of "focus" is irrelevant when the user cannot interact with the document, the UA would not need to support any of the focus-related DOM APIs.

Visual user agents that support the suggested default rendering

User agents, whether interactive or not, may be designated (possibly as a user option) as supporting the suggested default rendering defined by this specification.

This is not required. In particular, even user agents that do implement the suggested default rendering are encouraged to offer settings that override this default to improve the experience for the user, e.g. changing the color contrast, using different focus styles, or otherwise making the experience more accessible and usable to the user.

User agents that are designated as supporting the suggested default rendering must, while so designated, implement the rules the Rendering section[p1406] defines as the behavior that user agents are *expected* to implement.

User agents with no scripting support

Implementations that do not support scripting (or which have their scripting features disabled entirely) are exempt from supporting the events and DOM interfaces mentioned in this specification. For the parts of this specification that are defined in terms of an events model or in terms of the DOM, such user agents must still act as if events and the DOM were supported.

Note

Scripting can form an integral part of an application. Web browsers that do not support scripting, or that have scripting disabled, might be unable to fully convey the author's intent.

Conformance checkers

Conformance checkers must verify that a document conforms to the applicable conformance criteria described in this specification. Automated conformance checkers are exempt from detecting errors that require interpretation of the author's intent (for example, while a document is non-conforming if the content of a `blockquote` element is not a quote, conformance checkers running without the input of human judgement do not have to check that `blockquote` elements only contain quoted material).

Conformance checkers must check that the input document conforms when parsed without a browsing context (meaning that no scripts are run, and that the parser's scripting flag is disabled), and should also check that the input document conforms when parsed with a browsing context in which scripts execute, and that the scripts never cause non-conforming states to occur other than transiently during script execution itself. (This is only a "SHOULD" and not a "MUST" requirement because it has been proven to be impossible. [COMPUTABLE])

The term "HTML validator" can be used to refer to a conformance checker that itself conforms to the applicable requirements of this specification.

Note

XML DTDs cannot express all the conformance requirements of this specification. Therefore, a validating XML processor and a DTD cannot constitute a conformance checker. Also, since neither of the two authoring formats defined in this specification are applications of SGML, a validating SGML system cannot constitute a conformance checker either.

To put it another way, there are three types of conformance criteria:

1. *Criteria that can be expressed in a DTD.*
2. *Criteria that cannot be expressed by a DTD, but can still be checked by a machine.*
3. *Criteria that can only be checked by a human.*

A conformance checker must check for the first two. A simple DTD-based validator only checks for the first class of errors and is therefore not a conforming conformance checker according to this specification.

Data mining tools

Applications and tools that process HTML and XML documents for reasons other than to either render the documents or check them for conformance should act in accordance with the semantics of the documents that they process.

Example

A tool that generates document outlines but increases the nesting level for each paragraph and does not increase the nesting level for headings would not be conforming.

Authoring tools and markup generators

Authoring tools and markup generators must generate conforming documents. Conformance criteria that apply to authors also apply to authoring tools, where appropriate.

Authoring tools are exempt from the strict requirements of using elements only for their specified purpose, but only to the extent that authoring tools are not yet able to determine author intent. However, authoring tools must not automatically misuse elements or encourage their users to do so.

Example

For example, it is not conforming to use an `address` element for arbitrary contact information; that element can only be used for marking up contact information for its nearest `article` or `body` element ancestor. However, since an authoring tool is likely unable to determine the difference, an authoring tool is exempt from that requirement. This does not mean, though, that

authoring tools can use address[p223] elements for any block of italics text (for instance); it just means that the authoring tool doesn't have to verify that when the user uses a tool for inserting contact information for an article[p207] element, that the user really is doing that and not inserting something else instead.

Note

In terms of conformance checking, an editor has to output documents that conform to the same extent that a conformance checker will verify.

When an authoring tool is used to edit a non-conforming document, it may preserve the conformance errors in sections of the document that were not edited during the editing session (i.e. an editing tool is allowed to round-trip erroneous content). However, an authoring tool must not claim that the output is conformant if errors have been so preserved.

Authoring tools are expected to come in two broad varieties: tools that work from structure or semantic data, and tools that work on a What-You-See-Is-What-You-Get media-specific editing basis (WYSIWYG).

The former is the preferred mechanism for tools that author HTML, since the structure in the source information can be used to make informed choices regarding which HTML elements and attributes are most appropriate.

However, WYSIWYG tools are legitimate. WYSIWYG tools should use elements they know are appropriate, and should not use elements that they do not know to be appropriate. This might in certain extreme cases mean limiting the use of flow elements to just a few elements, like div[p257], b[p293], i[p292], and span[p299] and making liberal use of the style[p164] attribute.

All authoring tools, whether WYSIWYG or not, should make a best effort attempt at enabling users to create well-structured, semantically rich, media-independent content.

For compatibility with existing content and prior specifications, this specification describes two authoring formats: one based on XML[p1402], and one using a custom format[p1277] inspired by SGML (referred to as the HTML syntax[p1277]). Implementations must support at least one of these two formats, although supporting both is encouraged.

Some conformance requirements are phrased as requirements on elements, attributes, methods or objects. Such requirements fall into two categories: those describing content model restrictions, and those describing implementation behavior. Those in the former category are requirements on documents and authoring tools. Those in the second category are requirements on user agents. Similarly, some conformance requirements are phrased as requirements on authors; such requirements are to be interpreted as conformance requirements on the documents that authors produce. (In other words, this specification does not distinguish between conformance criteria on authors and conformance criteria on documents.)

2.1.9 Dependencies §[p51]

This specification relies on several other underlying specifications.

Infra

The following terms are defined in *Infra*: [INFRA][p1497]

- The general iteration terms **while**, **continue**, and **break**.
- **Assert**
- **implementation-defined**
- **willful violation**
- **tracking vector**
- **code point** and its synonym **character**
- **surrogate**
- **scalar value**
- **tuple**
- **noncharacter**
- **string**, **code unit**, **code unit prefix**, **code unit less than**, **starts with**, **ends with**, **length**, and **code point length**
- The string equality operations **is** and **identical to**
- **scalar value string**
- **convert**
- **ASCII string**
- **ASCII tab or newline**
- **ASCII whitespace**
- **control**
- **ASCII digit**
- **ASCII upper hex digit**
- **ASCII lower hex digit**
- **ASCII hex digit**

- **ASCII upper alpha**
- **ASCII lower alpha**
- **ASCII alpha**
- **ASCII alphanumeric**
- **isomorphic decode**
- **isomorphic encode**
- **ASCII lowercase**
- **ASCII uppercase**
- **ASCII case-insensitive**
- **strip newlines**
- **normalize newlines**
- **strip leading and trailing ASCII whitespace**
- **strip and collapse ASCII whitespace**
- **split a string on ASCII whitespace**
- **split a string on commas**
- **collect a sequence of code points** and its associated **position variable**
- **skip ASCII whitespace**
- The **ordered map** data structure and the associated definitions for **key**, **value**, **empty**, **entry**, **exists**, **getting the value of an entry**, **setting the value of an entry**, **removing an entry**, **clear**, **getting the keys**, **getting the values**, **sorting in descending order**, **size**, and **iterate**
- The **list** data structure and the associated definitions for **append**, **extend**, **prepend**, **replace**, **remove**, **empty**, **contains**, **size**, **indices**, **is empty**, **item**, **iterate**, and **clone sort in ascending order sort in descending order**
- The **stack** data structure and the associated definitions for **push** and **pop**
- The **queue** data structure and the associated definitions for **enqueue** and **dequeue**
- The **ordered set** data structure and the associated definition for **append** and **union**
- The **struct** specification type and the associated definition for **item**
- The **byte sequence** data structure
- The **forgiving-base64 encode** and **forgiving-base64 decode** algorithms
- **exclusive range**
- **parse a JSON string to an Infra value**
- **HTML namespace**
- **MathML namespace**
- **SVG namespace**
- **XLink namespace**
- **XML namespace**
- **XMLNS namespace**

Unicode and Encoding

The Unicode character set is used to represent textual data, and *Encoding* defines requirements around character encodings. [UNICODE][p1500]

Note

This specification introduces terminology[p48] based on the terms defined in those specifications, as described earlier.

The following terms are used as defined in *Encoding*: [ENCODING][p1496]

- **Getting an encoding**
- **Get an output encoding**
- The generic **decode** algorithm which takes a byte stream and an encoding and returns a character stream
- The **UTF-8 decode** algorithm which takes a byte stream and returns a character stream, additionally stripping one leading UTF-8 Byte Order Mark (BOM), if any
- The **UTF-8 decode without BOM** algorithm which is identical to UTF-8 decode except that it does not strip one leading UTF-8 Byte Order Mark (BOM)
- The **encode** algorithm which takes a character stream and an encoding and returns a byte stream
- The **UTF-8 encode** algorithm which takes a character stream and returns a byte stream
- The **BOM sniff** algorithm which takes a byte stream and returns an encoding or null.

XML and related specifications

Implementations that support the XML syntax[p1402] for HTML must support some version of XML, as well as its corresponding namespaces specification, because that syntax uses an XML serialization with namespaces. [XML][p1502] [XMLNS][p1502]

Data mining tools and other user agents that perform operations on content without running scripts, evaluating CSS or XPath expressions, or otherwise exposing the resulting DOM to arbitrary content, may "support namespaces" by just asserting that their DOM node analogues are in certain namespaces, without actually exposing the namespace strings.

Note

In the HTML syntax[p1277], namespace prefixes and namespace declarations do not have the same effect as in XML. For instance, the colon has no special meaning in HTML element names.

The attribute with the name **space** in the XML namespace is defined by *Extensible Markup Language* (*XML*). [XML][p1502]

The **Name** production is defined in *XML*. [XML][p1502]

This specification also references the **<?xml-stylesheet?>** processing instruction, defined in *Associating Style Sheets with XML documents*. [XMLSSPI][p1502]

This specification also non-normatively mentions the **XSLTProcessor** interface and its **transformToFragment()** and **transformToDocument()** methods. [XSLTP][p1502]

URLs

The following terms are defined in *URL*: [URL][p1501]

- **host**
- **public suffix**
- **domain**
- **IP address**
- **URL**
- **Origin** of URLs
- **Absolute URL**
- **Relative URL**
- **registrable domain**
- The **URL parser**
- The **basic URL parser** and its ***url*** and ***state override*** arguments, as well as these parser states:
  - **scheme start state**
  - **host state**
  - **hostname state**
  - **port state**
  - **path start state**
  - **query state**
  - **fragment state**
- **URL record**, as well as its individual components:
  - **scheme**
  - **username**
  - **password**
  - **host**
  - **port**
  - **path**
  - **query**
  - **fragment**
  - **blob URL entry**
- **valid URL string**
- The **cannot have a username/password/port** concept
- The **opaque path** concept
- **URL serializer** and its **exclude fragment** argument
- **URL path serializer**
- The **host parser**
- The **host serializer**
- **Host equals**
- **URL equals** and its **exclude fragments** argument
- **serialize an integer**
- **Default encode set**
- **component percent-encode set**
- **UTF-8 percent-encode**
- **percent-decode**
- **set the username**
- **set the password**
- The **application/x-www-form-urlencoded** format
- The **application/x-www-form-urlencoded serializer**
- **is special**

A number of schemes and protocols are referenced by this specification also:

- The **about:** scheme [ABOUT][p1493]
- The **blob:** scheme [FILEAPI][p1496]
- The **data:** scheme [RFC2397][p1499]
- The **http:** scheme [HTTP][p1496]
- The **https:** scheme [HTTP][p1496]
- The **mailto:** scheme [MAILTO][p1497]
- The **sms:** scheme [SMS][p1500]
- The **urn:** scheme [URN][p1501]

Media fragment syntax is defined in *Media Fragments URI*. [MEDIAFRAG][p1497]

HTTP and related specifications

The following terms are defined in the HTTP specifications: [HTTP][p1496]

- `Accept` header
- `Accept-Language` header
- `Cache-Control` header
- `Content-Disposition` header
- `Content-Language` header

- `Content-Range` header
- `Last-Modified` header
- `Range` header
- `Referer` header

The following terms are defined in *HTTP State Management Mechanism*: [COOKIES][p1494]

- **cookie-string**
- **receives a set-cookie-string**
- `Cookie` header

The following term is defined in *Web Linking*: [WEBLINK][p1501]

- `Link` header
- **Parsing a `Link` field value**

The following terms are defined in *Structured Field Values for HTTP*: [STRUCTURED-FIELDS][p1500]

- **structured header**
- **boolean**
- **token**
- **parameters**

The following terms are defined in *MIME Sniffing*: [MIMESNIFF][p1498]

- **MIME type**
- **MIME type essence**
- **valid MIME type string**
- **valid MIME type string with no parameters**
- **HTML MIME type**
- **JavaScript MIME type** and **JavaScript MIME type essence match**
- **JSON MIME type**
- **XML MIME type**
- **image MIME type**
- **audio or video MIME type**
- **font MIME type**
- **parse a MIME type**
- **is MIME type supported by the user agent?**

Fetch

The following terms are defined in *Fetch*: [FETCH][p1496]

- **ABNF**
- `about:blank`
- An **HTTP(S) scheme**
- A URL which **is local**
- A **local scheme**
- A **fetch scheme**
- **CORS protocol**
- **default `User-Agent` value**
- **extract a MIME type**
- **legacy extract an encoding**
- **fetch**
- **fetch controller**
- **process the next manual redirect**
- **ok status**
- **navigation request**
- **network error**
- **aborted network error**
- `Origin` header
- `Cross-Origin-Resource-Policy` header
- **getting a structured field value**
- **header list**
- **set**
- **get, decode, and split**
- **abort**
- **cross-origin resource policy check**
- the `RequestCredentials` enumeration
- the `RequestDestination` enumeration
- the `fetch()` method
- **report timing**
- **serialize a response URL for reporting**
- **safely extracting a body**
- **incrementally reading a body**
- **processResponseConsumeBody**
- **processResponseEndOfBody**
- **processResponse**
- **useParallelQueue**
- **processEarlyHintsResponse**
- **connection pool**
- **obtain a connection**

- **determine the network partition key**
- **extract full timing info**
- **as a body**
- **response body info**
- **resolve an origin**
- **response** and its associated:
    - **type**
    - **URL**
    - **URL list**
    - **status**
    - **header list**
    - **body**
    - **body info**
    - **internal response**
    - **location URL**
    - **timing info**
    - **service worker timing info**
    - **has-cross-origin-redirects**
    - **timing allow passed**
    - **extract content-range values**
- **request** and its associated:
    - **URL**
    - **method**
    - **header list**
    - **body**
    - **client**
    - **URL list**
    - **current URL**
    - **reserved client**
    - **replaces client id**
    - **initiator**
    - **destination**
    - **potential destination**
    - **translating** a potential destination
    - **script-like** destinations
    - **priority**
    - **origin**
    - **referrer**
    - **synchronous flag**
    - **mode**
    - **credentials mode**
    - **use-URL-credentials flag**
    - **unsafe-request flag**
    - **cache mode**
    - **redirect count**
    - **redirect mode**
    - **policy container**
    - **referrer policy**
    - **cryptographic nonce metadata**
    - **integrity metadata**
    - **parser metadata**
    - **reload-navigation flag**
    - **history-navigation flag**
    - **user-activation**
    - **render-blocking**
    - **initiator type**
    - **service-workers mode**
    - **traversable for user prompts**
    - **add a range header**
- **fetch timing info** and its associated:
    - **start time**
    - **end time**

The following terms are defined in *Referrer Policy*: [REFERRERPOLICY]p1499

- **referrer policy**
- The `Referrer-Policy` HTTP header
- The **parse a referrer policy from a `Referrer-Policy` header** algorithm
- The "**no-referrer**", "**no-referrer-when-downgrade**", "**origin-when-cross-origin**", and "**unsafe-url**" referrer policies
- The **default referrer policy**

The following terms are defined in *Mixed Content*: [MIX]p1498

- ***a priori* authenticated URL**

The following terms are defined in *Subresource Integrity*: [SRI]p1500

- **parse integrity metadata**
- **the requirements of the integrity attribute**
- **get the strongest metadata from set**
- **integrity policy**
- **parse Integrity-Policy headers**

Paint Timing

The following terms are defined in *Paint Timing*: [PAINTTIMING][p1498]

- **mark paint timing**

Navigation Timing

The following terms are defined in *Navigation Timing*: [NAVIGATIONTIMING][p1498]

- **create the navigation timing entry**
- **queue the navigation timing entry**
- `NavigationTimingType` and its "`navigate`", "`reload`", and "`back_forward`" values.

Resource Timing

The following terms are defined in *Resource Timing*: [RESOURCETIMING][p1499]

- **Mark resource timing**

Performance Timeline

The following terms are defined in *Performance Timeline*: [PERFORMANCETIMELINE][p1498]

- `PerformanceEntry` and its `name`, `entryType`, `startTime`, and `duration` attributes.
- **Queue a performance entry**

Long Animation Frames

The following terms are defined in *Long Animation Frames*: [LONGANIMATIONFRAMES][p1497]

- **record task start time**
- **record task end time**
- **record rendering time**
- **record classic script creation time**
- **record classic script execution start time**
- **record module script execution start time**
- **Record pause duration**
- **record timing info for timer handler**
- **record timing info for microtask checkpoint**

Long Tasks

The following terms are defined in *Long Tasks*: [LONGTASKS][p1497]

- **report long tasks**

Web IDL

The IDL fragments in this specification must be interpreted as required for conforming IDL fragments, as described in *Web IDL*. [WEBIDL][p1501]

The following terms are defined in *Web IDL*:

- **this**
- **extended attribute**
- **named constructor**
- **constructor operation**
- **overridden constructor steps**
- **internally create a new object implementing the interface**
- **array index property name**
- **buffer source byte length**
- **supports indexed properties**
- **supported property indices**
- **determine the value of an indexed property**
- **set the value of an existing indexed property**
- **set the value of a new indexed property**
- **support named properties**
- **supported property names**
- **determine the value of a named property**
- **set the value of an existing named property**
- **set the value of a new named property**
- **delete an existing named property**
- **perform a security check**
- **platform object**
- **legacy platform object**
- **primary interface**
- **interface object**
- **named properties object**
- **include**
- **inherit**
- **interface prototype object**
- **implements**

- **associated realm**
- **[[Realm]] field of a platform object**
- **[[GetOwnProperty]] internal method of a named properties object**
- **callback context**
- **frozen array** and **creating a frozen array**
- **create a new object implementing the interface**
- **callback this value**
- **converting** between Web IDL types and JS types
- **invoking** and **constructing** callback functions
- **overload resolution algorithm**
- **exposed**
- **a promise resolved with**
- **a promise rejected with**
- **wait for all**
- **upon rejection**
- **upon fulfillment**
- **mark as handled**
- `[Global]`
- `[LegacyFactoryFunction]`
- `[LegacyLenientThis]`
- `[LegacyNullToEmptyString]`
- `[LegacyOverrideBuiltIns]`
- **LegacyPlatformObjectGetOwnProperty**
- `[LegacyTreatNonObjectAsNull]`
- `[LegacyUnenumerableNamedProperties]`
- `[LegacyUnforgeable]`
- **set entries**

Web IDL also defines the following types that are used in Web IDL fragments in this specification:

- `ArrayBuffer`
- `ArrayBufferView`
- `boolean`
- `DOMString`
- `double`
- **enumeration**
- `Float16Array`
- `Function`
- `long`
- `object`
- `Promise`
- `Uint8ClampedArray`
- `unrestricted double`
- `unsigned long`
- `USVString`
- `VoidFunction`

The term **throw** in this specification is used as defined in *Web IDL*. The `DOMException` type and the following exception names are defined by Web IDL and used by this specification:

- `"IndexSizeError"`
- `"HierarchyRequestError"`
- `"InvalidCharacterError"`
- `"NoModificationAllowedError"`
- `"NotFoundError"`
- `"NotSupportedError"`
- `"InvalidStateError"`
- `"SyntaxError"`
- `"InvalidAccessError"`
- `"SecurityError"`
- `"NetworkError"`
- `"AbortError"`
- `"QuotaExceededError"`
- `"DataCloneError"`
- `"EncodingError"`
- `"NotAllowedError"`

When this specification requires a user agent to **create a `Date` object** representing a particular time (which could be the special value Not-a-Number), the milliseconds component of that time, if any, must be truncated to an integer, and the time value of the newly created `Date` object must represent the resulting truncated time.

Example

For instance, given the time 23045 millionths of a second after 01:00 UTC on January 1st 2000, i.e. the time 2000-01-01T00:00:00.023045Z, then the `Date` object created representing that time would represent the same time as that created representing the time 2000-01-01T00:00:00.023Z, 45 millionths earlier. If the given time is NaN, then the result is a `Date` object that represents a time value NaN (indicating that the object does not represent a specific instant of time).

JavaScript

Some parts of the language described by this specification only support JavaScript as the underlying scripting language. [JAVASCRIPT][p1497]

Note

The term "JavaScript" is used to refer to ECMA-262, rather than the official term ECMAScript, since the term JavaScript is more widely known.

The following terms are defined in the JavaScript specification and used in this specification:

- **active function object**
- **agent** and **agent cluster**
- **automatic semicolon insertion**
- **candidate execution**
- The **current realm**
- **clamping** a mathematical value
- **early error**
- **forward progress**
- **invariants of the essential internal methods**
- **JavaScript execution context**
- **JavaScript execution context stack**
- **realm**
- **JobCallback Record**
- **NewTarget**
- **running JavaScript execution context**
- **surrounding agent**
- **abstract closure**
- **immutable prototype exotic object**
- **Well-Known Symbols**, including **%Symbol.hasInstance%**, **%Symbol.isConcatSpreadable%**, **%Symbol.toPrimitive%**, and **%Symbol.toStringTag%**
- **Well-Known Intrinsic Objects**, including **%Array.prototype%**, **%Error.prototype%**, **%EvalError.prototype%**, **%Function.prototype%**, **%Object.prototype%**, **%Object.prototype.valueOf%**, **%RangeError.prototype%**, **%ReferenceError.prototype%**, **%SyntaxError.prototype%**, **%TypeError.prototype%**, and **%URIError.prototype%**
- The ***FunctionBody*** production
- The ***Module*** production
- The ***Pattern*** production
- The ***Script*** production
- The **BigInt**, **Boolean**, **Number**, **String**, **Symbol**, and **Object** ECMAScript language types
- The **Completion Record** specification type
- The **List** and **Record** specification types
- The **Property Descriptor** specification type
- The **ModuleRequest Record** specification type
- The **Script Record** specification type
- The **Synthetic Module Record** specification type
- The **Cyclic Module Record** specification type
- The **Source Text Module Record** specification type and its **Evaluate**, **Link** and **LoadRequestedModules** methods
- The **ArrayCreate** abstract operation
- The **Call** abstract operation
- The **ClearKeptObjects** abstract operation
- The **CleanupFinalizationRegistry** abstract operation
- The **Construct** abstract operation
- The **CopyDataBlockBytes** abstract operation
- The **CreateBuiltinFunction** abstract operation
- The **CreateByteDataBlock** abstract operation
- The **CreateDataProperty** abstract operation
- The **CreateDefaultExportSyntheticModule** abstract operation
- The **DefinePropertyOrThrow** abstract operation
- The **DetachArrayBuffer** abstract operation
- The **EnumerableOwnProperties** abstract operation
- The **FinishLoadingImportedModule** abstract operation
- The **OrdinaryFunctionCreate** abstract operation
- The **Get** abstract operation
- The **GetActiveScriptOrModule** abstract operation
- The **GetFunctionRealm** abstract operation
- The **HasOwnProperty** abstract operation
- The **HostCallJobCallback** abstract operation
- The **HostEnqueueFinalizationRegistryCleanupJob** abstract operation
- The **HostEnqueueGenericJob** abstract operation
- The **HostEnqueuePromiseJob** abstract operation
- The **HostEnqueueTimeoutJob** abstract operation
- The **HostEnsureCanAddPrivateElement** abstract operation
- The **HostGetSupportedImportAttributes** abstract operation
- The **HostLoadImportedModule** abstract operation
- The **HostMakeJobCallback** abstract operation
- The **HostPromiseRejectionTracker** abstract operation
- The **InitializeHostDefinedRealm** abstract operation
- The **IsArrayBufferViewOutOfBounds** abstract operation
- The **IsAccessorDescriptor** abstract operation
- The **IsCallable** abstract operation

- The **IsConstructor** abstract operation
- The **IsDataDescriptor** abstract operation
- The **IsDetachedBuffer** abstract operation
- The **IsSharedArrayBuffer** abstract operation
- The **NewObjectEnvironment** abstract operation
- The **NormalCompletion** abstract operation
- The **OrdinaryGetPrototypeOf** abstract operation
- The **OrdinarySetPrototypeOf** abstract operation
- The **OrdinaryIsExtensible** abstract operation
- The **OrdinaryPreventExtensions** abstract operation
- The **OrdinaryGetOwnProperty** abstract operation
- The **OrdinaryDefineOwnProperty** abstract operation
- The **OrdinaryGet** abstract operation
- The **OrdinarySet** abstract operation
- The **OrdinaryDelete** abstract operation
- The **OrdinaryOwnPropertyKeys** abstract operation
- The **OrdinaryObjectCreate** abstract operation
- The **ParseJSONModule** abstract operation
- The **ParseModule** abstract operation
- The **ParseScript** abstract operation
- The **NewPromiseReactionJob** abstract operation
- The **NewPromiseResolveThenableJob** abstract operation
- The **RegExpBuiltinExec** abstract operation
- The **RegExpCreate** abstract operation
- The **RunJobs** abstract operation
- The **SameValue** abstract operation
- The **ScriptEvaluation** abstract operation
- The **SetSyntheticModuleExport** abstract operation
- The **SetImmutablePrototype** abstract operation
- The **ThrowCompletion** abstract operation
- The **ToBoolean** abstract operation
- The **ToString** abstract operation
- The **ToUint32** abstract operation
- The **TypedArrayCreate** abstract operation
- The **IsLooselyEqual** abstract operation
- The **IsStrictlyEqual** abstract operation
- The `Atomics` object
- The `Atomics.waitAsync` object
- The `Date` class
- The `FinalizationRegistry` class
- The `RegExp` class
- The `SharedArrayBuffer` class
- The `SyntaxError` class
- The `TypeError` class
- The `RangeError` class
- The `WeakRef` class
- The `eval()` function
- The `WeakRef.prototype.deref()` function
- The **[[IsHTMLDDA]]** internal slot
- `import()`
- `import.meta`
- The **HostGetImportMetaProperties** abstract operation
- The `typeof` operator
- The `delete` operator
- **The *TypedArray* Constructors** table

User agents that support JavaScript must also implement the *Dynamic Code Brand Checks* proposal. The following terms are defined there, and used in this specification: [JSDYNAMICCODEBRANDCHECKS][p1497]

- The **HostEnsureCanCompileStrings** abstract operation
- The **HostGetCodeForEval** abstract operation

User agents that support JavaScript must also implement *ECMAScript Internationalization API*. [JSINTL][p1497]

User agents that support JavaScript must also implement the *Temporal* proposal. The following terms are defined there, and used in this specification: [JSTEMPORAL][p1497]

- The **HostSystemUTCEpochNanoseconds** abstract operation
- The **nsMaxInstant** and **nsMinInstant** values

WebAssembly

The following term is defined in *WebAssembly JavaScript Interface*: [WASMJS][p1501]

- `WebAssembly.Module`

DOM

The Document Object Model (DOM) is a representation — a model — of a document and its content. The DOM is not just an API; the conformance criteria of HTML implementations are defined, in this specification, in terms of operations on the DOM. [DOM][p1496]

Implementations must support DOM and the events defined in UI Events, because this specification is defined in terms of the DOM, and some of the features are defined as extensions to the DOM interfaces. [DOM][p1496] [UIEVENTS][p1500]

In particular, the following features are defined in *DOM*: [DOM][p1496]

- `Attr` interface
- `CharacterData` interface
- `Comment` interface
- `DOMImplementation` interface
- `Document` interface and its `doctype` attribute
- `DocumentOrShadowRoot` interface
- `DocumentFragment` interface
- `DocumentType` interface
- `ChildNode` interface
- `Element` interface
- `attachShadow()` method.
- An element's **shadow root**
- A shadow root's **mode**
- A shadow root's **declarative** member
- The **attach a shadow root** algorithm
- The **retargeting algorithm**
- `Node` interface
- `NodeList` interface
- `ProcessingInstruction` interface
- `ShadowRoot` interface
- `Text` interface
- `Range` interface
- **node document** concept
- **document type** concept
- **host** concept
- The **shadow root** concept, and its **delegates focus**, **available to element internals**, **clonable**, **serializable**, **custom element registry**, and **keep custom element registry null**.
- The **shadow host** concept
- `HTMLCollection` interface, its `length` attribute, and its `item()` and `namedItem()` methods
- The terms **collection** and **represented by the collection**
- `DOMTokenList` interface, and its `value` attribute and `supports` operation
- `createDocument()` method
- `createHTMLDocument()` method
- `createElement()` method
- `createElementNS()` method
- `getElementById()` method
- `getElementsByClassName()` method
- `append()` method
- `appendChild()` method
- `cloneNode()` method
- `moveBefore()` method
- `importNode()` method
- `preventDefault()` method
- `id` attribute
- `setAttribute()` method
- `textContent` attribute
- The **tree**, **shadow tree**, and **node tree** concepts
- The **tree order** and **shadow-including tree order** concepts
- The **element** concept
- The **child** concept
- The **root** and **shadow-including root** concepts
- The **inclusive ancestor**, **descendant**, **shadow-including ancestor**, **shadow-including descendant**, **shadow-including inclusive descendant**, and **shadow-including inclusive ancestor** concepts
- The **first child**, **next sibling**, **previous sibling**, and **parent** concepts
- The **parent element** concept
- The **document element** concept
- The **in a document tree**, **in a document** (legacy), and **connected** concepts
- The **slot** concept, and its **name** and **assigned nodes**
- The **assigned slot** concept
- The **slot assignment** concept
- The **slottable** concept
- The **assign slottables for a tree** algorithm
- The `slotchange` event
- The **inclusive descendant** concept
- The **find flattened slottables** algorithm
- The **manual slot assignment** concept
- The **assign a slot** algorithm
- The **pre-insert**, **insert**, **append**, **replace**, **replace all**, **string replace all**, **remove**, and **adopt** algorithms for nodes
- The **descendant** concept
- The **insertion steps**,
- The **post-connection steps**, **removing steps**, **moving steps**, **adopting steps**, and **children changed steps** hooks for elements
- The **change**, **append**, **remove**, **replace**, **get an attribute by namespace and local name**, **set value**, and **remove an attribute by namespace and local name** algorithms for attributes
- The **attribute change steps** hook for attributes
- The **value** concept for attributes
- The **local name** concept for attributes

- The **attribute list** concept
- The **data** of a CharacterData node and its **replace data** algorithm
- The **child text content** of a node
- The **descendant text content** of a node
- The **name**, **public ID**, and **system ID** of a doctype
- Event interface
- Event and derived interfaces constructor behavior
- EventTarget interface
- The **activation behavior** hook
- The **legacy-pre-activation behavior** hook
- The **legacy-canceled-activation behavior** hook
- The **create an event** algorithm
- The **fire an event** algorithm
- The **canceled flag**
- The **dispatch flag**
- The **dispatch** algorithm
- EventInit dictionary type
- type attribute
- An event's **target**
- currentTarget attribute
- bubbles attribute
- cancelable attribute
- composed attribute
- **composed flag**
- isTrusted attribute
- initEvent() method
- **add an event listener**
- addEventListener() method
- The **remove an event listener** and **remove all event listeners** algorithms
- EventListener callback interface
- The **type** of an event
- An **event listener** and its **type** and **callback**
- The **encoding** (herein the *character encoding*), **mode**, **custom element registry**, **allow declarative shadow roots**, and **content type** of a Document[p131]
- The distinction between **XML documents** and **HTML documents**
- The terms **quirks mode**, **limited-quirks mode**, and **no-quirks mode**
- The algorithm **clone a node** with its arguments ***document***, ***subtree***, ***parent***, and ***fallbackRegistry***, and the concept of **cloning steps**
- The concept of **base URL change steps** and the definition of what happens when an element is **affected by a base URL change**
- The concept of an element's **unique identifier (ID)**
- The concept of an element's **classes**
- The term **supported tokens**
- The concept of a DOM **range**, and the terms **start node**, **start**, **end**, and **boundary point** as applied to ranges.
- The **create an element** algorithm
- The **element interface** concept
- The concepts of **custom element state**, and of **defined** and **custom** elements
- An element's **namespace**, **namespace prefix**, **local name**, **custom element registry**, **custom element definition**, and **is value**
- MutationObserver interface and **mutation observers** in general
- AbortController and its **signal**
- AbortSignal
- **aborted**
- **signal abort**
- **add**
- The **get an attribute by name** algorithm
- **valid element local name**

The following features are defined in *UI Events*: [UIEVENTS][p1500]

- The MouseEvent interface
- The MouseEvent interface's relatedTarget attribute
- MouseEventInit dictionary type
- The FocusEvent interface
- The FocusEvent interface's relatedTarget attribute
- The UIEvent interface
- The UIEvent interface's view attribute
- auxclick event
- beforeinput event
- click event
- contextmenu event
- dblclick event
- input event
- mousedown event
- mouseenter event
- mouseleave event
- mousemove event
- mouseout event
- mouseover event
- mouseup event
- wheel event
- keydown event
- keypress event

- **keyup** event

The following features are defined in *Touch Events*: [TOUCH][p1500]

- **Touch** interface
- **Touch point** concept
- **touchend** event

The following features are defined in *Pointer Events*: [POINTEREVENTS][p1498]

- The **PointerEvent** interface
- The PointerEvent interface's **pointerType** attribute
- **fire a pointer event**
- **pointerdown** event
- **pointerup** event
- **pointercancel** event

The following events are defined in *Clipboard API and events*: [CLIPBOARD-APIS][p1493]

- **copy** event
- **cut** event
- **paste** event

This specification sometimes uses the term **name** to refer to the event's type; as in, "an event named `click`" or "if the event name is `keypress`". The terms "name" and "type" for events are synonymous.

The following features are defined in *DOM Parsing and Serialization*: [DOMPARSING][p1496]

- **XML serialization**

The following features are defined in *Selection API*: [SELECTION][p1500]

- **selection**
- **Selection**

Note

User agents are encouraged to implement the features described in execCommand. *[EXECCOMMAND][p1496]*

The following features are defined in *Fullscreen API*: [FULLSCREEN][p1496]

- **requestFullscreen()**
- **fullscreenchange**
- **run the fullscreen steps**
- **fully exit fullscreen**
- **fullscreen element**
- **fullscreen flag**

High Resolution Time provides the following features: [HRT][p1496]

- **current high resolution time**
- **relative high resolution time**
- **unsafe shared current time**
- **shared monotonic clock**
- **unsafe moment**
- **duration from**
- **coarsen time**
- **current wall time**
- **Unix epoch**
- **DOMHighResTimeStamp**

File API

This specification uses the following features defined in *File API*: [FILEAPI][p1496]

- The **Blob** interface and its **type** attribute
- The **File** interface and its **name** and **lastModified** attributes
- The **FileList** interface
- The concept of a Blob's **snapshot state**
- The concept of **read errors**
- **Blob URL Store**
- **blob URL entry** and its **environment**
- The **obtain a blob object** algorithm

Indexed Database API

The following terms are defined in *Indexed Database API*: [INDEXEDDB][p1496]

- **cleanup Indexed Database transactions**
- **IDBVersionChangeEvent**

Media Source Extensions

The following terms are defined in *Media Source Extensions*: [MEDIASOURCE]p1497

- **MediaSource** interface
- **detaching from a media element**

Media Capture and Streams

The following terms are defined in *Media Capture and Streams*: [MEDIASTREAM]p1497

- **MediaStream** interface
- **MediaStreamTrack**
- **live state**
- **getUserMedia()**

Reporting

The following terms are defined in *Reporting*: [REPORTING]p1498

- **Queue a report**
- **report type**
- **visible to ReportingObservers**

XMLHttpRequest

The following features and terms are defined in *XMLHttpRequest*: [XHR]p1502

- The **XMLHttpRequest** interface, and its **responseXML** attribute
- The **ProgressEvent** interface, and its **lengthComputable**, **loaded**, and **total** attributes
- The **FormData** interface, and its associated **entry list**

Battery Status

The following features are defined in *Battery Status API*: [BATTERY]p1493

- **getBattery()** method

Media Queries

Implementations must support *Media Queries*. The **<media-condition>** feature is defined therein. [MQ]p1498

CSS modules

While support for CSS as a whole is not required of implementations of this specification (though it is encouraged, at least for web browsers), some features are defined in terms of specific CSS requirements.

When this specification requires that something be **parsed according to a particular CSS grammar**, the relevant algorithm in *CSS Syntax* must be followed, including error handling rules. [CSSSYNTAX]p1495

Example

For example, user agents are required to close all open constructs upon finding the end of a style sheet unexpectedly. Thus, when parsing the string "`rgb(0,0,0`" (with a missing close-parenthesis) for a color value, the close parenthesis is implied by this error handling rule, and a value is obtained (the color 'black'). However, the similar construct "`rgb(0,0,`" (with both a missing parenthesis and a missing "blue" value) cannot be parsed, as closing the open construct does not result in a viable value.

The following terms and features are defined in *Cascading Style Sheets* (*CSS*): [CSS]p1494

- **viewport**
- **line box**
- **out-of-flow**
- **in-flow**
- **collapsing margins**
- **containing block**
- **inline box**
- **block box**
- The **'top'**, **'bottom'**, **'left'**, and **'right'** properties
- The **'float'** property
- The **'clear'** property
- The **'width'** property
- The **'height'** property
- The **'min-width'** property
- The **'min-height'** property
- The **'max-width'** property
- The **'max-height'** property
- The **'line-height'** property

- The **'vertical-align'** property
- The **'content'** property
- The **'inline-block'** value of the 'display' property
- The **'visibility'** property

The basic version of the **'display'** property is defined in *CSS*, and the property is extended by other CSS modules. [CSS]p1494 [CSSRUBY]p1495 [CSSTABLE]p1495

The following terms and features are defined in *CSS Box Model*: [CSSBOX]p1494

- **content area**
- **content box**
- **border box**
- **margin box**
- **border edge**
- **margin edge**
- The **'margin-top'**, **'margin-bottom'**, **'margin-left'**, and **'margin-right'** properties
- The **'padding-top'**, **'padding-bottom'**, **'padding-left'**, and **'padding-right'** properties

The following features are defined in *CSS Logical Properties*: [CSSLOGICAL]p1495

- The **'margin-block'**, **'margin-block-start'**, **'margin-block-end'**, **'margin-inline'**, **'margin-inline-start'**, and **'margin-inline-end'** properties
- The **'padding-block'**, **'padding-block-start'**, **'padding-block-end'**, **'padding-inline'**, **'padding-inline-start'**, and **'padding-inline-end'** properties
- The **'border-block-width'**, **'border-block-start-width'**, **'border-block-end-width'**, **'border-inline-width'**, **'border-inline-start-width'**, **'border-inline-end-width'**, **'border-block-style'**, **'border-block-start-style'**, **'border-block-end-style'**, **'border-inline-style'**, **'border-inline-start-style'**, **'border-inline-end-style'**, **'border-block-start-color'**, **'border-block-end-color'**, **'border-inline-start-color'**, **'border-inline-end-color'**, **'border-start-start-radius'**, **'border-start-end-radius'**, **'border-end-start-radius'**, and **'border-end-end-radius'** properties
- The **'block-size'** property
- The **'inline-size'** property
- The **'inset-block-start'** property
- The **'inset-block-end'** property

The following terms and features are defined in *CSS Color*: [CSSCOLOR]p1494

- **named color**
- **<color>**
- The **'color'** property
- The **'currentcolor'** value
- **opaque black**
- **transparent black**
- **'srgb'** color space
- **'display-p3'** color space
- **'relative-colorimetric'** rendering intent
- **parse a CSS <color> value**
- **serialize a CSS <color> value** including **HTML-compatible serialization is requested**
- **Converting Colors**
- **'color()'**

The following terms are defined in *CSS Images*: [CSSIMAGES]p1494

- **default object size**
- **concrete object size**
- **natural dimensions**
- **natural height**
- **natural width**
- The **'image-orientation'** property
- **'conic-gradient'**
- The **'object-fit'** property

The term **paint source** is used as defined in *CSS Images Level 4* to define the interaction of certain HTML elements with the CSS 'element()' function. [CSSIMAGES4]p1494

The following features are defined in *CSS Backgrounds and Borders*: [CSSBG]p1494

- The **'background-color'**, **'background-image'**, **'background-repeat'**, **'background-attachment'**, **'background-position'**, **'background-clip'**, **'background-origin'**, and **'background-size'** properties
- The **'border-radius'**, **'border-top-left-radius'**, **'border-top-right-radius'**, **'border-bottom-right-radius'**, **'border-bottom-left-radius'** properties

- The **'border-image-source'**, **'border-image-slice'**, **'border-image-width'**, **'border-image-outset'**, and **'border-image-repeat'** properties

CSS Backgrounds and Borders also defines the following border properties: [CSSBG][p1494]

Border properties

	Top	Bottom	Left	Right
Width	**'border-top-width'**	**'border-bottom-width'**	**'border-left-width'**	**'border-right-width'**
Style	**'border-top-style'**	**'border-bottom-style'**	**'border-left-style'**	**'border-right-style'**
Color	**'border-top-color'**	**'border-bottom-color'**	**'border-left-color'**	**'border-right-color'**

The following features are defined in *CSS Box Alignment*: [CSSALIGN][p1494]

- The **'align-content'** property
- The **'align-items'** property
- The **'align-self'** property
- The **'justify-self'** property
- The **'justify-content'** property
- The **'justify-items'** property

The following terms and features are defined in *CSS Display*: [CSSDISPLAY][p1494]

- **outer display type**
- **inner display type**
- **block-level**
- **block container**
- **formatting context**
- **block formatting context**
- **inline formatting context**
- **replaced element**
- **CSS box**

The following features are defined in *CSS Flexible Box Layout*: [CSSFLEXBOX][p1494]

- The **'flex-direction'** property
- The **'flex-wrap'** property

The following terms and features are defined in *CSS Fonts*: [CSSFONTS][p1494]

- **first available font**
- The **'font-family'** property
- The **'font-weight'** property
- The **'font-size'** property
- The **'font'** property
- The **'font-kerning'** property
- The **'font-stretch'** property
- The **'font-variant-caps'** property
- The **'small-caps'** value
- The **'all-small-caps'** value
- The **'petite-caps'** value
- The **'all-petite-caps'** value
- The **'unicase'** value
- The **'titling-caps'** value
- The **'ultra-condensed'** value
- The **'extra-condensed'** value
- The **'condensed'** value
- The **'semi-condensed'** value
- The **'semi-expanded'** value
- The **'expanded'** value
- The **'extra-expanded'** value
- The **'ultra-expanded'** value

The following features are defined in *CSS Grid Layout*: [CSSGRID][p1494]

- The **'grid-auto-columns'** property
- The **'grid-auto-flow'** property
- The **'grid-auto-rows'** property
- The **'grid-column-gap'** property
- The **'grid-row-gap'** property
- The **'grid-template-areas'** property
- The **'grid-template-columns'** property
- The **'grid-template-rows'** property

The following terms are defined in *CSS Inline Layout*: [CSSINLINE][p1495]

- **alphabetic baseline**
- **ascent metric**
- **descent metric**

- **em-over baseline**
- **em-under baseline**
- **hanging baseline**
- **ideographic-under baseline**

The following terms and features are defined in *CSS Box Sizing*: [CSSSIZING]p1495

- **fit-content inline size**
- **'aspect-ratio'** property
- **intrinsic size**

The following features are defined in *CSS Lists and Counters*. [CSSLISTS]p1495

- **list item**
- The **'counter-reset'** property
- The **'counter-set'** property
- The **'list-style-type'** property

The following features are defined in *CSS Overflow*. [CSSOVERFLOW]p1495

- The **'overflow'** property and its **'hidden'** value
- The **'text-overflow'** property
- The term **scroll container**

The following terms and features are defined in *CSS Positioned Layout*: [CSSPOSITION]p1495

- **absolutely-positioned**
- The **'position'** property and its **'static'** value
- The **top layer** (an ordered set)
- **add an element to the top layer**
- **request an element to be removed from the top layer**
- **remove an element from the top layer immediately**
- **process top layer removals**

The following features are defined in *CSS Multi-column Layout*. [CSSMULTICOL]p1495

- The **'column-count'** property
- The **'column-fill'** property
- The **'column-gap'** property
- The **'column-rule'** property
- The **'column-width'** property

The **'ruby-base'** value of the 'display' property is defined in *CSS Ruby Layout*. [CSSRUBY]p1495

The following features are defined in *CSS Table*: [CSSTABLE]p1495

- The **'border-spacing'** property
- The **'border-collapse'** property
- The **'table-cell'**, **'table-row'**, **'table-caption'**, and **'table'** values of the 'display' property

The following features are defined in *CSS Text*: [CSSTEXT]p1495

- The **content language** concept
- The **'text-transform'** property
- The **'white-space'** property
- The **'text-align'** property
- The **'letter-spacing'** property
- The **'word-spacing'** property

The following features are defined in *CSS Writing Modes*: [CSSWM]p1495

- The **'direction'** property
- The **'unicode-bidi'** property
- The **'writing-mode'** property
- The **block flow direction**, **block axis**, **inline axis**, **block size**, **inline size**, **block-start**, **block-end**, **inline-start**, **inline-end**, **line-left**, and **line-right** concepts

The following features are defined in *CSS Basic User Interface*: [CSSUI]p1495

- The **'outline'** property
- The **'cursor'** property
- The **'appearance'** property, its **<compat-auto>** non-terminal value type, its **'textfield'** value, and its **'menulist-button'** value.
- The **'field-sizing'** property, and its **'content'** value.
- The concept **widget**
- The concept **native appearance**
- The concept **primitive appearance**
- The concept **element with default preferred size**
- The **non-devolvable widget** and **devolvable widget** classification, and the related **devolved widget** state.

- The **'pointer-events'** property
- The **'user-select'** property

The algorithm to **update animations and send events** is defined in *Web Animations*. [WEBANIMATIONS]p1501

Implementations that support scripting must support the CSS Object Model. The following features and terms are defined in the CSSOM specifications: [CSSOM]p1495 [CSSOMVIEW]p1495

- **Screen** interface
- **LinkStyle** interface
- **CSSStyleDeclaration** interface
- **style** IDL attribute
- **cssText** attribute of CSSStyleDeclaration
- **StyleSheet** interface
- **CSSStyleSheet** interface
- **create a CSS style sheet**
- **remove a CSS style sheet**
- **associated CSS style sheet**
- **create a constructed CSSStyleSheet**
- **synchronously replace the rules of a CSSStyleSheet**
- **disable a CSS style sheet**
- **CSS style sheets** and their properties:
  - **type**
  - **location**
  - **parent CSS style sheet**
  - **owner node**
  - **owner CSS rule**
  - **media**
  - **title**
  - **alternate flag**
  - **disabled flag**
  - **CSS rules**
  - **origin-clean flag**
- **CSS style sheet set**
- **CSS style sheet set name**
- **preferred CSS style sheet set name**
- **change the preferred CSS style sheet set name**
- **Serializing a CSS value**
- **run the resize steps**
- **run the scroll steps**
- **evaluate media queries and report changes**
- **Scroll a target into view**
- **Scroll to the beginning of the document**
- The **resize** event
- The **scroll** event
- The **scrollend** event
- **set up browsing context features**
- The **clientX** and **clientY** extension attributes of the MouseEvent interface

The following features and terms are defined in *CSS Syntax*: [CSSSYNTAX]p1495

- **conformant style sheet**
- **parse a list of component values**
- **parse a comma-separated list of component values**
- **component value**
- **environment encoding**
- **<whitespace-token>**

The following terms are defined in *Selectors*: [SELECTORS]p1500

- **type selector**
- **attribute selector**
- **pseudo-class**
- **:focus-visible** pseudo-class
- **indicate focus**
- **pseudo-element**

The following features are defined in *CSS Values and Units*: [CSSVALUES]p1495

- **<length>**
- The **'em'** unit
- The **'ex'** unit
- The **'vw'** unit
- The **'in'** unit
- The **'px'** unit
- The **'pt'** unit
- The **'attr()'** function
- The **math functions**

The following features are defined in *CSS View Transitions*: [CSSVIEWTRANSITIONS]p1495

- **perform pending transition operations**
- **rendering suppression for view transitions**
- **activate view transition**
- `ViewTransition`
- **view transition page visibility change steps**
- **resolving inbound cross-document view-transition**
- **setting up a cross-document view-transition**
- **can navigation trigger a cross-document view-transition?**

The term **style attribute** is defined in *CSS Style Attributes*. [CSSATTR][p1494]

The following terms are defined in the *CSS Cascading and Inheritance*: [CSSCASCADE][p1494]

- **cascaded value**
- **specified value**
- **computed value**
- **used value**
- **cascade origin**
- **Author Origin**
- **User Origin**
- **User Agent Origin**
- **Animation Origin**
- **Transition Origin**
- **initial value**

The `CanvasRenderingContext2D`[p690] object's use of fonts depends on the features described in the CSS *Fonts* and *Font Loading* specifications, including in particular `FontFace` objects and the **font source** concept. [CSSFONTS][p1494] [CSSFONTLOAD][p1494]

The following interfaces and terms are defined in *Geometry Interfaces*: [GEOMETRY][p1496]

- `DOMMatrix` interface, and associated **m11 element**, **m12 element**, **m21 element**, **m22 element**, **m41 element**, and **m42 element**
- `DOMMatrix2DInit` and `DOMMatrixInit` dictionaries
- The **create a `DOMMatrix` from a dictionary** and **create a `DOMMatrix` from a 2D dictionary** algorithms for `DOMMatrix2DInit` or `DOMMatrixInit`
- The `DOMPointInit` dictionary, and associated **x** and **y** members
- **Matrix multiplication**

The following terms are defined in the *CSS Scoping*: [CSSSCOPING][p1495]

- **flat tree**

The following terms and features are defined in *CSS Color Adjustment*: [CSSCOLORADJUST][p1494]

- **'color-scheme'**
- **page's supported color-schemes**

The following terms are defined in *CSS Pseudo-Elements*: [CSSPSEUDO][p1495]

- **'::details-content'**
- **'::file-selector-button'**

The following terms are defined in *CSS Containment*: [CSSCONTAIN][p1494]

- **skips its contents**
- **relevant to the user**
- **proximity to the viewport**
- **layout containment**
- **'content-visibility'** property
- **'auto'** value for 'content-visibility'

The following terms are defined in *CSS Anchor Positioning*: [CSSANCHOR][p1494]

- **implicit anchor element**

Intersection Observer

The following term is defined in *Intersection Observer*: [INTERSECTIONOBSERVER][p1497]

- **run the update intersection observations steps**
- `IntersectionObserver`
- `IntersectionObserverInit`
- `observe`
- `unobserve`
- `isIntersecting`
- `target`

Resize Observer

The following terms are defined in *Resize Observer*: [RESIZEOBSERVER][p1497]

- **gather active resize observations at depth**
- **has active resize observations**
- **has skipped resize observations**
- **broadcast active resize observations**
- **deliver resize loop error**

WebGL

The following interfaces are defined in the WebGL specifications: [WEBGL][p1501]

- `WebGLRenderingContext` interface
- `WebGL2RenderingContext` interface
- `WebGLContextAttributes` dictionary

WebGPU

The following interfaces are defined in *WebGPU*: [WEBGPU][p1501]

- `GPUCanvasContext` interface

WebVTT

Implementations may support WebVTT as a text track format for subtitles, captions, metadata, etc., for media resources. [WEBVTT][p1502]

The following terms, used in this specification, are defined in *WebVTT*:

- **WebVTT file**
- **WebVTT file using cue text**
- **WebVTT file using only nested cues**
- **WebVTT parser**
- The **rules for updating the display of WebVTT text tracks**
- The WebVTT **text track cue writing direction**
- `VTTCue` interface

ARIA

The `role` attribute is defined in *Accessible Rich Internet Applications* (*ARIA*), as are the following roles: [ARIA][p1493]

- `button`
- `presentation`

In addition, the following `aria-*` content attributes are defined in *ARIA*: [ARIA][p1493]

- `aria-checked`
- `aria-describedby`
- `aria-disabled`
- `aria-label`

Finally, the following terms are defined in *ARIA*: [ARIA][p1493]

- **role**
- **accessible name**
- The `ARIAMixin` interface, with its associated `ARIAMixin` **getter steps** and `ARIAMixin` **setter steps** hooks, and its `role` and `aria*` attributes

Content Security Policy

The following terms are defined in *Content Security Policy*: [CSP][p1494]

- **Content Security Policy**
- **disposition**
- **directive set**
- **Content Security Policy directive**
- **CSP list**
- The **Content Security Policy syntax**
- **enforce the policy**
- The **parse a serialized Content Security Policy** algorithm
- The **Run CSP initialization for a Document** algorithm
- The **Run CSP initialization for a global object** algorithm
- The **Should element's inline behavior be blocked by Content Security Policy?** algorithm
- The **Should navigation request of type be blocked by Content Security Policy?** algorithm
- The **Should navigation response to navigation request of type in target be blocked by Content Security Policy?** algorithm
- The `report-uri` **directive**
- The **EnsureCSPDoesNotBlockStringCompilation** abstract operation
- The **Is base allowed for Document?** algorithm
- The `frame-ancestors` **directive**

- The **sandbox directive**
- The **contains a header-delivered Content Security Policy** property.
- The **Parse a response's Content Security Policies** algorithm.
- `SecurityPolicyViolationEvent` interface
- The `securitypolicyviolation` event

Service Workers

The following terms are defined in *Service Workers*: [SW][p1500]

- **active worker**
- **client message queue**
- **control**
- **handle fetch**
- **match service worker registration**
- **service worker**
- **service worker client**
- **service worker registration**
- `ServiceWorker` interface
- `ServiceWorkerContainer` interface
- `ServiceWorkerGlobalScope` interface
- `unregister`

Secure Contexts

The following algorithms are defined in *Secure Contexts*: [SECURE-CONTEXTS][p1500]

- **Is url potentially trustworthy?**

Permissions Policy

The following terms are defined in *Permissions Policy*: [PERMISSIONSPOLICY][p1498]

- **permissions policy**
- **policy-controlled feature**
- **container policy**
- **serialized permissions policy**
- **default allowlist**
- The **creating a permissions policy** algorithm
- The **creating a permissions policy from a response** algorithm
- The **is feature enabled by policy for origin** algorithm
- The **process permissions policy attributes** algorithm

Payment Request API

The following feature is defined in *Payment Request API*: [PAYMENTREQUEST][p1498]

- `PaymentRequest` interface

MathML

While support for MathML as a whole is not required by this specification (though it is encouraged, at least for web browsers), certain features depend upon small parts of MathML being implemented. [MATHML][p1497]

The following features are defined in *Mathematical Markup Language* (*MathML*):

- **MathML** `annotation-xml` element
- **MathML** `math` element
- **MathML** `merror` element
- **MathML** `mi` element
- **MathML** `mn` element
- **MathML** `mo` element
- **MathML** `ms` element
- **MathML** `mtext` element

SVG

While support for SVG as a whole is not required by this specification (though it is encouraged, at least for web browsers), certain features depend upon parts of SVG being implemented.

User agents that implement SVG must implement the *SVG 2* specification, and not any earlier revisions.

The following features are defined in the *SVG 2* specification: [SVG][p1500]

- `SVGElement` interface
- `SVGImageElement` interface
- `SVGScriptElement` interface
- `SVGSVGElement` interface
- **SVG** `a` element
- **SVG** `desc` element
- **SVG** `foreignObject` element

- **SVG `image` element**
- **SVG `script` element**
- **SVG `svg` element**
- **SVG `title` element**
- **SVG `use` element**
- **SVG `text-rendering` property**

Filter Effects

The following features are defined in *Filter Effects*: [FILTERS][p1496]

- **<filter-value-list>**

Compositing

The following features are defined in *Compositing and Blending*: [COMPOSITE][p1493]

- **<blend-mode>**
- **<composite-mode>**
- **source-over**
- **copy**

Cooperative Scheduling of Background Tasks

The following features are defined in *Cooperative Scheduling of Background Tasks*: [REQUESTIDLECALLBACK][p1499]

- **`requestIdleCallback()`**
- **start an idle period algorithm**

Screen Orientation

The following terms are defined in *Screen Orientation*: [SCREENORIENTATION][p1500]

- **screen orientation change steps**

Storage

The following terms are defined in *Storage*: [STORAGE][p1500]

- **obtain a local storage bottle map**
- **obtain a session storage bottle map**
- **obtain a storage key for non-storage purposes**
- **storage key equal**
- **storage proxy map**
- **legacy-clone a traversable storage shed**

Web App Manifest

The following features are defined in *Web App Manifest*: [MANIFEST][p1497]

- **application manifest**
- **installed web application**
- **process the manifest**

WebAssembly JavaScript Interface: ESM Integration

The following terms are defined in *WebAssembly JavaScript Interface: ESM Integration*: [WASMESM][p1501]

- **WebAssembly Module Record**
- **parse a WebAssembly module**

WebCodecs

The following features are defined in *WebCodecs*: [WEBCODECS][p1501]

- **`VideoFrame` interface.**
- **[[display width]]**
- **[[display height]]**

WebDriver

The following terms are defined in *WebDriver*: [WEBDRIVER][p1501]

- **extension command**
- **remote end steps**
- **WebDriver error**
- **WebDriver error code**
- **invalid argument**
- **getting a property**
- **success**
- **WebDriver's security considerations**
- **current browsing context**

WebDriver BiDi

The following terms are defined in *WebDriver BiDi*: [WEBDRIVERBIDI][p1501]

- **WebDriver BiDi navigation status**
- **navigation status id**
- **navigation status status**
- **navigation status canceled**
- **navigation status committed**
- **navigation status pending**
- **navigation status complete**
- **navigation status url**
- **navigation status suggested filename**
- **WebDriver BiDi navigation aborted**
- **WebDriver BiDi navigation committed**
- **WebDriver BiDi navigation failed**
- **WebDriver BiDi navigation started**
- **WebDriver BiDi download started**
- **WebDriver BiDi fragment navigated**
- **WebDriver BiDi DOM content loaded**
- **WebDriver BiDi load complete**
- **WebDriver BiDi history updated**
- **WebDriver BiDi navigable created**
- **WebDriver BiDi navigable destroyed**
- **WebDriver BiDi user prompt closed**
- **WebDriver BiDi user prompt opened**
- **WebDriver BiDi file dialog opened**

Web Cryptography API

The following terms are defined in *Web Cryptography API*: [WEBCRYPTO][p1501]

- **generating a random UUID**

WebSockets

The following terms are defined in *WebSockets*: [WEBSOCKETS][p1502]

- `WebSocket`
- **make disappear**

WebTransport

The following terms are defined in *WebTransport*: [WEBTRANSPORT][p1502]

- `WebTransport`
- `context cleanup steps`

Web Authentication: An API for accessing Public Key Credentials

The following terms are defined in *Web Authentication: An API for accessing Public Key Credentials*: [WEBAUTHN][p1501]

- **public key credential**

Credential Management

The following terms are defined in *Credential Management*: [CREDMAN][p1494]

- **conditional mediation**
- **credential**
- `navigator.credentials.get()`

Console

The following terms are defined in *Console*: [CONSOLE][p1493]

- **report a warning to the console**

Web Locks API

The following terms are defined in *Web Locks API*: [WEBLOCKS][p1501]

- **locks**
- **lock requests**

Trusted Types

This specification uses the following features defined in *Trusted Types*: [TRUSTED-TYPES][p1500]

- `TrustedHTML`
- **data**
- `TrustedScript`
- `data`

- `TrustedScriptURL`
- **Get Trusted Type compliant string**

WebRTC API

The following terms are defined in *WebRTC API*: [WEBRTC][p1502]

- `RTCDataChannel`
- `RTCPeerConnection`

Picture-in-Picture API

The following terms are defined in *Picture-in-Picture API*: [PICTUREINPICTURE][p1498]

- `PictureInPictureWindow`

Idle Detection API

The following terms are defined in *Idle Detection API*:

- `IdleDetector`

Web Speech API

The following terms are defined in *Web Speech API*:

- `SpeechRecognition`

WebOTP API

The following terms are defined in *WebOTP API*:

- `OTPCredential`

Web Share API

The following terms are defined in *Web Share API*:

- **share()**

Web Smart Card API

The following terms are defined in *Web Smart Card API*:

- `SmartCardConnection`

Web Background Synchronization

The following terms are defined in *Web Background Synchronization*:

- `SyncManager`
- `register()`

Web Periodic Background Synchronization

The following terms are defined in *Web Periodic Background Synchronization*:

- `PeriodicSyncManager`
- `register()`

Web Background Fetch

The following terms are defined in *Background Fetch*:

- `BackgroundFetchManager`
- `fetch()`

Keyboard Lock

The following terms are defined in *Keyboard Lock*:

- `Keyboard`
- `lock()`

Web MIDI API

The following terms are defined in *Web MIDI API*:

- `requestMIDIAccess()`

Generic Sensor API

The following terms are defined in *Generic Sensor API*:

- **request sensor access**

WebHID API

The following terms are defined in *WebHID API*:

- **requestDevice**

WebXR Device API

The following terms are defined in *WebXR Device API*:

- **XRSystem**

This specification does not *require* support of any particular network protocol, style sheet language, scripting language, or any of the DOM specifications beyond those required in the list above. However, the language described by this specification is biased towards CSS as the styling language, JavaScript as the scripting language, and HTTP as the network protocol, and several features assume that those languages and protocols are in use.

A user agent that implements the HTTP protocol must implement *HTTP State Management Mechanism* (Cookies) as well. [HTTP] [COOKIES]

Note

This specification might have certain additional requirements on character encodings, image formats, audio formats, and video formats in the respective sections.

2.1.10 Extensibility

Vendor-specific proprietary user agent extensions to this specification are strongly discouraged. Documents must not use such extensions, as doing so reduces interoperability and fragments the user base, allowing only users of specific user agents to access the content in question.

All extensions must be defined so that the use of extensions neither contradicts nor causes the non-conformance of functionality defined in the specification.

Example

For example, while strongly discouraged from doing so, an implementation could add a new IDL attribute "`typeTime`" to a control that returned the time it took the user to select the current value of a control (say). On the other hand, defining a new control that appears in a form's `elements` array would be in violation of the above requirement, as it would violate the definition of `elements` given in this specification.

When vendor-neutral extensions to this specification are needed, either this specification can be updated accordingly, or an extension specification can be written that overrides the requirements in this specification. When someone applying this specification to their activities decides that they will recognize the requirements of such an extension specification, it becomes an **applicable specification** for the purposes of conformance requirements in this specification.

Note

Someone could write a specification that defines any arbitrary byte stream as conforming, and then claim that their random junk is conforming. However, that does not mean that their random junk actually is conforming for everyone's purposes: if someone else decides that that specification does not apply to their work, then they can quite legitimately say that the aforementioned random junk is just that, junk, and not conforming at all. As far as conformance goes, what matters in a particular community is what that community agrees *is applicable.*

User agents must treat elements and attributes that they do not understand as semantically neutral; leaving them in the DOM (for DOM processors), and styling them according to CSS (for CSS processors), but not inferring any meaning from them.

When support for a feature is disabled (e.g. as an emergency measure to mitigate a security problem, or to aid in development, or for performance reasons), user agents must act as if they had no support for the feature whatsoever, and as if the feature was not mentioned in this specification. For example, if a particular feature is accessed via an attribute in a Web IDL interface, the attribute

itself would be omitted from the objects that implement that interface — leaving the attribute on the object but making it return null or throw an exception is insufficient.

2.1.11 Interactions with XPath and XSLT §[p75]

Implementations of XPath 1.0 that operate on HTML documents parsed or created in the manners described in this specification (e.g. as part of the `document.evaluate()` API) must act as if the following edit was applied to the XPath 1.0 specification.

First, remove this paragraph:

> *A QName in the node test is expanded into an expanded-name using the namespace declarations from the expression context. This is the same way expansion is done for element type names in start and end-tags except that the default namespace declared with `xmlns` is not used: if the QName does not have a prefix, then the namespace URI is null (this is the same way attribute names are expanded). It is an error if the QName has a prefix for which there is no namespace declaration in the expression context.*

Then, insert in its place the following:

> *A QName in the node test is expanded into an expanded-name using the namespace declarations from the expression context. If the QName has a prefix, then there must be a namespace declaration for this prefix in the expression context, and the corresponding namespace URI is the one that is associated with this prefix. It is an error if the QName has a prefix for which there is no namespace declaration in the expression context.*
>
> *If the QName has no prefix and the principal node type of the axis is element, then the default element namespace is used. Otherwise, if the QName has no prefix, the namespace URI is null. The default element namespace is a member of the context for the XPath expression. The value of the default element namespace when executing an XPath expression through the DOM3 XPath API is determined in the following way:*
>
> 1. *If the context node is from an HTML DOM, the default element namespace is "http://www.w3.org/1999/xhtml".*
> 2. *Otherwise, the default element namespace URI is null.*

Note

This is equivalent to adding the default element namespace feature of XPath 2.0 to XPath 1.0, and using the HTML namespace as the default element namespace for HTML documents. It is motivated by the desire to have implementations be compatible with legacy HTML content while still supporting the changes that this specification introduces to HTML regarding the namespace used for HTML elements, and by the desire to use XPath 1.0 rather than XPath 2.0.

Note

This change is a willful violation of the XPath 1.0 specification, motivated by desire to have implementations be compatible with legacy content while still supporting the changes that this specification introduces to HTML regarding which namespace is used for HTML elements. [XPATH10][p1502]

XSLT 1.0 processors outputting to a DOM when the output method is "html" (either explicitly or via the defaulting rule in XSLT 1.0) are affected as follows:

If the transformation program outputs an element in no namespace, the processor must, prior to constructing the corresponding DOM element node, change the namespace of the element to the HTML namespace, ASCII-lowercase the element's local name, and ASCII-lowercase the names of any non-namespaced attributes on the element.

Note

This requirement is a willful violation of the XSLT 1.0 specification, required because this specification changes the namespaces and case-sensitivity rules of HTML in a manner that would otherwise be incompatible with DOM-based XSLT transformations. (Processors that serialize the output are unaffected.) [XSLT10][p1502]

This specification does not specify precisely how XSLT processing interacts with the HTML parser[p1289] infrastructure (for example, whether an XSLT processor acts as if it puts any elements into a stack of open elements[p1304]). However, XSLT processors must stop parsing[p1376] if they successfully complete, and must update the current document readiness[p134] first to "`interactive`" and then to

"`complete`" if they are aborted.

This specification does not specify how XSLT interacts with the navigation[p1028] algorithm, how it fits in with the event loop[p1138], nor how error pages are to be handled (e.g. whether XSLT errors are to replace an incremental XSLT output, or are rendered inline, etc.).

Note

There are also additional non-normative comments regarding the interaction of XSLT and HTML in the `script` element section[p676], and of XSLT, XPath, and HTML in the `template` element section[p682].

2.2 Policy-controlled features §[p76]

This document defines the following policy-controlled features:

- "**`autoplay`**", which has a default allowlist of `'self'`.
- "**`cross-origin-isolated`**", which has a default allowlist of `'self'`.
- "**`focus-without-user-activation`**", which has a default allowlist of `'self'`.

2.3 Common microsyntaxes §[p76]

There are various places in HTML that accept particular data types, such as dates or numbers. This section describes what the conformance criteria for content in those formats is, and how to parse them.

Note

Implementers are strongly urged to carefully examine any third-party libraries they might consider using to implement the parsing of syntaxes described below. For example, date libraries are likely to implement error handling behavior that differs from what is required in this specification, since error-handling behavior is often not defined in specifications that describe date syntaxes similar to those used in this specification, and thus implementations tend to vary greatly in how they handle errors.

2.3.1 Common parser idioms §[p76]

Some of the micro-parsers described below follow the pattern of having an *input* variable that holds the string being parsed, and having a *position* variable pointing at the next character to parse in *input*.

2.3.2 Boolean attributes §[p76]

A number of attributes are **boolean attributes**. The presence of a boolean attribute on an element represents the true value, and the absence of the attribute represents the false value.

If the attribute is present, its value must either be the empty string or a value that is an ASCII case-insensitive match for the attribute's canonical name, with no leading or trailing whitespace.

Note

The values "true" and "false" are not allowed on boolean attributes. To represent a false value, the attribute has to be omitted altogether.

Example

Here is an example of a checkbox that is checked and disabled. The `checked`[p526] and `disabled`[p605] attributes are the boolean attributes.

```
<label><input type=checkbox checked name=cheese disabled> Cheese</label>
```

This could be equivalently written as this:

```
<label><input type=checkbox checked=checked name=cheese disabled=disabled> Cheese</label>
```

You can also mix styles; the following is still equivalent:

```
<label><input type='checkbox' checked name=cheese disabled=""> Cheese</label>
```

2.3.3 Keywords and enumerated attributes §[p77]

Some attributes, called **enumerated attributes**, take on a finite set of states. The state for such an attribute is derived by combining the attribute's value, a set of keyword/state mappings given in the specification of each attribute, and two possible special states that can also be given in the specification of the attribute. These special states are the ***invalid value default*** and the ***missing value default***.

Note

Multiple keywords can map to the same state.

Note

The empty string can be a valid keyword. Note that the missing value default[p77] *applies only when the attribute is* missing*, not when it is present with an empty string value.*

To determine the state of an attribute, use the following steps:

1. If the attribute is not specified:
    1. If the attribute has a *missing value default*[p77] state defined, then return that *missing value default*[p77] state.
    2. Otherwise, return no state.
2. If the attribute's value is an ASCII case-insensitive match for one of the keywords defined for the attribute, then return the state represented by that keyword.
3. If the attribute has an *invalid value default*[p77] state defined, then return that *invalid value default*[p77] state.
4. Return no state.

For authoring conformance purposes, if an enumerated attribute is specified, the attribute's value must be an ASCII case-insensitive match for one of the conforming keywords for that attribute, with no leading or trailing whitespace.

For reflection[p105] purposes, states which have any keywords mapping to them are said to have a **canonical keyword**. This is determined as follows:

- If there is only one keyword mapping to the given state, then it is that keyword.
- If there is only one *conforming* keyword mapping to the given state, then it is that conforming keyword.
- If there are two conforming keywords mapping to the given state, and one is the empty string, then the canonical keyword will be the conforming keyword that is not the empty string.
- Otherwise, the canonical keyword for the state will be explicitly given in the specification for the attribute.

2.3.4 Numbers §p78

2.3.4.1 Signed integers §p78

A string is a **valid integer** if it consists of one or more ASCII digits, optionally prefixed with a U+002D HYPHEN-MINUS character (-).

A valid integer[p78] without a U+002D HYPHEN-MINUS (-) prefix represents the number that is represented in base ten by that string of digits. A valid integer[p78] *with* a U+002D HYPHEN-MINUS (-) prefix represents the number represented in base ten by the string of digits that follows the U+002D HYPHEN-MINUS, subtracted from zero.

The **rules for parsing integers** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either an integer or an error.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *sign* have the value "positive".
4. Skip ASCII whitespace within *input* given *position*.
5. If *position* is past the end of *input*, return an error.
6. If the character indicated by *position* (the first character) is a U+002D HYPHEN-MINUS character (-):
    1. Let *sign* be "negative".
    2. Advance *position* to the next character.
    3. If *position* is past the end of *input*, return an error.

    Otherwise, if the character indicated by *position* (the first character) is a U+002B PLUS SIGN character (+):
    1. Advance *position* to the next character. (The "+" is ignored, but it is not conforming.)
    2. If *position* is past the end of *input*, return an error.
7. If the character indicated by *position* is not an ASCII digit, then return an error.
8. Collect a sequence of code points that are ASCII digits from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Let *value* be that integer.
9. If *sign* is "positive", return *value*, otherwise return the result of subtracting *value* from zero.

2.3.4.2 Non-negative integers §p78

A string is a **valid non-negative integer** if it consists of one or more ASCII digits.

A valid non-negative integer[p78] represents the number that is represented in base ten by that string of digits.

The **rules for parsing non-negative integers** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either zero, a positive integer, or an error.

1. Let *input* be the string being parsed.
2. Let *value* be the result of parsing *input* using the rules for parsing integers[p78].
3. If *value* is an error, return an error.
4. If *value* is less than zero, return an error.
5. Return *value*.

2.3.4.3 Floating-point numbers §p78

A string is a **valid floating-point number** if it consists of:

1. Optionally, a U+002D HYPHEN-MINUS character (-).
2. One or both of the following, in the given order:
    1. A series of one or more ASCII digits.
    2. Both of the following, in the given order:
        1. A single U+002E FULL STOP character (.).
        2. A series of one or more ASCII digits.
3. Optionally:
    1. Either a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E).
    2. Optionally, a U+002D HYPHEN-MINUS character (-) or U+002B PLUS SIGN character (+).
    3. A series of one or more ASCII digits.

A valid floating-point number[p78] represents the number obtained by multiplying the significand by ten raised to the power of the exponent, where the significand is the first number, interpreted as base ten (including the decimal point and the number after the decimal point, if any, and interpreting the significand as a negative number if the whole string starts with a U+002D HYPHEN-MINUS character (-) and the number is not zero), and where the exponent is the number after the E, if any (interpreted as a negative number if there is a U+002D HYPHEN-MINUS character (-) between the E and the number and the number is not zero, or else ignoring a U+002B PLUS SIGN character (+) between the E and the number if there is one). If there is no E, then the exponent is treated as zero.

Note

The Infinity and Not-a-Number (NaN) values are not valid floating-point numbers[p78].

Note

The valid floating-point number[p78] concept is typically only used to restrict what is allowed for authors, while the user agent requirements use the rules for parsing floating-point number values[p79] below (e.g., the `max`[p591] attribute of the `progress`[p590] element). However, in some cases the user agent requirements include checking if a string is a valid floating-point number[p78] (e.g., the value sanitization algorithm[p526] for the Number[p538] state of the `input`[p521] element, or the parse a srcset attribute[p374] algorithm).

The **best representation of the number *n* as a floating-point number** is the string obtained from running ToString(*n*). The abstract operation ToString is not uniquely determined. When there are multiple possible strings that could be obtained from ToString for a particular value, the user agent must always return the same string for that value (though it may differ from the value used by other user agents).

The **rules for parsing floating-point number values** are as given in the following algorithm. This algorithm must be aborted at the first step that returns something. This algorithm will return either a number or an error.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *value* have the value 1.
4. Let *divisor* have the value 1.
5. Let *exponent* have the value 1.
6. Skip ASCII whitespace within *input* given *position*.
7. If *position* is past the end of *input*, return an error.
8. If the character indicated by *position* is a U+002D HYPHEN-MINUS character (-):
    1. Change *value* and *divisor* to −1.
    2. Advance *position* to the next character.
    3. If *position* is past the end of *input*, return an error.

    Otherwise, if the character indicated by *position* (the first character) is a U+002B PLUS SIGN character (+):

1. Advance *position* to the next character. (The "+" is ignored, but it is not conforming.)
2. If *position* is past the end of *input*, return an error.

9. If the character indicated by *position* is a U+002E FULL STOP (.), and that is not the last character in *input*, and the character after the character indicated by *position* is an ASCII digit, then set *value* to zero and jump to the step labeled *fraction*.
10. If the character indicated by *position* is not an ASCII digit, then return an error.
11. Collect a sequence of code points that are ASCII digits from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Multiply *value* by that integer.
12. If *position* is past the end of *input*, jump to the step labeled *conversion*.
13. *Fraction*: If the character indicated by *position* is a U+002E FULL STOP (.), run these substeps:
    1. Advance *position* to the next character.
    2. If *position* is past the end of *input*, or if the character indicated by *position* is not an ASCII digit, U+0065 LATIN SMALL LETTER E (e), or U+0045 LATIN CAPITAL LETTER E (E), then jump to the step labeled *conversion*.
    3. If the character indicated by *position* is a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E), skip the remainder of these substeps.
    4. *Fraction loop*: Multiply *divisor* by ten.
    5. Add the value of the character indicated by *position*, interpreted as a base-ten digit (0..9) and divided by *divisor*, to *value*.
    6. Advance *position* to the next character.
    7. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
    8. If the character indicated by *position* is an ASCII digit, jump back to the step labeled *fraction loop* in these substeps.
14. If the character indicated by *position* is U+0065 (e) or a U+0045 (E), then:
    1. Advance *position* to the next character.
    2. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
    3. If the character indicated by *position* is a U+002D HYPHEN-MINUS character (-):
        1. Change *exponent* to −1.
        2. Advance *position* to the next character.
        3. If *position* is past the end of *input*, then jump to the step labeled *conversion*.

       Otherwise, if the character indicated by *position* is a U+002B PLUS SIGN character (+):
        1. Advance *position* to the next character.
        2. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
    4. If the character indicated by *position* is not an ASCII digit, then jump to the step labeled *conversion*.
    5. Collect a sequence of code points that are ASCII digits from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Multiply *exponent* by that integer.
    6. Multiply *value* by ten raised to the *exponent*th power.
15. *Conversion*: Let *S* be the set of finite IEEE 754 double-precision floating-point values except −0, but with two special values added: 2^{1024} and -2^{1024}.
16. Let *rounded-value* be the number in *S* that is closest to *value*, selecting the number with an even significand if there are two equally close values. (The two special values 2^{1024} and -2^{1024} are considered to have even significands for this purpose.)
17. If *rounded-value* is 2^{1024} or -2^{1024}, return an error.
18. Return *rounded-value*.

2.3.4.4 Percentages and lengths §[p81]

The **rules for parsing dimension values** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a number greater than or equal to 0.0, or failure; if a number is returned, then it is further categorized as either a percentage or a length.

1. Let *input* be the string being parsed.
2. Let *position* be a position variable for *input*, initially pointing at the start of *input*.
3. Skip ASCII whitespace within *input* given *position*.
4. If *position* is past the end of *input* or the code point at *position* within *input* is not an ASCII digit, then return failure.
5. Collect a sequence of code points that are ASCII digits from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Let *value* be that number.
6. If *position* is past the end of *input*, then return *value* as a length.
7. If the code point at *position* within *input* is U+002E (.), then:
    1. Advance *position* by 1.
    2. If *position* is past the end of *input* or the code point at *position* within *input* is not an ASCII digit, then return the current dimension value[p81] with *value*, *input*, and *position*.
    3. Let *divisor* have the value 1.
    4. While true:
        1. Multiply *divisor* by ten.
        2. Add the value of the code point at *position* within *input*, interpreted as a base-ten digit (0..9) and divided by *divisor*, to *value*.
        3. Advance *position* by 1.
        4. If *position* is past the end of *input*, then return *value* as a length.
        5. If the code point at *position* within *input* is not an ASCII digit, then break.
8. Return the current dimension value[p81] with *value*, *input*, and *position*.

The **current dimension value**, given *value*, *input*, and *position*, is determined as follows:

1. If *position* is past the end of *input*, then return *value* as a length.
2. If the code point at *position* within *input* is U+0025 (%), then return *value* as a percentage.
3. Return *value* as a length.

2.3.4.5 Nonzero percentages and lengths §[p81]

The **rules for parsing nonzero dimension values** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a number greater than 0.0, or an error; if a number is returned, then it is further categorized as either a percentage or a length.

1. Let *input* be the string being parsed.
2. Let *value* be the result of parsing *input* using the rules for parsing dimension values[p81].
3. If *value* is an error, return an error.
4. If *value* is zero, return an error.
5. If *value* is a percentage, return *value* as a percentage.
6. Return *value* as a length.

2.3.4.6 Lists of floating-point numbers §[p82]

A **valid list of floating-point numbers** is a number of valid floating-point numbers[p78] separated by U+002C COMMA characters, with no other characters (e.g. no ASCII whitespace). In addition, there might be restrictions on the number of floating-point numbers that can be given, or on the range of values allowed.

The **rules for parsing a list of floating-point numbers** are as follows:

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *numbers* be an initially empty list of floating-point numbers. This list will be the result of this algorithm.
4. Collect a sequence of code points that are ASCII whitespace, U+002C COMMA, or U+003B SEMICOLON characters from *input* given *position*. This skips past any leading delimiters.
5. While *position* is not past the end of *input*:
    1. Collect a sequence of code points that are not ASCII whitespace, U+002C COMMA, U+003B SEMICOLON, ASCII digits, U+002E FULL STOP, or U+002D HYPHEN-MINUS characters from *input* given *position*. This skips past leading garbage.
    2. Collect a sequence of code points that are not ASCII whitespace, U+002C COMMA, or U+003B SEMICOLON characters from *input* given *position*, and let *unparsed number* be the result.
    3. Let *number* be the result of parsing *unparsed number* using the rules for parsing floating-point number values[p79].
    4. If *number* is an error, set *number* to zero.
    5. Append *number* to *numbers*.
    6. Collect a sequence of code points that are ASCII whitespace, U+002C COMMA, or U+003B SEMICOLON characters from *input* given *position*. This skips past the delimiter.
6. Return *numbers*.

2.3.4.7 Lists of dimensions §[p82]

The **rules for parsing a list of dimensions** are as follows. These rules return a list of zero or more pairs consisting of a number and a unit, the unit being one of *percentage*, *relative*, and *absolute*.

1. Let *raw input* be the string being parsed.
2. If the last character in *raw input* is a U+002C COMMA character (,), then remove that character from *raw input*.
3. Split the string *raw input* on commas. Let *raw tokens* be the resulting list of tokens.
4. Let *result* be an empty list of number/unit pairs.
5. For each token in *raw tokens*, run the following substeps:
    1. Let *input* be the token.
    2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
    3. Let *value* be the number 0.
    4. Let *unit* be *absolute*.
    5. If *position* is past the end of *input*, set *unit* to *relative* and jump to the last substep.
    6. If the character at *position* is an ASCII digit, collect a sequence of code points that are ASCII digits from *input* given *position*, interpret the resulting sequence as an integer in base ten, and increment *value* by that integer.
    7. If the character at *position* is U+002E (.), then:
        1. Collect a sequence of code points consisting of ASCII whitespace and ASCII digits from *input* given *position*. Let *s* be the resulting sequence.

2. Remove all ASCII whitespace in *s*.
3. If *s* is not the empty string, then:
    1. Let *length* be the number of characters in *s* (after the spaces were removed).
    2. Let *fraction* be the result of interpreting *s* as a base-ten integer, and then dividing that number by 10^{length}.
    3. Increment *value* by *fraction*.

8. Skip ASCII whitespace within *input* given *position*.
9. If the character at *position* is a U+0025 PERCENT SIGN character (%), then set *unit* to *percentage*.

    Otherwise, if the character at *position* is a U+002A ASTERISK character (*), then set *unit* to *relative*.
10. Add an entry to *result* consisting of the number given by *value* and the unit given by *unit*.

6. Return the list *result*.

2.3.5 Dates and times §[p83]

In the algorithms below, the **number of days in month *month* of year *year*** is: *31* if *month* is 1, 3, 5, 7, 8, 10, or 12; *30* if *month* is 4, 6, 9, or 11; *29* if *month* is 2 and *year* is a number divisible by 400, or if *year* is a number divisible by 4 but not by 100; and *28* otherwise. This takes into account leap years in the Gregorian calendar. [GREGORIAN][p1496]

When ASCII digits are used in the date and time syntaxes defined in this section, they express numbers in base ten.

Note

While the formats described here are intended to be subsets of the corresponding ISO8601 formats, this specification defines parsing rules in much more detail than ISO8601. Implementers are therefore encouraged to carefully examine any date parsing libraries before using them to implement the parsing rules described below; ISO8601 libraries might not parse dates and times in exactly the same manner. [ISO8601][p1497]

Where this specification refers to the **proleptic Gregorian calendar**, it means the modern Gregorian calendar, extrapolated backwards to year 1. A date in the proleptic Gregorian calendar[p83], sometimes explicitly referred to as a **proleptic-Gregorian date**, is one that is described using that calendar even if that calendar was not in use at the time (or place) in question. [GREGORIAN][p1496]

Note

The use of the Gregorian calendar as the wire format in this specification is an arbitrary choice resulting from the cultural biases of those involved in the decision. See also the section discussing date, time, and number formats[p514] in forms (for authors), implementation notes regarding localization of form controls[p552], and the `time`[p280] element.

2.3.5.1 Months §[p83]

A **month** consists of a specific proleptic-Gregorian date[p83] with no time-zone information and no date information beyond a year and a month. [GREGORIAN][p1496]

A string is a **valid month string** representing a year *year* and month *month* if it consists of the following components in the given order:

1. Four or more ASCII digits, representing *year*, where *year* > 0
2. A U+002D HYPHEN-MINUS character (-)
3. Two ASCII digits, representing the month *month*, in the range 1 ≤ *month* ≤ 12

The rules to **parse a month string** are as follows. This will return either a year and month, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Parse a month component[p84] to obtain *year* and *month*. If this returns nothing, then fail.
4. If *position* is *not* beyond the end of *input*, then fail.
5. Return *year* and *month*.

The rules to **parse a month component**, given an *input* string and a *position*, are as follows. This will return either a year and a month, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not at least four characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *year* be that number.
2. If *year* is not a number greater than zero, then fail.
3. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
4. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *month* be that number.
5. If *month* is not a number in the range 1 ≤ *month* ≤ 12, then fail.
6. Return *year* and *month*.

2.3.5.2 Dates §[p84]

A **date** consists of a specific proleptic-Gregorian date[p83] with no time-zone information, consisting of a year, a month, and a day. [GREGORIAN][p1496]

A string is a **valid date string** representing a year *year*, month *month*, and day *day* if it consists of the following components in the given order:

1. A valid month string[p83], representing *year* and *month*
2. A U+002D HYPHEN-MINUS character (-)
3. Two ASCII digits, representing *day*, in the range 1 ≤ *day* ≤ *maxday* where *maxday* is the number of days in the month *month* and year *year*[p83]

The rules to **parse a date string** are as follows. This will return either a date, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Parse a date component[p84] to obtain *year*, *month*, and *day*. If this returns nothing, then fail.
4. If *position* is *not* beyond the end of *input*, then fail.
5. Let *date* be the date with year *year*, month *month*, and day *day*.
6. Return *date*.

The rules to **parse a date component**, given an *input* string and a *position*, are as follows. This will return either a year, a month, and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Parse a month component[p84] to obtain *year* and *month*. If this returns nothing, then fail.
2. Let *maxday* be the number of days in month *month* of year *year*[p83].
3. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.

4. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *day* be that number.
5. If *day* is not a number in the range 1 ≤ *day* ≤ *maxday*, then fail.
6. Return *year*, *month*, and *day*.

2.3.5.3 Yearless dates §[p85]

A **yearless date** consists of a Gregorian month and a day within that month, but with no associated year. [GREGORIAN][p1496]

A string is a **valid yearless date string** representing a month *month* and a day *day* if it consists of the following components in the given order:

1. Optionally, two U+002D HYPHEN-MINUS characters (-)
2. Two ASCII digits, representing the month *month*, in the range 1 ≤ *month* ≤ 12
3. A U+002D HYPHEN-MINUS character (-)
4. Two ASCII digits, representing *day*, in the range 1 ≤ *day* ≤ *maxday* where *maxday* is the number of days[p83] in the month *month* and any arbitrary leap year (e.g. 4 or 2000)

Note

In other words, if the month *is* "02"*, meaning February, then the day can be 29, as if the year was a leap year.*

The rules to **parse a yearless date string** are as follows. This will return either a month and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Parse a yearless date component[p85] to obtain *month* and *day*. If this returns nothing, then fail.
4. If *position* is *not* beyond the end of *input*, then fail.
5. Return *month* and *day*.

The rules to **parse a yearless date component**, given an *input* string and a *position*, are as follows. This will return either a month and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Collect a sequence of code points that are U+002D HYPHEN-MINUS characters (-) from *input* given *position*. If the collected sequence is not exactly zero or two characters long, then fail.
2. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *month* be that number.
3. If *month* is not a number in the range 1 ≤ *month* ≤ 12, then fail.
4. Let *maxday* be the number of days[p83] in month *month* of any arbitrary leap year (e.g. 4 or 2000).
5. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
6. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *day* be that number.
7. If *day* is not a number in the range 1 ≤ *day* ≤ *maxday*, then fail.
8. Return *month* and *day*.

2.3.5.4 Times §[p86]

A **time** consists of a specific time with no time-zone information, consisting of an hour, a minute, a second, and a fraction of a second.

A string is a **valid time string** representing an hour *hour*, a minute *minute*, and a second *second* if it consists of the following components in the given order:

1. Two ASCII digits, representing *hour*, in the range 0 ≤ *hour* ≤ 23
2. A U+003A COLON character (:)
3. Two ASCII digits, representing *minute*, in the range 0 ≤ *minute* ≤ 59
4. If *second* is nonzero, or optionally if *second* is zero:
    1. A U+003A COLON character (:)
    2. Two ASCII digits, representing the integer part of *second*, in the range 0 ≤ *s* ≤ 59
    3. If *second* is not an integer, or optionally if *second* is an integer:
        1. A U+002E FULL STOP character (.)
        2. One, two, or three ASCII digits, representing the fractional part of *second*

Note

The second *component cannot be 60 or 61; leap seconds cannot be represented.*

The rules to **parse a time string** are as follows. This will return either a time, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Parse a time component[p86] to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
4. If *position* is *not* beyond the end of *input*, then fail.
5. Let *time* be the time with hour *hour*, minute *minute*, and second *second*.
6. Return *time*.

The rules to **parse a time component**, given an *input* string and a *position*, are as follows. This will return either an hour, a minute, and a second, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *hour* be that number.
2. If *hour* is not a number in the range 0 ≤ *hour* ≤ 23, then fail.
3. If *position* is beyond the end of *input* or if the character at *position* is not a U+003A COLON character, then fail. Otherwise, move *position* forwards one character.
4. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *minute* be that number.
5. If *minute* is not a number in the range 0 ≤ *minute* ≤ 59, then fail.
6. Let *second* be 0.
7. If *position* is not beyond the end of *input* and the character at *position* is U+003A (:), then:
    1. Advance *position* to the next character in *input*.
    2. If *position* is beyond the end of *input*, or at the last character in *input*, or if the next *two* characters in *input* starting at *position* are not both ASCII digits, then fail.
    3. Collect a sequence of code points that are either ASCII digits or U+002E FULL STOP characters from *input* given *position*. If the collected sequence is three characters long, or if it is longer than three characters long and the third character is not a U+002E FULL STOP character, or if it has more than one U+002E FULL STOP character, then fail. Otherwise, interpret the resulting sequence as a base-ten number (possibly with a fractional part). Set *second* to

that number.

4. If *second* is not a number in the range 0 ≤ *second* < 60, then fail.

8. Return *hour*, *minute*, and *second*.

2.3.5.5 Local dates and times §[p87]

A **local date and time** consists of a specific proleptic-Gregorian date[p83], consisting of a year, a month, and a day, and a time, consisting of an hour, a minute, a second, and a fraction of a second, but expressed without a time zone. [GREGORIAN][p1496]

A string is a **valid local date and time string** representing a date and time if it consists of the following components in the given order:

1. A valid date string[p84] representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character
3. A valid time string[p86] representing the time

A string is a **valid normalized local date and time string** representing a date and time if it consists of the following components in the given order:

1. A valid date string[p84] representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T)
3. A valid time string[p86] representing the time, expressed as the shortest possible string for the given time (e.g. omitting the seconds component entirely if the given time is zero seconds past the minute)

The rules to **parse a local date and time string** are as follows. This will return either a date and time, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Parse a date component[p84] to obtain *year*, *month*, and *day*. If this returns nothing, then fail.
4. If *position* is beyond the end of *input* or if the character at *position* is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then fail. Otherwise, move *position* forwards one character.
5. Parse a time component[p86] to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
6. If *position* is *not* beyond the end of *input*, then fail.
7. Let *date* be the date with year *year*, month *month*, and day *day*.
8. Let *time* be the time with hour *hour*, minute *minute*, and second *second*.
9. Return *date* and *time*.

2.3.5.6 Time zones §[p87]

A **time-zone offset** consists of a signed number of hours and minutes.

A string is a **valid time-zone offset string** representing a time-zone offset if it consists of either:

- A U+005A LATIN CAPITAL LETTER Z character (Z), allowed only if the time zone is UTC
- Or, the following components, in the given order:
    1. Either a U+002B PLUS SIGN character (+) or, if the time-zone offset is not zero, a U+002D HYPHEN-MINUS character (-), representing the sign of the time-zone offset
    2. Two ASCII digits, representing the hours component *hour* of the time-zone offset, in the range 0 ≤ *hour* ≤ 23

3. Optionally, a U+003A COLON character (:)
4. Two ASCII digits, representing the minutes component *minute* of the time-zone offset, in the range 0 ≤ *minute* ≤ 59

Note

This format allows for time-zone offsets from -23:59 to +23:59. Right now, in practice, the range of offsets of actual time zones is -12:00 to +14:00, and the minutes component of offsets of actual time zones is always either 00, 30, or 45. There is no guarantee that this will remain so forever, however, since time zones are used as political footballs and are thus subject to very whimsical policy decisions.

Note

See also the usage notes and examples in the global date and time[p89] section below for details on using time-zone offsets with historical times that predate the formation of formal time zones.

The rules to **parse a time-zone offset string** are as follows. This will return either a time-zone offset, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Parse a time-zone offset component[p88] to obtain $timezone_{hours}$ and $timezone_{minutes}$. If this returns nothing, then fail.
4. If *position* is *not* beyond the end of *input*, then fail.
5. Return the time-zone offset that is $timezone_{hours}$ hours and $timezone_{minutes}$ minutes from UTC.

The rules to **parse a time-zone offset component**, given an *input* string and a *position*, are as follows. This will return either time-zone hours and time-zone minutes, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. If the character at *position* is a U+005A LATIN CAPITAL LETTER Z character (Z), then:
    1. Let $timezone_{hours}$ be 0.
    2. Let $timezone_{minutes}$ be 0.
    3. Advance *position* to the next character in *input*.

    Otherwise, if the character at *position* is either a U+002B PLUS SIGN (+) or a U+002D HYPHEN-MINUS (-), then:

    1. If the character at *position* is a U+002B PLUS SIGN (+), let *sign* be "positive". Otherwise, it's a U+002D HYPHEN-MINUS (-); let *sign* be "negative".
    2. Advance *position* to the next character in *input*.
    3. Collect a sequence of code points that are ASCII digits from *input* given *position*. Let *s* be the collected sequence.
    4. If *s* is exactly two characters long, then:
        1. Interpret *s* as a base-ten integer. Let $timezone_{hours}$ be that number.
        2. If *position* is beyond the end of *input* or if the character at *position* is not a U+003A COLON character, then fail. Otherwise, move *position* forwards one character.
        3. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let $timezone_{minutes}$ be that number.

    If *s* is exactly four characters long, then:

    1. Interpret the first two characters of *s* as a base-ten integer. Let $timezone_{hours}$ be that number.
    2. Interpret the last two characters of *s* as a base-ten integer. Let $timezone_{minutes}$ be that number.

    Otherwise, fail.
5. If $timezone_{hours}$ is not a number in the range 0 ≤ $timezone_{hours}$ ≤ 23, then fail.

6. If *sign* is "negative", then negate $timezone_{hours}$.
7. If $timezone_{minutes}$ is not a number in the range $0 \leq timezone_{minutes} \leq 59$, then fail.
8. If *sign* is "negative", then negate $timezone_{minutes}$.

Otherwise, fail.

2. Return $timezone_{hours}$ and $timezone_{minutes}$.

2.3.5.7 Global dates and times §[p89]

A **global date and time** consists of a specific proleptic-Gregorian date[p83], consisting of a year, a month, and a day, and a time, consisting of an hour, a minute, a second, and a fraction of a second, expressed with a time-zone offset, consisting of a signed number of hours and minutes. [GREGORIAN][p1496]

A string is a **valid global date and time string** representing a date, time, and a time-zone offset if it consists of the following components in the given order:

1. A valid date string[p84] representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character
3. A valid time string[p86] representing the time
4. A valid time-zone offset string[p87] representing the time-zone offset

Times in dates before the formation of UTC in the mid-twentieth century must be expressed and interpreted in terms of UT1 (contemporary Earth solar time at the 0° longitude), not UTC (the approximation of UT1 that ticks in SI seconds). Time before the formation of time zones must be expressed and interpreted as UT1 times with explicit time zones that approximate the contemporary difference between the appropriate local time and the time observed at the location of Greenwich, London.

Example

The following are some examples of dates written as valid global date and time strings[p89].

"0037-12-13 00:00Z"
Midnight in areas using London time on the birthday of Nero (the Roman Emperor). See below for further discussion on which date this actually corresponds to.

"1979-10-14T12:00:00.001-04:00"
One millisecond after noon on October 14th 1979, in the time zone in use on the east coast of the USA during daylight saving time.

"8592-01-01T02:09+02:09"
Midnight UTC on the 1st of January, 8592. The time zone associated with that time is two hours and nine minutes ahead of UTC, which is not currently a real time zone, but is nonetheless allowed.

Several things are notable about these dates:

- Years with fewer than four digits have to be zero-padded. The date "37-12-13" would not be a valid date.
- If the "T" is replaced by a space, it must be a single space character. The string "2001-12-21 12:00Z" (with two spaces between the components) would not be parsed successfully.
- To unambiguously identify a moment in time prior to the introduction of the Gregorian calendar (insofar as moments in time before the formation of UTC can be unambiguously identified), the date has to be first converted to the Gregorian calendar from the calendar in use at the time (e.g. from the Julian calendar). The date of Nero's birth is the 15th of December 37, in the Julian Calendar, which is the 13th of December 37 in the proleptic Gregorian calendar[p83].
- The time and time-zone offset components are not optional.
- Dates before the year one can't be represented as a datetime in this version of HTML.
- Times of specific events in ancient times are, at best, approximations, since time was not well coordinated or measured

until relatively recent decades.

- Time-zone offsets differ based on daylight saving time.

The rules to **parse a global date and time string** are as follows. This will return either a time in UTC, with associated time-zone offset information for round-tripping or display purposes, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Parse a date component[p84] to obtain *year*, *month*, and *day*. If this returns nothing, then fail.
4. If *position* is beyond the end of *input* or if the character at *position* is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then fail. Otherwise, move *position* forwards one character.
5. Parse a time component[p86] to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
6. If *position* is beyond the end of *input*, then fail.
7. Parse a time-zone offset component[p88] to obtain $timezone_{hours}$ and $timezone_{minutes}$. If this returns nothing, then fail.
8. If *position* is *not* beyond the end of *input*, then fail.
9. Let *time* be the moment in time at year *year*, month *month*, day *day*, hours *hour*, minute *minute*, second *second*, subtracting $timezone_{hours}$ hours and $timezone_{minutes}$ minutes. That moment in time is a moment in the UTC time zone.
10. Let *timezone* be $timezone_{hours}$ hours and $timezone_{minutes}$ minutes from UTC.
11. Return *time* and *timezone*.

2.3.5.8 Weeks §[p90]

A **week** consists of a week-year number and a week number representing a seven-day period starting on a Monday. Each week-year in this calendaring system has either 52 or 53 such seven-day periods, as defined below. The seven-day period starting on the Gregorian date Monday December 29th 1969 (1969-12-29) is defined as week number 1 in week-year 1970. Consecutive weeks are numbered sequentially. The week before the number 1 week in a week-year is the last week in the previous week-year, and vice versa. [GREGORIAN][p1496]

A week-year with a number *year* has 53 weeks if it corresponds to either a year *year* in the proleptic Gregorian calendar[p83] that has a Thursday as its first day (January 1st), or a year *year* in the proleptic Gregorian calendar[p83] that has a Wednesday as its first day (January 1st) and where *year* is a number divisible by 400, or a number divisible by 4 but not by 100. All other week-years have 52 weeks.

The **week number of the last day** of a week-year with 53 weeks is 53; the week number of the last day of a week-year with 52 weeks is 52.

Note

The week-year number of a particular day can be different than the number of the year that contains that day in the proleptic Gregorian calendar[p83]. The first week in a week-year y is the week that contains the first Thursday of the Gregorian year y.

Note

For modern purposes, a week[p90] as defined here is equivalent to ISO weeks as defined in ISO 8601. [ISO8601][p1497]

A string is a **valid week string** representing a week-year *year* and week *week* if it consists of the following components in the given order:

1. Four or more ASCII digits, representing *year*, where *year* > 0
2. A U+002D HYPHEN-MINUS character (-)

3. A U+0057 LATIN CAPITAL LETTER W character (W)
4. Two ASCII digits, representing the week *week*, in the range 1 ≤ *week* ≤ *maxweek*, where *maxweek* is the week number of the last day[p90] of week-year *year*

The rules to **parse a week string** are as follows. This will return either a week-year number and week number, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not at least four characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *year* be that number.
4. If *year* is not a number greater than zero, then fail.
5. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
6. If *position* is beyond the end of *input* or if the character at *position* is not a U+0057 LATIN CAPITAL LETTER W character (W), then fail. Otherwise, move *position* forwards one character.
7. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let *week* be that number.
8. Let *maxweek* be the week number of the last day[p90] of year *year*.
9. If *week* is not a number in the range 1 ≤ *week* ≤ *maxweek*, then fail.
10. If *position* is *not* beyond the end of *input*, then fail.
11. Return the week-year number *year* and the week number *week*.

2.3.5.9 Durations §[p91]

A **duration** consists of a number of seconds.

Note

Since months and seconds are not comparable (a month is not a precise number of seconds, but is instead a period whose exact length depends on the precise day from which it is measured) a duration[p91] as defined in this specification cannot include months (or years, which are equivalent to twelve months). Only durations that describe a specific number of seconds can be described.

A string is a **valid duration string** representing a duration[p91] *t* if it consists of either of the following:

- A literal U+0050 LATIN CAPITAL LETTER P character followed by one or more of the following subcomponents, in the order given, where the number of days, hours, minutes, and seconds corresponds to the same number of seconds as in *t*:
    1. One or more ASCII digits followed by a U+0044 LATIN CAPITAL LETTER D character, representing a number of days.
    2. A U+0054 LATIN CAPITAL LETTER T character followed by one or more of the following subcomponents, in the order given:
        1. One or more ASCII digits followed by a U+0048 LATIN CAPITAL LETTER H character, representing a number of hours.
        2. One or more ASCII digits followed by a U+004D LATIN CAPITAL LETTER M character, representing a number of minutes.
        3. The following components:
            1. One or more ASCII digits, representing a number of seconds.
            2. Optionally, a U+002E FULL STOP character (.) followed by one, two, or three ASCII digits, representing a fraction of a second.
            3. A U+0053 LATIN CAPITAL LETTER S character.

Note

This, as with a number of other date- and time-related microsyntaxes defined in this specification, is based on one of the formats defined in ISO 8601. [ISO8601][p1497]

- One or more duration time components[p92], each with a different duration time component scale[p92], in any order; the sum of the represented seconds being equal to the number of seconds in *t*.

  A **duration time component** is a string consisting of the following components:

  1. Zero or more ASCII whitespace.
  2. One or more ASCII digits, representing a number of time units, scaled by the duration time component scale[p92] specified (see below) to represent a number of seconds.
  3. If the duration time component scale[p92] specified is 1 (i.e. the units are seconds), then, optionally, a U+002E FULL STOP character (.) followed by one, two, or three ASCII digits, representing a fraction of a second.
  4. Zero or more ASCII whitespace.
  5. One of the following characters, representing the **duration time component scale** of the time unit used in the numeric part of the duration time component[p92]:

     U+0057 LATIN CAPITAL LETTER W character
     U+0077 LATIN SMALL LETTER W character
     Weeks. The scale is 604800.

     U+0044 LATIN CAPITAL LETTER D character
     U+0064 LATIN SMALL LETTER D character
     Days. The scale is 86400.

     U+0048 LATIN CAPITAL LETTER H character
     U+0068 LATIN SMALL LETTER H character
     Hours. The scale is 3600.

     U+004D LATIN CAPITAL LETTER M character
     U+006D LATIN SMALL LETTER M character
     Minutes. The scale is 60.

     U+0053 LATIN CAPITAL LETTER S character
     U+0073 LATIN SMALL LETTER S character
     Seconds. The scale is 1.

  6. Zero or more ASCII whitespace.

Note

This is not based on any of the formats in ISO 8601. It is intended to be a more human-readable alternative to the ISO 8601 duration format.

The rules to **parse a duration string** are as follows. This will return either a duration[p91] or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *months*, *seconds*, and *component count* all be zero.
4. Let *M-disambiguator* be *minutes*.

   Note

   This flag's other value is months*. It is used to disambiguate the "M" unit in ISO8601 durations, which use the same unit for months and minutes. Months are not allowed, but are parsed for future compatibility and to avoid misinterpreting ISO8601 durations that would be valid in other contexts.*

5. Skip ASCII whitespace within *input* given *position*.

6. If *position* is past the end of *input*, then fail.
7. If the character in *input* pointed to by *position* is a U+0050 LATIN CAPITAL LETTER P character, then advance *position* to the next character, set *M-disambiguator* to *months*, and skip ASCII whitespace within *input* given *position*.
8. While true:
    1. Let *units* be undefined. It will be assigned one of the following values: *years*, *months*, *weeks*, *days*, *hours*, *minutes*, and *seconds*.
    2. Let *next character* be undefined. It is used to process characters from the *input*.
    3. If *position* is past the end of *input*, then break.
    4. If the character in *input* pointed to by *position* is a U+0054 LATIN CAPITAL LETTER T character, then advance *position* to the next character, set *M-disambiguator* to *minutes*, skip ASCII whitespace within *input* given *position*, and continue.
    5. Set *next character* to the character in *input* pointed to by *position*.
    6. If *next character* is a U+002E FULL STOP character (.), then let *N* be 0. (Do not advance *position*. That is taken care of below.)

       Otherwise, if *next character* is an ASCII digit, then collect a sequence of code points that are ASCII digits from *input* given *position*, interpret the resulting sequence as a base-ten integer, and let *N* be that number.

       Otherwise, *next character* is not part of a number; fail.
    7. If *position* is past the end of *input*, then fail.
    8. Set *next character* to the character in *input* pointed to by *position*, and this time advance *position* to the next character. (If *next character* was a U+002E FULL STOP character (.) before, it will still be that character this time.)
    9. If *next character* is U+002E (.), then:
        1. Collect a sequence of code points that are ASCII digits from *input* given *position*. Let *s* be the resulting sequence.
        2. If *s* is the empty string, then fail.
        3. Let *length* be the number of characters in *s*.
        4. Let *fraction* be the result of interpreting *s* as a base-ten integer, and then dividing that number by 10^{length}.
        5. Increment *N* by *fraction*.
        6. Skip ASCII whitespace within *input* given *position*.
        7. If *position* is past the end of *input*, then fail.
        8. Set *next character* to the character in *input* pointed to by *position*, and advance *position* to the next character.
        9. If *next character* is neither a U+0053 LATIN CAPITAL LETTER S character nor a U+0073 LATIN SMALL LETTER S character, then fail.
        10. Set *units* to *seconds*.

       Otherwise:
        1. If *next character* is ASCII whitespace, then skip ASCII whitespace within *input* given *position*, set *next character* to the character in *input* pointed to by *position*, and advance *position* to the next character.
        2. If *next character* is a U+0059 LATIN CAPITAL LETTER Y character, or a U+0079 LATIN SMALL LETTER Y character, set *units* to *years* and set *M-disambiguator* to *months*.

           If *next character* is a U+004D LATIN CAPITAL LETTER M character or a U+006D LATIN SMALL LETTER M character, and *M-disambiguator* is *months*, then set *units* to *months*.

           If *next character* is a U+0057 LATIN CAPITAL LETTER W character or a U+0077 LATIN SMALL LETTER W

character, set *units* to *weeks* and set *M-disambiguator* to *minutes*.

If *next character* is a U+0044 LATIN CAPITAL LETTER D character or a U+0064 LATIN SMALL LETTER D character, set *units* to *days* and set *M-disambiguator* to *minutes*.

If *next character* is a U+0048 LATIN CAPITAL LETTER H character or a U+0068 LATIN SMALL LETTER H character, set *units* to *hours* and set *M-disambiguator* to *minutes*.

If *next character* is a U+004D LATIN CAPITAL LETTER M character or a U+006D LATIN SMALL LETTER M character, and *M-disambiguator* is *minutes*, then set *units* to *minutes*.

If *next character* is a U+0053 LATIN CAPITAL LETTER S character or a U+0073 LATIN SMALL LETTER S character, set *units* to *seconds* and set *M-disambiguator* to *minutes*.

Otherwise, if *next character* is none of the above characters, then fail.

10. Increment *component count*.
11. Let *multiplier* be 1.
12. If *units* is *years*, multiply *multiplier* by 12 and set *units* to *months*.
13. If *units* is *months*, add the product of *N* and *multiplier* to *months*.

    Otherwise:

    1. If *units* is *weeks*, multiply *multiplier* by 7 and set *units* to *days*.
    2. If *units* is *days*, multiply *multiplier* by 24 and set *units* to *hours*.
    3. If *units* is *hours*, multiply *multiplier* by 60 and set *units* to *minutes*.
    4. If *units* is *minutes*, multiply *multiplier* by 60 and set *units* to *seconds*.
    5. Forcibly, *units* is now *seconds*. Add the product of *N* and *multiplier* to *seconds*.
14. Skip ASCII whitespace within *input* given *position*.

9. If *component count* is zero, fail.
10. If *months* is not zero, fail.
11. Return the duration[p91] consisting of *seconds* seconds.

2.3.5.10 Vaguer moments in time §[p94]

A string is a **valid date string with optional time** if it is also one of the following:

- A valid date string[p84]
- A valid global date and time string[p89]

The rules to **parse a date or time string** are as follows. The algorithm will return either a date[p84], a time[p86], a global date and time[p89], or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Set *start position* to the same position as *position*.
4. Set the *date present* and *time present* flags to true.
5. Parse a date component[p84] to obtain *year*, *month*, and *day*. If this fails, then set the *date present* flag to false.
6. If *date present* is true, and *position* is not beyond the end of *input*, and the character at *position* is either a U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character, then advance *position* to the next character in *input*.

Otherwise, if *date present* is true, and either *position* is beyond the end of *input* or the character at *position* is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then set *time present* to false.

Otherwise, if *date present* is false, set *position* back to the same position as *start position*.

7. If the *time present* flag is true, then parse a time component[p86] to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
8. If the *date present* and *time present* flags are both true, but *position* is beyond the end of *input*, then fail.
9. If the *date present* and *time present* flags are both true, parse a time-zone offset component[p88] to obtain $timezone_{hours}$ and $timezone_{minutes}$. If this returns nothing, then fail.
10. If *position* is *not* beyond the end of *input*, then fail.
11. If the *date present* flag is true and the *time present* flag is false, then let *date* be the date with year *year*, month *month*, and day *day*, and return *date*.

    Otherwise, if the *time present* flag is true and the *date present* flag is false, then let *time* be the time with hour *hour*, minute *minute*, and second *second*, and return *time*.

    Otherwise, let *time* be the moment in time at year *year*, month *month*, day *day*, hours *hour*, minute *minute*, second *second*, subtracting $timezone_{hours}$ hours and $timezone_{minutes}$ minutes, that moment in time being a moment in the UTC time zone; let *timezone* be $timezone_{hours}$ hours and $timezone_{minutes}$ minutes from UTC; and return *time* and *timezone*.

2.3.6 Legacy colors §[p95]

Some obsolete legacy attributes parse colors using the **rules for parsing a legacy color value**, given a string *input*. They will return either a CSS color or failure.

1. If *input* is the empty string, then return failure.
2. Strip leading and trailing ASCII whitespace from *input*.
3. If *input* is an ASCII case-insensitive match for "`transparent`", then return failure.
4. If *input* is an ASCII case-insensitive match for one of the named colors, then return the CSS color corresponding to that keyword. [CSSCOLOR][p1494]

   Note

   CSS2 System Colors are not recognized.

5. If *input*'s code point length is four, and the first character in *input* is U+0023 (#), and the last three characters of *input* are all ASCII hex digits, then:
   1. Let *result* be a CSS color.
   2. Interpret the second character of *input* as a hexadecimal digit; let the red component of *result* be the resulting number multiplied by 17.
   3. Interpret the third character of *input* as a hexadecimal digit; let the green component of *result* be the resulting number multiplied by 17.
   4. Interpret the fourth character of *input* as a hexadecimal digit; let the blue component of *result* be the resulting number multiplied by 17.
   5. Return *result*.
6. Replace any code points greater than U+FFFF in *input* (i.e., any characters that are not in the basic multilingual plane) with "`00`".
7. If *input*'s code point length is greater than 128, truncate *input*, leaving only the first 128 characters.
8. If the first character in *input* is U+0023 (#), then remove it.
9. Replace any character in *input* that is not an ASCII hex digit with U+0030 (0).

10. While *input*'s code point length is zero or not a multiple of three, append U+0030 (0) to *input*.
11. Split *input* into three strings of equal code point length, to obtain three components. Let *length* be the code point length that all of those components have (one third the code point length of *input*).
12. If *length* is greater than 8, then remove the leading *length*-8 characters in each component, and let *length* be 8.
13. While *length* is greater than two and the first character in each component is U+0030 (0), remove that character and reduce *length* by one.
14. If *length* is *still* greater than two, truncate each component, leaving only the first two characters in each.
15. Let *result* be a CSS color.
16. Interpret the first component as a hexadecimal number; let the red component of *result* be the resulting number.
17. Interpret the second component as a hexadecimal number; let the green component of *result* be the resulting number.
18. Interpret the third component as a hexadecimal number; let the blue component of *result* be the resulting number.
19. Return *result*.

2.3.7 Space-separated tokens §[p96]

A **set of space-separated tokens** is a string containing zero or more words (known as tokens) separated by one or more ASCII whitespace, where words consist of any string of one or more characters, none of which are ASCII whitespace.

A string containing a set of space-separated tokens[p96] may have leading or trailing ASCII whitespace.

An **unordered set of unique space-separated tokens** is a set of space-separated tokens[p96] where none of the tokens are duplicated.

An **ordered set of unique space-separated tokens** is a set of space-separated tokens[p96] where none of the tokens are duplicated but where the order of the tokens is meaningful.

Sets of space-separated tokens[p96] sometimes have a defined set of allowed values. When a set of allowed values is defined, the tokens must all be from that list of allowed values; other values are non-conforming. If no such set of allowed values is provided, then all values are conforming.

Note

How tokens in a set of space-separated tokens[p96] are to be compared (e.g. case-sensitively or not) is defined on a per-set basis.

2.3.8 Comma-separated tokens §[p96]

A **set of comma-separated tokens** is a string containing zero or more tokens each separated from the next by a single U+002C COMMA character (,), where tokens consist of any string of zero or more characters, neither beginning nor ending with ASCII whitespace, nor containing any U+002C COMMA characters (,), and optionally surrounded by ASCII whitespace.

Example

For instance, the string `" a ,b,,d d "` consists of four tokens: "a", "b", the empty string, and "d d". Leading and trailing whitespace around each token doesn't count as part of the token, and the empty string can be a token.

Sets of comma-separated tokens[p96] sometimes have further restrictions on what consists a valid token. When such restrictions are defined, the tokens must all fit within those restrictions; other values are non-conforming. If no such restrictions are specified, then all values are conforming.

2.3.9 References §[p97]

A **valid hash-name reference** to an element of type *type* is a string consisting of a U+0023 NUMBER SIGN character (#) followed by a string which exactly matches the value of the `name` attribute of an element with type *type* in the same tree.

The **rules for parsing a hash-name reference** to an element of type *type*, given a context node *scope*, are as follows:

1. If the string being parsed does not contain a U+0023 NUMBER SIGN character, or if the first such character in the string is the last character in the string, then return null.
2. Let *s* be the string from the character immediately after the first U+0023 NUMBER SIGN character in the string being parsed up to the end of that string.
3. Return the first element of type *type* in *scope*'s tree, in tree order, that has an `id`[p156] or `name` attribute whose value is *s*, or null if there is no such element.

> **Note**
>
> *Although `id`[p156] attributes are accounted for when parsing, they are not used in determining whether a value is a valid hash-name reference[p97]. That is, a hash-name reference that refers to an element based on `id`[p156] is a conformance error (unless that element also has a `name` attribute with the same value).*

2.3.10 Media queries §[p97]

A string is a **valid media query list** if it matches the `<media-query-list>` production of *Media Queries*. [MQ][p1498]

A string **matches the environment** of the user if it is the empty string, a string consisting of only ASCII whitespace, or is a media query list that matches the user's environment according to the definitions given in *Media Queries*. [MQ][p1498]

2.3.11 Unique internal values §[p97]

A **unique internal value** is a value that is serializable, comparable by value, and never exposed to script.

To create a **new unique internal value**, return a unique internal value[p97] that has never previously been returned by this algorithm.

2.4 URLs §[p97]

2.4.1 Terminology §[p97]

A string is a **valid non-empty URL** if it is a valid URL string but it is not the empty string.

A string is a **valid URL potentially surrounded by spaces** if, after stripping leading and trailing ASCII whitespace from it, it is a valid URL string.

A string is a **valid non-empty URL potentially surrounded by spaces** if, after stripping leading and trailing ASCII whitespace from it, it is a valid non-empty URL[p97].

This specification defines the URL **`about:legacy-compat`** as a reserved, though unresolvable, `about:` URL, for use in DOCTYPE[p1277]s in HTML documents when needed for compatibility with XML tools. [ABOUT][p1493]

This specification defines the URL **`about:html-kind`** as a reserved, though unresolvable, `about:` URL, that is used as an identifier for kinds of media tracks. [ABOUT][p1493]

This specification defines the URL **`about:srcdoc`** as a reserved, though unresolvable, `about:` URL, that is used as the URL of `iframe srcdoc` documents[p392]. [ABOUT][p1493]

The **fallback base URL** of a `Document`[p131] object *document* is the URL record obtained by running these steps:

1. If *document* is an `iframe srcdoc` document[p392], then:

1. Assert: *document*'s about base URL[p132] is non-null.
2. Return *document*'s about base URL[p132].

2. If *document*'s URL matches about:blank[p98] and *document*'s about base URL[p132] is non-null, then return *document*'s about base URL[p132].
3. Return *document*'s URL.

The **document base URL** of a Document[p131] object is the URL record obtained by running these steps:

1. If there is no base[p176] element that has an href[p177] attribute in the Document[p131], then return the Document[p131]'s fallback base URL[p97].
2. Otherwise, return the frozen base URL[p177] of the first base[p176] element in the Document[p131] that has an href[p177] attribute, in tree order.

A URL **matches about:blank** if its scheme is "about", its path contains a single string "blank", its username and password are the empty string, and its host is null.

Note

Such a URL's query and fragment can be non-null. For example, the URL record created by parsing "about:blank?foo#bar" matches about:blank[p98].

A URL **matches about:srcdoc** if its scheme is "about", its path contains a single string "srcdoc", its query is null, its username and password are the empty string, and its host is null.

Note

The reason that matches about:srcdoc[p98] ensures that the URL's query is null is because it is not possible to create an iframe srcdoc document[p392] whose URL has a non-null query, unlike Document[p131]s whose URL matches about:blank[p98]. In other words, the set of all URLs that match about:srcdoc[p98] only vary in their fragment.

2.4.2 Parsing URLs §[p98]

Parsing a URL is the process of taking a string and obtaining the URL record that it represents. While this process is defined in *URL*, the HTML standard defines several wrappers to abstract base URLs and encodings. [URL][p1501]

Note

Most new APIs are to use parse a URL[p98]. Older APIs and HTML elements might have reason to use encoding-parse a URL[p98]. When a custom base URL is needed or no base URL is desired, the URL parser can of course be used directly as well.

To **parse a URL**, given a string *url*, relative to a Document[p131] object or environment settings object[p1091] *environment*, run these steps. They return failure or a URL.

1. Let *baseURL* be *environment*'s base URL[p98], if *environment* is a Document[p131] object; otherwise *environment*'s API base URL[p1091].
2. Return the result of applying the URL parser to *url*, with *baseURL*.

To **encoding-parse a URL**, given a string *url*, relative to a Document[p131] object or environment settings object[p1091] *environment*, run these steps. They return failure or a URL.

1. Let *encoding* be UTF-8.
2. If *environment* is a Document[p131] object, then set *encoding* to *environment*'s character encoding.
3. Otherwise, if *environment*'s relevant global object[p1098] is a Window[p934] object, set *encoding* to *environment*'s relevant global object[p1098]'s associated Document[p935]'s character encoding.
4. Let *baseURL* be *environment*'s base URL[p98], if *environment* is a Document[p131] object; otherwise *environment*'s API base

URL[p1091].

5. Return the result of applying the URL parser to *url*, with *baseURL* and *encoding*.

To **encoding-parse-and-serialize a URL**, given a string *url*, relative to a `Document`[p131] object or environment settings object[p1091] *environment*, run these steps. They return failure or a string.

1. Let *url* be the result of encoding-parsing a URL[p98] given *url*, relative to *environment*.
2. If *url* is failure, then return failure.
3. Return the result of applying the URL serializer to *url*.

2.4.3 Dynamic changes to base URLs §[p99]

When a document's document base URL[p98] changes, all elements in that document are affected by a base URL change[p61].

The following are base URL change steps[p61], which run when an element is affected by a base URL change[p61] (as defined by *DOM*):

↪ **If the element creates a hyperlink[p303]**

If the URL identified by the hyperlink is being shown to the user, or if any data derived from that URL is affecting the display, then the `href`[p304] attribute's value should be reparsed[p98], relative to the element's node document and the UI updated appropriately.

Example

For example, the CSS `:link`[p791]/`:visited`[p791] pseudo-classes might have been affected.

If the hyperlink has a `ping`[p304] attribute and its URL(s) are being shown to the user, then the `ping`[p304] attribute's tokens should be reparsed[p98], relative to the element's node document and the UI updated appropriately.

↪ **If the element is a `q`[p267], `blockquote`[p236], `ins`[p338], or `del`[p339] element with a `cite` attribute**

If the URL identified by the `cite` attribute is being shown to the user, or if any data derived from that URL is affecting the display, then the `cite` attribute's value should be reparsed[p98], relative to the element's node document and the UI updated appropriately.

↪ **Otherwise**

The element is not directly affected.

Example

For instance, changing the base URL doesn't affect the image displayed by `img`[p347] elements, although subsequent accesses of the `src`[p351] IDL attribute from script will return a new absolute URL that might no longer correspond to the image being shown.

2.5 Fetching resources §[p99]

2.5.1 Terminology §[p99]

A response whose type is "`basic`", "`cors`", or "`default`" is **CORS-same-origin**. [FETCH][p1496]

A response whose type is "`opaque`" or "`opaqueredirect`" is **CORS-cross-origin**.

A response's **unsafe response** is its internal response if it has one, and the response itself otherwise.

To **create a potential-CORS request**, given a *url*, *destination*, *corsAttributeState*, and an optional *same-origin fallback flag*, run these steps:

1. Let *mode* be "`no-cors`" if *corsAttributeState* is No CORS[p101], and "`cors`" otherwise.

2. If *same-origin fallback flag* is set and *mode* is "`no-cors`", set *mode* to "`same-origin`".
3. Let *credentialsMode* be "`include`".
4. If *corsAttributeState* is Anonymous[p101], set *credentialsMode* to "`same-origin`".
5. Return a new request whose URL is *url*, destination is *destination*, mode is *mode*, credentials mode is *credentialsMode*, and whose use-URL-credentials flag is set.

2.5.2 Determining the type of a resource §[p10]

The **Content-Type metadata** of a resource must be obtained and interpreted in a manner consistent with the requirements of *MIME Sniffing*. [MIMESNIFF][p1498]

The **computed MIME type** of a resource must be found in a manner consistent with the requirements given in *MIME Sniffing*. [MIMESNIFF][p1498]

The **rules for sniffing images specifically**, the **rules for distinguishing if a resource is text or binary**, and the **rules for sniffing audio and video specifically** are also defined in *MIME Sniffing*. These rules return a MIME type as their result. [MIMESNIFF][p1498]

⚠Warning!

It is imperative that the rules in* MIME Sniffing *be followed exactly. When a user agent uses different heuristics for content type detection than the server expects, security problems can occur. For more details, see* MIME Sniffing. *[MIMESNIFF][p1498]

2.5.3 Extracting character encodings from `meta`[p190] elements §[p10]

The **algorithm for extracting a character encoding from a `meta` element**, given a string *s*, is as follows. It returns either a character encoding or nothing.

1. Let *position* be a pointer into *s*, initially pointing at the start of the string.
2. *Loop*: Find the first seven characters in *s* after *position* that are an ASCII case-insensitive match for the word "`charset`". If no such match is found, return nothing.
3. Skip any ASCII whitespace that immediately follow the word "`charset`" (there might not be any).
4. If the next character is not a U+003D EQUALS SIGN (=), then move *position* to point just before that next character, and jump back to the step labeled *loop*.
5. Skip any ASCII whitespace that immediately follow the equals sign (there might not be any).
6. Process the next character as follows:

   ↪ **If it is a U+0022 QUOTATION MARK character (") and there is a later U+0022 QUOTATION MARK character (") in *s***

   ↪ **If it is a U+0027 APOSTROPHE character (') and there is a later U+0027 APOSTROPHE character (') in *s***

   Return the result of getting an encoding from the substring that is between this character and the next earliest occurrence of this character.

   ↪ **If it is an unmatched U+0022 QUOTATION MARK character (")**

   ↪ **If it is an unmatched U+0027 APOSTROPHE character (')**

   ↪ **If there is no next character**

   Return nothing.

   ↪ **Otherwise**

   Return the result of getting an encoding from the substring that consists of this character up to but not including the first ASCII whitespace or U+003B SEMICOLON character (;), or the end of *s*, whichever comes first.

Note

This algorithm is distinct from those in the HTTP specifications (for example, HTTP doesn't allow the use of single quotes and requires supporting a backslash-escape mechanism that is not supported by this algorithm). While the algorithm is used in contexts that, historically, were related to HTTP, the syntax as supported by implementations diverged some time ago. [HTTP]

2.5.4 CORS settings attributes

A **CORS settings attribute** is an enumerated attribute with the following keywords and states:

Keyword	State	Brief description
`anonymous`	**Anonymous**	Requests for the element will have their mode set to "`cors`" and their credentials mode set to "`same-origin`".
(the empty string)		
`use-credentials`	**Use Credentials**	Requests for the element will have their mode set to "`cors`" and their credentials mode set to "`include`".

The attribute's *missing value default* is the **No CORS** state, and its *invalid value default* is the Anonymous state.

The majority of fetches governed by CORS settings attributes will be done via the create a potential-CORS request algorithm.

For more modern features, where the request's mode is always "`cors`", certain CORS settings attributes have been repurposed to have a slightly different meaning, wherein they only impact the request's credentials mode. To perform this translation, we define the **CORS settings attribute credentials mode** for a given CORS settings attribute to be determined by switching on the attribute's state:

↪ **No CORS**

↪ **Anonymous**

"`same-origin`"

↪ **Use Credentials**

"`include`"

2.5.5 Referrer policy attributes

A **referrer policy attribute** is an enumerated attribute. Each referrer policy, including the empty string, is a keyword for this attribute, mapping to a state of the same name.

The attribute's *missing value default* and *invalid value default* are both the empty string state.

The impact of these states on the processing model of various fetches is defined in more detail throughout this specification, in *Fetch*, and in *Referrer Policy*. [FETCH] [REFERRERPOLICY]

Note

Several signals can contribute to which processing model is used for a given fetch; a referrer policy attribute is only one of them. In general, the order in which these signals are processed are:

1. *First, the presence of a* `noreferrer` *link type;*
2. *Then, the value of a referrer policy attribute;*
3. *Then, the presence of any* `meta` *element with* `name` *attribute set to* `referrer`*.*
4. *Finally, the* `Referrer-Policy` *HTTP header.*

2.5.6 Nonce attributes

A **`nonce`** content attribute represents a cryptographic nonce ("number used once") which can be used by *Content Security Policy* to determine whether or not a given fetch will be allowed to proceed. The value is text. [CSP]

Elements that have a nonce[p101] content attribute ensure that the cryptographic nonce is only exposed to script (and not to side-channels like CSS attribute selectors) by taking the value from the content attribute, moving it into an internal slot named **[[CryptographicNonce]]**, exposing it to script via the HTMLOrSVGElement[p144] interface mixin, and setting the content attribute to the empty string. Unless otherwise specified, the slot's value is the empty string.

For web developers (non-normative)

***element*.nonce[p102]**

Returns the value set for *element*'s cryptographic nonce. If the setter was not used, this will be the value originally found in the nonce[p101] content attribute.

element*.nonce[p102] = *value

Updates *element*'s cryptographic nonce value.

The **nonce** IDL attribute must, on getting, return the value of this element's [[CryptographicNonce]][p102]; and on setting, set this element's [[CryptographicNonce]][p102] to the given value.

MDN

¶[p102] Note

Note how the setter for the nonce[p102] IDL attribute does not update the corresponding content attribute. This, as well as the below setting of the nonce[p101] content attribute to the empty string when an element becomes browsing-context connected[p47], is meant to prevent exfiltration of the nonce value through mechanisms that can easily read content attributes, such as selectors. Learn more in issue #2369, where this behavior was introduced.

The following attribute change steps are used for the nonce[p101] content attribute:

1. If *element* does not include HTMLOrSVGElement[p144], then return.
2. If *localName* is not nonce[p101] or *namespace* is not null, then return.
3. If *value* is null, then set *element*'s [[CryptographicNonce]][p102] to the empty string.
4. Otherwise, set *element*'s [[CryptographicNonce]][p102] to *value*.

Whenever an element including HTMLOrSVGElement[p144] becomes browsing-context connected[p47], the user agent must execute the following steps on the *element*:

1. Let *CSP list* be *element*'s shadow-including root's policy container[p132]'s CSP list[p929].
2. If *CSP list* contains a header-delivered Content Security Policy, and *element* has a nonce[p101] content attribute whose value is not the empty string, then:
    1. Let *nonce* be *element*'s [[CryptographicNonce]][p102].
    2. Set an attribute value for *element* using "nonce[p101]" and the empty string.
    3. Set *element*'s [[CryptographicNonce]][p102] to *nonce*.

    Note

    If element's [[CryptographicNonce]][p102] were not restored it would be the empty string at this point.

The cloning steps for elements that include HTMLOrSVGElement[p144] given *node*, *copy*, and *subtree* are to set *copy*'s [[CryptographicNonce]][p102] to *node*'s [[CryptographicNonce]][p102].

✓ MDN

2.5.7 Lazy loading attributes §[p102]

A **lazy loading attribute** is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
lazy	**Lazy**	Used to defer fetching a resource until some conditions are met.
eager	**Eager**	Used to fetch a resource immediately; the default state.

The attribute directs the user agent to fetch a resource immediately or to defer fetching until some conditions associated with the

element are met, according to the attribute's current state.

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the Eager[p102] state.

The **will lazy load element steps**, given an element *element*, are as follows:

1. If scripting is disabled[p1099] for *element*, then return false.

   Note

   This is an anti-tracking measure, because if a user agent supported lazy loading when scripting is disabled, it would still be possible for a site to track a user's approximate scroll position throughout a session, by strategically placing images in a page's markup such that a server can track how many images are requested and when.

2. If *element*'s lazy loading attribute[p102] is in the Lazy[p102] state, then return true.
3. Return false.

Each `img`[p347] and `iframe`[p391] element has associated **lazy load resumption steps**, initially null.

Note

For `img`[p347] and `iframe`[p391] elements that will lazy load[p103], these steps are run from the lazy load intersection observer[p103]'s callback or when their lazy loading attribute[p102] is set to the Eager[p102] state. This causes the element to continue loading.

Each `Document`[p131] has a **lazy load intersection observer**, initially set to null but can be set to an `IntersectionObserver` instance.

To **start intersection-observing a lazy loading element** *element*, run these steps:

1. Let *doc* be *element*'s node document.
2. If *doc*'s lazy load intersection observer[p103] is null, set it to a new `IntersectionObserver` instance, initialized as follows:

   The intention is to use the original value of the `IntersectionObserver` constructor. However, we're forced to use the JavaScript-exposed constructor in this specification, until *Intersection Observer* exposes low-level hooks for use in specifications. See bug w3c/IntersectionObserver#464 which tracks this. [INTERSECTIONOBSERVER][p1497]

   - The *callback* is these steps, with arguments *entries* and *observer*:

     1. For each *entry* in *entries* using a method of iteration which does not trigger developer-modifiable array accessors or iteration hooks:

        1. Let *resumptionSteps* be null.
        2. If *entry*.`isIntersecting` is true, then set *resumptionSteps* to *entry*.`target`'s lazy load resumption steps[p103].
        3. If *resumptionSteps* is null, then return.
        4. Stop intersection-observing a lazy loading element[p104] for *entry*.`target`.
        5. Set *entry*.`target`'s lazy load resumption steps[p103] to null.
        6. Invoke *resumptionSteps*.

        The intention is to use the original value of the `isIntersecting` and `target` getters. See w3c/IntersectionObserver#464. [INTERSECTIONOBSERVER][p1497]

   - The *options* is an `IntersectionObserverInit` dictionary with the following dictionary members: «["`scrollMargin`" → lazy load scroll margin[p104]]»

     Note

     This allows for fetching the image during scrolling, when it does not yet — but is about to — intersect the viewport.

> The lazy load scroll margin[p104] suggestions imply dynamic changes to the value, but the `IntersectionObserver` API does not support changing the scroll margin. See issue w3c/IntersectionObserver#428.

3. Call *doc*'s lazy load intersection observer[p103]'s `observe` method with *element* as the argument.

> The intention is to use the original value of the `observe` method. See w3c/IntersectionObserver#464. [INTERSECTIONOBSERVER][p1497]

To **stop intersection-observing a lazy loading element** *element*, run these steps:

1. Let *doc* be *element*'s node document.
2. Assert: *doc*'s lazy load intersection observer[p103] is not null.
3. Call *doc*'s lazy load intersection observer[p103]'s `unobserve` method with *element* as the argument.

> The intention is to use the original value of the `unobserve` method. See w3c/IntersectionObserver#464. [INTERSECTIONOBSERVER][p1497]

The **lazy load scroll margin** is an implementation-defined value, but with the following suggestions to consider:

- Set a minimum value that most often results in the resources being loaded before they intersect the viewport under normal usage patterns for the given device.
- The typical scrolling speed: increase the value for devices with faster typical scrolling speeds.
- The current scrolling speed or momentum: the UA can attempt to predict where the scrolling will likely stop, and adjust the value accordingly.
- The network quality: increase the value for slow or high-latency connections.
- User preferences can influence the value.

Note

It is important for privacy that the lazy load scroll margin[p104] not leak additional information. For example, the typical scrolling speed on the current device could be imprecise so as to not introduce a new fingerprinting vector.

2.5.8 Blocking attributes §[p104]

A **blocking attribute** explicitly indicates that certain operations should be blocked on the fetching of an external resource. The operations that can be blocked are represented by **possible blocking tokens**, which are strings listed by the following table:

Possible blocking token	Description
"`render`"	The element is potentially render-blocking[p105].

¶[p104] **Note**

In the future, there might be more possible blocking tokens[p104].

A blocking attribute[p104] must have a value that is an unordered set of unique space-separated tokens[p96], each of which are possible blocking tokens[p104]. The supported tokens of a blocking attribute[p104] are the possible blocking tokens[p104]. Any element can have at most one blocking attribute[p104].

The **blocking tokens set** for an element *el* are the result of the following steps:

1. Let *value* be the value of *el*'s blocking attribute[p104], or the empty string if no such attribute exists.
2. Set *value* to *value*, converted to ASCII lowercase.
3. Let *rawTokens* be the result of splitting *value* on ASCII whitespace.

4. Return a set containing the elements of *rawTokens* that are possible blocking tokens[p104].

An element is **potentially render-blocking** if its blocking tokens set[p104] contains "render[p104]", or if it is **implicitly potentially render-blocking**, which will be defined at the individual elements. By default, an element is not implicitly potentially render-blocking[p105].

2.5.9 Fetch priority attributes §[p105]

A **fetch priority attribute** is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
`high`	**High**	Signals a high-priority fetch relative to other resources with the same destination.
`low`	**Low**	Signals a low-priority fetch relative to other resources with the same destination.
`auto`	**Auto**	Signals automatic determination of fetch priority relative to other resources with the same destination.

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the Auto[p105] state.

2.6 Common DOM interfaces §[p105]

2.6.1 Reflecting content attributes in IDL attributes §[p105]

The building blocks for reflecting are as follows:

- A **reflected target** is an element or `ElementInternals`[p779] object. It is typically clear from context and typically identical to the interface of the reflected IDL attribute[p105]. It is always identical to that interface when it is an `ElementInternals`[p779] object.
- A **reflected IDL attribute** is an attribute interface member.
- A **reflected content attribute name** is a string. When the reflected target[p105] is an element, it represents the local name of a content attribute whose namespace is null. When the reflected target[p105] is an `ElementInternals`[p779] object, it represents a key of the reflected target[p105]'s target element[p780]'s internal content attribute map[p783].

A reflected IDL attribute[p105] can be defined to **reflect** a reflected content attribute name[p105] of a reflected target[p105]. In general this means that the IDL attribute getter returns the current value of the content attribute, and the setter changes the value of the content attribute to the given value.

If the reflected target[p105] is an element, then the reflected IDL attribute[p105] can additionally declare to **support `ElementInternals`**. This means that the `ElementInternals`[p779] interface also has a reflected IDL attribute[p105], with the same identifier, and that reflected IDL attribute[p105] reflects[p105] the same reflected content attribute name[p105].

¶[p105] **Example**

The *fooBar* IDL attribute must reflect[p105] the *foobar* content attribute and support `ElementInternals`[p105].

Reflected targets[p105] have these associated algorithms:

- **get the element**: takes no arguments; returns an element.
- **get the content attribute**: takes no arguments; returns null or a string.
- **set the content attribute**: takes a string *value*; returns nothing.
- **delete the content attribute**: takes no arguments; returns nothing.

For a reflected target[p105] that is an element *element*, these are defined as follows:

get the element[p105]

1. Return *element*.

get the content attribute[p105]

1. Let *attribute* be the result of running get an attribute by namespace and local name given null, the reflected content

attribute name[p105], and *element*.

2. If *attribute* is null, then return null.

3. Return *attribute*'s value.

set the content attribute[p105] with a string *value*

1. Set an attribute value given *element*, the reflected content attribute name[p105], and *value*.

delete the content attribute[p105]

1. Remove an attribute by namespace and local name given null, the reflected content attribute name[p105], and *element*.

For a reflected target[p105] that is an `ElementInternals`[p779] object *elementInternals*, they are defined as follows:

get the element[p105]

1. Return *elementInternals*'s target element[p780].

get the content attribute[p105]

1. If *elementInternals*'s target element[p780]'s internal content attribute map[p783][the reflected content attribute name[p105]] does not exist, then return null.

2. Return *elementInternals*'s target element[p780]'s internal content attribute map[p783][the reflected content attribute name[p105]].

set the content attribute[p105] with a string *value*

1. Set *elementInternals*'s target element[p780]'s internal content attribute map[p783][the reflected content attribute name[p105]] to *value*.

delete the content attribute[p105]

1. Remove *elementInternals*'s target element[p780]'s internal content attribute map[p783][the reflected content attribute name[p105]].

Note

This results in somewhat redundant data structures for `ElementInternals`[p779] objects as their target element[p780]'s internal content attribute map[p783] cannot be directly manipulated and as such reflection is only happening in a single direction. This approach was nevertheless chosen to make it less error-prone to define IDL attributes that are shared between reflected targets[p105] and benefit from common API semantics.

IDL attributes of type `DOMString` or `DOMString?` that reflect[p105] enumerated[p77] content attributes can be **limited to only known values**. Per the processing models below, those will cause the getters for such IDL attributes to only return keywords for those enumerated attributes, or the empty string or null.

If a reflected IDL attribute[p105] has the type `DOMString`:

- The getter steps are:

    1. Let *element* be the result of running this's get the element[p105].

    2. Let *contentAttributeValue* be the result of running this's get the content attribute[p105].

    3. Let *attributeDefinition* be the attribute definition of *element*'s content attribute whose namespace is null and local name is the reflected content attribute name[p105].

    4. If *attributeDefinition* indicates it is an enumerated attribute[p77] and the reflected IDL attribute[p105] is defined to be limited to only known values[p106]:

        1. If *contentAttributeValue* does not correspond to any state of *attributeDefinition* (e.g., it is null and there is no *missing value default*[p77]), or if it is in a state of *attributeDefinition* with no associated keyword value, then return the empty string.

        2. Return the canonical keyword[p77] for the state of *attributeDefinition* that *contentAttributeValue* corresponds to.

5. If *contentAttributeValue* is null, then return the empty string.
6. Return *contentAttributeValue*.

- The setter steps are to run this's set the content attribute[p105] with the given value.

If a reflected IDL attribute[p105] has the type `DOMString?`:

- The getter steps are:
  1. Let *element* be the result of running this's get the element[p105].
  2. Let *contentAttributeValue* be the result of running this's get the content attribute[p105].
  3. Let *attributeDefinition* be the attribute definition of *element*'s content attribute whose namespace is null and local name is the reflected content attribute name[p105].
  4. If *attributeDefinition* indicates it is an enumerated attribute[p77]:
     1. Assert: the reflected IDL attribute[p105] is limited to only known values[p106].
     2. Assert: *contentAttributeValue* corresponds to a state of *attributeDefinition*.
     3. If *contentAttributeValue* corresponds to a state of *attributeDefinition* with no associated keyword value, then return null.
     4. Return the canonical keyword[p77] for the state of *attributeDefinition* that *contentAttributeValue* corresponds to.
  5. Return *contentAttributeValue*.
- The setter steps are:
  1. If the given value is null, then run this's delete the content attribute[p105].
  2. Otherwise, run this's set the content attribute[p105] with the given value.

If a reflected IDL attribute[p105] has the type `USVString`:

- The getter steps are:
  1. Let *element* be the result of running this's get the element[p105].
  2. Let *contentAttributeValue* be the result of running this's get the content attribute[p105].
  3. Let *attributeDefinition* be the attribute definition of *element*'s content attribute whose namespace is null and local name is the reflected content attribute name[p105].
  4. If *attributeDefinition* indicates it contains a URL:
     1. If *contentAttributeValue* is null, then return the empty string.
     2. Let *urlString* be the result of encoding-parsing-and-serializing a URL[p99] given *contentAttributeValue*, relative to *element*'s node document.
     3. If *urlString* is not failure, then return *urlString*.
  5. Return *contentAttributeValue*, converted to a scalar value string.
- The setter steps are to run this's set the content attribute[p105] with the given value.

If a reflected IDL attribute[p105] has the type `boolean`:

- The getter steps are:
  1. Let *contentAttributeValue* be the result of running this's get the content attribute[p105].
  2. If *contentAttributeValue* is null, then return false.
  3. Return true.
- The setter steps are:

1. If the given value is false, then run this's delete the content attribute[p105].
2. If the given value is true, then run this's set the content attribute[p105] with the empty string.

Note

This corresponds to the rules for boolean content attributes[p76].

If a reflected IDL attribute[p105] has the type `long`, optionally **limited to only non-negative numbers** and optionally with a **default value** *defaultValue*:

- The getter steps are:
    1. Let *contentAttributeValue* be the result of running this's get the content attribute[p105].
    2. If *contentAttributeValue* is not null:
        1. Let *parsedValue* be the result of integer parsing[p78] *contentAttributeValue* if the reflected IDL attribute[p105] is not limited to only non-negative numbers[p108]; otherwise the result of non-negative integer parsing[p78] *contentAttributeValue*.
        2. If *parsedValue* is not an error and is within the `long` range, then return *parsedValue*.
    3. If the reflected IDL attribute[p105] has a default value[p108], then return *defaultValue*.
    4. If the reflected IDL attribute[p105] is limited to only non-negative numbers[p108], then return −1.
    5. Return 0.
- The setter steps are:
    1. If the reflected IDL attribute[p105] is limited to only non-negative numbers[p108] and the given value is negative, then throw an `"IndexSizeError"` `DOMException`.
    2. Run this's set the content attribute[p105] with the given value converted to the shortest possible string representing the number as a valid integer[p78].

If a reflected IDL attribute[p105] has the type `unsigned long`, optionally **limited to only positive numbers**, **limited to only positive numbers with fallback**, or **clamped to the range** [*clampedMin*, *clampedMax*], and optionally with a default value[p108] *defaultValue*:

- The getter steps are:
    1. Let *contentAttributeValue* be the result of running this's get the content attribute[p105].
    2. Let *minimum* be 0.
    3. If the reflected IDL attribute[p105] is limited to only positive numbers[p108] or limited to only positive numbers with fallback[p108], then set *minimum* to 1.
    4. If the reflected IDL attribute[p105] is clamped to the range[p108], then set *minimum* to *clampedMin*.
    5. Let *maximum* be 2147483647 if the reflected IDL attribute[p105] is not clamped to the range[p108]; otherwise *clampedMax*.
    6. If *contentAttributeValue* is not null:
        1. Let *parsedValue* be the result of non-negative integer parsing[p78] *contentAttributeValue*.
        2. If *parsedValue* is not an error and is in the range *minimum* to *maximum*, inclusive, then return *parsedValue*.
        3. If *parsedValue* is not an error and the reflected IDL attribute[p105] is clamped to the range[p108]:
            1. If *parsedValue* is less than *minimum*, then return *minimum*.
            2. Return *maximum*.
    7. If the reflected IDL attribute[p105] has a default value[p108], then return *defaultValue*.
    8. Return *minimum*.

- The setter steps are:

    1. If the reflected IDL attribute[p105] is limited to only positive numbers[p108] and the given value is 0, then throw an "IndexSizeError" DOMException.
    2. Let *minimum* be 0.
    3. If the reflected IDL attribute[p105] is limited to only positive numbers[p108] or limited to only positive numbers with fallback[p108], then set *minimum* to 1.
    4. Let *newValue* be *minimum*.
    5. If the reflected IDL attribute[p105] has a default value[p108], then set *newValue* to *defaultValue*.
    6. If the given value is in the range *minimum* to 2147483647, inclusive, then set *newValue* to it.
    7. Run this's set the content attribute[p105] with *newValue* converted to the shortest possible string representing the number as a valid non-negative integer[p78].

Note

Clamped to the range[p108] has no effect on the setter steps.

If a reflected IDL attribute[p105] has the type double, optionally limited to only positive numbers[p108] and optionally with a default value[p108] *defaultValue*:

- The getter steps are:

    1. Let *contentAttributeValue* be the result of running this's get the content attribute[p105].
    2. If *contentAttributeValue* is not null:

        1. Let *parsedValue* be the result of floating-point number parsing[p79] *contentAttributeValue*.
        2. If *parsedValue* is not an error and is greater than 0, then return *parsedValue*.
        3. If *parsedValue* is not an error and the reflected IDL attribute[p105] is not limited to only positive numbers[p108], then return *parsedValue*.

    3. If the reflected IDL attribute[p105] has a default value[p108], then return *defaultValue*.
    4. Return 0.

- The setter steps are:

    1. If the reflected IDL attribute[p105] is limited to only positive numbers[p108] and the given value is not greater than 0, then return.
    2. Run this's set the content attribute[p105] with the given value, converted to the best representation of the number as a floating-point number[p79].

Note

The values Infinity and Not-a-Number (NaN) values throw an exception on setting, as defined in Web IDL. *[WEBIDL][p1501]*

If a reflected IDL attribute[p105] has the type DOMTokenList, then its getter steps are to return a DOMTokenList object whose associated element is this and associated attribute's local name is the reflected content attribute name[p105]. Specification authors cannot use support ElementInternals[p105] for IDL attributes of this type.

If a reflected IDL attribute[p105] has the type *T*?, where *T* is either Element or an interface that inherits from Element, then with *attr* being the reflected content attribute name[p105]:

- Its reflected target[p105] has an **explicitly set *attr*-element**, which is a weak reference to an element or null. It is initially null.
- Its reflected target[p105] *reflectedTarget* has a **get the *attr*-associated element** algorithm, that runs these steps:

    1. Let *element* be the result of running *reflectedTarget*'s get the element[p105].
    2. Let *contentAttributeValue* be the result of running *reflectedTarget*'s get the content attribute[p105].

3. If *reflectedTarget*'s explicitly set *attr*-element[p109] is not null:

    1. If *reflectedTarget*'s explicitly set *attr*-element[p109] is a descendant of any of *element*'s shadow-including ancestors, then return *reflectedTarget*'s explicitly set *attr*-element[p109].

    2. Return null.

4. Otherwise, if *contentAttributeValue* is not null, return the first element *candidate*, in tree order, that meets the following criteria:

    - *candidate*'s root is the same as *element*'s root;
    - *candidate*'s ID is *contentAttributeValue*; and
    - *candidate* implements *T*.

    If no such element exists, then return null.

5. Return null.

- The getter steps are to return the result of running this's get the *attr*-associated element[p109].
- The setter steps are:

    1. If the given value is null, then:

        1. Set this's explicitly set *attr*-element[p109] to null.

        2. Run this's delete the content attribute[p105].

        3. Return.

    2. Run this's set the content attribute[p105] with the empty string.

    3. Set this's explicitly set *attr*-element[p109] to a weak reference to the given value.

- For element reflected targets[p105] only: the following attribute change steps, given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used to synchronize between the content attribute and the IDL attribute:

    1. If *localName* is not *attr* or *namespace* is not null, then return.

    2. Set *element*'s explicitly set *attr*-element[p109] to null.

Note

Reflected IDL attributes[p105] of this type are strongly encouraged to have their identifier end in "Element" for consistency.

If a reflected IDL attribute[p105] has the type `FrozenArray<T>?`, where *T* is either `Element` or an interface that inherits from `Element`, then with *attr* being the reflected content attribute name[p105]:

- Its reflected target[p105] has an **explicitly set *attr*-elements**, which is either a list of weak references to elements or null. It is initially null.
- Its reflected target[p105] has a **cached *attr*-associated elements**, which is a list of elements. It is initially « ».
- Its reflected target[p105] has a **cached *attr*-associated elements object**, which is a `FrozenArray<T>?`. It is initially null.
- Its reflected target[p105] *reflectedTarget* has a **get the *attr*-associated elements** algorithm, which runs these steps:

    1. Let *elements* be an empty list.

    2. Let *element* be the result of running *reflectedTarget*'s get the element[p105].

    3. If *reflectedTarget*'s explicitly set *attr*-elements[p110] is not null:

        1. For each *attrElement* in *reflectedTarget*'s explicitly set *attr*-elements[p110]:

            1. If *attrElement* is not a descendant of any of *element*'s shadow-including ancestors, then continue.

            2. Append *attrElement* to *elements*.

4. Otherwise:
    1. Let *contentAttributeValue* be the result of running *reflectedTarget*'s get the content attribute[p105].
    2. If *contentAttributeValue* is null, then return null.
    3. Let *tokens* be *contentAttributeValue*, split on ASCII whitespace.
    4. For each *id* of *tokens*:
        1. Let *candidate* be the first element, in tree order, that meets the following criteria:
            - *candidate*'s root is the same as *element*'s root;
            - *candidate*'s ID is *id*; and
            - *candidate* implements *T*.

            If no such element exists, then continue.
        2. Append *candidate* to *elements*.
    5. Return *elements*.

- The getter steps are:
    1. Let *elements* be the result of running this's get the *attr*-associated elements[p110].
    2. If the contents of *elements* is equal to the contents of this's cached *attr*-associated elements[p110], then return this's cached *attr*-associated elements object[p110].
    3. Let *elementsAsFrozenArray* be *elements*, converted to a `FrozenArray<T>?`.
    4. Set this's cached *attr*-associated elements[p110] to *elements*.
    5. Set this's cached *attr*-associated elements object[p110] to *elementsAsFrozenArray*.
    6. Return *elementsAsFrozenArray*.

    Note

    This extra caching layer is necessary to preserve the invariant that `element.reflectedElements === element.reflectedElements`.

- The setter steps are:
    1. If the given value is null:
        1. Set this's explicitly set *attr*-elements[p110] to null.
        2. Run this's delete the content attribute[p105].
        3. Return.
    2. Run this's set the content attribute[p105] with the empty string.
    3. Let *elements* be an empty list.
    4. For each *element* in the given value:
        1. Append a weak reference to *element* to *elements*.
    5. Set this's explicitly set *attr*-elements[p110] to *elements*.

- For element reflected targets[p105] only: the following attribute change steps, given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used to synchronize between the content attribute and the IDL attribute:
    1. If *localName* is not *attr* or *namespace* is not null, then return.
    2. Set *element*'s explicitly set *attr*-elements[p110] to null.

Note

Reflected IDL attributes[p105] of this type are strongly encouraged to have their identifier end in "Elements" for consistency.

2.6.2 Using reflect in specifications §[p11]

Reflection[p105] is primarily about improving web developer ergonomics by giving them typed access to content attributes through reflected IDL attributes[p105]. The ultimate source of truth, which the web platform builds upon, is the content attributes themselves. That is, specification authors must not use the reflected IDL attribute[p105] getter or setter steps, but instead must use the content attribute presence and value. (Or an abstraction on top, such as the state of an enumerated attribute[p77].)

Two important exceptions to this are reflected IDL attributes[p105] whose type is one of the following:

- *T*?, where *T* is either Element or an interface that inherits from Element
- FrozenArray<*T*>?, where *T* is either Element or an interface that inherits from Element

For those, specification authors must use the reflected target[p105]'s get the *attr*-associated element[p109] and get the *attr*-associated elements[p110], respectively. The content attribute presence and value must not be used as they cannot be fully synchronized with the reflected IDL attribute[p105].

A reflected target[p105]'s explicitly set *attr*-element[p109], explicitly set *attr*-elements[p110], cached *attr*-associated elements[p110], and cached *attr*-associated elements object[p110] are to be treated as internal implementation details and not to be built upon.

2.6.3 Collections §[p11]

The HTMLFormControlsCollection[p114] and HTMLOptionsCollection[p115] interfaces are collections derived from the HTMLCollection interface. The HTMLAllCollection[p113] interface is a collection, but is not so derived.

2.6.3.1 The HTMLAllCollection[p113] interface §[p11]

The HTMLAllCollection[p113] interface is used for the legacy document.all[p1461] attribute. It operates similarly to HTMLCollection; the main differences are that it allows a staggering variety of different (ab)uses of its methods to all end up returning something, and that it can be called as a function as an alternative to property access.

Note

All HTMLAllCollection[p113] objects are rooted at a Document[p131] and have a filter that matches all elements, so the elements represented by the collection of an HTMLAllCollection[p113] object consist of all the descendant elements of the root Document[p131].

Objects that implement the HTMLAllCollection[p113] interface are legacy platform objects with an additional [[Call]] internal method described in the section below[p114]. They also have an [[IsHTMLDDA]] internal slot.

Note

Objects that implement the HTMLAllCollection[p113] interface have several unusual behaviors, due of the fact that they have an [[IsHTMLDDA]] internal slot:

- *The ToBoolean abstract operation in JavaScript returns false when given objects implementing the HTMLAllCollection[p113] interface.*
- *The IsLooselyEqual abstract operation, when given objects implementing the HTMLAllCollection[p113] interface, returns true when compared to the undefined and null values. (Comparisons using the IsStrictlyEqual abstract operation, and IsLooselyEqual comparisons to other values such as strings or objects, are unaffected.)*
- *The typeof operator in JavaScript returns the string "undefined" when applied to objects implementing the HTMLAllCollection[p113] interface.*

These special behaviors are motivated by a desire for compatibility with two classes of legacy content: one that uses the presence

of document.all[p1461] as a way to detect legacy user agents, and one that only supports those legacy user agents and uses the document.all[p1461] object without testing for its presence first. [JAVASCRIPT][p1497]

IDL

```
[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface HTMLAllCollection {
  readonly attribute unsigned long length;
  getter Element (unsigned long index);
  getter (HTMLCollection or Element)? namedItem(DOMString name);
  (HTMLCollection or Element)? item(optional DOMString nameOrIndex);

  // Note: HTMLAllCollection objects have a custom [[Call]] internal method and an [[IsHTMLDDA]]
internal slot.
};
```

The object's supported property indices are as defined for HTMLCollection objects.

The supported property names consist of the non-empty values of all the id[p156] attributes of all the elements represented by the collection, and the non-empty values of all the name attributes of all the "all"-named elements[p113] represented by the collection, in tree order, ignoring later duplicates, with the id[p156] of an element preceding its name if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

The **length** getter steps are to return the number of nodes represented by the collection.

The indexed property getter must return the result of getting the "all"-indexed element[p113] from this given the passed index.

The **namedItem(*name*)** method steps are to return the result of getting the "all"-named element(s)[p113] from this given *name*.

The **item(*nameOrIndex*)** method steps are:

1. If *nameOrIndex* was not provided, return null.
2. Return the result of getting the "all"-indexed or named element(s)[p113] from this, given *nameOrIndex*.

The following elements are **"all"-named elements**: a[p258], button[p567], embed[p400], form[p515], frame[p1451], frameset[p1451], iframe[p391], img[p347], input[p521], map[p471], meta[p190], object[p403], select[p572], and textarea[p583]

To **get the "all"-indexed element** from an HTMLAllCollection[p113] *collection* given an index *index*, return the *index*th element in *collection*, or null if there is no such *index*th element.

To **get the "all"-named element(s)** from an HTMLAllCollection[p113] *collection* given a name *name*, perform the following steps:

1. If *name* is the empty string, return null.
2. Let *subCollection* be an HTMLCollection object rooted at the same Document[p131] as *collection*, whose filter matches only elements that are either:
   - "all"-named elements[p113] with a name attribute equal to *name*, or
   - elements with an ID equal to *name*.
3. If there is exactly one element in *subCollection*, then return that element.
4. Otherwise, if *subCollection* is empty, return null.
5. Otherwise, return *subCollection*.

To **get the "all"-indexed or named element(s)** from an HTMLAllCollection[p113] *collection* given *nameOrIndex*:

1. If *nameOrIndex*, converted to a JavaScript String value, is an array index property name, return the result of getting the "all"-indexed element[p113] from *collection* given the number represented by *nameOrIndex*.

2. Return the result of getting the "all"-named element(s)[p113] from *collection* given *nameOrIndex*.

2.6.3.1.1 [[Call]] (thisArgument, argumentsList) §[p11 4]

1. If *argumentsList*'s size is zero, or if *argumentsList*[0] is undefined, return null.
2. Let *nameOrIndex* be the result of converting *argumentsList*[0] to a DOMString.
3. Let *result* be the result of getting the "all"-indexed or named element(s)[p113] from this HTMLAllCollection[p113] given *nameOrIndex*.
4. Return the result of converting *result* to an ECMAScript value.

Note

The thisArgument *is ignored, and thus code such as* `Function.prototype.call.call(document.all, null, "x")` *will still search for elements. (*`document.all.call` *does not exist, since* `document.all` *does not inherit from* `Function.prototype`*.)*

2.6.3.2 The HTMLFormControlsCollection[p114] interface §[p11 4]

The HTMLFormControlsCollection[p114] interface is used for collections of listed elements[p514] in form[p515] elements.

IDL

```
[Exposed=Window]
interface HTMLFormControlsCollection : HTMLCollection {
  // inherits length and item()
  getter (RadioNodeList or Element)? namedItem(DOMString name); // shadows inherited namedItem()
};

[Exposed=Window]
interface RadioNodeList : NodeList {
  attribute DOMString value;
};
```

For web developers (non-normative)

***collection*.length**

Returns the number of elements in *collection*.

***element* = *collection*.item(*index*)**
***element* = *collection*[*index*]**

Returns the item at index *index* in *collection*. The items are sorted in tree order.

***element* = *collection*.namedItem[p115](*name*)**
***radioNodeList* = *collection*.namedItem[p115](*name*)**
***element* = *collection*[*name*]**
***radioNodeList* = *collection*[*name*]**

Returns the item with ID or name[p603] *name* from *collection*.

If there are multiple matching items, then a RadioNodeList[p114] object containing all those elements is returned.

***radioNodeList*.value[p115]**

Returns the value of the first checked radio button represented by *radioNodeList*.

radioNodeList*.value[p115] = *value

Checks the first radio button represented by *radioNodeList* that has value *value*.

The object's supported property indices are as defined for HTMLCollection objects.

The supported property names consist of the non-empty values of all the id[p156] and name[p603] attributes of all the elements represented by the collection, in tree order, ignoring later duplicates, with the id[p156] of an element preceding its name[p603] if it contributes both, they

differ from each other, and neither is the duplicate of an earlier entry.

The **namedItem(*name*)** method must act according to the following algorithm:

1. If *name* is the empty string, return null and stop the algorithm.
2. If, at the time the method is called, there is exactly one node in the collection that has either an id[p156] attribute or a name[p603] attribute equal to *name*, then return that node and stop the algorithm.
3. Otherwise, if there are no nodes in the collection that have either an id[p156] attribute or a name[p603] attribute equal to *name*, then return null and stop the algorithm.
4. Otherwise, create a new RadioNodeList[p114] object representing a live[p48] view of the HTMLFormControlsCollection[p114] object, further filtered so that the only nodes in the RadioNodeList[p114] object are those that have either an id[p156] attribute or a name[p603] attribute equal to *name*. The nodes in the RadioNodeList[p114] object must be sorted in tree order.
5. Return that RadioNodeList[p114] object.

Members of the RadioNodeList[p114] interface inherited from the NodeList interface must behave as they would on a NodeList object.

The **value** IDL attribute on the RadioNodeList[p114] object, on getting, must return the value returned by running the following steps:

1. Let *element* be the first element in tree order represented by the RadioNodeList[p114] object that is an input[p521] element whose type[p524] attribute is in the Radio Button[p544] state and whose checkedness[p601] is true. Otherwise, let it be null.
2. If *element* is null, return the empty string.
3. If *element* is an element with no value[p526] attribute, return the string "on".
4. Otherwise, return the value of *element*'s value[p526] attribute.

On setting, the value[p115] IDL attribute must run the following steps:

1. If the new value is the string "on": let *element* be the first element in tree order represented by the RadioNodeList[p114] object that is an input[p521] element whose type[p524] attribute is in the Radio Button[p544] state and whose value[p526] content attribute is either absent, or present and equal to the new value, if any. If no such element exists, then instead let *element* be null.

   Otherwise: let *element* be the first element in tree order represented by the RadioNodeList[p114] object that is an input[p521] element whose type[p524] attribute is in the Radio Button[p544] state and whose value[p526] content attribute is present and equal to the new value, if any. If no such element exists, then instead let *element* be null.
2. If *element* is not null, then set its checkedness[p601] to true.

2.6.3.3 The HTMLOptionsCollection[p115] interface §[p115]

The HTMLOptionsCollection[p115] interface is used for collections of option[p580] elements. It is always rooted on a select[p572] element and has attributes and methods that manipulate that element's descendants.

IDL

```
[Exposed=Window]
interface HTMLOptionsCollection : HTMLCollection {
  // inherits item(), namedItem()
  [CEReactions] attribute unsigned long length; // shadows inherited length
  [CEReactions] setter undefined (unsigned long index, HTMLOptionElement? option);
  [CEReactions] undefined add((HTMLOptionElement or HTMLOptGroupElement) element, optional (HTMLElement
or long)? before = null);
  [CEReactions] undefined remove(long index);
  attribute long selectedIndex;
};
```

For web developers (non-normative)

***collection*.length**[p116]

Returns the number of elements in *collection*.

collection*.length**[p116] **= *value

When set to a smaller number than the existing length, truncates the number of option[p580] elements in the container corresponding to *collection*.

When set to a greater number than the existing length, if that number is less than or equal to 100000, adds new blank option[p580] elements to the container corresponding to *collection*.

***element* = *collection*.item(*index*)**

***element* = *collection*[*index*]**

Returns the item at index *index* in *collection*. The items are sorted in tree order.

collection*[*index*] = *element

When *index* is a greater number than the number of items in *collection*, adds new blank option[p580] elements in the corresponding container.

When set to null, removes the item at index *index* from *collection*.

When set to an option[p580] element, adds or replaces it at index *index* in *collection*.

***element* = *collection*.namedItem(*name*)**

***element* = *collection*[*name*]**

Returns the item with ID or name[p1445] *name* from *collection*.

If there are multiple matching items, then the first is returned.

***collection*.add**[p117]**(*element*[, *before*])**

Inserts *element* before the node given by *before*.

The *before* argument can be a number, in which case *element* is inserted before the item with that number, or an element from *collection*, in which case *element* is inserted before that element.

If *before* is omitted, null, or a number out of range, then *element* will be added at the end of the list.

Throws a "HierarchyRequestError" DOMException if *element* is an ancestor of the element into which it is to be inserted.

***collection*.remove**[p117]**(*index*)**

Removes the item with index *index* from *collection*.

***collection*.selectedIndex**[p117]

Returns the index of the first selected item, if any, or −1 if there is no selected item.

collection*.selectedIndex**[p117] **= *index

Changes the selection to the option[p580] element at index *index* in *collection*.

The object's supported property indices are as defined for HTMLCollection objects.

The **length** getter steps are to return the number of nodes represented by the collection.

The length[p116] setter steps are:

1. Let *current* be the number of nodes represented by the collection.
2. If the given value is greater than *current*, then:
    1. If the given value is greater than 100,000, then return.
    2. Let *n* be *value* − *current*.
    3. Append *n* new option[p580] elements with no attributes and no child nodes to the select[p572] element on which this is rooted.
3. If the given value is less than *current*, then:
    1. Let *n* be *current* − *value*.
    2. Remove the last *n* nodes in the collection from their parent nodes.

Note

Setting length[p116] *never removes or adds any* optgroup[p579] *elements, and never adds new children to existing* optgroup[p579] *elements (though it can remove children from them).*

The supported property names consist of the non-empty values of all the id[p156] and name[p1445] attributes of all the elements represented by the collection, in tree order, ignoring later duplicates, with the id[p156] of an element preceding its name[p1445] if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

When the user agent is to set the value of a new indexed property or set the value of an existing indexed property for a given property index *index* to a new value *value*, it must run the following algorithm:

1. If *value* is null, invoke the steps for the remove[p117] method with *index* as the argument, and return.
2. Let *length* be the number of nodes represented by the collection.
3. Let *n* be *index* minus *length*.
4. If *n* is greater than zero, then append a DocumentFragment consisting of *n*-1 new option[p580] elements with no attributes and no child nodes to the select[p572] element on which the HTMLOptionsCollection[p115] is rooted.
5. If *n* is greater than or equal to zero, append *value* to the select[p572] element. Otherwise, replace the *index*th element in the collection by *value*.

The **add(*element*, *before*)** method must act according to the following algorithm:

1. If *element* is an ancestor of the select[p572] element on which the HTMLOptionsCollection[p115] is rooted, then throw a "HierarchyRequestError" DOMException.
2. If *before* is an element, but that element isn't a descendant of the select[p572] element on which the HTMLOptionsCollection[p115] is rooted, then throw a "NotFoundError" DOMException.
3. If *element* and *before* are the same element, then return.
4. If *before* is a node, then let *reference* be that node. Otherwise, if *before* is an integer, and there is a *before*th node in the collection, let *reference* be that node. Otherwise, let *reference* be null.
5. If *reference* is not null, let *parent* be the parent node of *reference*. Otherwise, let *parent* be the select[p572] element on which the HTMLOptionsCollection[p115] is rooted.
6. Pre-insert *element* into *parent* node before *reference*.

The **remove(*index*)** method must act according to the following algorithm:

1. If the number of nodes represented by the collection is zero, return.
2. If *index* is not a number greater than or equal to 0 and less than the number of nodes represented by the collection, return.
3. Let *element* be the *index*th element in the collection.
4. Remove *element* from its parent node.

The **selectedIndex** IDL attribute must act like the identically named attribute on the select[p572] element on which the HTMLOptionsCollection[p115] is rooted

2.6.4 The DOMStringList[p117] interface §[p117]

The DOMStringList[p117] interface is a non-fashionable retro way of representing a list of strings.

IDL

```
[Exposed=(Window,Worker)]
interface DOMStringList {
  readonly attribute unsigned long length;
  getter DOMString? item(unsigned long index);
  boolean contains(DOMString string);
};
```

⚠Warning!

New APIs must use `sequence<DOMString>` ***or equivalent rather than*** `DOMStringList`[p117]***.***

For web developers (non-normative)

***strings*.length**[p118]

Returns the number of strings in *strings*.

***strings*[*index*]**

***strings*.item**[p118]**(*index*)**

Returns the string with index *index* from *strings*.

***strings*.contains**[p118]**(*string*)**

Returns true if *strings* contains *string*, and false otherwise.

Each `DOMStringList`[p117] object has an associated list.

The `DOMStringList`[p117] interface supports indexed properties. The supported property indices are the indices of this's associated list.

The **length** getter steps are to return this's associated list's size.

The **item(*index*)** method steps are to return the *index*th item in this's associated list, or null if *index* plus one is greater than this's associated list's size.

The **contains(*string*)** method steps are to return true if this's associated list contains *string*, and false otherwise.

2.7 Safe passing of structured data §[p118]

To support passing JavaScript objects, including platform objects, across realm boundaries, this specification defines the following infrastructure for serializing and deserializing objects, including in some cases transferring the underlying data instead of copying it. Collectively this serialization/deserialization process is known as "structured cloning", although most APIs perform separate serialization and deserialization steps. (With the notable exception being the `structuredClone()`[p130] method.)

This section uses the terminology and typographic conventions from the JavaScript specification. [JAVASCRIPT][p1497]

2.7.1 Serializable objects §[p118]

Serializable objects[p118] support being serialized, and later deserialized, in a way that is independent of any given realm. This allows them to be stored on disk and later restored, or cloned across agent and even agent cluster boundaries.

Not all objects are serializable objects[p118], and not all aspects of objects that are serializable objects[p118] are necessarily preserved when they are serialized.

Platform objects can be serializable objects[p118] if their primary interface is decorated with the **[Serializable]** IDL extended attribute. Such interfaces must also define the following algorithms:

serialization steps*, taking a platform object *value*, a Record *serialized*, and a boolean *forStorage

A set of steps that serializes the data in *value* into fields of *serialized*. The resulting data serialized into *serialized* must be independent of any realm.

These steps may throw an exception if serialization is not possible.

These steps may perform a sub-serialization[p123] to serialize nested data structures. They should not call StructuredSerialize[p124] directly, as doing so will omit the important *memory* argument.

The introduction of these steps should omit mention of the *forStorage* argument if it is not relevant to the algorithm.

deserialization steps*, taking a Record *serialized*, a platform object *value*, and a realm *targetRealm

A set of steps that deserializes the data in *serialized*, using it to set up *value* as appropriate. *value* will be a newly-created instance

of the platform object type in question, with none of its internal data set up; setting that up is the job of these steps.

These steps may throw an exception if deserialization is not possible.

These steps may perform a sub-deserialization[p127] to deserialize nested data structures. They should not call StructuredDeserialize[p124] directly, as doing so will omit the important *targetRealm* and *memory* arguments.

It is up to the definition of individual platform objects to determine what data is serialized and deserialized by these steps. Typically the steps are very symmetric.

The `[Serializable]`[p118] extended attribute must take no arguments, and must only appear on an interface. It must not appear more than once on an interface.

For a given platform object, only the object's primary interface is considered during the (de)serialization process. Thus, if inheritance is involved in defining the interface, each `[Serializable]`[p118]-annotated interface in the inheritance chain needs to define standalone serialization steps[p118] and deserialization steps[p118], including taking into account any important data that might come from inherited interfaces.

Example

Let's say we were defining a platform object `Person`, which had associated with it two pieces of associated data:

- a name value, which is a string; and
- a best friend value, which is either another `Person` instance or null.

We could then define `Person` instances to be serializable objects[p118] by annotating the `Person` interface with the `[Serializable]`[p118] extended attribute, and defining the following accompanying algorithms:

Their serialization steps[p118], given *value* and *serialized*:

1. Set *serialized*.[[Name]] to *value*'s associated name value.
2. Let *serializedBestFriend* be the sub-serialization[p123] of *value*'s associated best friend value.
3. Set *serialized*.[[BestFriend]] to *serializedBestFriend*.

Their deserialization steps[p118], given *serialized*, *value*, and *targetRealm*:

1. Set *value*'s associated name value to *serialized*.[[Name]].
2. Let *deserializedBestFriend* be the sub-deserialization[p127] of *serialized*.[[BestFriend]].
3. Set *value*'s associated best friend value to *deserializedBestFriend*.

Objects defined in the JavaScript specification are handled by the StructuredSerialize[p124] abstract operation directly.

¶[p119] **Note**

Originally, this specification defined the concept of "cloneable objects", which could be cloned from one realm to another. However, to better specify the behavior of certain more complex situations, the model was updated to make the serialization and deserialization explicit.

2.7.2 Transferable objects §[p119]

Transferable objects[p119] support being transferred across agents. Transferring is effectively recreating the object while sharing a reference to the underlying data and then detaching the object being transferred. This is useful to transfer ownership of expensive resources. Not all objects are transferable objects[p119] and not all aspects of objects that are transferable objects[p119] are necessarily preserved when transferred.

Note

Transferring is an irreversible and non-idempotent operation. Once an object has been transferred, it cannot be transferred, or

indeed used, again.

Platform objects can be transferable objects[p119] if their primary interface is decorated with the **[Transferable]** IDL extended attribute. Such interfaces must also define the following algorithms:

transfer steps*, taking a platform object *value* and a Record *dataHolder

A set of steps that transfers the data in *value* into fields of *dataHolder*. The resulting data held in *dataHolder* must be independent of any realm.

These steps may throw an exception if transferral is not possible.

transfer-receiving steps*, taking a Record *dataHolder* and a platform object *value

A set of steps that receives the data in *dataHolder*, using it to set up *value* as appropriate. *value* will be a newly-created instance of the platform object type in question, with none of its internal data set up; setting that up is the job of these steps.

These steps may throw an exception if it is not possible to receive the transfer.

It is up to the definition of individual platform objects to determine what data is transferred by these steps. Typically the steps are very symmetric.

The `[Transferable]`[p120] extended attribute must take no arguments, and must only appear on an interface. It must not appear more than once on an interface.

For a given platform object, only the object's primary interface is considered during the transferring process. Thus, if inheritance is involved in defining the interface, each `[Transferable]`[p120]-annotated interface in the inheritance chain needs to define standalone transfer steps[p120] and transfer-receiving steps[p120], including taking into account any important data that might come from inherited interfaces.

Platform objects that are transferable objects[p119] have a **[[Detached]]** internal slot. This is used to ensure that once a platform object has been transferred, it cannot be transferred again.

Objects defined in the JavaScript specification are handled by the StructuredSerializeWithTransfer[p127] abstract operation directly.

2.7.3 StructuredSerializeInternal (*value*, *forStorage* [, *memory*]) §[p120]

The StructuredSerializeInternal[p120] abstract operation takes as input a JavaScript value *value* and serializes it to a realm-independent form, represented here as a Record. This serialized form has all the information necessary to later deserialize into a new JavaScript value in a different realm.

This process can throw an exception, for example when trying to serialize un-serializable objects.

1. If *memory* was not supplied, let *memory* be an empty map.

   Note

   The purpose of the memory *map is to avoid serializing objects twice. This ends up preserving cycles and the identity of duplicate objects in graphs.*

2. If *memory*[*value*] exists, then return *memory*[*value*].
3. Let *deep* be false.
4. If *value* is undefined, null, a Boolean, a Number, a BigInt, or a String, then return { [[Type]]: "primitive", [[Value]]: *value* }.
5. If *value* is a Symbol, then throw a `"DataCloneError"` `DOMException`.
6. Let *serialized* be an uninitialized value.
7. If *value* has a [[BooleanData]] internal slot, then set *serialized* to { [[Type]]: "Boolean", [[BooleanData]]: *value*.[[BooleanData]] }.
8. Otherwise, if *value* has a [[NumberData]] internal slot, then set *serialized* to { [[Type]]: "Number", [[NumberData]]: *value*.[[NumberData]] }.

9. Otherwise, if *value* has a [[BigIntData]] internal slot, then set *serialized* to { [[Type]]: "BigInt", [[BigIntData]]: *value*.[[BigIntData]] }.

10. Otherwise, if *value* has a [[StringData]] internal slot, then set *serialized* to { [[Type]]: "String", [[StringData]]: *value*.[[StringData]] }.

11. Otherwise, if *value* has a [[DateValue]] internal slot, then set *serialized* to { [[Type]]: "Date", [[DateValue]]: *value*.[[DateValue]] }.

12. Otherwise, if *value* has a [[RegExpMatcher]] internal slot, then set *serialized* to { [[Type]]: "RegExp", [[RegExpMatcher]]: *value*.[[RegExpMatcher]], [[OriginalSource]]: *value*.[[OriginalSource]], [[OriginalFlags]]: *value*.[[OriginalFlags]] }.

13. Otherwise, if *value* has an [[ArrayBufferData]] internal slot, then:

    1. If IsSharedArrayBuffer(*value*) is true, then:

        1. If the current settings object[p1098]'s cross-origin isolated capability[p1091] is false, then throw a "DataCloneError" DOMException.

            Note

            This check is only needed when serializing (and not when deserializing) as the cross-origin isolated capability[p1091] cannot change over time and a SharedArrayBuffer cannot leave an agent cluster.

        2. If *forStorage* is true, then throw a "DataCloneError" DOMException.

        3. If *value* has an [[ArrayBufferMaxByteLength]] internal slot, then set *serialized* to { [[Type]]: "GrowableSharedArrayBuffer", [[ArrayBufferData]]: *value*.[[ArrayBufferData]], [[ArrayBufferByteLengthData]]: *value*.[[ArrayBufferByteLengthData]], [[ArrayBufferMaxByteLength]]: *value*.[[ArrayBufferMaxByteLength]], [[AgentCluster]]: the surrounding agent's agent cluster }.

        4. Otherwise, set *serialized* to { [[Type]]: "SharedArrayBuffer", [[ArrayBufferData]]: *value*.[[ArrayBufferData]], [[ArrayBufferByteLength]]: *value*.[[ArrayBufferByteLength]], [[AgentCluster]]: the surrounding agent's agent cluster }.

    2. Otherwise:

        1. If IsDetachedBuffer(*value*) is true, then throw a "DataCloneError" DOMException.

        2. Let *size* be *value*.[[ArrayBufferByteLength]].

        3. Let *dataCopy* be ? CreateByteDataBlock(*size*).

            Note

            This can throw a RangeError exception upon allocation failure.

        4. Perform CopyDataBlockBytes(*dataCopy*, 0, *value*.[[ArrayBufferData]], 0, *size*).

        5. If *value* has an [[ArrayBufferMaxByteLength]] internal slot, then set *serialized* to { [[Type]]: "ResizableArrayBuffer", [[ArrayBufferData]]: *dataCopy*, [[ArrayBufferByteLength]]: *size*, [[ArrayBufferMaxByteLength]]: *value*.[[ArrayBufferMaxByteLength]] }.

        6. Otherwise, set *serialized* to { [[Type]]: "ArrayBuffer", [[ArrayBufferData]]: *dataCopy*, [[ArrayBufferByteLength]]: *size* }.

14. Otherwise, if *value* has a [[ViewedArrayBuffer]] internal slot, then:

    1. If IsArrayBufferViewOutOfBounds(*value*) is true, then throw a "DataCloneError" DOMException.

    2. Let *buffer* be the value of *value*'s [[ViewedArrayBuffer]] internal slot.

    3. Let *bufferSerialized* be ? StructuredSerializeInternal[p120](*buffer*, *forStorage*, *memory*).

    4. Assert: *bufferSerialized*.[[Type]] is "ArrayBuffer", "ResizableArrayBuffer", "SharedArrayBuffer", or "GrowableSharedArrayBuffer".

    5. If *value* has a [[DataView]] internal slot, then set *serialized* to { [[Type]]: "ArrayBufferView", [[Constructor]]: "DataView", [[ArrayBufferSerialized]]: *bufferSerialized*, [[ByteLength]]: *value*.[[ByteLength]], [[ByteOffset]]: *value*.[[ByteOffset]] }.

6. Otherwise:

    1. Assert: *value* has a [[TypedArrayName]] internal slot.

    2. Set *serialized* to { [[Type]]: "ArrayBufferView", [[Constructor]]: *value*.[[TypedArrayName]], [[ArrayBufferSerialized]]: *bufferSerialized*, [[ByteLength]]: *value*.[[ByteLength]], [[ByteOffset]]: *value*.[[ByteOffset]], [[ArrayLength]]: *value*.[[ArrayLength]] }.

15. Otherwise, if *value* has a [[MapData]] internal slot, then:

    1. Set *serialized* to { [[Type]]: "Map", [[MapData]]: a new empty List }.

    2. Set *deep* to true.

16. Otherwise, if *value* has a [[SetData]] internal slot, then:

    1. Set *serialized* to { [[Type]]: "Set", [[SetData]]: a new empty List }.

    2. Set *deep* to true.

17. Otherwise, if *value* has an [[ErrorData]] internal slot and *value* is not a platform object, then:

    1. Let *name* be ? Get(*value*, "name").

    2. If *name* is not one of "Error", "EvalError", "RangeError", "ReferenceError", "SyntaxError", "TypeError", or "URIError", then set *name* to "Error".

    3. Let *valueMessageDesc* be ? *value*.[[GetOwnProperty]]("`message`").

    4. Let *message* be undefined if IsDataDescriptor(*valueMessageDesc*) is false, and ? ToString(*valueMessageDesc*.[[Value]]) otherwise.

    5. Set *serialized* to { [[Type]]: "Error", [[Name]]: *name*, [[Message]]: *message* }.

    6. User agents should attach a serialized representation of any interesting accompanying data which are not yet specified, notably the `stack` property, to *serialized*.

    Note

    See the Error Stacks *proposal for in-progress work on specifying this data. [JSERRORSTACKS]*[p1497]

18. Otherwise, if *value* is an Array exotic object, then:

    1. Let *valueLenDescriptor* be ? OrdinaryGetOwnProperty(*value*, "`length`").

    2. Let *valueLen* be *valueLenDescriptor*.[[Value]].

    3. Set *serialized* to { [[Type]]: "Array", [[Length]]: *valueLen*, [[Properties]]: a new empty List }.

    4. Set *deep* to true.

19. Otherwise, if *value* is a platform object that is a serializable object[p118]:

    1. If *value* has a [[Detached]][p120] internal slot whose value is true, then throw a "`DataCloneError`" `DOMException`.

    2. Let *typeString* be the identifier of the primary interface of *value*.

    3. Set *serialized* to { [[Type]]: *typeString* }.

    4. Set *deep* to true.

20. Otherwise, if *value* is a platform object, then throw a "`DataCloneError`" `DOMException`.

21. Otherwise, if IsCallable(*value*) is true, then throw a "`DataCloneError`" `DOMException`.

22. Otherwise, if *value* has any internal slot other than [[Prototype]], [[Extensible]], or [[PrivateElements]], then throw a "`DataCloneError`" `DOMException`.

    Example

    For instance, a [[PromiseState]] or [[WeakMapData]] internal slot.

23. Otherwise, if *value* is an exotic object and *value* is not the %Object.prototype% intrinsic object associated with any realm,

then throw a "DataCloneError" DOMException.

Example

For instance, a proxy object.

24. Otherwise:

    1. Set *serialized* to { [[Type]]: "Object", [[Properties]]: a new empty List }.

    2. Set *deep* to true.

Note

%Object.prototype% will end up being handled via this step and subsequent steps. The end result is that its exoticness is ignored, and after deserialization the result will be an empty object (not an immutable prototype exotic object).

25. Set *memory*[*value*] to *serialized*.

26. If *deep* is true, then:

    1. If *value* has a [[MapData]] internal slot, then:

        1. Let *copiedList* be a new empty List.

        2. For each Record { [[Key]], [[Value]] } *entry* of *value*.[[MapData]]:

            1. Let *copiedEntry* be a new Record { [[Key]]: *entry*.[[Key]], [[Value]]: *entry*.[[Value]] }.

            2. If *copiedEntry*.[[Key]] is not the special value *empty*, append *copiedEntry* to *copiedList*.

        3. For each Record { [[Key]], [[Value]] } *entry* of *copiedList*:

            1. Let *serializedKey* be ? StructuredSerializeInternal[p120](*entry*.[[Key]], *forStorage*, *memory*).

            2. Let *serializedValue* be ? StructuredSerializeInternal[p120](*entry*.[[Value]], *forStorage*, *memory*).

            3. Append { [[Key]]: *serializedKey*, [[Value]]: *serializedValue* } to *serialized*.[[MapData]].

    2. Otherwise, if *value* has a [[SetData]] internal slot, then:

        1. Let *copiedList* be a new empty List.

        2. For each *entry* of *value*.[[SetData]]:

            1. If *entry* is not the special value *empty*, append *entry* to *copiedList*.

        3. For each *entry* of *copiedList*:

            1. Let *serializedEntry* be ? StructuredSerializeInternal[p120](*entry*, *forStorage*, *memory*).

            2. Append *serializedEntry* to *serialized*.[[SetData]].

    3. Otherwise, if *value* is a platform object that is a serializable object[p118], then perform the serialization steps[p118] for *value*'s primary interface, given *value*, *serialized*, and *forStorage*.

        The serialization steps[p118] may need to perform a **sub-serialization**. This is an operation which takes as input a value *subValue*, and returns StructuredSerializeInternal[p120](*subValue*, *forStorage*, *memory*). (In other words, a sub-serialization[p123] is a specialization of StructuredSerializeInternal[p120] to be consistent within this invocation.)

    4. Otherwise, for each *key* in ! EnumerableOwnProperties(*value*, key):

        1. If ! HasOwnProperty(*value*, *key*) is true, then:

            1. Let *inputValue* be ? *value*.[[Get]](*key*, *value*).

            2. Let *outputValue* be ? StructuredSerializeInternal[p120](*inputValue*, *forStorage*, *memory*).

            3. Append { [[Key]]: *key*, [[Value]]: *outputValue* } to *serialized*.[[Properties]].

27. Return *serialized*.

Example

It's important to realize that the Records produced by StructuredSerializeInternal[p120] might contain "pointers" to other records that create circular references. For example, when we pass the following JavaScript object into StructuredSerializeInternal[p120]:

```
const o = {};
o.myself = o;
```

it produces the following result:

```
{
  [[Type]]: "Object",
  [[Properties]]: «
    {
      [[Key]]: "myself",
      [[Value]]: <a pointer to this whole structure>
    }
  »
}
```

2.7.4 StructuredSerialize (*value*) §[p12]

1. Return ? StructuredSerializeInternal[p120](*value*, false).

2.7.5 StructuredSerializeForStorage (*value*) §[p12]

1. Return ? StructuredSerializeInternal[p120](*value*, true).

2.7.6 StructuredDeserialize (*serialized*, *targetRealm* [, *memory*]) §[p12]

The StructuredDeserialize[p124] abstract operation takes as input a Record *serialized*, which was previously produced by StructuredSerialize[p124] or StructuredSerializeForStorage[p124], and deserializes it into a new JavaScript value, created in *targetRealm*.

This process can throw an exception, for example when trying to allocate memory for the new objects (especially `ArrayBuffer` objects).

1. If *memory* was not supplied, let *memory* be an empty map.

   Note

   The purpose of the memory *map is to avoid deserializing objects twice. This ends up preserving cycles and the identity of duplicate objects in graphs.*

2. If *memory*[*serialized*] exists, then return *memory*[*serialized*].
3. Let *deep* be false.
4. Let *value* be an uninitialized value.
5. If *serialized*.[[Type]] is "primitive", then set *value* to *serialized*.[[Value]].
6. Otherwise, if *serialized*.[[Type]] is "Boolean", then set *value* to a new Boolean object in *targetRealm* whose [[BooleanData]] internal slot value is *serialized*.[[BooleanData]].
7. Otherwise, if *serialized*.[[Type]] is "Number", then set *value* to a new Number object in *targetRealm* whose [[NumberData]] internal slot value is *serialized*.[[NumberData]].
8. Otherwise, if *serialized*.[[Type]] is "BigInt", then set *value* to a new BigInt object in *targetRealm* whose [[BigIntData]] internal slot value is *serialized*.[[BigIntData]].

9. Otherwise, if *serialized*.[[Type]] is "String", then set *value* to a new String object in *targetRealm* whose [[StringData]] internal slot value is *serialized*.[[StringData]].

10. Otherwise, if *serialized*.[[Type]] is "Date", then set *value* to a new Date object in *targetRealm* whose [[DateValue]] internal slot value is *serialized*.[[DateValue]].

11. Otherwise, if *serialized*.[[Type]] is "RegExp", then set *value* to a new RegExp object in *targetRealm* whose [[RegExpMatcher]] internal slot value is *serialized*.[[RegExpMatcher]], whose [[OriginalSource]] internal slot value is *serialized*.[[OriginalSource]], and whose [[OriginalFlags]] internal slot value is *serialized*.[[OriginalFlags]].

12. Otherwise, if *serialized*.[[Type]] is "SharedArrayBuffer", then:

    1. If *targetRealm*'s corresponding agent cluster is not *serialized*.[[AgentCluster]], then throw a `"DataCloneError"` `DOMException`.

    2. Otherwise, set *value* to a new SharedArrayBuffer object in *targetRealm* whose [[ArrayBufferData]] internal slot value is *serialized*.[[ArrayBufferData]] and whose [[ArrayBufferByteLength]] internal slot value is *serialized*.[[ArrayBufferByteLength]].

13. Otherwise, if *serialized*.[[Type]] is "GrowableSharedArrayBuffer", then:

    1. If *targetRealm*'s corresponding agent cluster is not *serialized*.[[AgentCluster]], then throw a `"DataCloneError"` `DOMException`.

    2. Otherwise, set *value* to a new SharedArrayBuffer object in *targetRealm* whose [[ArrayBufferData]] internal slot value is *serialized*.[[ArrayBufferData]], whose [[ArrayBufferByteLengthData]] internal slot value is *serialized*.[[ArrayBufferByteLengthData]], and whose [[ArrayBufferMaxByteLength]] internal slot value is *serialized*.[[ArrayBufferMaxByteLength]].

14. Otherwise, if *serialized*.[[Type]] is "ArrayBuffer", then set *value* to a new ArrayBuffer object in *targetRealm* whose [[ArrayBufferData]] internal slot value is *serialized*.[[ArrayBufferData]], and whose [[ArrayBufferByteLength]] internal slot value is *serialized*.[[ArrayBufferByteLength]].

    If this throws an exception, catch it, and then throw a `"DataCloneError"` `DOMException`.

    Note

    This step might throw an exception if there is not enough memory available to create such an ArrayBuffer object.

15. Otherwise, if *serialized*.[[Type]] is "ResizableArrayBuffer", then set *value* to a new ArrayBuffer object in *targetRealm* whose [[ArrayBufferData]] internal slot value is *serialized*.[[ArrayBufferData]], whose [[ArrayBufferByteLength]] internal slot value is *serialized*.[[ArrayBufferByteLength]], and whose [[ArrayBufferMaxByteLength]] internal slot value is *serialized*.[[ArrayBufferMaxByteLength]].

    If this throws an exception, catch it, and then throw a `"DataCloneError"` `DOMException`.

    Note

    This step might throw an exception if there is not enough memory available to create such an ArrayBuffer object.

16. Otherwise, if *serialized*.[[Type]] is "ArrayBufferView", then:

    1. Let *deserializedArrayBuffer* be ? StructuredDeserialize[p124](*serialized*.[[ArrayBufferSerialized]], *targetRealm*, *memory*).

    2. If *serialized*.[[Constructor]] is "DataView", then set *value* to a new DataView object in *targetRealm* whose [[ViewedArrayBuffer]] internal slot value is *deserializedArrayBuffer*, whose [[ByteLength]] internal slot value is *serialized*.[[ByteLength]], and whose [[ByteOffset]] internal slot value is *serialized*.[[ByteOffset]].

    3. Otherwise, set *value* to a new typed array object in *targetRealm*, using the constructor given by *serialized*.[[Constructor]], whose [[ViewedArrayBuffer]] internal slot value is *deserializedArrayBuffer*, whose [[TypedArrayName]] internal slot value is *serialized*.[[Constructor]], whose [[ByteLength]] internal slot value is *serialized*.[[ByteLength]], whose [[ByteOffset]] internal slot value is *serialized*.[[ByteOffset]], and whose [[ArrayLength]] internal slot value is *serialized*.[[ArrayLength]].

17. Otherwise, if *serialized*.[[Type]] is "Map", then:

    1. Set *value* to a new Map object in *targetRealm* whose [[MapData]] internal slot value is a new empty List.

    2. Set *deep* to true.

18. Otherwise, if *serialized*.[[Type]] is "Set", then:
    1. Set *value* to a new Set object in *targetRealm* whose [[SetData]] internal slot value is a new empty List.
    2. Set *deep* to true.
19. Otherwise, if *serialized*.[[Type]] is "Array", then:
    1. Let *outputProto* be *targetRealm*.[[Intrinsics]].[[%Array.prototype%]].
    2. Set *value* to ! ArrayCreate(*serialized*.[[Length]], *outputProto*).
    3. Set *deep* to true.
20. Otherwise, if *serialized*.[[Type]] is "Object", then:
    1. Set *value* to a new Object in *targetRealm*.
    2. Set *deep* to true.
21. Otherwise, if *serialized*.[[Type]] is "Error", then:
    1. Let *prototype* be %Error.prototype%.
    2. If *serialized*.[[Name]] is "EvalError", then set *prototype* to %EvalError.prototype%[p58].
    3. If *serialized*.[[Name]] is "RangeError", then set *prototype* to %RangeError.prototype%[p58].
    4. If *serialized*.[[Name]] is "ReferenceError", then set *prototype* to %ReferenceError.prototype%[p58].
    5. If *serialized*.[[Name]] is "SyntaxError", then set *prototype* to %SyntaxError.prototype%[p58].
    6. If *serialized*.[[Name]] is "TypeError", then set *prototype* to %TypeError.prototype%[p58].
    7. If *serialized*.[[Name]] is "URIError", then set *prototype* to %URIError.prototype%[p58].
    8. Let *message* be *serialized*.[[Message]].
    9. Set *value* to OrdinaryObjectCreate(*prototype*, « [[ErrorData]] »).
    10. Let *messageDesc* be PropertyDescriptor { [[Value]]: *message*, [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: true }.
    11. If *message* is not undefined, then perform ! OrdinaryDefineOwnProperty(*value*, "`message`", *messageDesc*).
    12. Any interesting accompanying data attached to *serialized* should be deserialized and attached to *value*.
22. Otherwise:
    1. Let *interfaceName* be *serialized*.[[Type]].
    2. If the interface identified by *interfaceName* is not exposed in *targetRealm*, then throw a "`DataCloneError`" `DOMException`.
    3. Set *value* to a new instance of the interface identified by *interfaceName*, created in *targetRealm*.
    4. Set *deep* to true.
23. Set *memory*[*serialized*] to *value*.
24. If *deep* is true, then:
    1. If *serialized*.[[Type]] is "Map", then:
        1. For each Record { [[Key]], [[Value]] } *entry* of *serialized*.[[MapData]]:
            1. Let *deserializedKey* be ? StructuredDeserialize[p124](*entry*.[[Key]], *targetRealm*, *memory*).
            2. Let *deserializedValue* be ? StructuredDeserialize[p124](*entry*.[[Value]], *targetRealm*, *memory*).
            3. Append { [[Key]]: *deserializedKey*, [[Value]]: *deserializedValue* } to *value*.[[MapData]].
    2. Otherwise, if *serialized*.[[Type]] is "Set", then:

1. For each *entry* of *serialized*.[[SetData]]:
    1. Let *deserializedEntry* be ? StructuredDeserialize[p124](*entry*, *targetRealm*, *memory*).
    2. Append *deserializedEntry* to *value*.[[SetData]].
3. Otherwise, if *serialized*.[[Type]] is "Array" or "Object", then:
    1. For each Record { [[Key]], [[Value]] } *entry* of *serialized*.[[Properties]]:
        1. Let *deserializedValue* be ? StructuredDeserialize[p124](*entry*.[[Value]], *targetRealm*, *memory*).
        2. Let *result* be ! CreateDataProperty(*value*, *entry*.[[Key]], *deserializedValue*).
        3. Assert: *result* is true.
4. Otherwise:
    1. Perform the appropriate deserialization steps[p118] for the interface identified by *serialized*.[[Type]], given *serialized*, *value*, and *targetRealm*.

       The deserialization steps[p118] may need to perform a **sub-deserialization**. This is an operation which takes as input a previously-serialized Record *subSerialized*, and returns StructuredDeserialize[p124](*subSerialized*, *targetRealm*, *memory*). (In other words, a sub-deserialization[p127] is a specialization of StructuredDeserialize[p124] to be consistent within this invocation.)

25. Return *value*.

2.7.7 StructuredSerializeWithTransfer (*value*, *transferList*) §[p127]

1. Let *memory* be an empty map.

   Note

   In addition to how it is used normally by StructuredSerializeInternal[p120], in this algorithm memory *is also used to ensure that StructuredSerializeInternal[p120] ignores items in* transferList*, and let us do our own handling instead.*

2. For each *transferable* of *transferList*:
    1. If *transferable* has neither an [[ArrayBufferData]] internal slot nor a [[Detached]][p120] internal slot, then throw a "DataCloneError" DOMException.
    2. If *transferable* has an [[ArrayBufferData]] internal slot and IsSharedArrayBuffer(*transferable*) is true, then throw a "DataCloneError" DOMException.
    3. If *memory*[*transferable*] exists, then throw a "DataCloneError" DOMException.
    4. Set *memory*[*transferable*] to { [[Type]]: an uninitialized value }.

       Note

       transferable *is not transferred yet as transferring has side effects and StructuredSerializeInternal[p120] needs to be able to throw first.*

3. Let *serialized* be ? StructuredSerializeInternal[p120](*value*, false, *memory*).
4. Let *transferDataHolders* be a new empty List.
5. For each *transferable* of *transferList*:
    1. If *transferable* has an [[ArrayBufferData]] internal slot and IsDetachedBuffer(*transferable*) is true, then throw a "DataCloneError" DOMException.
    2. If *transferable* has a [[Detached]][p120] internal slot and *transferable*.[[Detached]][p120] is true, then throw a "DataCloneError" DOMException.
    3. Let *dataHolder* be *memory*[*transferable*].

4. If *transferable* has an [[ArrayBufferData]] internal slot, then:
    1. If *transferable* has an [[ArrayBufferMaxByteLength]] internal slot, then:
        1. Set *dataHolder*.[[Type]] to "ResizableArrayBuffer".
        2. Set *dataHolder*.[[ArrayBufferData]] to *transferable*.[[ArrayBufferData]].
        3. Set *dataHolder*.[[ArrayBufferByteLength]] to *transferable*.[[ArrayBufferByteLength]].
        4. Set *dataHolder*.[[ArrayBufferMaxByteLength]] to *transferable*.[[ArrayBufferMaxByteLength]].
    2. Otherwise:
        1. Set *dataHolder*.[[Type]] to "ArrayBuffer".
        2. Set *dataHolder*.[[ArrayBufferData]] to *transferable*.[[ArrayBufferData]].
        3. Set *dataHolder*.[[ArrayBufferByteLength]] to *transferable*.[[ArrayBufferByteLength]].
    3. Perform ? DetachArrayBuffer(*transferable*).

        Note

        Specifications can use the [[ArrayBufferDetachKey]] internal slot to prevent ArrayBuffers from being detached. This is used in WebAssembly JavaScript Interface*, for example. [WASMJS]*[p1501]
5. Otherwise:
    1. Assert: *transferable* is a platform object that is a transferable object[p119].
    2. Let *interfaceName* be the identifier of the primary interface of *transferable*.
    3. Set *dataHolder*.[[Type]] to *interfaceName*.
    4. Perform the appropriate transfer steps[p120] for the interface identified by *interfaceName*, given *transferable* and *dataHolder*.
    5. Set *transferable*.[[Detached]][p120] to true.
6. Append *dataHolder* to *transferDataHolders*.

6. Return { [[Serialized]]: *serialized*, [[TransferDataHolders]]: *transferDataHolders* }.

2.7.8 StructuredDeserializeWithTransfer (*serializeWithTransferResult*, *targetRealm*) §[p128]

1. Let *memory* be an empty map.

    Note

    Analogous to StructuredSerializeWithTransfer[p127], in addition to how it is used normally by StructuredDeserialize[p124], in this algorithm memory *is also used to ensure that StructuredDeserialize[p124] ignores items in* serializeWithTransferResult.*[[TransferDataHolders]], and let us do our own handling instead.*
2. Let *transferredValues* be a new empty List.
3. For each *transferDataHolder* of *serializeWithTransferResult*.[[TransferDataHolders]]:
    1. Let *value* be an uninitialized value.
    2. If *transferDataHolder*.[[Type]] is "ArrayBuffer", then set *value* to a new ArrayBuffer object in *targetRealm* whose [[ArrayBufferData]] internal slot value is *transferDataHolder*.[[ArrayBufferData]], and whose [[ArrayBufferByteLength]] internal slot value is *transferDataHolder*.[[ArrayBufferByteLength]].

        Note

        In cases where the original memory occupied by [[ArrayBufferData]] is accessible during the deserialization, this step is unlikely to throw an exception, as no new memory needs to be allocated: the memory occupied by

[[ArrayBufferData]] is instead just getting transferred into the new ArrayBuffer. This could be true, for example, when both the source and target realms are in the same process.

3. Otherwise, if *transferDataHolder*.[[Type]] is "ResizableArrayBuffer", then set *value* to a new ArrayBuffer object in *targetRealm* whose [[ArrayBufferData]] internal slot value is *transferDataHolder*.[[ArrayBufferData]], whose [[ArrayBufferByteLength]] internal slot value is *transferDataHolder*.[[ArrayBufferByteLength]], and whose [[ArrayBufferMaxByteLength]] internal slot value is *transferDataHolder*.[[ArrayBufferMaxByteLength]].

   Note

   For the same reason as the previous step, this step is also unlikely to throw an exception.

4. Otherwise:

   1. Let *interfaceName* be *transferDataHolder*.[[Type]].
   2. If the interface identified by *interfaceName* is not exposed in *targetRealm*, then throw a "DataCloneError" DOMException.
   3. Set *value* to a new instance of the interface identified by *interfaceName*, created in *targetRealm*.
   4. Perform the appropriate transfer-receiving steps[p120] for the interface identified by *interfaceName* given *transferDataHolder* and *value*.

5. Set *memory*[*transferDataHolder*] to *value*.
6. Append *value* to *transferredValues*.

4. Let *deserialized* be ? StructuredDeserialize[p124](*serializeWithTransferResult*.[[Serialized]], *targetRealm*, *memory*).
5. Return { [[Deserialized]]: *deserialized*, [[TransferredValues]]: *transferredValues* }.

2.7.9 Performing serialization and transferring from other specifications §[p129]

Other specifications may use the abstract operations defined here. The following provides some guidance on when each abstract operation is typically useful, with examples.

StructuredSerializeWithTransfer[p127]

StructuredDeserializeWithTransfer[p128]

Cloning a value to another realm, with a transfer list, but where the target realm is not known ahead of time. In this case the serialization step can be performed immediately, with the deserialization step delayed until the target realm becomes known.

Example

`messagePort.postMessage()`[p1226] uses this pair of abstract operations, as the destination realm is not known until the `MessagePort`[p1223] has been shipped[p1224].

StructuredSerialize[p124]

StructuredSerializeForStorage[p124]

StructuredDeserialize[p124]

Creating a realm-independent snapshot of a given value which can be saved for an indefinite amount of time, and then reified back into a JavaScript value later, possibly multiple times.

StructuredSerializeForStorage[p124] can be used for situations where the serialization is anticipated to be stored in a persistent manner, instead of passed between realms. It throws when attempting to serialize `SharedArrayBuffer` objects, since storing shared memory does not make sense. Similarly, it can throw or possibly have different behavior when given a platform object with custom serialization steps[p118] when the *forStorage* argument is true.

Example

`history.pushState()`[p958] and `history.replaceState()`[p958] use StructuredSerializeForStorage[p124] on author-supplied state objects, storing them as serialized state[p1019] in the appropriate session history entry[p1018]. Then, StructuredDeserialize[p124] is used

so that the `history.state` property can return a clone of the originally-supplied state object.

Example

`broadcastChannel.postMessage()` uses StructuredSerialize on its input, then uses StructuredDeserialize multiple times on the result to produce a fresh clone for each destination being broadcast to. Note that transferring does not make sense in multi-destination situations.

Example

Any API for persisting JavaScript values to the filesystem would also use StructuredSerializeForStorage on its input and StructuredDeserialize on its output.

In general, call sites may pass in Web IDL values instead of JavaScript values; this is to be understood to perform an implicit conversion to the JavaScript value before invoking these algorithms.

Call sites that are not invoked as a result of author code synchronously calling into a user agent method must take care to properly prepare to run script and prepare to run a callback before invoking StructuredSerialize, StructuredSerializeForStorage, or StructuredSerializeWithTransfer abstract operations, if they are being performed on arbitrary objects. This is necessary because the serialization process can invoke author-defined accessors as part of its final deep-serialization steps, and these accessors could call into operations that rely on the entry and incumbent concepts being properly set up.

Example

`window.postMessage()` performs StructuredSerializeWithTransfer on its arguments, but is careful to do so immediately, inside the synchronous portion of its algorithm. Thus it is able to use the algorithms without needing to prepare to run script and prepare to run a callback.

Example

In contrast, a hypothetical API that used StructuredSerialize to serialize some author-supplied object periodically, directly from a task on the event loop, would need to ensure it performs the appropriate preparations beforehand. As of this time, we know of no such APIs on the platform; usually it is simpler to perform the serialization ahead of time, as a synchronous consequence of author code.

2.7.10 Structured cloning API

For web developers (non-normative)

***result* = self.structuredClone(*value*[, { transfer }])**

Takes the input value and returns a deep copy by performing the structured clone algorithm. Transferable objects listed in the `transfer` array are transferred, not just cloned, meaning that they are no longer usable in the input value.

Throws a `"DataCloneError"` `DOMException` if any part of the input value is not serializable.

The **`structuredClone(value, options)`** method steps are:

1. Let *serialized* be ? StructuredSerializeWithTransfer(*value*, *options*["`transfer`"]).
2. Let *deserializeRecord* be ? StructuredDeserializeWithTransfer(*serialized*, this's relevant realm).
3. Return *deserializeRecord*.[[Deserialized]].

3 Semantics, structure, and APIs of HTML documents §p13 1

3.1 Documents §p13 1

Every XML and HTML document in an HTML UA is represented by a Document p131 object. [DOM] p1496

The Document p131 object's **URL** is defined in *DOM*. It is initially set when the Document p131 object is created, but can change during the lifetime of the Document p131 object; for example, it changes when the user navigates p1028 to a fragment p1035 on the page and when the pushState() p958 method is called with a new URL. [DOM] p1496

⚠Warning!

Interactive user agents typically expose the Document p131 object's URL in their user interface. This is the primary mechanism by which a user can tell if a site is attempting to impersonate another.

The Document p131 object's **origin** is defined in *DOM*. It is initially set when the Document p131 object is created, and can change during the lifetime of the Document p131 only upon setting document.domain p912. A Document p131's origin can differ from the origin of its URL; for example when a child navigable p1004 is created p1005, its active document p1002's origin is inherited from its parent p1001's active document p1002's origin, even though its active document p1002's URL is about:blank p54. [DOM] p1496

When a Document p131 is created by a script p1099 using the createDocument() or createHTMLDocument() methods, the Document p131 is ready for post-load tasks p1377 immediately.

The document's referrer is a string (representing a URL) that can be set when the Document p131 is created. If it is not explicitly set, then its value is the empty string.

3.1.1 The Document p131 object §p13 1

DOM defines a Document interface, which this specification extends significantly.

IDL

```
enum DocumentReadyState { "loading", "interactive", "complete" };
enum DocumentVisibilityState { "visible", "hidden" };
typedef (HTMLScriptElement or SVGScriptElement) HTMLOrSVGScriptElement;

[LegacyOverrideBuiltIns]
partial interface Document {
  static Document parseHTMLUnsafe((TrustedHTML or DOMString) html);

  // resource metadata management
  [PutForwards=href, LegacyUnforgeable] readonly attribute Location? location;
  attribute USVString domain;
  readonly attribute USVString referrer;
  attribute USVString cookie;
  readonly attribute DOMString lastModified;
  readonly attribute DocumentReadyState readyState;

  // DOM tree accessors
  getter object (DOMString name);

  boolean queryCommandState(DOMString commandId);
  boolean queryCommandSupported(DOMString commandId);
  DOMString queryCommandValue(DOMString commandId);
  readonly attribute boolean hidden;
  readonly attribute DocumentVisibilityState visibilityState;

  // special event handler IDL attributes that only apply to Document objects
  [LegacyLenientThis] attribute EventHandler onreadystatechange;
  attribute EventHandler onvisibilitychange;

  // also has obsolete members
};
Document includes GlobalEventHandlers;
```

Each Document[p131] has a **policy container** (a policy container[p929]), initially a new policy container, which contains policies which apply to the Document[p131].

Each Document[p131] has a **permissions policy**, which is a permissions policy, which is initially empty.

Each Document[p131] has a **module map**, which is a module map[p1134], initially empty.

Each Document[p131] has an **opener policy**, which is an opener policy[p915], initially a new opener policy.

Each Document[p131] has an **is initial `about:blank`**, which is a boolean, initially false.

Each Document[p131] has a **during-loading navigation ID for WebDriver BiDi**, which is a navigation ID[p1027] or null, initially null.

Note

As the name indicates, this is used for interfacing with the WebDriver BiDi *specification, which needs to be informed about certain occurrences during the early parts of the* Document[p131]*'s lifecycle, in a way that ties them to the original navigation ID[p1027] used when the navigation that created this* Document[p131] *was the ongoing navigation[p1041]. This eventually gets set back to null, after* WebDriver BiDi *considers the loading process to be finished. [BIDI][p1493]*

Each Document[p131] has an **about base URL**, which is a URL or null, initially null.

Note

This is only populated for `"about:"`*-schemed* Document[p131]*s.*

Each Document[p131] has a **bfcache blocking details**, which is a set of not restored reason details[p997], initially empty.

Each Document[p131] has an **open dialogs list**, which is a list of `dialog`[p650] elements, initially empty.

3.1.2 The DocumentOrShadowRoot[p133] interface §[p133]

DOM defines the DocumentOrShadowRoot mixin, which this specification extends.

IDL
```
partial interface mixin DocumentOrShadowRoot {
  readonly attribute Element? activeElement;
};
```

3.1.3 Resource metadata management §[p133]

For web developers (non-normative)

***document*.referrer[p133]**

Returns the URL of the Document[p131] from which the user navigated to this one, unless it was blocked or there was no such document, in which case it returns the empty string.

The noreferrer[p326] link type can be used to block the referrer.

The **referrer** attribute must return the document's referrer[p131].

For web developers (non-normative)

***document*.cookie[p133] [= *value*]**

Returns the HTTP cookies that apply to the Document[p131]. If there are no cookies or cookies can't be applied to this resource, the empty string will be returned.

Can be set, to add a new cookie to the element's set of HTTP cookies.

If the contents are sandboxed into an opaque origin[p927] (e.g., in an iframe[p391] with the sandbox[p396] attribute), a "SecurityError" DOMException will be thrown on getting and setting.

The **cookie** attribute represents the cookies of the resource identified by the document's URL.

A Document[p131] object that falls into one of the following conditions is a **cookie-averse Document object**:

- A Document[p131] object whose browsing context[p1012] is null.
- A Document[p131] whose URL's scheme is not an HTTP(S) scheme.

On getting, if the document is a cookie-averse Document object[p133], then the user agent must return the empty string. Otherwise, if the Document[p131]'s origin is an opaque origin[p909], the user agent must throw a "SecurityError" DOMException. Otherwise, the user agent must return the cookie-string for the document's URL for a "non-HTTP" API, decoded using UTF-8 decode without BOM. [COOKIES][p1494]

On setting, if the document is a cookie-averse Document object[p133], then the user agent must do nothing. Otherwise, if the Document[p131]'s origin is an opaque origin[p909], the user agent must throw a "SecurityError" DOMException. Otherwise, the user agent must act as it would when receiving a set-cookie-string for the document's URL via a "non-HTTP" API, consisting of the new value encoded as UTF-8. [COOKIES][p1494] [ENCODING][p1496]

Note

Since the cookie[p133] attribute is accessible across frames, the path restrictions on cookies are only a tool to help manage which cookies are sent to which parts of the site, and are not in any way a security feature.

⚠Warning!

The cookie[p133] attribute's getter and setter synchronously access shared state. Since there is no locking mechanism, other browsing contexts in a multiprocess user agent can modify cookies while scripts are running. A site could, for instance, try to read a cookie, increment its value, then write it back out, using the new value of the cookie as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same "unique" identifier for both sessions, with potentially disastrous effects.

For web developers (non-normative)

***document*.lastModified**[p134]

Returns the date of the last modification to the document, as reported by the server, in the form "MM/DD/YYYY hh:mm:ss", in the user's local time zone.

If the last modification date is not known, the current time is returned instead.

The **lastModified** attribute, on getting, must return the date and time of the Document[p131]'s source file's last modification, in the user's local time zone, in the following format:

1. The month component of the date.
2. A U+002F SOLIDUS character (/).
3. The day component of the date.
4. A U+002F SOLIDUS character (/).
5. The year component of the date.
6. A U+0020 SPACE character.
7. The hours component of the time.
8. A U+003A COLON character (:).
9. The minutes component of the time.
10. A U+003A COLON character (:).
11. The seconds component of the time.

All the numeric components above, other than the year, must be given as two ASCII digits representing the number in base ten, zero-padded if necessary. The year must be given as the shortest possible string of four or more ASCII digits representing the number in base ten, zero-padded if necessary.

The Document[p131]'s source file's last modification date and time must be derived from relevant features of the networking protocols used, e.g. from the value of the HTTP `Last-Modified` header of the document, or from metadata in the file system for local files. If the last modification date and time are not known, the attribute must return the current date and time in the above format.

3.1.4 Reporting document loading status §[p134]

For web developers (non-normative)

***document*.readyState**[p134]

Returns "loading" while the Document[p131] is loading, "interactive" once it is finished parsing but still loading subresources, and "complete" once it has loaded.

The readystatechange[p1490] event fires on the Document[p131] object when this value changes.

The DOMContentLoaded[p1489] event fires after the transition to "interactive" but before the transition to "complete", at the point where all subresources apart from async[p662] script[p660] elements have loaded.

Each Document[p131] has a **current document readiness**, a string, initially "complete".

Note

For Document[p131] objects created via the create and initialize a Document object[p1071] algorithm, this will be immediately reset to "loading" before any script can observe the value of document.readyState[p134]. This default applies to other cases such as initial about:blank[p132] Document[p131]s or Document[p131]s without a browsing context[p1012].

The **readyState** getter steps are to return this's current document readiness[p134].

To **update the current document readiness** for Document[p131] *document* to *readinessValue*:

1. If *document*'s current document readiness[p134] equals *readinessValue*, then return.

2. Set *document*'s current document readiness[p134] to *readinessValue*.

3. If *document* is associated with an HTML parser[p1289], then:

    1. Let *now* be the current high resolution time given *document*'s relevant global object[p1098].

    2. If *readinessValue* is "`complete`", and *document*'s load timing info[p135]'s DOM complete time[p135] is 0, then set *document*'s load timing info[p135]'s DOM complete time[p135] to *now*.

    3. Otherwise, if *readinessValue* is "`interactive`", and *document*'s load timing info[p135]'s DOM interactive time[p135] is 0, then set *document*'s load timing info[p135]'s DOM interactive time[p135] to *now*.

4. Fire an event named `readystatechange`[p1490] at *document*.

A `Document`[p131] is said to have an **active parser** if it is associated with an HTML parser[p1289] or an XML parser[p1402] that has not yet been stopped[p1376] or aborted[p1377].

A `Document`[p131] has a document load timing info[p135] **load timing info**.

A `Document`[p131] has a document unload timing info[p135] **previous document unload timing**.

A `Document`[p131] has a boolean **was created via cross-origin redirects**, initially false.

The **document load timing info** struct has the following items:

navigation start time **(default 0)**
: A number

DOM interactive time **(default 0)**
DOM content loaded event start time **(default 0)**
DOM content loaded event end time **(default 0)**
DOM complete time **(default 0)**
load event start time **(default 0)**
load event end time **(default 0)**
: `DOMHighResTimeStamp` values

The **document unload timing info** struct has the following items:

unload event start time **(default 0)**
unload event end time **(default 0)**
: `DOMHighResTimeStamp` values

3.1.5 Render-blocking mechanism §[p135]

Each `Document`[p131] has a **render-blocking element set**, a set of elements, initially the empty set.

A `Document`[p131] *document* **allows adding render-blocking elements** if *document*'s content type is "`text/html`[p1462]" and the body element[p137] of *document* is null.

A `Document`[p131] *document* is **render-blocked** if both of the following are true:

- *document*'s render-blocking element set[p135] is non-empty, or *document* allows adding render-blocking elements[p135].
- The current high resolution time given *document*'s relevant global object[p1098] has not exceeded an implementation-defined timeout value.

An element *el* is **render-blocking** if *el*'s node document *document* is render-blocked[p135], and *el* is in *document*'s render-blocking element set[p135].

To **block rendering** on an element *el*:

1. Let *document* be *el*'s node document.
2. If *document* allows adding render-blocking elements[p135], then append *el* to *document*'s render-blocking element set[p135].

To **unblock rendering** on an element *el*:

1. Let *document* be *el*'s node document.
2. Remove *el* from *document*'s render-blocking element set[p135].

Whenever a render-blocking[p135] element *el* becomes browsing-context disconnected[p47], or *el*'s blocking attribute[p104]'s value is changed so that *el* is no longer potentially render-blocking[p105], then unblock rendering[p136] on *el*.

3.1.6 DOM tree accessors §[p136]

The `html` element of a document is its document element, if it's an `html`[p173] element, and null otherwise.

For web developers (non-normative)

***document*.head**[p136]

Returns the head element[p136].

The `head` element of a document is the first `head`[p174] element that is a child of the `html` element[p136], if there is one, or null otherwise.

The **`head`** attribute, on getting, must return the head element[p136] of the document (a `head`[p174] element or null).

For web developers (non-normative)

***document*.title**[p136] **[= *value*]**

Returns the document's title, as given by the `title` element[p136] for HTML and as given by the SVG `title` element for SVG.

Can be set, to update the document's title. If there is no appropriate element to update, the new value is ignored.

The `title` element of a document is the first `title`[p175] element in the document (in tree order), if there is one, or null otherwise.

The **`title`** attribute must, on getting, run the following algorithm:

1. If the document element is an SVG `svg` element, then let *value* be the child text content of the first SVG `title` element that is a child of the document element.
2. Otherwise, let *value* be the child text content of the `title` element[p136], or the empty string if the `title` element[p136] is null.
3. Strip and collapse ASCII whitespace in *value*.
4. Return *value*.

On setting, the steps corresponding to the first matching condition in the following list must be run:

↪ **If the document element is an SVG `svg` element**

1. If there is an SVG `title` element that is a child of the document element, let *element* be the first such element.
2. Otherwise:
    1. Let *element* be the result of creating an element given the document element's node document, "`title`", and the SVG namespace.
    2. Insert *element* as the first child of the document element.
3. String replace all with the given value within *element*.

↪ **If the document element is in the HTML namespace**

1. If the `title` element[p136] is null and the head element[p136] is null, then return.

2. If the title element[p136] is non-null, let *element* be the title element[p136].

3. Otherwise:

    1. Let *element* be the result of creating an element given the document element's node document, "title", and the HTML namespace.

    2. Append *element* to the head element[p136].

4. String replace all with the given value within *element*.

↪ **Otherwise**

Do nothing.

For web developers (non-normative)

***document*.body[p137] [= *value*]**

Returns the body element[p137].

Can be set, to replace the body element[p137].

If the new value is not a body[p206] or frameset[p1451] element, this will throw a "HierarchyRequestError" DOMException.

The body element of a document is the first of the html element[p136]'s children that is either a body[p206] element or a frameset[p1451] element, or null if there is no such element.

The **body** attribute, on getting, must return the body element[p137] of the document (either a body[p206] element, a frameset[p1451] element, or null). On setting, the following algorithm must be run:

1. If the new value is not a body[p206] or frameset[p1451] element, then throw a "HierarchyRequestError" DOMException.
2. Otherwise, if the new value is the same as the body element[p137], return.
3. Otherwise, if the body element[p137] is not null, then replace the body element[p137] with the new value within the body element[p137]'s parent and return.
4. Otherwise, if there is no document element, throw a "HierarchyRequestError" DOMException.
5. Otherwise, the body element[p137] is null, but there's a document element. Append the new value to the document element.

Note

The value returned by the body[p137] getter is not always the one passed to the setter.

Example

In this example, the setter successfully inserts a body[p206] element (though this is non-conforming since SVG does not allow a body[p206] as child of SVG svg). However the getter will return null because the document element is not html[p173].

```
<svg xmlns="http://www.w3.org/2000/svg">
 <script>
  document.body = document.createElementNS("http://www.w3.org/1999/xhtml", "body");
  console.assert(document.body === null);
 </script>
</svg>
```

For web developers (non-normative)

***document*.images[p138]**

Returns an HTMLCollection of the img[p347] elements in the Document[p131].

***document*.embeds[p138]**

***document*.plugins[p138]**

Returns an HTMLCollection of the embed[p400] elements in the Document[p131].

***document*.links**[p138]

Returns an HTMLCollection of the a[p258] and area[p472] elements in the Document[p131] that have href[p304] attributes.

***document*.forms**[p138]

Returns an HTMLCollection of the form[p515] elements in the Document[p131].

***document*.scripts**[p138]

Returns an HTMLCollection of the script[p660] elements in the Document[p131].

The **images** attribute must return an HTMLCollection rooted at the Document[p131] node, whose filter matches only img[p347] elements.

The **embeds** attribute must return an HTMLCollection rooted at the Document[p131] node, whose filter matches only embed[p400] elements.

The **plugins** attribute must return the same object as that returned by the embeds[p138] attribute.

The **links** attribute must return an HTMLCollection rooted at the Document[p131] node, whose filter matches only a[p258] elements with href[p304] attributes and area[p472] elements with href[p304] attributes.

The **forms** attribute must return an HTMLCollection rooted at the Document[p131] node, whose filter matches only form[p515] elements.

The **scripts** attribute must return an HTMLCollection rooted at the Document[p131] node, whose filter matches only script[p660] elements.

For web developers (non-normative)

***collection* = *document*.getElementsByName**[p138]**(*name*)**

Returns a NodeList of elements in the Document[p131] that have a name attribute with the value *name*.

The **getElementsByName(*elementName*)** method steps are to return a live[p48] NodeList containing all the HTML elements[p46] in that document that have a name attribute whose value is identical to the *elementName* argument, in tree order. When the method is invoked on a Document[p131] object again with the same argument, the user agent may return the same as the object returned by the earlier call. In other cases, a new NodeList object must be returned.

For web developers (non-normative)

***document*.currentScript**[p138]

Returns the script[p660] element, or the SVG script element, that is currently executing, as long as the element represents a classic script[p1100]. In the case of reentrant script execution, returns the one that most recently started executing amongst those that have not yet finished executing.

Returns null if the Document[p131] is not currently executing a script[p660] or SVG script element (e.g., because the running script is an event handler, or a timeout), or if the currently executing script[p660] or SVG script element represents a module script[p1100].

The **currentScript** attribute, on getting, must return the value to which it was most recently set. When the Document[p131] is created, the currentScript[p138] must be initialized to null.

Note

This API has fallen out of favor in the implementer and standards community, as it globally exposes script[p660] or SVG script elements. As such, it is not available in newer contexts, such as when running module scripts[p1100] or when running scripts in a shadow tree. We are looking into creating a new solution for identifying the running script in such contexts, which does not make it globally available: see issue #1013.

The Document[p131] interface supports named properties. The supported property names of a Document[p131] object *document* at any moment consist of the following, in tree order according to the element that contributed them, ignoring later duplicates, and with values from id[p156] attributes coming before values from name attributes when the same element contributes both:

- the value of the name content attribute for all exposed[p139] embed[p400], form[p515], iframe[p391], img[p347], and exposed[p139] object[p403] elements that have a non-empty name content attribute and are in a document tree with *document* as their root;

- the value of the id content attribute for all exposed object elements that have a non-empty id content attribute and are in a document tree with *document* as their root; and
- the value of the id content attribute for all img elements that have both a non-empty id content attribute and a non-empty name content attribute, and are in a document tree with *document* as their root.

To determine the value of a named property *name* for a Document, the user agent must return the value obtained using the following steps:

1. Let *elements* be the list of named elements with the name *name* that are in a document tree with the Document as their root.

   Note

   There will be at least one such element, since the algorithm would otherwise not have been invoked by Web IDL.

2. If *elements* has only one element, and that element is an iframe element, and that iframe element's content navigable is not null, then return the active WindowProxy of the element's content navigable.
3. Otherwise, if *elements* has only one element, return that element.
4. Otherwise, return an HTMLCollection rooted at the Document node, whose filter matches only named elements with the name *name*.

Named elements with the name *name*, for the purposes of the above algorithm, are those that are either:

- Exposed embed, form, iframe, img, or exposed object elements that have a name content attribute whose value is *name*, or
- Exposed object elements that have an id content attribute whose value is *name*, or
- img elements that have an id content attribute whose value is *name*, and that have a non-empty name content attribute present also.

An embed or object element is said to be **exposed** if it has no exposed object ancestor, and, for object elements, is additionally either not showing its fallback content or has no object or embed descendants.

Note

The dir attribute on the Document interface is defined along with the dir content attribute.

3.2 Elements

3.2.1 Semantics

Elements, attributes, and attribute values in HTML are defined (by this specification) to have certain meanings (semantics). For example, the ol element represents an ordered list, and the lang attribute represents the language of the content.

These definitions allow HTML processors, such as web browsers or search engines, to present and use documents and applications in a wide variety of contexts that the author might not have considered.

Example

As a simple example, consider a web page written by an author who only considered desktop computer web browsers:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>My Page</title>
 </head>
 <body>
  <h1>Welcome to my page</h1>
```

```
  <p>I like cars and lorries and have a big Jeep!</p>
  <h2>Where I live</h2>
  <p>I live in a small hut on a mountain!</p>
 </body>
</html>
```

Because HTML conveys *meaning*, rather than presentation, the same page can also be used by a small browser on a mobile phone, without any change to the page. Instead of headings being in large letters as on the desktop, for example, the browser on the mobile phone might use the same size text for the whole page, but with the headings in bold.

But it goes further than just differences in screen size: the same page could equally be used by a blind user using a browser based around speech synthesis, which instead of displaying the page on a screen, reads the page to the user, e.g. using headphones. Instead of large text for the headings, the speech browser might use a different volume or a slower voice.

That's not all, either. Since the browsers know which parts of the page are the headings, they can create a document outline that the user can use to quickly navigate around the document, using keys for "jump to next heading" or "jump to previous heading". Such features are especially common with speech browsers, where users would otherwise find quickly navigating a page quite difficult.

Even beyond browsers, software can make use of this information. Search engines can use the headings to more effectively index a page, or to provide quick links to subsections of the page from their results. Tools can use the headings to create a table of contents (that is in fact how this very specification's table of contents is generated).

This example has focused on headings, but the same principle applies to all of the semantics in HTML.

Authors must not use elements, attributes, or attribute values for purposes other than their appropriate intended semantic purpose, as doing so prevents software from correctly processing the page.

Example

For example, the following snippet, intended to represent the heading of a corporate site, is non-conforming because the second line is not intended to be a heading of a subsection, but merely a subheading or subtitle (a subordinate heading for the same section).

```
<body>
 <h1>ACME Corporation</h1>
 <h2>The leaders in arbitrary fast delivery since 1920</h2>
 ...
```

The hgroup[p219] element can be used for these kinds of situations:

```
<body>
 <hgroup>
  <h1>ACME Corporation</h1>
  <p>The leaders in arbitrary fast delivery since 1920</p>
 </hgroup>
 ...
```

Example

The document in this next example is similarly non-conforming, despite being syntactically correct, because the data placed in the cells is clearly not tabular data, and the cite[p266] element mis-used:

```
<!DOCTYPE HTML>
<html lang="en-GB">
 <head> <title> Demonstration </title> </head>
 <body>
  <table>
   <tr> <td> My favourite animal is the cat. </td> </tr>
   <tr>
```

```
    <td>
     —<a href="https://example.org/~ernest/"><cite>Ernest</cite></a>,
     in an essay from 1992
    </td>
   </tr>
  </table>
 </body>
</html>
```

This would make software that relies on these semantics fail: for example, a speech browser that allowed a blind user to navigate tables in the document would report the quote above as a table, confusing the user; similarly, a tool that extracted titles of works from pages would extract "Ernest" as the title of a work, even though it's actually a person's name, not a title.

A corrected version of this document might be:

```
<!DOCTYPE HTML>
<html lang="en-GB">
 <head> <title> Demonstration </title> </head>
 <body>
  <blockquote>
   <p> My favourite animal is the cat. </p>
  </blockquote>
  <p>
   —<a href="https://example.org/~ernest/">Ernest</a>,
   in an essay from 1992
  </p>
 </body>
</html>
```

Authors must not use elements, attributes, or attribute values that are not permitted by this specification or other applicable specifications[p74], as doing so makes it significantly harder for the language to be extended in the future.

Example

In the next example, there is a non-conforming attribute value ("carpet") and a non-conforming attribute ("texture"), which is not permitted by this specification:

```
<label>Carpet: <input type="carpet" name="c" texture="deep pile"></label>
```

Here would be an alternative and correct way to mark this up:

```
<label>Carpet: <input type="text" class="carpet" name="c" data-texture="deep pile"></label>
```

DOM nodes whose node document's browsing context[p1012] is null are exempt from all document conformance requirements other than the HTML syntax[p1277] requirements and XML syntax[p1402] requirements.

Example

In particular, the `template`[p679] element's template contents[p680]'s node document's browsing context[p1012] is null. For example, the content model[p147] requirements and attribute value microsyntax requirements do not apply to a `template`[p679] element's template contents[p680]. In this example an `img`[p347] element has attribute values that are placeholders that would be invalid outside a `template`[p679] element.

```
<template>
 <article>
  <img src="{{src}}" alt="{{alt}}">
  <h1></h1>
 </article>
</template>
```

However, if the above markup were to omit the </h1> end tag, that would be a violation of the HTML syntax[p1277], and would thus be flagged as an error by conformance checkers.

Through scripting and using other mechanisms, the values of attributes, text, and indeed the entire structure of the document may change dynamically while a user agent is processing it. The semantics of a document at an instant in time are those represented by the state of the document at that instant in time, and the semantics of a document can therefore change over time. User agents must update their presentation of the document as this occurs.

Example

HTML has a progress[p590] element that describes a progress bar. If its "value" attribute is dynamically updated by a script, the UA would update the rendering to show the progress changing.

3.2.2 Elements in the DOM §[p14] 2

The nodes representing HTML elements[p46] in the DOM must implement, and expose to scripts, the interfaces listed for them in the relevant sections of this specification. This includes HTML elements[p46] in XML documents, even when those documents are in another context (e.g. inside an XSLT transform).

Elements in the DOM **represent** things; that is, they have intrinsic *meaning*, also known as semantics.

Example

For example, an ol[p239] element represents an ordered list.

Elements can be **referenced** (referred to) in some way, either explicitly or implicitly. One way that an element in the DOM can be explicitly referenced is by giving an id[p156] attribute to the element, and then creating a hyperlink[p303] with that id[p156] attribute's value as the fragment[p1035] for the hyperlink[p303]'s href[p304] attribute value. Hyperlinks are not necessary for a reference, however; any manner of referring to the element in question will suffice.

Example

Consider the following figure[p250] element, which is given an id[p156] attribute:

```
<figure id="module-script-graph">
  <img src="module-script-graph.svg"
       alt="Module A depends on module B, which depends
            on modules C and D.">
  <figcaption>Figure 27: a simple module graph</figcaption>
</figure>
```

A hyperlink[p303]-based reference[p142] could be created using the a[p258] element, like so:

```
As we can see in <a href="#module-script-graph">figure 27</a>, ...
```

However, there are many other ways of referencing[p142] the figure[p250] element, such as:

- "As depicted in the figure of modules A, B, C, and D..."
- "In Figure 27..." (without a hyperlink)
- "From the contents of the 'simple module graph' figure..."
- "In the figure below..." (but this is discouraged[p250])

The basic interface, from which all the HTML elements[p46]' interfaces inherit, and which must be used by elements that have no additional requirements, is the HTMLElement[p143] interface.

IDL

```
[Exposed=Window]
interface HTMLElement : Element {
  [HTMLConstructor] constructor();

  // metadata attributes
  [CEReactions] attribute DOMString title;
  [CEReactions] attribute DOMString lang;
  [CEReactions] attribute boolean translate;
  [CEReactions] attribute DOMString dir;

  // user interaction
  [CEReactions] attribute (boolean or unrestricted double or DOMString)? hidden;
  [CEReactions] attribute boolean inert;
  undefined click();
  [CEReactions] attribute DOMString accessKey;
  readonly attribute DOMString accessKeyLabel;
  [CEReactions] attribute boolean draggable;
  [CEReactions] attribute boolean spellcheck;
  [CEReactions] attribute DOMString writingSuggestions;
  [CEReactions] attribute DOMString autocapitalize;
  [CEReactions] attribute boolean autocorrect;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString innerText;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString outerText;

  ElementInternals attachInternals();

  // The popover API
  undefined showPopover(optional ShowPopoverOptions options = {});
  undefined hidePopover();
  boolean togglePopover(optional (TogglePopoverOptions or boolean) options = {});
  [CEReactions] attribute DOMString? popover;
};

dictionary ShowPopoverOptions {
  HTMLElement source;
};

dictionary TogglePopoverOptions : ShowPopoverOptions {
  boolean force;
};

HTMLElement includes GlobalEventHandlers;
HTMLElement includes ElementContentEditable;
HTMLElement includes HTMLOrSVGElement;

[Exposed=Window]
interface HTMLUnknownElement : HTMLElement {
  // Note: intentionally no [HTMLConstructor]
};
```

The HTMLElement[p143] interface holds methods and attributes related to a number of disparate features, and the members of this interface are therefore described in various different sections of this specification.

The element interface for an element with name *name* in the HTML namespace is determined as follows:

1. If *name* is applet[p1444], bgsound[p1444], blink[p1445], isindex[p1444], keygen[p1444], multicol[p1445], nextid[p1444], or spacer[p1445], then return HTMLUnknownElement[p143].
2. If *name* is acronym[p1444], basefont[p1445], big[p1445], center[p1445], nobr[p1445], noembed[p1444], noframes[p1444], plaintext[p1444], rb[p1445], rtc[p1445], strike[p1445], or tt[p1445], then return HTMLElement[p143].

3. If *name* is `listing`[p1444] or `xmp`[p1445], then return `HTMLPreElement`[p234].

4. Otherwise, if this specification defines an interface appropriate for the element type[p46] corresponding to the local name *name*, then return that interface.

5. If other applicable specifications[p74] define an appropriate interface for *name*, then return the interface they define.

6. If *name* is a valid custom element name[p767], then return `HTMLElement`[p143].

7. Return `HTMLUnknownElement`[p143].

Note

The use of `HTMLElement`[p143] instead of `HTMLUnknownElement`[p143] in the case of valid custom element names[p767] is done to ensure that any potential future upgrades[p773] only cause a linear transition of the element's prototype chain, from `HTMLElement`[p143] to a subclass, instead of a lateral one, from `HTMLUnknownElement`[p143] to an unrelated subclass.

Features shared between HTML and SVG elements use the `HTMLOrSVGElement`[p144] interface mixin: [SVG][p1500]

IDL

```
interface mixin HTMLOrSVGElement {
  [SameObject] readonly attribute DOMStringMap dataset;
  attribute DOMString nonce; // intentionally no [CEReactions]

  [CEReactions] attribute boolean autofocus;
  [CEReactions] attribute long tabIndex;
  undefined focus(optional FocusOptions options = {});
  undefined blur();
};
```

Example

An example of an element that is neither an HTML nor SVG element is one created as follows:

```
const el = document.createElementNS("some namespace", "example");
console.assert(el.constructor === Element);
```

3.2.3 HTML element constructors §[p14 4]

To support the custom elements[p756] feature, all HTML elements have special constructor behavior. This is indicated via the **`[HTMLConstructor]`** IDL extended attribute. It indicates that the interface object for the given interface will have a specific behavior when called, as defined in detail below.

The `[HTMLConstructor]`[p144] extended attribute must take no arguments, and must only appear on constructor operations. It must appear only once on a constructor operation, and the interface must contain only the single, annotated constructor operation, and no others. The annotated constructor operation must be declared to take no arguments.

Interfaces declared with constructor operations that are annotated with the `[HTMLConstructor]`[p144] extended attribute have the following overridden constructor steps:

1. If NewTarget is equal to the active function object, then throw a `TypeError`.

   Example

   This can occur when a custom element is defined using an element interface as its constructor:

   ```
   customElements.define("bad-1", HTMLButtonElement);
   new HTMLButtonElement();          // (1)
   document.createElement("bad-1");  // (2)
   ```

   In this case, during the execution of `HTMLButtonElement`[p568] (either explicitly, as in (1), or implicitly, as in (2)), both the active function object and NewTarget are `HTMLButtonElement`[p568]. If this check was not present, it would be possible to

create an instance of HTMLButtonElement[p568] whose local name was `bad-1`.

2. Let *registry* be null.
3. If the surrounding agent's active custom element constructor map[p769][NewTarget] exists:
    1. Set *registry* to the surrounding agent's active custom element constructor map[p769][NewTarget].
    2. Remove the surrounding agent's active custom element constructor map[p769][NewTarget].
4. Otherwise, set *registry* to the current global object[p1098]'s associated Document[p935]'s custom element registry.
5. Let *definition* be the item in *registry*'s custom element definition set[p769] with constructor[p768] equal to NewTarget. If there is no such item, then throw a TypeError.

    Note

    Since there can be no item in registry's custom element definition set[p769] with a constructor[p768] of undefined, this step also prevents HTML element constructors from being called as functions (since in that case NewTarget will be undefined).

6. Let *isValue* be null.
7. If *definition*'s local name[p768] is equal to *definition*'s name[p768] (i.e., *definition* is for an autonomous custom element[p766]):
    1. If the active function object is not HTMLElement[p143], then throw a TypeError.

        Example

        This can occur when a custom element is defined to not extend any local names, but inherits from a non-HTMLElement[p143] class:

        ```
        customElements.define("bad-2", class Bad2 extends HTMLParagraphElement {});
        ```

        In this case, during the (implicit) `super()` call that occurs when constructing an instance of `Bad2`, the active function object is HTMLParagraphElement[p230], not HTMLElement[p143].

8. Otherwise (i.e., if *definition* is for a customized built-in element[p766]):
    1. Let *valid local names* be the list of local names for elements defined in this specification or in other applicable specifications[p74] that use the active function object as their element interface.
    2. If *valid local names* does not contain *definition*'s local name[p768], then throw a TypeError.

        Example

        This can occur when a custom element is defined to extend a given local name but inherits from the wrong class:

        ```
        customElements.define("bad-3", class Bad3 extends HTMLQuoteElement {}, { extends:
        "p" });
        ```

        In this case, during the (implicit) `super()` call that occurs when constructing an instance of `Bad3`, *valid local names* is the list containing q[p267] and blockquote[p236], but *definition*'s local name[p768] is p[p230], which is not in that list.

    3. Set *isValue* to *definition*'s name[p768].
9. If *definition*'s construction stack[p768] is empty:
    1. Let *element* be the result of internally creating a new object implementing the interface to which the active function object corresponds, given the current realm and NewTarget.
    2. Set *element*'s node document to the current global object[p1098]'s associated Document[p935].
    3. Set *element*'s namespace to the HTML namespace.
    4. Set *element*'s namespace prefix to null.

5. Set *element*'s local name to *definition*'s local name[p768].
6. Set *element*'s custom element registry to *registry*.
7. Set *element*'s custom element state to "`custom`".
8. Set *element*'s custom element definition to *definition*.
9. Set *element*'s `is` value to *isValue*.
10. Return *element*.

Note

This occurs when author script constructs a new custom element directly, e.g., via `new MyCustomElement()`.

10. Let *prototype* be ? Get(NewTarget, "prototype").
11. If *prototype* is not an Object, then:
    1. Let *realm* be ? GetFunctionRealm(NewTarget).
    2. Set *prototype* to the interface prototype object of *realm* whose interface is the same as the interface of the active function object.

Note

The realm of the active function object might not be realm*, so we are using the more general concept of "the same interface" across realms; we are not looking for equality of interface objects. This fallback behavior, including using the realm of NewTarget and looking up the appropriate prototype there, is designed to match analogous behavior for the JavaScript built-ins and Web IDL's internally create a new object implementing the interface algorithm.*

12. Let *element* be the last entry in *definition*'s construction stack[p768].
13. If *element* is an *already constructed* marker[p768], then throw a `TypeError`.

Example

This can occur when the author code inside the custom element constructor[p766] non-conformantly[p764] creates another instance of the class being constructed, before calling `super()`:

```
let doSillyThing = true;

class DontDoThis extends HTMLElement {
  constructor() {
    if (doSillyThing) {
      doSillyThing = false;
      new DontDoThis();
      // Now the construction stack will contain an already constructed marker.
    }

    // This will then fail with a TypeError:
    super();
  }
}
```

Example

This can also occur when author code inside the custom element constructor[p766] non-conformantly[p764] calls `super()` twice, since per the JavaScript specification, this actually executes the superclass constructor (i.e. this algorithm) twice, before throwing an error:

```
class DontDoThisEither extends HTMLElement {
  constructor() {
    super();

    // This will throw, but not until it has already called into the HTMLElement
```

```
    constructor
        super();
      }
    }
```

14. Perform ? *element*.[[SetPrototypeOf]](*prototype*).
15. Replace the last entry in *definition*'s construction stack[p768] with an *already constructed* marker[p768].
16. Return *element*.

Note

This step is normally reached when upgrading[p773] a custom element; the existing element is returned, so that the `super()` *call inside the custom element constructor[p766] assigns that existing element to* ***this****.*

In addition to the constructor behavior implied by `[HTMLConstructor]`[p144], some elements also have named constructors (which are really factory functions with a modified `prototype` property).

Example

Named constructors for HTML elements can also be used in an `extends`[p769] clause when defining a custom element constructor[p766]:

```
class AutoEmbiggenedImage extends Image {
  constructor(width, height) {
    super(width * 10, height * 10);
  }
}

customElements.define("auto-embiggened", AutoEmbiggenedImage, { extends: "img" });

const image = new AutoEmbiggenedImage(15, 20);
console.assert(image.width === 150);
console.assert(image.height === 200);
```

3.2.4 Element definitions §[p147]

Each element in this specification has a definition that includes the following information:

Categories

A list of categories[p149] to which the element belongs. These are used when defining the content models[p148] for each element.

Contexts in which this element can be used

A *non-normative* description of where the element can be used. This information is redundant with the content models of elements that allow this one as a child, and is provided only as a convenience.

Note

For simplicity, only the most specific expectations are listed.

For example, all phrasing content[p151] is flow content[p150]. Thus, elements that are phrasing content[p151] will only be listed as "where phrasing content[p151] is expected", since this is the more-specific expectation. Anywhere that expects flow content[p150] also expects phrasing content[p151], and thus also meets this expectation.

Content model

A normative description of what content must be included as children and descendants of the element.

Tag omission in text/html

A *non-normative* description of whether, in the `text/html` syntax, the start and end tags can be omitted. This information is redundant with the normative requirements given in the optional tags section, and is provided in the element definitions only as a convenience.

Content attributes

A normative list of attributes that may be specified on the element (except where otherwise disallowed), along with non-normative descriptions of those attributes. (The content to the left of the dash is normative, the content to the right of the dash is not.)

Accessibility considerations

For authors: Conformance requirements for use of *ARIA* `role` and `aria-*` attributes are defined in *ARIA in HTML*. [ARIA] [ARIAHTML]

For implementers: User agent requirements for implementing accessibility API semantics are defined in *HTML Accessibility API Mappings*. [HTMLAAM]

DOM interface

A normative definition of a DOM interface that such elements must implement.

This is then followed by a description of what the element represents, along with any additional normative conformance criteria that may apply to authors and implementations. Examples are sometimes also included.

3.2.4.1 Attributes

An attribute value is a string. Except where otherwise specified, attribute values on HTML elements may be any string value, including the empty string, and there is no restriction on what text can be specified in such attribute values.

3.2.5 Content models

Each element defined in this specification has a content model: a description of the element's expected contents. An HTML element must have contents that match the requirements described in the element's content model. The **contents** of an element are its children in the DOM.

ASCII whitespace is always allowed between elements. User agents represent these characters between elements in the source markup as `Text` nodes in the DOM. Empty `Text` nodes and `Text` nodes consisting of just sequences of those characters are considered **inter-element whitespace**.

Inter-element whitespace, comment nodes, and processing instruction nodes must be ignored when establishing whether an element's contents match the element's content model or not, and must be ignored when following algorithms that define document and element semantics.

Note

Thus, an element A *is said to be* preceded or followed *by a second element* B *if* A *and* B *have the same parent node and there are no other element nodes or* `Text` *nodes (other than inter-element whitespace) between them. Similarly, a node is the* only child *of an element if that element contains no other nodes other than inter-element whitespace, comment nodes, and processing instruction nodes.*

Authors must not use HTML elements anywhere except where they are explicitly allowed, as defined for each element, or as explicitly required by other specifications. For XML compound documents, these contexts could be inside elements from other namespaces, if those elements are defined as providing the relevant contexts.

Example

The Atom Syndication Format defines a `content` element. When its `type` attribute has the value `xhtml`, *The Atom Syndication Format* requires that it contain a single HTML `div` element. Thus, a `div` element is allowed in that context, even though this is not explicitly normatively stated by this specification. [ATOM]

In addition, HTML elements may be orphan nodes (i.e. without a parent node).

Example

For example, creating a td[p494] element and storing it in a global variable in a script is conforming, even though td[p494] elements are otherwise only supposed to be used inside tr[p493] elements.

```
var data = {
  name: "Banana",
  cell: document.createElement('td'),
};
```

3.2.5.1 The "nothing" content model §[p14]

When an element's content model is **nothing**, the element must contain no Text nodes (other than inter-element whitespace[p148]) and no element nodes.

Note

Most HTML elements whose content model is "nothing" are also, for convenience, void elements[p1278] (elements that have no end tag[p1280] in the HTML syntax[p1277]). However, these are entirely separate concepts.

3.2.5.2 Kinds of content §[p14]

Each element in HTML falls into zero or more **categories** that group elements with similar characteristics together. The following broad categories are used in this specification:

- Metadata content[p150]
- Flow content[p150]
- Sectioning content[p150]
- Heading content[p151]
- Phrasing content[p151]
- Embedded content[p151]
- Interactive content[p151]

Note

Some elements also fall into other categories, which are defined in other parts of this specification.

These categories are related as follows:

Sectioning content, heading content, phrasing content, embedded content, and interactive content are all types of flow content. Metadata is sometimes flow content. Metadata and interactive content are sometimes phrasing content. Embedded content is also a

type of phrasing content, and sometimes is interactive content.

Other categories are also used for specific purposes, e.g. form controls are specified using a number of categories to define common requirements. Some elements have unique requirements and do not fit into any particular category.

3.2.5.2.1 Metadata content §p15 0

Metadata content is content that sets up the presentation or behavior of the rest of the content, or that sets up the relationship of the document with other documents, or that conveys other "out of band" information.

⇒ base p176, link p178, meta p190, noscript p677, script p660, style p201, template p679, title p175

Elements from other namespaces whose semantics are primarily metadata-related (e.g. RDF) are also metadata content p150.

Example

Thus, in the XML serialization, one can use RDF, like this:

```
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:r="http://www.w3.org/1999/02/22-rdf-syntax-ns#" xml:lang="en">
 <head>
  <title>Hedral's Home Page</title>
  <r:RDF>
   <Person xmlns="http://www.w3.org/2000/10/swap/pim/contact#"
           r:about="https://hedral.example.com/#">
    <fullName>Cat Hedral</fullName>
    <mailbox r:resource="mailto:hedral@damowmow.com"/>
    <personalTitle>Sir</personalTitle>
   </Person>
  </r:RDF>
 </head>
 <body>
  <h1>My home page</h1>
  <p>I like playing with string, I guess. Sister says squirrels are fun
  too so sometimes I follow her to play with them.</p>
 </body>
</html>
```

This isn't possible in the HTML serialization, however.

3.2.5.2.2 Flow content §p15 0

Most elements that are used in the body of documents and applications are categorized as **flow content**.

⇒ a p258, abbr p270, address p223, area p472 (if it is a descendant of a map p471 element), article p207, aside p215, audio p411, b p293, bdi p298, bdo p299, blockquote p236, br p300, button p567, canvas p684, cite p266, code p287, data p279, datalist p578, del p339, details p641, dfn p269, dialog p650, div p257, dl p245, em p261, embed p400, fieldset p597, figure p250, footer p221, form p515, h1 p217, h2 p217, h3 p217, h4 p217, h5 p217, h6 p217, header p219, hgroup p219, hr p232, i p292, iframe p391, img p347, input p521, ins p338, kbd p290, label p519, link p178 (if it is allowed in the body p180), main p254 (if it is a hierarchically correct main element p254), map p471, mark p295, MathML math, menu p241, meta p190 (if the itemprop p803 attribute is present), meter p592, nav p212, noscript p677, object p403, ol p239, output p588, p p230, picture p343, pre p234, progress p590, q p267, ruby p271, s p265, samp p289, script p660, search p255, section p210, select p572, slot p683, small p263, span p299, strong p262, sub p291, sup p291, SVG svg, table p479, template p679, textarea p583, time p280, u p295, ul p240, var p288, video p407, wbr p301, autonomous custom elements p766, text p151

3.2.5.2.3 Sectioning content §p15 0

Sectioning content is content that defines the scope of header p219 and footer p221 elements.

⇒ article p207, aside p215, nav p212, section p210

3.2.5.2.4 Heading content §[p15 1]

Heading content defines the heading of a section (whether explicitly marked up using sectioning content[p150] elements, or implied by the heading content itself).

⇒ h1[p217], h2[p217], h3[p217], h4[p217], h5[p217], h6[p217], hgroup[p219] (if it has a descendant h1[p217] to h6[p217] element)

3.2.5.2.5 Phrasing content §[p15 1]

Phrasing content is the text of the document, as well as elements that mark up that text at the intra-paragraph level. Runs of phrasing content[p151] form paragraphs[p153].

⇒ a[p258], abbr[p270], area[p472] (if it is a descendant of a map[p471] element), audio[p411], b[p293], bdi[p298], bdo[p299], br[p300], button[p567], canvas[p684], cite[p266], code[p287], data[p279], datalist[p578], del[p339], dfn[p269], em[p261], embed[p400], i[p292], iframe[p391], img[p347], input[p521], ins[p338], kbd[p290], label[p519], link[p178] (if it is allowed in the body[p180]), map[p471], mark[p295], MathML math, meta[p190] (if the itemprop[p803] attribute is present), meter[p592], noscript[p677], object[p403], output[p588], picture[p343], progress[p590], q[p267], ruby[p271], s[p265], samp[p289], script[p660], select[p572], slot[p683], small[p263], span[p299], strong[p262], sub[p291], sup[p291], SVG svg, template[p679], textarea[p583], time[p280], u[p295], var[p288], video[p407], wbr[p301], autonomous custom elements[p766], text[p151]

Note

Most elements that are categorized as phrasing content can only contain elements that are themselves categorized as phrasing content, not any flow content.

Text, in the context of content models, means either nothing, or Text nodes. Text[p151] is sometimes used as a content model on its own, but is also phrasing content[p151], and can be inter-element whitespace[p148] (if the Text nodes are empty or contain just ASCII whitespace).

Text nodes and attribute values must consist of scalar values, excluding noncharacters, and controls other than ASCII whitespace. This specification includes extra constraints on the exact value of Text nodes and attribute values depending on their precise context.

3.2.5.2.6 Embedded content §[p15 1]

Embedded content is content that imports another resource into the document, or content from another vocabulary that is inserted into the document.

⇒ audio[p411], canvas[p684], embed[p400], iframe[p391], img[p347], MathML math, object[p403], picture[p343], SVG svg, video[p407]

Elements that are from namespaces other than the HTML namespace and that convey content but not metadata, are embedded content[p151] for the purposes of the content models defined in this specification. (For example, MathML or SVG.)

Some embedded content elements can have **fallback content**: content that is to be used when the external resource cannot be used (e.g. because it is of an unsupported format). The element definitions state what the fallback is, if any.

3.2.5.2.7 Interactive content §[p15 1]

Interactive content is content that is specifically intended for user interaction.

⇒ a[p258] (if the href[p304] attribute is present), audio[p411] (if the controls[p465] attribute is present), button[p567], details[p641], embed[p400], iframe[p391], img[p347] (if the usemap[p474] attribute is present), input[p521] (if the type[p524] attribute is *not* in the Hidden[p528] state), label[p519], select[p572], textarea[p583], video[p407] (if the controls[p465] attribute is present)

3.2.5.2.8 Palpable content §[p15 1]

As a general rule, elements whose content model allows any flow content[p150] or phrasing content[p151] should have at least one node in its contents[p148] that is **palpable content** and that does not have the hidden[p832] attribute specified.

Note

Palpable content[p151] makes an element non-empty by providing either some descendant non-empty text[p151], or else something users can hear (audio[p411] elements) or view (video[p407], img[p347], or canvas[p684] elements) or otherwise interact with (for example, interactive form controls).

This requirement is not a hard requirement, however, as there are many cases where an element can be empty legitimately, for example when it is used as a placeholder which will later be filled in by a script, or when the element is part of a template and would on most pages be filled in but on some pages is not relevant.

Conformance checkers are encouraged to provide a mechanism for authors to find elements that fail to fulfill this requirement, as an authoring aid.

The following elements are palpable content:

⇒ a[p258], abbr[p270], address[p223], article[p207], aside[p215], audio[p411] (if the controls[p465] attribute is present), b[p293], bdi[p298], bdo[p299], blockquote[p236], button[p567], canvas[p684], cite[p266], code[p287], data[p279], del[p339], details[p641], dfn[p269], div[p257], dl[p245] (if the element's children include at least one name-value group), em[p261], embed[p400], fieldset[p597], figure[p250], footer[p221], form[p515], h1[p217], h2[p217], h3[p217], h4[p217], h5[p217], h6[p217], header[p219], hgroup[p219], i[p292], iframe[p391], img[p347], input[p521] (if the type[p524] attribute is *not* in the Hidden[p528] state), ins[p338], kbd[p290], label[p519], main[p254], map[p471], mark[p295], MathML math, menu[p241] (if the element's children include at least one li[p242] element), meter[p592], nav[p212], object[p403], ol[p239] (if the element's children include at least one li[p242] element), output[p588], p[p230], picture[p343], pre[p234], progress[p590], q[p267], ruby[p271], s[p265], samp[p289], search[p255], section[p210], select[p572], small[p263], span[p299], strong[p262], sub[p291], sup[p291], SVG svg, table[p479], textarea[p583], time[p280], u[p295], ul[p240] (if the element's children include at least one li[p242] element), var[p288], video[p407], autonomous custom elements[p766], text[p151] that is not inter-element whitespace[p148]

3.2.5.2.9 Script-supporting elements §[p15 2]

Script-supporting elements are those that do not represent[p142] anything themselves (i.e. they are not rendered), but are used to support scripts, e.g. to provide functionality for the user.

The following elements are script-supporting elements:

⇒ script[p660], template[p679]

3.2.5.3 Transparent content models §[p15 2]

Some elements are described as **transparent**; they have "transparent" in the description of their content model. The content model of a transparent[p152] element is derived from the content model of its parent element: the elements required in the part of the content model that is "transparent" are the same elements as required in the part of the content model of the parent of the transparent element in which the transparent element finds itself.

Example

For instance, an ins[p338] element inside a ruby[p271] element cannot contain an rt[p278] element, because the part of the ruby[p271] element's content model that allows ins[p338] elements is the part that allows phrasing content[p151], and the rt[p278] element is not phrasing content[p151].

Note

In some cases, where transparent elements are nested in each other, the process has to be applied iteratively.

Example

Consider the following markup fragment:

```
<p><object><ins><map><a href="/">Apples</a></map></ins></object></p>
```

To check whether "Apples" is allowed inside the a[p258] element, the content models are examined. The a[p258] element's content model is transparent, as is the map[p471] element's, as is the ins[p338] element's, as is the object[p403] element's. The object[p403] element is found in the p[p230] element, whose content model is phrasing content[p151]. Thus, "Apples" is allowed, as text is phrasing

content.

When a transparent element has no parent, then the part of its content model that is "transparent" must instead be treated as accepting any flow content[p150].

3.2.5.4 Paragraphs §[p153]

Note

The term paragraph[p153] as defined in this section is used for more than just the definition of the p[p230] element. The paragraph[p153] concept defined here is used to describe how to interpret documents. The p[p230] element is merely one of several ways of marking up a paragraph[p153].

A **paragraph** is typically a run of phrasing content[p151] that forms a block of text with one or more sentences that discuss a particular topic, as in typography, but can also be used for more general thematic grouping. For instance, an address is also a paragraph, as is a part of a form, a byline, or a stanza in a poem.

Example

In the following example, there are two paragraphs in a section. There is also a heading, which contains phrasing content that is not a paragraph. Note how the comments and inter-element whitespace[p148] do not form paragraphs.

```
<section>
  <h2>Example of paragraphs</h2>
  This is the <em>first</em> paragraph in this example.
  <p>This is the second.</p>
  <!-- This is not a paragraph. -->
</section>
```

Paragraphs in flow content[p150] are defined relative to what the document looks like without the a[p258], ins[p338], del[p339], and map[p471] elements complicating matters, since those elements, with their hybrid content models, can straddle paragraph boundaries, as shown in the first two examples below.

Note

Generally, having elements straddle paragraph boundaries is best avoided. Maintaining such markup can be difficult.

Example

The following example takes the markup from the earlier example and puts ins[p338] and del[p339] elements around some of the markup to show that the text was changed (though in this case, the changes admittedly don't make much sense). Notice how this example has exactly the same paragraphs as the previous one, despite the ins[p338] and del[p339] elements — the ins[p338] element straddles the heading and the first paragraph, and the del[p339] element straddles the boundary between the two paragraphs.

```
<section>
  <ins><h2>Example of paragraphs</h2>
  This is the <em>first</em> paragraph in</ins> this example<del>.
  <p>This is the second.</p></del>
  <!-- This is not a paragraph. -->
</section>
```

Let *view* be a view of the DOM that replaces all a[p258], ins[p338], del[p339], and map[p471] elements in the document with their contents[p148]. Then, in *view*, for each run of sibling phrasing content[p151] nodes uninterrupted by other types of content, in an element that accepts content other than phrasing content[p151] as well as phrasing content[p151], let *first* be the first node of the run, and let *last* be the last node of the run. For each such run that consists of at least one node that is neither embedded content[p151] nor inter-element whitespace[p148], a paragraph exists in the original DOM from immediately before *first* to immediately after *last*. (Paragraphs can thus span across a[p258], ins[p338], del[p339], and map[p471] elements.)

Conformance checkers may warn authors of cases where they have paragraphs that overlap each other (this can happen with object[p403], video[p407], audio[p411], and canvas[p684] elements, and indirectly through elements in other namespaces that allow HTML to be further embedded therein, like SVG svg or MathML math).

A paragraph[p153] is also formed explicitly by p[p230] elements.

Note

The p[p230] element can be used to wrap individual paragraphs when there would otherwise not be any content other than phrasing content to separate the paragraphs from each other.

Example

In the following example, the link spans half of the first paragraph, all of the heading separating the two paragraphs, and half of the second paragraph. It straddles the paragraphs and the heading.

```
<header>
 Welcome!
 <a href="about.html">
  This is home of...
  <h1>The Falcons!</h1>
  The Lockheed Martin multirole jet fighter aircraft!
 </a>
 This page discusses the F-16 Fighting Falcon's innermost secrets.
</header>
```

Here is another way of marking this up, this time showing the paragraphs explicitly, and splitting the one link element into three:

```
<header>
 <p>Welcome! <a href="about.html">This is home of...</a></p>
 <h1><a href="about.html">The Falcons!</a></h1>
 <p><a href="about.html">The Lockheed Martin multirole jet
 fighter aircraft!</a> This page discusses the F-16 Fighting
 Falcon's innermost secrets.</p>
</header>
```

Example

It is possible for paragraphs to overlap when using certain elements that define fallback content. For example, in the following section:

```
<section>
 <h2>My Cats</h2>
 You can play with my cat simulator.
 <object data="cats.sim">
  To see the cat simulator, use one of the following links:
  <ul>
   <li><a href="cats.sim">Download simulator file</a>
   <li><a href="https://sims.example.com/watch?v=LYds5xY4INU">Use online simulator</a>
  </ul>
  Alternatively, upgrade to the Mellblom Browser.
 </object>
 I'm quite proud of it.
</section>
```

There are five paragraphs:

1. The paragraph that says "You can play with my cat simulator. *object* I'm quite proud of it.", where *object* is the object[p403] element.
2. The paragraph that says "To see the cat simulator, use one of the following links:".
3. The paragraph that says "Download simulator file".
4. The paragraph that says "Use online simulator".
5. The paragraph that says "Alternatively, upgrade to the Mellblom Browser.".

The first paragraph is overlapped by the other four. A user agent that supports the "cats.sim" resource will only show the first one, but a user agent that shows the fallback will confusingly show the first sentence of the first paragraph as if it was in the same paragraph as the second one, and will show the last paragraph as if it was at the start of the second sentence of the first paragraph.

To avoid this confusion, explicit p[p230] elements can be used. For example:

```
<section>
 <h2>My Cats</h2>
 <p>You can play with my cat simulator.</p>
 <object data="cats.sim">
  <p>To see the cat simulator, use one of the following links:</p>
  <ul>
   <li><a href="cats.sim">Download simulator file</a>
   <li><a href="https://sims.example.com/watch?v=LYds5xY4INU">Use online simulator</a>
  </ul>
  <p>Alternatively, upgrade to the Mellblom Browser.</p>
 </object>
 <p>I'm quite proud of it.</p>
</section>
```

MDN

3.2.6 Global attributes §[p155]

The following attributes are common to and may be specified on all HTML elements[p46] (even those not defined in this specification):

- accesskey[p860]
- autocapitalize[p868]
- autocorrect[p869]
- autofocus[p857]
- contenteditable[p862]
- dir[p161]
- draggable[p894]
- enterkeyhint[p870]
- hidden[p832]
- inert[p836]
- inputmode[p870]
- is[p766]
- itemid[p802]
- itemprop[p803]
- itemref[p802]
- itemscope[p801]
- itemtype[p801]
- lang[p159]
- nonce[p101]
- popover[p895]
- spellcheck[p864]
- style[p164]
- tabindex[p847]
- title[p158]
- translate[p160]
- writingsuggestions[p866]

These attributes are only defined by this specification as attributes for HTML elements[p46]. When this specification refers to elements having these attributes, elements from namespaces that are not defined as having these attributes must not be considered as being elements with these attributes.

Example

For example, in the following XML fragment, the "bogus" element does not have a dir[p161] attribute as defined in this specification, despite having an attribute with the literal name "dir". Thus, the directionality[p161] of the inner-most span[p299] element is 'rtl[p161]', inherited from the div[p257] element indirectly through the "bogus" element.

```
<div xmlns="http://www.w3.org/1999/xhtml" dir="rtl">
 <bogus xmlns="https://example.net/ns" dir="ltr">
  <span xmlns="http://www.w3.org/1999/xhtml">
  </span>
 </bogus>
</div>
```

DOM defines the user agent requirements for the **class**, **id**, and **slot** attributes for any element in any namespace. [DOM][p1496]

The class[p156], id[p156], and slot[p156] attributes may be specified on all HTML elements[p46].

When specified on HTML elements[p46], the class[p156] attribute must have a value that is a set of space-separated tokens[p96] representing the various classes that the element belongs to.

Note

Assigning classes to an element affects class matching in selectors in CSS, the getElementsByClassName() method in the DOM, and other such features.

There are no additional restrictions on the tokens authors can use in the class[p156] attribute, but authors are encouraged to use values that describe the nature of the content, rather than values that describe the desired presentation of the content.

When specified on HTML elements[p46], the id[p156] attribute value must be unique amongst all the IDs in the element's tree and must contain at least one character. The value must not contain any ASCII whitespace.

Note

The id[p156] attribute specifies its element's unique identifier (ID).

There are no other restrictions on what form an ID can take; in particular, IDs can consist of just digits, start with a digit, start with an underscore, consist of just punctuation, etc.

An element's unique identifier can be used for a variety of purposes, most notably as a way to link to specific parts of a document using fragments, as a way to target an element when scripting, and as a way to style a specific element from CSS.

Identifiers are opaque strings. Particular meanings should not be derived from the value of the id[p156] attribute.

There are no conformance requirements for the slot[p156] attribute specific to HTML elements[p46].

Note

The slot[p156] attribute is used to assign a slot to an element: an element with a slot[p156] attribute is assigned to the slot created by the slot[p683] element whose name[p683] attribute's value matches that slot[p156] attribute's value — but only if that slot[p683] element finds itself in the shadow tree whose root's host has the corresponding slot[p156] attribute value.

To enable assistive technology products to expose a more fine-grained interface than is otherwise possible with HTML elements and attributes, a set of annotations for assistive technology products[p171] can be specified (the ARIA role[p69] and aria-*[p69] attributes). [ARIA][p1493]

The following event handler content attributes[p1152] may be specified on any HTML element[p46]:

- onauxclick[p1158]
- onbeforeinput[p1158]
- onbeforematch[p1158]
- onbeforetoggle[p1158]
- onblur[p1160]*
- oncancel[p1158]
- oncanplay[p1158]
- oncanplaythrough[p1158]
- onchange[p1158]

- onclick[p1158]
- onclose[p1158]
- oncommand[p1158]
- oncontextlost[p1158]
- oncontextmenu[p1158]
- oncontextrestored[p1158]
- oncopy[p1158]
- oncuechange[p1158]
- oncut[p1158]
- ondblclick[p1158]
- ondrag[p1158]
- ondragend[p1158]
- ondragenter[p1158]
- ondragleave[p1159]
- ondragover[p1159]
- ondragstart[p1159]
- ondrop[p1159]
- ondurationchange[p1159]
- onemptied[p1159]
- onended[p1159]
- onerror[p1160]*
- onfocus[p1160]*
- onformdata[p1159]
- oninput[p1159]
- oninvalid[p1159]
- onkeydown[p1159]
- onkeypress[p1159]
- onkeyup[p1159]
- onload[p1160]*
- onloadeddata[p1159]
- onloadedmetadata[p1159]
- onloadstart[p1159]
- onmousedown[p1159]
- onmouseenter[p1159]
- onmouseleave[p1159]
- onmousemove[p1159]
- onmouseout[p1159]
- onmouseover[p1159]
- onmouseup[p1159]
- onpaste[p1159]
- onpause[p1159]
- onplay[p1159]
- onplaying[p1159]
- onprogress[p1159]
- onratechange[p1159]
- onreset[p1159]
- onresize[p1160]*
- onscroll[p1160]*
- onscrollend[p1159]*
- onsecuritypolicyviolation[p1159]
- onseeked[p1159]
- onseeking[p1159]
- onselect[p1159]
- onslotchange[p1159]
- onstalled[p1159]
- onsubmit[p1159]
- onsuspend[p1159]
- ontimeupdate[p1159]
- ontoggle[p1159]
- onvolumechange[p1159]
- onwaiting[p1159]
- onwheel[p1159]

Note

The attributes marked with an asterisk have a different meaning when specified on `body`[p206] elements as those elements expose event handlers[p1151] of the `Window`[p934] object with the same names.

Note

While these attributes apply to all elements, they are not useful on all elements. For example, only media elements[p415] will ever receive a `volumechange`[p469] event fired by the user agent.

Custom data attributes[p165] (e.g. `data-foldername` or `data-msgid`) can be specified on any HTML element[p46], to store custom data, state, annotations, and similar, specific to the page.

In HTML documents, elements in the HTML namespace may have an `xmlns` attribute specified, if, and only if, it has the exact value "`http://www.w3.org/1999/xhtml`". This does not apply to XML documents.

Note

In HTML, the `xmlns` attribute has absolutely no effect. It is basically a talisman. It is allowed merely to make migration to and from XML mildly easier. When parsed by an HTML parser[p1289], the attribute ends up in no namespace, not the "`http://www.w3.org/2000/xmlns/`" namespace like namespace declaration attributes in XML do.

Note

In XML, an `xmlns` attribute is part of the namespace declaration mechanism, and an element cannot actually have an `xmlns` attribute in no namespace specified.

XML also allows the use of the `xml:space` attribute in the XML namespace on any element in an XML document. This attribute has no effect on HTML elements[p46], as the default behavior in HTML is to preserve whitespace. [XML][p1502]

Note

There is no way to serialize the `xml:space` attribute on HTML elements[p46] in the `text/html`[p1462] syntax.

3.2.6.1 The `title`[p158] attribute §[p158]

The **`title`** attribute represents[p142] advisory information for the element, such as would be appropriate for a tooltip. On a link, this could be the title or a description of the target resource; on an image, it could be the image credit or a description of the image; on a paragraph, it could be a footnote or commentary on the text; on a citation, it could be further information about the source; on interactive content[p151], it could be a label for, or instructions for, use of the element; and so forth. The value is text.

Note

Relying on the `title`[p158] attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g., requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

If this attribute is omitted from an element, then it implies that the `title`[p158] attribute of the nearest ancestor HTML element[p46] with a `title`[p158] attribute set is also relevant to this element. Setting the attribute overrides this, explicitly stating that the advisory information of any ancestors is not relevant to this element. Setting the attribute to the empty string indicates that the element has no advisory information.

If the `title`[p158] attribute's value contains U+000A LINE FEED (LF) characters, the content is split into multiple lines. Each U+000A LINE FEED (LF) character represents a line break.

Example

Caution is advised with respect to the use of newlines in `title`[p158] attributes.

For instance, the following snippet actually defines an abbreviation's expansion *with a line break in it*:

```
<p>My logs show that there was some interest in <abbr title="Hypertext
Transport Protocol">HTTP</abbr> today.</p>
```

Some elements, such as `link`[p178], `abbr`[p270], and `input`[p521], define additional semantics for the `title`[p158] attribute beyond the semantics described above.

The **advisory information** of an element is the value that the following algorithm returns, with the algorithm being aborted once a value is returned. When the algorithm returns the empty string, then there is no advisory information.

1. If the element has a `title`[p158] attribute, then return the result of running normalize newlines on its value.
2. If the element has a parent element, then return the parent element's advisory information[p158].
3. Return the empty string.

User agents should inform the user when elements have advisory information[p158], otherwise the information would not be discoverable.

The **`title`** IDL attribute must reflect[p105] the `title`[p158] content attribute.

3.2.6.2 The `lang`[p159] and `xml:lang` attributes §[p159]

The **`lang`** attribute (in no namespace) specifies the primary language for the element's contents and for any of the element's attributes that contain text. Its value must be a valid BCP 47 language tag, or the empty string. Setting the attribute to the empty string indicates that the primary language is unknown. [BCP47][p1493]

The **`lang`** attribute in the XML namespace is defined in XML. [XML][p1502]

If these attributes are omitted from an element, then the language of this element is the same as the language of its parent element, if any (except for `slot`[p683] elements in a shadow tree).

The `lang`[p159] attribute in no namespace may be used on any HTML element[p46].

The `lang` attribute in the XML namespace may be used on HTML elements[p46] in XML documents, as well as elements in other namespaces if the relevant specifications allow it (in particular, MathML and SVG allow `lang` attributes in the XML namespace to be specified on their elements). If both the `lang`[p159] attribute in no namespace and the `lang` attribute in the XML namespace are specified on the same element, they must have exactly the same value when compared in an ASCII case-insensitive manner.

Authors must not use the `lang` attribute in the XML namespace on HTML elements[p46] in HTML documents. To ease migration to and from XML, authors may specify an attribute in no namespace with no prefix and with the literal localname "`xml:lang`" on HTML elements[p46] in HTML documents, but such attributes must only be specified if a `lang`[p159] attribute in no namespace is also specified, and both attributes must have the same value when compared in an ASCII case-insensitive manner.

Note

The attribute in no namespace with no prefix and with the literal localname "`xml:lang`" has no effect on language processing.

To determine the **language** of a node, user agents must use the first appropriate step in the following list:

↪ **If the node is an element that has a `lang` attribute in the XML namespace set**

Use the value of that attribute.

↪ **If the node is an HTML element[p46] or an element in the SVG namespace, and it has a `lang`[p159] in no namespace attribute set**

Use the value of that attribute.

↪ **If the node's parent is a shadow root**

Use the language[p159] of that shadow root's host.

↪ **If the node's parent element is not null**

Use the language[p159] of that parent element.

↪ **Otherwise**

If there is a pragma-set default language[p197] set, then that is the language of the node. If there is no pragma-set default language[p197] set, then language information from a higher-level protocol (such as HTTP), if any, must be used as the final fallback language instead. In the absence of any such language information, and in cases where the higher-level protocol reports multiple languages, the language of the node is unknown, and the corresponding language tag is the empty string.

If the resulting value is not a recognized language tag, then it must be treated as an unknown language having the given language tag, distinct from all other languages. For the purposes of round-tripping or communicating with other services that expect language

tags, user agents should pass unknown language tags through unmodified, and tagged as being BCP 47 language tags, so that subsequent services do not interpret the data as another type of language description. [BCP47]p1493

Example

Thus, for instance, an element with `lang="xyzzy"` would be matched by the selector `:lang(xyzzy)` (e.g. in CSS), but it would not be matched by `:lang(abcde)`, even though both are equally invalid. Similarly, if a web browser and screen reader working in unison communicated about the language of the element, the browser would tell the screen reader that the language was "xyzzy", even if it knew it was invalid, just in case the screen reader actually supported a language with that tag after all. Even if the screen reader supported both BCP 47 and another syntax for encoding language names, and in that other syntax the string "xyzzy" was a way to denote the Belarusian language, it would be *incorrect* for the screen reader to then start treating text as Belarusian, because "xyzzy" is not how Belarusian is described in BCP 47 codes (BCP 47 uses the code "be" for Belarusian).

If the resulting value is the empty string, then it must be interpreted as meaning that the language of the node is **explicitly unknown**.

User agents may use the element's language to determine proper processing or rendering (e.g. in the selection of appropriate fonts or pronunciations, for dictionary selection, or for the user interfaces of form controls such as date pickers).

The **lang** IDL attribute must reflectp105 the langp159 content attribute in no namespace.

3.2.6.3 The translatep160 attribute §p160

The **translate** attribute is used to specify whether an element's attribute values and the values of its Text node children are to be translated when the page is localized, or whether to leave them unchanged. It is an attribute is an enumerated attributep77 with the following keywords and states:

Keyword	State	Brief description
yes	Yes	Sets translation modep160 to translate-enabledp160.
(the empty string)		
no	No	Sets translation modep160 to no-translatep160.

The attribute's *missing value defaultp77* and *invalid value defaultp77* are both the **Inherit** state.

Each element (even non-HTML elements) has a **translation mode**, which is in either the translate-enabledp160 state or the no-translatep160 state. If an HTML elementp46's translatep160 attribute is in the Yesp160 state, then the element's translation modep160 is in the translate-enabledp160 state; otherwise, if the element's translatep160 attribute is in the Nop160 state, then the element's translation modep160 is in the no-translatep160 state. Otherwise, either the element's translatep160 attribute is in the Inheritp160 state, or the element is not an HTML elementp46 and thus does not have a translatep160 attribute; in either case, the element's translation modep160 is in the same state as its parent element's, if any, or in the translate-enabledp160 state, if the element's parent element is null.

When an element is in the **translate-enabled** state, the element's translatable attributesp160 and the values of its Text node children are to be translated when the page is localized.

When an element is in the **no-translate** state, the element's attribute values and the values of its Text node children are to be left as-is when the page is localized, e.g. because the element contains a person's name or a name of a computer program.

The following attributes are **translatable attributes**:

- abbrp496 on thp496 elements
- alt on areap473, imgp348, and inputp549 elements
- contentp191 on metap190 elements, if the namep191 attribute specifies a metadata name whose value is known to be translatable
- downloadp304 on ap258 and areap472 elements
- label on optgroupp580, optionp581, and trackp414 elements
- langp159 on HTML elementsp46; must be "translated" to match the language used in the translation
- placeholder on inputp561 and textareap586 elements
- srcdocp392 on iframep391 elements; must be parsed and recursively processed
- stylep164 on HTML elementsp46; must be parsed and recursively processed (e.g. for the values of 'content' properties)
- titlep158 on all HTML elementsp46

- `value`[p526] on `input`[p521] elements with a `type`[p524] attribute in the Button[p551] state or the Reset Button[p551] state

Other specifications may define other attributes that are also translatable attributes[p160]. For example, *ARIA* would define the `aria-label` attribute as translatable.

The **`translate`** IDL attribute must, on getting, return true if the element's translation mode[p160] is translate-enabled[p160], and false otherwise. On setting, it must set the content attribute's value to "`yes`" if the new value is true, and set the content attribute's value to "`no`" otherwise.

Example

In this example, everything in the document is to be translated when the page is localized, except the sample keyboard input and sample program output:

```
<!DOCTYPE HTML>
<html lang=en> <!-- default on the document element is translate=yes -->
 <head>
  <title>The Bee Game</title> <!-- implied translate=yes inherited from ancestors -->
 </head>
 <body>
  <p>The Bee Game is a text adventure game in English.</p>
  <p>When the game launches, the first thing you should do is type
  <kbd translate=no>eat honey</kbd>. The game will respond with:</p>
  <pre><samp translate=no>Yum yum! That was some good honey!</samp></pre>
 </body>
</html>
```

3.2.6.4 The `dir`[p161] attribute §[p16]1

The **`dir`** attribute is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
`ltr`	**LTR**	The contents of the element are explicitly directionally isolated left-to-right text.
`rtl`	**RTL**	The contents of the element are explicitly directionally isolated right-to-left text.
`auto`	**Auto**	The contents of the element are explicitly directionally isolated text, but the direction is to be determined programmatically using the contents of the element (as described below).

Note

The heuristic used by the Auto[p161] state is very crude (it just looks at the first character with a strong directionality, in a manner analogous to the Paragraph Level determination in the bidirectional algorithm). Authors are urged to only use this value as a last resort when the direction of the text is truly unknown and no better server-side heuristic can be applied. [BIDI][p1493]

For `textarea`[p583] and `pre`[p234] elements, the heuristic is applied on a per-paragraph level.

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the **Undefined** state.

The **directionality** of an element (any element, not just an HTML element[p46]) is either '**ltr**' or '**rtl**'. To compute the directionality[p161] given an element *element*, switch on *element*'s `dir`[p161] attribute state:

↪ **LTR**[p161]

Return '`ltr`[p161]'.

↪ **RTL**[p161]

Return '`rtl`[p161]'.

↪ **Auto**[p161]

1. Let *result* be the auto directionality[p162] of *element*.

2. If *result* is null, then return '[ltr](#)'.

3. Return *result*.

↪ **Undefined**

↪ **If *element* is a `bdi` element**

1. Let *result* be the auto directionality of *element*.

2. If *result* is null, then return '[ltr](#)'.

3. Return *result*.

↪ **If *element* is an `input` element whose `type` attribute is in the Telephone state**

Return '[ltr](#)'.

↪ **Otherwise**

Return the parent directionality of *element*.

Note

Since the `dir` attribute is only defined for HTML elements, it cannot be present on elements from other namespaces. Thus, elements from other namespaces always end up using the parent directionality.

The **auto-directionality form-associated elements** are:

- `input` elements whose `type` attribute is in the Hidden, Text, Search, Telephone, URL, Email, Password, Submit Button, Reset Button, or Button state, and
- `textarea` elements.

To compute the **auto directionality** given an element *element*:

1. If *element* is an auto-directionality form-associated element:
    1. If *element*'s value contains a character of bidirectional character type AL or R, and there is no character of bidirectional character type L anywhere before it in the element's value, then return '[rtl](#)'. [BIDI]
    2. If *element*'s value is not the empty string, then return '[ltr](#)'.
    3. Return null.
2. If *element* is a `slot` element whose root is a shadow root and *element*'s assigned nodes are not empty:
    1. For each node *child* of *element*'s assigned nodes:
        1. Let *childDirection* be null.
        2. If *child* is a `Text` node, then set *childDirection* to the text node directionality of *child*.
        3. Otherwise:
            1. Assert: *child* is an `Element` node.
            2. Set *childDirection* to the contained text auto directionality of *child* with *canExcludeRoot* set to true.
        4. If *childDirection* is not null, then return *childDirection*.
    2. Return null.
3. Return the contained text auto directionality of *element* with *canExcludeRoot* set to false.

To compute the **contained text auto directionality** of an element *element* with a boolean ***canExcludeRoot***:

1. For each node *descendant* of *element*'s descendants, in tree order:
    1. If any of
        - *descendant*
        - any ancestor element of *descendant* that is a descendant of *element*

- if *canExcludeRoot* is true, *element*

is one of

- a bdi element
- a script element
- a style element
- a textarea element
- an element whose dir attribute is not in the Undefined state

then continue.

2. If *descendant* is a slot element whose root is a shadow root, then return the directionality of that shadow root's host.
3. If *descendant* is not a Text node, then continue.
4. Let *result* be the text node directionality of *descendant*.
5. If *result* is not null, then return *result*.

2. Return null.

To compute the **text node directionality** given a Text node *text*:

1. If *text*'s data does not contain a code point whose bidirectional character type is L, AL, or R, then return null. [BIDI]
2. Let *codePoint* be the first code point in *text*'s data whose bidirectional character type is L, AL, or R.
3. If *codePoint* is of bidirectional character type AL or R, then return 'rtl'.
4. If *codePoint* is of bidirectional character type L, then return 'ltr'.

To compute the **parent directionality** given an element *element*:

1. Let *parentNode* be *element*'s parent node.
2. If *parentNode* is a shadow root, then return the directionality of *parentNode*'s host.
3. If *parentNode* is an element, then return the directionality of *parentNode*.
4. Return 'ltr'.

Note

This attribute has rendering requirements involving the bidirectional algorithm.

The **directionality of an attribute** of an HTML element, which is used when the text of that attribute is to be included in the rendering in some manner, is determined as per the first appropriate set of steps from the following list:

↪ **If the attribute is a directionality-capable attribute and the element's dir attribute is in the Auto state**

Find the first character (in logical order) of the attribute's value that is of bidirectional character type L, AL, or R. [BIDI]

If such a character is found and it is of bidirectional character type AL or R, the directionality of the attribute is 'rtl'.

Otherwise, the directionality of the attribute is 'ltr'.

↪ **Otherwise**

The directionality of the attribute is the same as the element's directionality.

The following attributes are **directionality-capable attributes**:

- abbr on th elements
- alt on area, img, and input elements
- content on meta elements, if the name attribute specifies a metadata name whose value is primarily intended to be human-readable rather than machine-readable
- label on optgroup, option, and track elements
- placeholder on input and textarea elements
- title on all HTML elements

For web developers (non-normative)

***document*.dir[p164] [= *value*]**

Returns the html element[p136]'s dir[p161] attribute's value, if any.

Can be set, to either "ltr", "rtl", or "auto" to replace the html element[p136]'s dir[p161] attribute's value.

If there is no html element[p136], returns the empty string and ignores new values.

The **dir** IDL attribute on an element must reflect[p105] the dir[p161] content attribute of that element, limited to only known values[p106].

The **dir** IDL attribute on Document[p131] objects must reflect[p105] the dir[p161] content attribute of the html element[p136], if any, limited to only known values[p106]. If there is no such element, then the attribute must return the empty string and do nothing on setting.

Note

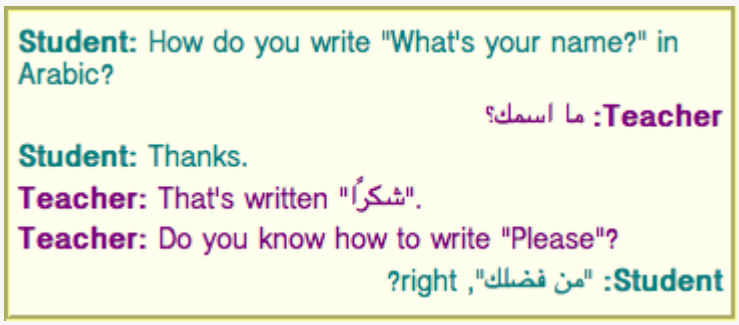
Authors are strongly encouraged to use the dir[p161] attribute to indicate text direction rather than using CSS, since that way their documents will continue to render correctly even in the absence of CSS (e.g. as interpreted by search engines).

Example

This markup fragment is of an IM conversation.

```
<p dir=auto class="u1"><b><bdi>Student</bdi>:</b> How do you write "What's your name?" in
Arabic?</p>
<p dir=auto class="u2"><b><bdi>Teacher</bdi>:</b> ما اسمك؟</p>
<p dir=auto class="u1"><b><bdi>Student</bdi>:</b> Thanks.</p>
<p dir=auto class="u2"><b><bdi>Teacher</bdi>:</b> That's written "شكرًا".</p>
<p dir=auto class="u2"><b><bdi>Teacher</bdi>:</b> Do you know how to write "Please"?</p>
<p dir=auto class="u1"><b><bdi>Student</bdi>:</b> "من فضلك", right?</p>
```

Given a suitable style sheet and the default alignment styles for the p[p230] element, namely to align the text to the *start edge* of the paragraph, the resulting rendering could be as follows:



As noted earlier, the auto[p161] value is not a panacea. The final paragraph in this example is misinterpreted as being right-to-left text, since it begins with an Arabic character, which causes the "right?" to be to the left of the Arabic text.

3.2.6.5 The style[p164] attribute §[p164]

All HTML elements[p46] may have the **style** content attribute set. This is a style attribute as defined by *CSS Style Attributes*. [CSSATTR][p1494]

In user agents that support CSS, the attribute's value must be parsed when the attribute is added or has its value changed, according to the rules given for style attributes. [CSSATTR][p1494]

However, if the Should element's inline behavior be blocked by Content Security Policy? algorithm returns "Blocked" when executed upon the attribute's element, "style attribute", and the attribute's value, then the style rules defined in the attribute's value must not be applied to the element. [CSP][p1494]

Documents that use style[p164] attributes on any of their elements must still be comprehensible and usable if those attributes were removed.

Note

In particular, using the style[p164] attribute to hide and show content, or to convey meaning that is otherwise not included in the document, is non-conforming. (To hide and show content, use the hidden[p832] attribute.)

For web developers (non-normative)

***element*.style**

Returns a CSSStyleDeclaration object for the element's style[p164] attribute.

The style IDL attribute is defined in *CSS Object Model*. [CSSOM][p1495]

Example

In the following example, the words that refer to colors are marked up using the span[p299] element and the style[p164] attribute to make those words show up in the relevant colors in visual media.

```
<p>My sweat suit is <span style="color: green; background:
transparent">green</span> and my eyes are <span style="color: blue;
background: transparent">blue</span>.</p>
```

3.2.6.6 Embedding custom non-visible data with the data-*[p165] attributes §[p165]

A **custom data attribute** is an attribute in no namespace whose name starts with the string "**data-**", has at least one character after the hyphen, is XML-compatible[p46], and contains no ASCII upper alphas.

Note

All attribute names on HTML elements[p46] in HTML documents get ASCII-lowercased automatically, so the restriction on ASCII uppercase letters doesn't affect such documents.

Custom data attributes[p165] are intended to store custom data, state, annotations, and similar, private to the page or application, for which there are no more appropriate attributes or elements.

These attributes are not intended for use by software that is not known to the administrators of the site that uses the attributes. For generic extensions that are to be used by multiple independent tools, either this specification should be extended to provide the feature explicitly, or a technology like microdata[p796] should be used (with a standardized vocabulary).

Example

For instance, a site about music could annotate list items representing tracks in an album with custom data attributes containing the length of each track. This information could then be used by the site itself to allow the user to sort the list by track length, or to filter the list for tracks of certain lengths.

```
<ol>
 <li data-length="2m11s">Beyond The Sea</li>
 ...
</ol>
```

It would be inappropriate, however, for the user to use generic software not associated with that music site to search for tracks of a certain length by looking at this data.

This is because these attributes are intended for use by the site's own scripts, and are not a generic extension mechanism for publicly-usable metadata.

Example

Similarly, a page author could write markup that provides information for a translation tool that they are intending to use:

```
<p>The third <span data-mytrans-de="Anspruch">claim</span> covers the case of <span
```

```
translate="no">HTML</span> markup.</p>
```

In this example, the "data-mytrans-de" attribute gives specific text for the MyTrans product to use when translating the phrase "claim" to German. However, the standard translate[p160] attribute is used to tell it that in all languages, "HTML" is to remain unchanged. When a standard attribute is available, there is no need for a custom data attribute[p165] to be used.

Example

In this example, custom data attributes are used to store the result of a feature detection for PaymentRequest, which could be used in CSS to style a checkout page differently.

```
<script>
 if ('PaymentRequest' in window) {
   document.documentElement.dataset.hasPaymentRequest = '';
 }
</script>
```

Here, the data-has-payment-request attribute is effectively being used as a boolean attribute[p76]; it is enough to check the presence of the attribute. However, if the author so wishes, it could later be populated with some value, maybe to indicate limited functionality of the feature.

Every HTML element[p46] may have any number of custom data attributes[p165] specified, with any value.

Authors should carefully design such extensions so that when the attributes are ignored and any associated CSS dropped, the page is still usable.

User agents must not derive any implementation behavior from these attributes or values. Specifications intended for user agents must not define these attributes to have any meaningful values.

JavaScript libraries may use the custom data attributes[p165], as they are considered to be part of the page on which they are used. Authors of libraries that are reused by many authors are encouraged to include their name in the attribute names, to reduce the risk of clashes. Where it makes sense, library authors are also encouraged to make the exact name used in the attribute names customizable, so that libraries whose authors unknowingly picked the same name can be used on the same page, and so that multiple versions of a particular library can be used on the same page even when those versions are not mutually compatible.

Example

For example, a library called "DoQuery" could use attribute names like data-doquery-range, and a library called "jJo" could use attributes names like data-jjo-range. The jJo library could also provide an API to set which prefix to use (e.g. J.setDataPrefix('j2'), making the attributes have names like data-j2-range).

For web developers (non-normative)

***element*.dataset**[p166]

Returns a DOMStringMap[p166] object for the element's data-*[p165] attributes.

Hyphenated names become camel-cased. For example, data-foo-bar="" becomes element.dataset.fooBar.

The **dataset** IDL attribute provides convenient accessors for all the data-*[p165] attributes on an element. On getting, the dataset[p166] IDL attribute must return a DOMStringMap[p166] whose associated element is this element.

The DOMStringMap[p166] interface is used for the dataset[p166] attribute. Each DOMStringMap[p166] has an **associated element**.

IDL

```
[Exposed=Window,
 LegacyOverrideBuiltIns]
interface DOMStringMap {
  getter DOMString (DOMString name);
  [CEReactions] setter undefined (DOMString name, DOMString value);
  [CEReactions] deleter undefined (DOMString name);
};
```

To **get a `DOMStringMap`'s name-value pairs**, run the following algorithm:

1. Let *list* be an empty list of name-value pairs.
2. For each content attribute on the `DOMStringMap`[p166]'s associated element[p166] whose first five characters are the string "`data-`" and whose remaining characters (if any) do not include any ASCII upper alphas, in the order that those attributes are listed in the element's attribute list, add a name-value pair to *list* whose name is the attribute's name with the first five characters removed and whose value is the attribute's value.
3. For each name in *list*, for each U+002D HYPHEN-MINUS character (-) in the name that is followed by an ASCII lower alpha, remove the U+002D HYPHEN-MINUS character (-) and replace the character that followed it by the same character converted to ASCII uppercase.
4. Return *list*.

The supported property names on a `DOMStringMap`[p166] object at any instant are the names of each pair returned from getting the `DOMStringMap`'s name-value pairs[p167] at that instant, in the order returned.

To determine the value of a named property *name* for a `DOMStringMap`[p166], return the value component of the name-value pair whose name component is *name* in the list returned from getting the `DOMStringMap`'s name-value pairs[p167].

To set the value of a new named property or set the value of an existing named property for a `DOMStringMap`[p166], given a property name *name* and a new value *value*, run the following steps:

1. If *name* contains a U+002D HYPHEN-MINUS character (-) followed by an ASCII lower alpha, then throw a `"SyntaxError"` `DOMException`.
2. For each ASCII upper alpha in *name*, insert a U+002D HYPHEN-MINUS character (-) before the character and replace the character with the same character converted to ASCII lowercase.
3. Insert the string `data-` at the front of *name*.
4. If *name* does not match the XML `Name` production, throw an `"InvalidCharacterError"` `DOMException`.
5. Set an attribute value for the `DOMStringMap`[p166]'s associated element[p166] using *name* and *value*.

To delete an existing named property *name* for a `DOMStringMap`[p166], run the following steps:

1. For each ASCII upper alpha in *name*, insert a U+002D HYPHEN-MINUS character (-) before the character and replace the character with the same character converted to ASCII lowercase.
2. Insert the string `data-` at the front of *name*.
3. Remove an attribute by name given *name* and the `DOMStringMap`[p166]'s associated element[p166].

Note

This algorithm will only get invoked by Web IDL *for names that are given by the earlier algorithm for getting the `DOMStringMap`'s name-value pairs[p167]. [WEBIDL][p1501]*

Example

If a web page wanted an element to represent a space ship, e.g. as part of a game, it would have to use the `class`[p156] attribute along with `data-*`[p165] attributes:

```
<div class="spaceship" data-ship-id="92432"
     data-weapons="laser 2" data-shields="50%"
     data-x="30" data-y="10" data-z="90">
 <button class="fire"
         onclick="spaceships[this.parentNode.dataset.shipId].fire()">
  Fire
 </button>
</div>
```

Notice how the hyphenated attribute name becomes camel-cased in the API.

Example

Given the following fragment and elements with similar constructions:

```
<img class="tower" id="tower5" data-x="12" data-y="5"
     data-ai="robotarget" data-hp="46" data-ability="flames"
     src="towers/rocket.png" alt="Rocket Tower">
```

...one could imagine a function `splashDamage()` that takes some arguments, the first of which is the element to process:

```
function splashDamage(node, x, y, damage) {
  if (node.classList.contains('tower') && // checking the 'class' attribute
      node.dataset.x == x && // reading the 'data-x' attribute
      node.dataset.y == y) { // reading the 'data-y' attribute
    var hp = parseInt(node.dataset.hp); // reading the 'data-hp' attribute
    hp = hp - damage;
    if (hp < 0) {
      hp = 0;
      node.dataset.ai = 'dead'; // setting the 'data-ai' attribute
      delete node.dataset.ability; // removing the 'data-ability' attribute
    }
    node.dataset.hp = hp; // setting the 'data-hp' attribute
  }
}
```

3.2.7 The innerText[p169] and outerText[p169] properties §[p168]

For web developers (non-normative)

***element*.innerText[p169] [= *value*]**

Returns the element's text content "as rendered".

Can be set, to replace the element's children with the given value, but with line breaks converted to br[p300] elements.

***element*.outerText[p169] [= *value*]**

Returns the element's text content "as rendered".

Can be set, to replace the element with the given value, but with line breaks converted to br[p300] elements.

The **get the text steps**, given an HTMLElement[p143] *element*, are:

1. If *element* is not being rendered[p1406] or if the user agent is a non-CSS user agent, then return *element*'s descendant text content.

   Note

   This step can produce surprising results, as when the innerText[p169] *getter is invoked on an element not being rendered[p1406], its text contents are returned, but when accessed on an element that is being rendered[p1406], all of its children that are not being rendered[p1406] have their text contents ignored.*

2. Let *results* be a new empty list.

3. For each child node *node* of *element*:

   1. Let *current* be the list resulting in running the rendered text collection steps[p169] with *node*. Each item in *results* will either be a string or a positive integer (a *required line break count*).

      Note

      Intuitively, a required line break count *item means that a certain number of line breaks appear at that point, but they can be collapsed with the line breaks induced by adjacent* required line break count *items, reminiscent to CSS margin-collapsing.*

   2. For each item *item* in *current*, append *item* to *results*.

4. Remove any items from *results* that are the empty string.
5. Remove any runs of consecutive *required line break count* items at the start or end of *results*.
6. Replace each remaining run of consecutive *required line break count* items with a string consisting of as many U+000A LF code points as the maximum of the values in the *required line break count* items.
7. Return the concatenation of the string items in *results*.

The **innerText** and **outerText** getter steps are to return the result of running get the text steps[p168] with this.

The **rendered text collection steps**, given a node *node*, are as follows:

1. Let *items* be the result of running the rendered text collection steps[p169] with each child node of *node* in tree order, and then concatenating the results to a single list.
2. If *node*'s computed value of 'visibility' is not 'visible', then return *items*.
3. If *node* is not being rendered[p1406], then return *items*. For the purpose of this step, the following elements must act as described if the computed value of the 'display' property is not 'none':
    - `select`[p572] elements have an associated non-replaced inline CSS box whose child boxes include only those of `optgroup`[p579] and `option`[p580] element child nodes;
    - `optgroup`[p579] elements have an associated non-replaced block-level CSS box whose child boxes include only those of `option`[p580] element child nodes; and
    - `option`[p580] elements have an associated non-replaced block-level CSS box whose child boxes are as normal for non-replaced block-level CSS boxes.

    Note

    items *can be non-empty due to 'display:contents'.*
4. If *node* is a `Text` node, then for each CSS text box produced by *node*, in content order, compute the text of the box after application of the CSS 'white-space' processing rules and 'text-transform' rules, set *items* to the list of the resulting strings, and return *items*. The CSS 'white-space' processing rules are slightly modified: collapsible spaces at the end of lines are always collapsed, but they are only removed if the line is the last line of the block, or it ends with a `br`[p300] element. Soft hyphens should be preserved. [CSSTEXT][p1495]
5. If *node* is a `br`[p300] element, then append a string containing a single U+000A LF code point to *items*.
6. If *node*'s computed value of 'display' is 'table-cell', and *node*'s CSS box is not the last 'table-cell' box of its enclosing 'table-row' box, then append a string containing a single U+0009 TAB code point to *items*.
7. If *node*'s computed value of 'display' is 'table-row', and *node*'s CSS box is not the last 'table-row' box of the nearest ancestor 'table' box, then append a string containing a single U+000A LF code point to *items*.
8. If *node* is a `p`[p230] element, then append 2 (a *required line break count*) at the beginning and end of *items*.
9. If *node*'s used value of 'display' is block-level or 'table-caption', then append 1 (a *required line break count*) at the beginning and end of *items*. [CSSDISPLAY][p1494]

    Note

    Floats and absolutely-positioned elements fall into this category.
10. Return *items*.

Note

Note that descendant nodes of most replaced elements (e.g., `textarea`[p583], `input`[p521], and `video`[p407] — but not `button`[p567]) are not rendered by CSS, strictly speaking, and therefore have no CSS boxes for the purposes of this algorithm.

This algorithm is amenable to being generalized to work on ranges. Then we can use it as the basis for `Selection`'s stringifier and maybe expose it directly on ranges. See Bugzilla bug 10583.

The **set the inner text steps**, given an HTMLElement[p143] *element*, and a string *value* are:

1. Let *fragment* be the rendered text fragment[p170] for *value* given *element*'s node document.
2. Replace all with *fragment* within *element*.

The `innerText`[p169] setter steps are to run set the inner text steps[p170].

The `outerText`[p169] setter steps are:

1. If this's parent is null, then throw a `"NoModificationAllowedError"` `DOMException`.
2. Let *next* be this's next sibling.
3. Let *previous* be this's previous sibling.
4. Let *fragment* be the rendered text fragment[p170] for the given value given this's node document.
5. If *fragment* has no children, then append a new `Text` node whose data is the empty string and node document is this's node document to *fragment*.
6. Replace this with *fragment* within this's parent.
7. If *next* is non-null and *next*'s previous sibling is a `Text` node, then merge with the next text node[p170] given *next*'s previous sibling.
8. If *previous* is a `Text` node, then merge with the next text node[p170] given *previous*.

The **rendered text fragment** for a string *input* given a `Document`[p131] *document* is the result of running the following steps:

1. Let *fragment* be a new `DocumentFragment` whose node document is *document*.
2. Let *position* be a position variable for *input*, initially pointing at the start of *input*.
3. Let *text* be the empty string.
4. While *position* is not past the end of *input*:
    1. Collect a sequence of code points that are not U+000A LF or U+000D CR from *input* given *position*, and set *text* to the result.
    2. If *text* is not the empty string, then append a new `Text` node whose data is *text* and node document is *document* to *fragment*.
    3. While *position* is not past the end of *input*, and the code point at *position* is either U+000A LF or U+000D CR:
        1. If the code point at *position* is U+000D CR and the next code point is U+000A LF, then advance *position* to the next code point in *input*.
        2. Advance *position* to the next code point in *input*.
        3. Append the result of creating an element given *document*, "`br`", and the HTML namespace to *fragment*.
5. Return *fragment*.

To **merge with the next text node** given a `Text` node *node*:

1. Let *next* be *node*'s next sibling.
2. If *next* is not a `Text` node, then return.
3. Replace data with *node*, *node*'s data's length, 0, and *next*'s data.
4. Remove *next*.

3.2.8 Requirements relating to the bidirectional algorithm §p17 1

3.2.8.1 Authoring conformance criteria for bidirectional-algorithm formatting characters §p17 1

Text contentp151 in HTML elementsp46 with Text nodes in their contentsp148, and text in attributes of HTML elementsp46 that allow free-form text, may contain characters in the ranges U+202A to U+202E and U+2066 to U+2069 (the bidirectional-algorithm formatting characters). [BIDI]p1493

Note

Authors are encouraged to use the dirp161 attribute, the bdop299 element, and the bdip298 element, rather than maintaining the bidirectional-algorithm formatting characters manually. The bidirectional-algorithm formatting characters interact poorly with CSS.

3.2.8.2 User agent conformance criteria §p17 1

User agents must implement the Unicode bidirectional algorithm to determine the proper ordering of characters when rendering documents and parts of documents. [BIDI]p1493

The mapping of HTML to the Unicode bidirectional algorithm must be done in one of three ways. Either the user agent must implement CSS, including in particular the CSS 'unicode-bidi', 'direction', and 'content' properties, and must have, in its user agent style sheet, the rules using those properties given in this specification's renderingp1406 section, or, alternatively, the user agent must act as if it implemented just the aforementioned properties and had a user agent style sheet that included all the aforementioned rules, but without letting style sheets specified in documents override them, or, alternatively, the user agent must implement another styling language with equivalent semantics. [CSSGC]p1494

The following elements and attributes have requirements defined by the renderingp1406 section that, due to the requirements in this section, are requirements on all user agents (not just those that support the suggested default renderingp49):

- dirp161 attribute
- bdip298 element
- bdop299 element
- brp300 element
- prep234 element
- textareap583 element
- wbrp301 element

3.2.9 Requirements related to ARIA and to platform accessibility APIs §p17 1

User agent requirements for implementing Accessibility API semantics on HTML elementsp46 are defined in *HTML Accessibility API Mappings*. In addition to the rules there, for a custom elementp766 *element*, the default ARIA role semantics are determined as follows: [HTMLAAM]p1496

1. Let *map* be *element*'s internal content attribute mapp783.
2. If *map*["role"] exists, then return it.
3. Return no role.

Similarly, for a custom elementp766 *element*, the default ARIA state and property semantics, for a state or property named *stateOrProperty*, are determined as follows:

1. If *element*'s attached internalsp779 is non-null:
    1. If *element*'s attached internalsp779's get the *stateOrProperty*-associated elementp109 exists, then return the result of running it.
    2. If *element*'s attached internalsp779's get the *stateOrProperty*-associated elementsp110 exists, then return the result of running it.
2. If *element*'s internal content attribute mapp783[*stateOrProperty*] exists, then return it.
3. Return the default value for *stateOrProperty*.

Note

The "default semantics" referred to here are sometimes also called "native", "implicit", or "host language" semantics in ARIA. *[ARIA]*[p1493]

Note

One implication of these definitions is that the default semantics can change over time. This allows custom elements the same expressivity as built-in elements; e.g., compare to how the default ARIA role semantics of an `a`[p258] *element change as the* `href`[p304] *attribute is added or removed.*

For an example of this in action, see the custom elements section[p758].

Conformance checker requirements for checking use of ARIA `role`[p69] and `aria-*`[p69] attributes on HTML elements[p46] are defined in *ARIA in HTML*. [ARIAHTML][p1493]

4 The elements of HTML §p17 3

4.1 The document element §p17 3

4.1.1 The `html` element §p17 3

Categoriesp147**:**

None.

Contexts in which this element can be usedp147**:**

As document's document element.
Wherever a subdocument fragment is allowed in a compound document.

Content modelp147**:**

A `head`p174 element followed by a `body`p206 element.

Tag omission in text/htmlp148**:**

An `html`p173 element's start tagp1279 can be omitted if the first thing inside the `html`p173 element is not a commentp1288.
An `html`p173 element's end tagp1280 can be omitted if the `html`p173 element is not immediately followed by a commentp1288.

Content attributesp148**:**

Global attributesp155

Accessibility considerationsp148**:**

For authors.
For implementers.

DOM interfacep148**:**

IDL

```
[Exposed=Window]
interface HTMLHtmlElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

The `html`p173 element representsp142 the root of an HTML document.

Authors are encouraged to specify a `lang`p159 attribute on the root `html`p173 element, giving the document's language. This aids speech synthesis tools to determine what pronunciations to use, translation tools to determine what rules to use, and so forth.

Example

The `html`p173 element in the following example declares that the document's language is English.

```
<!DOCTYPE html>
<html lang="en">
<head>
<title>Swapping Songs</title>
</head>
<body>
<h1>Swapping Songs</h1>
<p>Tonight I swapped some of the songs I wrote with some friends, who
gave me some of the songs they wrote. I love sharing my music.</p>
</body>
</html>
```

4.2 Document metadata §[p174]

4.2.1 The head element §[p174]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As the first element in an html[p173] element.

Content model[p147]:

If the document is an iframe srcdoc document[p392] or if title information is available from a higher-level protocol: Zero or more elements of metadata content[p150], of which no more than one is a title[p175] element and no more than one is a base[p176] element.

Otherwise: One or more elements of metadata content[p150], of which exactly one is a title[p175] element and no more than one is a base[p176] element.

Tag omission in text/html[p148]:

A head[p174] element's start tag[p1279] can be omitted if the element is empty, or if the first thing inside the head[p174] element is an element.

A head[p174] element's end tag[p1280] can be omitted if the head[p174] element is not immediately followed by ASCII whitespace or a comment[p1288].

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.

For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLHeadElement : HTMLElement {
  [HTMLConstructor] constructor();
};
```

The head[p174] element represents[p142] a collection of metadata for the Document[p131].

Example

The collection of metadata in a head[p174] element can be large or small. Here is an example of a very short one:

```
<!doctype html>
<html lang=en>
 <head>
  <title>A document with a short head</title>
 </head>
 <body>
 ...
```

Here is an example of a longer one:

```
<!DOCTYPE HTML>
<HTML LANG="EN">
 <HEAD>
  <META CHARSET="UTF-8">
  <BASE HREF="https://www.example.com/">
  <TITLE>An application with a long head</TITLE>
  <LINK REL="STYLESHEET" HREF="default.css">
  <LINK REL="STYLESHEET ALTERNATE" HREF="big.css" TITLE="Big Text">
  <SCRIPT SRC="support.js"></SCRIPT>
  <META NAME="APPLICATION-NAME" CONTENT="Long headed application">
 </HEAD>
```

```
<BODY>
...
```

Note

The title element is a required child in most situations, but when a higher-level protocol provides title information, e.g., in the subject line of an email when HTML is used as an email authoring format, the title element can be omitted.

4.2.2 The title element §

Categories:

Metadata content.

Contexts in which this element can be used:

In a head element containing no other title elements.

Content model:

Text that is not inter-element whitespace.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes

Accessibility considerations:

For authors.
For implementers.

DOM interface:

IDL

```
[Exposed=Window]
interface HTMLTitleElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString text;
};
```

The title element represents the document's title or name. Authors should use titles that identify their documents even when they are used out of context, for example in a user's history or bookmarks, or in search results. The document's title is often different from its first heading, since the first heading does not have to stand alone when taken out of context.

There must be no more than one title element per document.

Note

If it's reasonable for the Document to have no title, then the title element is probably not required. See the head element's content model for a description of when the element is required.

For web developers (non-normative)

***title*.text [= *value*]**

Returns the child text content of the element.

Can be set, to replace the element's children with the given value.

The **text** attribute's getter must return this title element's child text content.

The text attribute's setter must string replace all with the given value within this title element.

Example

Here are some examples of appropriate titles, contrasted with the top-level headings that might be used on those same pages.

```
<title>Introduction to The Mating Rituals of Bees</title>
  ...
<h1>Introduction</h1>
<p>This companion guide to the highly successful
<cite>Introduction to Medieval Bee-Keeping</cite> book is...
```

The next page might be a part of the same site. Note how the title describes the subject matter unambiguously, while the first heading assumes the reader knows what the context is and therefore won't wonder if the dances are Salsa or Waltz:

```
<title>Dances used during bee mating rituals</title>
  ...
<h1>The Dances</h1>
```

The string to use as the document's title is given by the document.title[p136] IDL attribute.

User agents should use the document's title when referring to the document in their user interface. When the contents of a title[p175] element are used in this way, the directionality[p161] of that title[p175] element should be used to set the directionality of the document's title in the user interface.

4.2.3 The base element §[p176]

Categories[p147]:

Metadata content[p150].

Contexts in which this element can be used[p147]:

In a head[p174] element containing no other base[p176] elements.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]
href[p177] — Document base URL[p98]
target[p177] — Default navigable[p1001] for hyperlink[p303] navigation[p1028] and form submission[p632]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLBaseElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute USVString href;
  [CEReactions] attribute DOMString target;
};
```

The base[p176] element allows authors to specify the document base URL[p98] for the purposes of parsing URLs, and the name of the default navigable[p1001] for the purposes of following hyperlinks[p310]. The element does not represent[p142] any content beyond this information.

There must be no more than one base[p176] element per document.

A base element must have either an href attribute, a target attribute, or both.

The **href** content attribute, if specified, must contain a valid URL potentially surrounded by spaces.

A base element, if it has an href attribute, must come before any other elements in the tree that have attributes defined as taking URLs.

Note

If there are multiple base elements with href attributes, all but the first are ignored.

The **target** attribute, if specified, must contain a valid navigable target name or keyword, which specifies which navigable is to be used as the default when hyperlinks and forms in the Document cause navigation.

A base element, if it has a target attribute, must come before any elements in the tree that represent hyperlinks.

Note

If there are multiple base elements with target attributes, all but the first are ignored.

To **get an element's target**, given an a, area, or form element *element*, and an optional string-or-null *target* (default null), run these steps:

1. If *target* is null, then:
    1. If *element* has a `target` attribute, then set *target* to that attribute's value.
    2. Otherwise, if *element*'s node document contains a base element with a target attribute, set *target* to the value of the target attribute of the first such base element.
2. If *target* is not null, and contains an ASCII tab or newline and a U+003C (<), then set *target* to "`_blank`".
3. Return *target*.

A base element that is the first base element with an href content attribute in a document tree has a **frozen base URL**. The frozen base URL must be immediately set for an element whenever any of the following situations occur:

- The base element becomes the first base element in tree order with an href content attribute in its Document.
- The base element is the first base element in tree order with an href content attribute in its Document, and its href content attribute is changed.

To **set the frozen base URL** for an element *element*:

1. Let *document* be *element*'s node document.
2. Let *urlRecord* be the result of parsing the value of *element*'s href content attribute with *document*'s fallback base URL, and *document*'s character encoding. (Thus, the base element isn't affected by itself.)
3. If any of the following are true:
    - *urlRecord* is failure;
    - *urlRecord*'s scheme is "`data`" or "`javascript`"; or
    - running Is base allowed for Document? on *urlRecord* and *document* returns "`Blocked`",

    then set *element*'s frozen base URL to *document*'s fallback base URL and return.
4. Set *element*'s frozen base URL to *urlRecord*.

The **href** IDL attribute, on getting, must return the result of running the following algorithm:

1. Let *document* be *element*'s node document.
2. Let *url* be the value of the href attribute of this element, if it has one, and the empty string otherwise.

3. Let *urlRecord* be the result of parsing *url* with *document*'s fallback base URL[p97], and *document*'s character encoding. (Thus, the base[p176] element isn't affected by other base[p176] elements or itself.)
4. If *urlRecord* is failure, return *url*.
5. Return the serialization of *urlRecord*.

The href[p177] IDL attribute, on setting, must set the href[p177] content attribute to the given new value.

The **target** IDL attribute must reflect[p105] the content attribute of the same name.

Example

In this example, a base[p176] element is used to set the document base URL[p98]:

```
<!DOCTYPE html>
<html lang="en">
    <head>
        <title>This is an example for the &lt;base&gt; element</title>
        <base href="https://www.example.com/news/index.html">
    </head>
    <body>
        <p>Visit the <a href="archives.html">archives</a>.</p>
    </body>
</html>
```

The link in the above example would be a link to "https://www.example.com/news/archives.html".

4.2.4 The link element §[p178]

Categories[p147]:

Metadata content[p150].
If the element is allowed in the body[p180]: flow content[p150].
If the element is allowed in the body[p180]: phrasing content[p151].

Contexts in which this element can be used[p147]:

Where metadata content[p150] is expected.
In a noscript[p677] element that is a child of a head[p174] element.
If the element is allowed in the body[p180]: where phrasing content[p151] is expected.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]
href[p179] — Address of the hyperlink[p303]
crossorigin[p180] — How the element handles crossorigin requests
rel[p179] — Relationship between the document containing the hyperlink[p303] and the destination resource
media[p180] — Applicable media
integrity[p180] — Integrity metadata used in *Subresource Integrity* checks [SRI][p1500]
hreflang[p180] — Language of the linked resource
type[p180] — Hint for the type of the referenced resource
referrerpolicy[p180] — Referrer policy for fetches initiated by the element
sizes[p181] — Sizes of the icons (for rel[p179]="icon[p321]")
imagesrcset[p181] — Images to use in different situations, e.g., high-resolution displays, small monitors, etc. (for rel[p179]="preload[p329]")
imagesizes[p181] — Image sizes for different page layouts (for rel[p179]="preload[p329]")
as[p182] — Potential destination for a preload request (for rel[p179]="preload[p329]" and rel[p179]="modulepreload[p324]")
blocking[p182] — Whether the element is potentially render-blocking[p105]

color[p182] — Color to use when customizing a site's icon (for rel[p179]="mask-icon")
disabled[p182] — Whether the link is disabled
fetchpriority[p182] — Sets the priority for fetches initiated by the element
Also, the title[p180] attribute has special semantics[p180] on this element: Title of the link; CSS style sheet set name

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLLinkElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute USVString href;
  [CEReactions] attribute DOMString? crossOrigin;
  [CEReactions] attribute DOMString rel;
  [CEReactions] attribute DOMString as;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList relList;
  [CEReactions] attribute DOMString media;
  [CEReactions] attribute DOMString integrity;
  [CEReactions] attribute DOMString hreflang;
  [CEReactions] attribute DOMString type;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList sizes;
  [CEReactions] attribute USVString imageSrcset;
  [CEReactions] attribute DOMString imageSizes;
  [CEReactions] attribute DOMString referrerPolicy;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList blocking;
  [CEReactions] attribute boolean disabled;
  [CEReactions] attribute DOMString fetchPriority;

  // also has obsolete members
};
HTMLLinkElement includes LinkStyle;
```

The link[p178] element allows authors to link their document to other resources.

The address of the link(s) is given by the **href** attribute. If the href[p179] attribute is present, then its value must be a valid non-empty URL potentially surrounded by spaces[p97]. One or both of the href[p179] or imagesrcset[p181] attributes must be present.

If both the href[p179] and imagesrcset[p181] attributes are absent, then the element does not define a link.

The types of link indicated (the relationships) are given by the value of the **rel** attribute, which, if present, must have a value that is a unordered set of unique space-separated tokens[p96]. The allowed keywords and their meanings[p315] are defined in a later section. If the rel[p179] attribute is absent, has no keywords, or if none of the keywords used are allowed according to the definitions in this specification, then the element does not create any links.

rel[p179]'s supported tokens are the keywords defined in HTML link types[p315] which are allowed on link[p178] elements, impact the processing model, and are supported by the user agent. The possible supported tokens are alternate[p316], dns-prefetch[p318], expect[p319], icon[p321], manifest[p323], modulepreload[p324], next[p336], pingback[p327], preconnect[p327], prefetch[p328], preload[p329], search[p332], and stylesheet[p332]. rel[p179]'s supported tokens must only include the tokens from this list that the user agent implements the processing model for.

Note

Theoretically a user agent could support the processing model for the canonical[p318] keyword — if it were a search engine that executed JavaScript. But in practice that's quite unlikely. So in most cases, canonical[p318] ought not be included in rel[p179]'s supported tokens.

A link[p178] element must have either a rel[p179] attribute or an itemprop[p803] attribute, but not both.

If a link[p178] element has an itemprop[p803] attribute, or has a rel[p179] attribute that contains only keywords that are body-ok[p315], then the

element is said to be **allowed in the body**. This means that the element can be used where phrasing content[p151] is expected.

Note

If the rel[p179] attribute is used, the element can only sometimes be used in the body[p206] of the page. When used with the itemprop[p803] attribute, the element can be used both in the head[p174] element and in the body[p206] of the page, subject to the constraints of the microdata model.

Two categories of links can be created using the link[p178] element: links to external resources[p303] and hyperlinks[p303]. The link types section[p315] defines whether a particular link type is an external resource or a hyperlink. One link[p178] element can create multiple links (of which some might be external resource links[p303] and some might be hyperlinks[p303]); exactly which and how many links are created depends on the keywords given in the rel[p179] attribute. User agents must process the links on a per-link basis, not a per-element basis.

Note

Each link created for a link[p178] element is handled separately. For instance, if there are two link[p178] elements with `rel="stylesheet"`*, they each count as a separate external resource, and each is affected by its own attributes independently. Similarly, if a single link[p178] element has a rel[p179] attribute with the value* `next stylesheet`*, it creates both a hyperlink[p303] (for the next[p336] keyword) and an external resource link[p303] (for the stylesheet[p332] keyword), and they are affected by other attributes (such as media[p180] or title[p180]) differently.*

Example

For example, the following link[p178] element creates two hyperlinks[p303] (to the same page):

```
<link rel="author license" href="/about">
```

The two links created by this element are one whose semantic is that the target page has information about the current page's author, and one whose semantic is that the target page has information regarding the license under which the current page is provided.

Hyperlinks[p303] created with the link[p178] element and its rel[p179] attribute apply to the whole document. This contrasts with the rel[p304] attribute of a[p258] and area[p472] elements, which indicates the type of a link whose context is given by the link's location within the document.

Unlike those created by a[p258] and area[p472] elements, hyperlinks[p303] created by link[p178] elements are not displayed as part of the document by default, in user agents that support the suggested default rendering[p49]. And even if they are force-displayed using CSS, they have no activation behavior. Instead, they primarily provide semantic information which might be used by the page or by other software that consumes the page's contents. Additionally, the user agent can provide its own UI for following such hyperlinks[p190].

The exact behavior for links to external resources[p303] depends on the exact relationship, as defined for the relevant link type[p315].

The **crossorigin** attribute is a CORS settings attribute[p101]. It is intended for use with external resource links[p303].

The **media** attribute says which media the resource applies to. The value must be a valid media query list[p97].

The **integrity** attribute represents the integrity metadata for requests which this element is responsible for. The value is text. The attribute must only be specified on link[p178] elements that have a rel[p179] attribute that contains the stylesheet[p332], preload[p329], or modulepreload[p324] keyword. [SRI][p1500]

The **hreflang** attribute on the link[p178] element has the same semantics as the hreflang attribute on the a element[p304].

The **type** attribute gives the MIME type of the linked resource. It is purely advisory. The value must be a valid MIME type string.

For external resource links[p303], the type[p180] attribute is used as a hint to user agents so that they can avoid fetching resources they do not support.

The **referrerpolicy** attribute is a referrer policy attribute[p101]. It is intended for use with external resource links[p303], where it helps set the referrer policy used when fetching and processing the linked resource[p184]. [REFERRERPOLICY][p1499]

The **title** attribute gives the title of the link. With one exception, it is purely advisory. The value is text. The exception is for style sheet links that are in a document tree, for which the title[p180] attribute defines CSS style sheet sets.

Note

The title attribute on link elements differs from the global title attribute of most other elements in that a link without a title does not inherit the title of the parent element: it merely has no title.

The **imagesrcset** attribute may be present, and is a srcset attribute.

The imagesrcset and href attributes (if width descriptors are not used) together contribute the image sources to the source set.

If the imagesrcset attribute is present and has any image candidate strings using a width descriptor, the **imagesizes** attribute must also be present, and is a sizes attribute. The imagesizes attribute contributes the source size to the source set.

The imagesrcset and imagesizes attributes must only be specified on link elements that have both a rel attribute that specifies the preload keyword, as well as an as attribute in the "image" state.

Example

These attributes allow preloading the appropriate resource that is later used by an img element that has the corresponding values for its srcset and sizes attributes:

```
<link rel="preload" as="image"
      imagesrcset="wolf_400px.jpg 400w, wolf_800px.jpg 800w, wolf_1600px.jpg 1600w"
      imagesizes="50vw">

<!-- ... later, or perhaps inserted dynamically ... -->
<img src="wolf.jpg" alt="A rad wolf"
     srcset="wolf_400px.jpg 400w, wolf_800px.jpg 800w, wolf_1600px.jpg 1600w"
     sizes="50vw">
```

Note how we omit the href attribute, as it would only be relevant for browsers that do not support imagesrcset, and in those cases it would likely cause the incorrect image to be preloaded.

Example

The imagesrcset attribute can be combined with the media attribute to preload the appropriate resource selected from a picture element's sources, for art direction:

```
<link rel="preload" as="image"
      imagesrcset="dog-cropped-1x.jpg, dog-cropped-2x.jpg 2x"
      media="(max-width: 800px)">
<link rel="preload" as="image"
      imagesrcset="dog-wide-1x.jpg, dog-wide-2x.jpg 2x"
      media="(min-width: 801px)">

<!-- ... later, or perhaps inserted dynamically ... -->
<picture>
  <source srcset="dog-cropped-1x.jpg, dog-cropped-2x.jpg 2x"
          media="(max-width: 800px)">
  <img src="dog-wide-1x.jpg" srcset="dog-wide-2x.jpg 2x"
       alt="An awesome dog">
</picture>
```

The **sizes** attribute gives the sizes of icons for visual media. Its value, if present, is merely advisory. User agents may use the value to decide which icon(s) to use if multiple icons are available. If specified, the attribute must have a value that is an unordered set of unique space-separated tokens which are ASCII case-insensitive. Each value must be either an ASCII case-insensitive match for the string "any", or a value that consists of two valid non-negative integers that do not have a leading U+0030 DIGIT ZERO (0) character and that are separated by a single U+0078 LATIN SMALL LETTER X or U+0058 LATIN CAPITAL LETTER X character. The attribute must only be specified on link elements that have a rel attribute that specifies the icon keyword or the `apple-touch-icon` keyword.

Note

The `apple-touch-icon` keyword is a registered extension to the predefined set of link types[p336], but user agents are not required to support it in any way.

The **as** attribute specifies the potential destination for a preload request for the resource given by the `href`[p179] attribute. It is an enumerated attribute[p77]. Each potential destination is a keyword for this attribute, mapping to a state of the same name. The attribute must be specified on `link`[p178] elements that have a `rel`[p179] attribute that contains the `preload`[p329] keyword. It may be specified on `link`[p178] elements that have a `rel`[p179] attribute that contains the `modulepreload`[p324] keyword; in such cases it must have a value which is a script-like destination. For other `link`[p178] elements, it must not be specified.

The processing model for how the `as`[p182] attribute is used is given in an individual link type's fetch and process the linked resource[p184] algorithm.

Note

The attribute does not have a missing value default[p77] or invalid value default[p77], meaning that invalid or missing values for the attribute map to no state. This is accounted for in the processing model. For `preload`[p329] links, both conditions are an error; for `modulepreload`[p324] links, a missing value will be treated as "`script`".

The **blocking** attribute is a blocking attribute[p104]. It is used by link types `stylesheet`[p332] and `expect`[p319], and it must only be specified on link elements that have a `rel`[p179] attribute containing those keywords.

The **color** attribute is used with the `mask-icon` link type. The attribute must only be specified on `link`[p178] elements that have a `rel`[p179] attribute that contains the `mask-icon` keyword. The value must be a string that matches the CSS <color> production, defining a suggested color that user agents can use to customize the display of the icon that the user sees when they pin your site.

Note

This specification does not have any user agent requirements for the `color`[p182] attribute.

Note

The `mask-icon` keyword is a registered extension to the predefined set of link types[p336], but user agents are not required to support it in any way.

`link`[p178] elements have an associated **explicitly enabled** boolean. It is initially false.

The **disabled** attribute is a boolean attribute[p76] that is used with the `stylesheet`[p332] link type. The attribute must only be specified on `link`[p178] elements that have a `rel`[p179] attribute that contains the `stylesheet`[p332] keyword.

Whenever the `disabled`[p182] attribute is removed, set the `link`[p178] element's explicitly enabled[p182] attribute to true.

Example

Removing the `disabled`[p182] attribute dynamically, e.g., using `document.querySelector("link").removeAttribute("disabled")`, will fetch and apply the style sheet:

```
<link disabled rel="alternate stylesheet" href="css/pooh">
```

The **fetchpriority** attribute is a fetch priority attribute[p105] that is intended for use with external resource links[p303], where it is used to set the priority used when fetching and processing the linked resource[p184].

The IDL attributes **href**, **hreflang**, **integrity**, **media**, **rel**, **sizes**, **type**, **blocking**, and **disabled** each must reflect[p105] the respective content attributes of the same name.

Note

There is no reflecting IDL attribute for the `color`[p182] attribute, but this might be added later.

The **as** IDL attribute must reflect[p105] the as[p182] content attribute, limited to only known values[p106].

The **crossOrigin** IDL attribute must reflect[p105] the crossorigin[p180] content attribute, limited to only known values[p106].

The **referrerPolicy** IDL attribute must reflect[p105] the referrerpolicy[p180] content attribute, limited to only known values[p106].

The **fetchPriority** IDL attribute must reflect[p105] the fetchpriority[p182] content attribute, limited to only known values[p106].

The **imageSrcset** IDL attribute must reflect[p105] the imagesrcset[p181] content attribute.

The **imageSizes** IDL attribute must reflect[p105] the imagesizes[p181] content attribute.

The **relList** IDL attribute must reflect[p105] the rel[p179] content attribute.

Note

The relList[p183] attribute can be used for feature detection, by calling its supports() method to check which types of links[p315] are supported.

4.2.4.1 Processing the media[p180] attribute §[p18]

If the link is a hyperlink[p303] then the media[p180] attribute is purely advisory, and describes for which media the document in question was designed.

However, if the link is an external resource link[p303], then the media[p180] attribute is prescriptive. The user agent must apply the external resource when the media[p180] attribute's value matches the environment[p97] and the other relevant conditions apply, and must not apply it otherwise.

The default, if the media[p180] attribute is omitted, is "all", meaning that by default links apply to all media.

Note

The external resource might have further restrictions defined within that limit its applicability. For example, a CSS style sheet might have some @media blocks. This specification does not override such further restrictions or requirements.

4.2.4.2 Processing the type[p180] attribute §[p18]

If the type[p180] attribute is present, then the user agent must assume that the resource is of the given type (even if that is not a valid MIME type string, e.g. the empty string). If the attribute is omitted, but the external resource link[p303] type has a default type defined, then the user agent must assume that the resource is of that type. If the UA does not support the given MIME type for the given link relationship, then the UA should not fetch and process the linked resource[p184]; if the UA does support the given MIME type for the given link relationship, then the UA should fetch and process the linked resource[p184] at the appropriate time as specified for the external resource link[p303]'s particular type. If the attribute is omitted, and the external resource link[p303] type does not have a default type defined, but the user agent would fetch and process the linked resource[p184] if the type was known and supported, then the user agent should fetch and process the linked resource[p184] under the assumption that it will be supported.

User agents must not consider the type[p180] attribute authoritative — upon fetching the resource, user agents must not use the type[p180] attribute to determine its actual type. Only the actual type (as defined in the next paragraph) is used to determine whether to *apply* the resource, not the aforementioned assumed type.

If the external resource link[p303] type defines rules for processing the resource's Content-Type metadata[p100], then those rules apply. Otherwise, if the resource is expected to be an image, user agents may apply the image sniffing rules, with the *official type* being the type determined from the resource's Content-Type metadata[p100], and use the resulting computed type of the resource as if it was the actual type. Otherwise, if neither of these conditions apply or if the user agent opts not to apply the image sniffing rules, then the user agent must use the resource's Content-Type metadata[p100] to determine the type of the resource. If there is no type metadata, but the external resource link[p303] type has a default type defined, then the user agent must assume that the resource is of that type.

Note

The stylesheet[p332] link type defines rules for processing the resource's Content-Type metadata[p100].

Once the user agent has established the type of the resource, the user agent must apply the resource if it is of a supported type and the other relevant conditions apply, and must ignore the resource otherwise.

Example

If a document contains style sheet links labeled as follows:

```
<link rel="stylesheet" href="A" type="text/plain">
<link rel="stylesheet" href="B" type="text/css">
<link rel="stylesheet" href="C">
```

...then a compliant UA that supported only CSS style sheets would fetch the B and C files, and skip the A file (since `text/plain` is not the MIME type for CSS style sheets).

For files B and C, it would then check the actual types returned by the server. For those that are sent as `text/css`[p1492], it would apply the styles, but for those labeled as `text/plain`, or any other type, it would not.

If one of the two files was returned without a Content-Type[p100] metadata, or with a syntactically incorrect type like `Content-Type: "null"`, then the default type for `stylesheet`[p332] links would kick in. Since that default type is `text/css`[p1492], the style sheet *would* nonetheless be applied.

4.2.4.3 Fetching and processing a resource from a `link`[p178] element §[p184]

All external resource links[p303] have a **fetch and process the linked resource** algorithm, which takes a `link`[p178] element *el*. They also have **linked resource fetch setup steps** which take a `link`[p178] element *el* and request *request*. Individual link types may provide their own fetch and process the linked resource[p184] algorithm, but unless explicitly stated, they use the default fetch and process the linked resource[p184] algorithm. Similarly, individual link types may provide their own linked resource fetch setup steps[p184], but unless explicitly stated, these steps just return true.

The **default fetch and process the linked resource**, given a `link`[p178] element *el*, is as follows:

1. Let *options* be the result of creating link options[p186] from *el*.
2. Let *request* be the result of creating a link request[p185] given *options*.
3. If *request* is null, then return.
4. Set *request*'s synchronous flag.
5. Run the linked resource fetch setup steps[p184], given *el* and *request*. If the result is false, then return.
6. Set *request*'s initiator type to "`css`" if *el*'s `rel`[p179] attribute contains the keyword `stylesheet`[p332]; "`link`" otherwise.
7. Fetch *request* with *processResponseConsumeBody* set to the following steps given response *response* and null, failure, or a byte sequence *bodyBytes*:
    1. Let *success* be true.
    2. If any of the following are true:
        - *bodyBytes* is null or failure; or
        - *response*'s status is not an ok status,

        then set *success* to false.

        Note

        Note that content-specific errors, e.g., CSS parse errors or PNG decoding errors, do not affect success.
    3. Otherwise, wait for the link resource[p303]'s critical subresources[p46] to finish loading.

        The specification that defines a link type's critical subresources[p46] (e.g., CSS) is expected to describe how these subresources are fetched and processed. However, since this is not currently explicit, this specification describes waiting for a link resource[p303]'s critical subresources[p46] to be fetched and processed, with the

expectation that this will be done correctly.

4. Process the linked resource[p185] given *el*, *success*, *response*, and *bodyBytes*.

To **create a link request** given a link processing options[p185] *options*:

1. Assert: *options*'s href[p186] is not the empty string.
2. If *options*'s destination[p186] is null, then return null.
3. Let *url* be the result of encoding-parsing a URL[p98] given *options*'s href[p186], relative to *options*'s base URL[p186].

   Passing the base URL instead of a document or environment is tracked by issue #9715.
4. If *url* is failure, then return null.
5. Let *request* be the result of creating a potential-CORS request[p99] given *url*, *options*'s destination[p186], and *options*'s crossorigin[p186].
6. Set *request*'s policy container to *options*'s policy container[p186].
7. Set *request*'s integrity metadata to *options*'s integrity[p186].
8. Set *request*'s cryptographic nonce metadata to *options*'s cryptographic nonce metadata[p186].
9. Set *request*'s referrer policy to *options*'s referrer policy[p186].
10. Set *request*'s client to *options*'s environment[p186].
11. Set *request*'s priority to *options*'s fetch priority[p186].
12. Return *request*.

User agents may opt to only try to fetch and process[p184] such resources when they are needed, instead of pro-actively fetching all the external resources[p303] that are not applied.

Similar to the fetch and process the linked resource[p184] algorithm, all external resource links[p303] have a **process the linked resource** algorithm which takes a `link`[p178] element *el*, boolean *success*, a response *response*, and a byte sequence *bodyBytes*. Individual link types may provide their own process the linked resource[p185] algorithm, but unless explicitly stated, that algorithm does nothing.

Unless otherwise specified for a given `rel`[p179] keyword, the element must delay the load event[p1377] of the element's node document until all the attempts to fetch and process the linked resource[p184] and its critical subresources[p46] are complete. (Resources that the user agent has not yet attempted to fetch and process, e.g., because it is waiting for the resource to be needed, do not delay the load event[p1377].)

4.2.4.4 Processing `Link` headers §[p185]

All link types that can be external resource links[p303] define a **process a link header** algorithm, which takes a link processing options[p185]. This algorithm defines whether and how they react to appearing in an HTTP `Link` response header.

Note

For most link types, this algorithm does nothing. The summary table[p315] is a good reference to quickly know whether a link type has defined process a link header[p185] steps.

A **link processing options** is a struct. It has the following items:

***href* (default the empty string)**
***destination* (default the empty string)**
***initiator* (default "`link`")**
***integrity* (default the empty string)**
***type* (default the empty string)**
***cryptographic nonce metadata* (default the empty string)**
A string

***crossorigin* (default No CORS[p101])**
A CORS settings attribute[p101] state

***referrer policy* (default the empty string)**
A referrer policy

***source set* (default null)**
Null or a source set[p365]

base URL
A URL

origin
An origin[p909]

environment
An environment[p1090]

policy container
A policy container[p929]

***document* (default null)**
Null or a `Document`[p131]

***on document ready* (default null)**
Null or an algorithm accepting a `Document`[p131]

***fetch priority* (default `Auto`[p105])**
A fetch priority attribute[p105] state

Note

A link processing options[p185] has a base URL[p186] and an href[p186] rather than a parsed URL because the URL could be a result of the options's source set[p186].

To **create link options from element** given a `link`[p178] element *el*:

1. Let *document* be *el*'s node document.
2. Let *options* be a new link processing options[p185] with

   destination[p186]
   the result of translating[p331] the state of *el*'s `as`[p182] attribute
   crossorigin[p186]
   the state of *el*'s `crossorigin`[p180] content attribute
   referrer policy[p186]
   the state of *el*'s `referrerpolicy`[p180] content attribute
   source set[p186]
   el's source set[p365]
   base URL[p186]
   document's document base URL[p98]
   origin[p186]
   document's origin
   environment[p186]
   document's relevant settings object[p1098]
   policy container[p186]
   document's policy container[p132]

document[p186]
document
cryptographic nonce metadata[p186]
the current value of *el*'s [[CryptographicNonce]][p102] internal slot
fetch priority[p186]
the state of *el*'s `fetchpriority`[p182] content attribute

3. If *el* has an `href`[p179] attribute, then set *options*'s href[p186] to the value of *el*'s `href`[p179] attribute.
4. If *el* has an `integrity`[p180] attribute, then set *options*'s integrity[p186] to the value of *el*'s `integrity`[p180] content attribute.
5. If *el* has a `type`[p180] attribute, then set *options*'s type[p186] to the value of *el*'s `type`[p180] attribute.
6. Assert: *options*'s href[p186] is not the empty string, or *options*'s source set[p186] is not null.

   A `link`[p178] element with neither an `href`[p179] or an `imagesrcset`[p181] does not represent a link.
7. Return *options*.

To **extract links from headers** given a header list *headers*:

1. Let *links* be a new list.
2. Let *rawLinkHeaders* be the result of getting, decoding, and splitting `` `Link`[p178] `` from *headers*.
3. For each *linkHeader* of *rawLinkHeaders*:
   1. Let *linkObject* be the result of parsing *linkHeader*. [WEBLINK][p1501]
   2. If *linkObject*["`target_uri`"] does not exist, then continue.
   3. Append *linkObject* to *links*.
4. Return *links*.

To **process link headers** given a `Document`[p131] *doc*, a response *response*, and a "`pre-media`" or "`media`" *phase*:

1. Let *links* be the result of extracting links[p187] from *response*'s header list.
2. For each *linkObject* in *links*:
   1. Let *rel* be *linkObject*["`relation_type`"].
   2. Let *attribs* be *linkObject*["`target_attributes`"].
   3. Let *expectedPhase* be "`media`" if either "`srcset`[p348]", "`imagesrcset`[p181]", or "`media`[p180]" exist in *attribs*; otherwise "`pre-media`".
   4. If *expectedPhase* is not *phase*, then continue.
   5. If *attribs*["`media`[p180]"] exists and *attribs*["`media`[p180]"] does not match the environment[p97], then continue.
   6. Let *options* be a new link processing options[p185] with

      href[p186]
      linkObject["`target_uri`"]
      base URL[p186]
      doc's document base URL[p98]
      origin[p186]
      doc's origin
      environment[p186]
      doc's relevant settings object[p1098]
      policy container[p186]
      doc's policy container[p132]
      document[p186]
      doc
   7. Apply link options from parsed header attributes[p188] to *options* given *attribs*.
   8. If *attribs*["`imagesrcset`[p181]"] exists and *attribs*["`imagesizes`[p181]"] exists, then set *options*'s source set[p186] to the

result of creating a source set[p373] given *linkObject*["target_uri"], *attribs*["imagesrcset[p181]"], *attribs*["imagesizes[p181]"], and null.

9. Run the process a link header[p185] steps for *rel* given *options*.

To **apply link options from parsed header attributes** to a link processing options[p185] *options* given *attribs*:

1. If *attribs*["as[p182]"] exists, then set *options*'s destination[p186] to the result of translating[p331] *attribs*["as[p182]"].
2. If *attribs*["crossorigin[p180]"] exists and is an ASCII case-insensitive match for one of the CORS settings attribute[p101] keywords[p77], then set *options*'s crossorigin[p186] to the CORS settings attribute[p101] state corresponding to that keyword.
3. If *attribs*["integrity[p180]"] exists, then set *options*'s integrity[p186] to *attribs*["integrity[p180]"].
4. If *attribs*["referrerpolicy[p180]"] exists and is an ASCII case-insensitive match for some referrer policy, then set *options*'s referrer policy[p186] to that referrer policy.
5. If *attribs*["nonce[p101]"] exists, then set *options*'s nonce[p186] to *attribs*["nonce[p101]"].
6. If *attribs*["type[p180]"] exists, then set *options*'s type[p186] to *attribs*["type[p180]"].
7. If *attribs*["fetchpriority[p182]"] exists and is an ASCII case-insensitive match for a fetch priority attribute[p105] keyword, then set *options*'s fetch priority[p186] to that fetch priority attribute[p105] keyword.

MDN

4.2.4.5 Early hints §[p188]

Early hints allow user-agents to perform some operations, such as to speculatively load resources that are likely to be used by the document, before the navigation request is fully handled by the server and a response code is served. Servers can indicate early hints by serving a response with a 103 status code before serving the final response.[RFC8297][p1500]

Note

For compatibility reasons early hints are typically delivered over HTTP/2 or above, but for readability we use HTTP/1.1-style notation below.

Example

For example, given the following sequence of responses:

```
103 Early Hint
Link: </image.png>; rel=preload; as=image

200 OK
Content-Type: text/html

<!DOCTYPE html>
...
<img src="/image.png">
```

the image will start loading before the HTML content arrives.

Note

Only the first early hint response served during the navigation is handled, and it is discarded if it is succeeded by a cross-origin redirect.

In addition to the `Link` headers, it is possible that the 103 response contains a Content Security Policy header, which is enforced when processing the early hint.

Example

For example, given the following sequence of responses:

```
103 Early Hint
Content-Security-Policy: style-src: self;
```

```
Link: </style.css>; rel=preload; as=style

103 Early Hint
Link: </image.png>; rel=preload; as=image

302 Redirect
Location: /alternate.html

200 OK
Content-Security-Policy: style-src: none;
Link: </font.ttf>; rel=preload; as=font
```

The font and style would be loaded, and the image will be discarded, as only the first early hint response in the final redirect chain is respected. The late Content Security Policy header comes after the request to fetch the style has already been performed, but the style will not be accessible to the document.

To **process early hint headers** given a response *response* and an environment[p1090] *reservedEnvironment*:

Note

Early-hint `Link` headers are always processed before `Link` headers from the final response, followed by `link`[p178] elements. This is equivalent to prepending the contents of the early and final `Link` headers to the `Document`[p131]'s `head`[p174] element, in respective order.

1. Let *earlyPolicyContainer* be the result of creating a policy container from a fetch response[p929] given *response* and *reservedEnvironment*.

   Note

   This allows the early hint response to include a Content Security Policy which would be enforced when fetching the early hint request.

2. Let *links* be the result of extracting links[p187] from *response*'s header list.

3. Let *earlyHints* be an empty list.

4. For each *linkObject* in *links*:

   Note

   The moment we receive the early hint link header, we begin fetching earlyRequest. *If it comes back before the `Document`[p131] is created, we set* earlyResponse *to the response of that fetch and once the `Document`[p131] is created we commit it (by making it available in the map of preloaded resources[p329] as if it was a `link`[p178] element). If the `Document`[p131] is created first, the response is committed as soon as it becomes available.*

   1. Let *rel* be *linkObject*["`relation_type`"].

   2. Let *options* be a new link processing options[p185] with

      href[p186]
      : *linkObject*["`target_uri`"]

      initiator[p186]
      : "`early-hint`"

      base URL[p186]
      : *response*'s URL

      origin[p186]
      : *response*'s URL's origin

      environment[p186]
      : *reservedEnvironment*

      policy container[p186]
      : *earlyPolicyContainer*

   3. Let *attribs* be *linkObject*["`target_attributes`"].

      Note

      Only the `as`[p182], `crossorigin`[p180], `integrity`[p180], and `type`[p180] attributes are handled as part of early hint

processing. The other ones, in particular `blocking`[p182], `imagesrcset`[p181], `imagesizes`[p181], *and* `media`[p180] *are only applicable once a* `Document`[p131] *is created.*

4. Apply link options from parsed header attributes[p188] to *options* given *attribs*.
5. Run the process a link header[p185] steps for *rel* given *options*.
6. Append *options* to *earlyHints*.

5. Return the following substeps given `Document`[p131] *doc*: for each *options* in *earlyHints*:
    1. If *options*'s on document ready[p186] is null, then set *options*'s document[p186] to *doc*.
    2. Otherwise, call *options*'s on document ready[p186] with *doc*.

4.2.4.6 Providing users with a means to follow hyperlinks created using the `link`[p178] element §[p190]

Interactive user agents may provide users with a means to follow the hyperlinks[p310] created using the `link`[p178] element, somewhere within their user interface. Such invocations of the follow the hyperlink[p310] algorithm must set the *userInvolvement*[p310] argument to "`browser UI`[p1028]". The exact interface is not defined by this specification, but it could include the following information (obtained from the element's attributes, again as defined below), in some form or another (possibly simplified), for each hyperlink[p303] created with each `link`[p178] element in the document:

- The relationship between this document and the resource (given by the `rel`[p179] attribute)
- The title of the resource (given by the `title`[p180] attribute).
- The address of the resource (given by the `href`[p179] attribute).
- The language of the resource (given by the `hreflang`[p180] attribute).
- The optimum media for the resource (given by the `media`[p180] attribute).

User agents could also include other information, such as the type of the resource (as given by the `type`[p180] attribute).

4.2.5 The `meta` element §[p190]

Categories[p147]**:**

Metadata content[p150].
If the `itemprop`[p803] attribute is present: flow content[p150].
If the `itemprop`[p803] attribute is present: phrasing content[p151].

Contexts in which this element can be used[p147]**:**

If the `charset`[p191] attribute is present, or if the element's `http-equiv`[p196] attribute is in the Encoding declaration state[p197]: in a `head`[p174] element.
If the `http-equiv`[p196] attribute is present but not in the Encoding declaration state[p197]: in a `head`[p174] element.
If the `http-equiv`[p196] attribute is present but not in the Encoding declaration state[p197]: in a `noscript`[p677] element that is a child of a `head`[p174] element.
If the `name`[p191] attribute is present: where metadata content[p150] is expected.
If the `itemprop`[p803] attribute is present: where metadata content[p150] is expected.
If the `itemprop`[p803] attribute is present: where phrasing content[p151] is expected.

Content model[p147]**:**

Nothing[p149].

Tag omission in text/html[p148]**:**

No end tag[p1280].

Content attributes[p148]**:**

Global attributes[p155]
`name`[p191] — Metadata name

`http-equiv`[p196] — Pragma directive
`content`[p191] — Value of the element
`charset`[p191] — Character encoding declaration[p200]
`media`[p191] — Applicable media

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLMetaElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString httpEquiv;
  [CEReactions] attribute DOMString content;
  [CEReactions] attribute DOMString media;

  // also has obsolete members
};
```

The `meta`[p190] element represents[p142] various kinds of metadata that cannot be expressed using the `title`[p175], `base`[p176], `link`[p178], `style`[p201], and `script`[p660] elements.

The `meta`[p190] element can represent document-level metadata with the `name`[p191] attribute, pragma directives with the `http-equiv`[p196] attribute, and the file's character encoding declaration[p200] when an HTML document is serialized to string form (e.g. for transmission over the network or for disk storage) with the `charset`[p191] attribute.

Exactly one of the `name`[p191], `http-equiv`[p196], `charset`[p191], and `itemprop`[p803] attributes must be specified.

If either `name`[p191], `http-equiv`[p196], or `itemprop`[p803] is specified, then the `content`[p191] attribute must also be specified. Otherwise, it must be omitted.

The **`charset`** attribute specifies the character encoding used by the document. This is a character encoding declaration[p200]. If the attribute is present, its value must be an ASCII case-insensitive match for the string "`utf-8`".

Note

The `charset`[p191] attribute on the `meta`[p190] element has no effect in XML documents, but is allowed in XML documents in order to facilitate migration to and from XML.

There must not be more than one `meta`[p190] element with a `charset`[p191] attribute per document.

The **`content`** attribute gives the value of the document metadata or pragma directive when the element is used for those purposes. The allowed values depend on the exact context, as described in subsequent sections of this specification.

If a `meta`[p190] element has a **`name`** attribute, it sets document metadata. Document metadata is expressed in terms of name-value pairs, the `name`[p191] attribute on the `meta`[p190] element giving the name, and the `content`[p191] attribute on the same element giving the value. The name specifies what aspect of metadata is being set; valid names and the meaning of their values are described in the following sections. If a `meta`[p190] element has no `content`[p191] attribute, then the value part of the metadata name-value pair is the empty string.

The **`media`** attribute says which media the metadata applies to. The value must be a valid media query list[p97]. Unless the `name`[p191] is `theme-color`[p194], the `media`[p191] attribute has no effect on the processing model and must not be used by authors.

The **`name`**, **`content`**, and **`media`** IDL attributes must reflect[p105] the respective content attributes of the same name. The IDL attribute **`httpEquiv`** must reflect[p105] the content attribute `http-equiv`[p196].

4.2.5.1 Standard metadata names §[p19]

This specification defines a few names for the `name`[p191] attribute of the `meta`[p190] element.

Names are case-insensitive, and must be compared in an ASCII case-insensitive manner.

`application-name`

The value must be a short free-form string giving the name of the web application that the page represents. If the page is not a web application, the `application-name`[p192] metadata name must not be used. Translations of the web application's name may be given, using the `lang`[p159] attribute to specify the language of each name.

There must not be more than one `meta`[p190] element with a given language[p159] and where the `name`[p191] attribute value is an ASCII case-insensitive match for `application-name`[p192] per document.

User agents may use the application name in UI in preference to the page's `title`[p175], since the title might include status messages and the like relevant to the status of the page at a particular moment in time instead of just being the name of the application.

To find the application name to use given an ordered list of languages (e.g. British English, American English, and English), user agents must run the following steps:

1. Let *languages* be the list of languages.
2. Let *default language* be the language[p159] of the `Document`[p131]'s document element, if any, and if that language is not unknown.
3. If there is a *default language*, and if it is not the same language as any of the languages in *languages*, append it to *languages*.
4. Let *winning language* be the first language in *languages* for which there is a `meta`[p190] element in the `Document`[p131] where the `name`[p191] attribute value is an ASCII case-insensitive match for `application-name`[p192] and whose language[p159] is the language in question.

   If none of the languages have such a `meta`[p190] element, then return; there's no given application name.
5. Return the value of the `content`[p191] attribute of the first `meta`[p190] element in the `Document`[p131] in tree order where the `name`[p191] attribute value is an ASCII case-insensitive match for `application-name`[p192] and whose language[p159] is *winning language*.

Note

This algorithm would be used by a browser when it needs a name for the page, for instance, to label a bookmark. The languages it would provide to the algorithm would be the user's preferred languages.

`author`

The value must be a free-form string giving the name of one of the page's authors.

`description`

The value must be a free-form string that describes the page. The value must be appropriate for use in a directory of pages, e.g. in a search engine. There must not be more than one `meta`[p190] element where the `name`[p191] attribute value is an ASCII case-insensitive match for `description`[p192] per document.

`generator`

The value must be a free-form string that identifies one of the software packages used to generate the document. This value must not be used on pages whose markup is not generated by software, e.g. pages whose markup was written by a user in a text editor.

Example

Here is what a tool called "Frontweaver" could include in its output, in the page's `head`[p174] element, to identify itself as the tool used to generate the page:

```
<meta name=generator content="Frontweaver 8.2">
```

`keywords`

The value must be a set of comma-separated tokens[p96], each of which is a keyword relevant to the page.

Example

This page about typefaces on British motorways uses a meta[p190] element to specify some keywords that users might use to look for the page:

```
<!DOCTYPE HTML>
<html lang="en-GB">
 <head>
  <title>Typefaces on UK motorways</title>
  <meta name="keywords" content="british,type face,font,fonts,highway,highways">
 </head>
 <body>
  ...
```

Note

Many search engines do not consider such keywords, because this feature has historically been used unreliably and even misleadingly as a way to spam search engine results in a way that is not helpful for users.

To obtain the list of keywords that the author has specified as applicable to the page, the user agent must run the following steps:

1. Let *keywords* be an empty list.
2. For each meta[p190] element with a name[p191] attribute and a content[p191] attribute and where the name[p191] attribute value is an ASCII case-insensitive match for keywords[p192]:
    1. Split the value of the element's content attribute on commas.
    2. Add the resulting tokens, if any, to *keywords*.
3. Remove any duplicates from *keywords*.
4. Return *keywords*. This is the list of keywords that the author has specified as applicable to the page.

User agents should not use this information when there is insufficient confidence in the reliability of the value.

Example

For instance, it would be reasonable for a content management system to use the keyword information of pages within the system to populate the index of a site-specific search engine, but a large-scale content aggregator that used this information would likely find that certain users would try to game its ranking mechanism through the use of inappropriate keywords.

referrer

The value must be a referrer policy, which defines the default referrer policy for the Document[p131]. [REFERRERPOLICY][p1499]

If any meta[p190] element *element* is inserted into the document[p47], or has its name[p191] or content[p191] attributes changed, user agents must run the following algorithm:

1. If *element* is not in a document tree, then return.
2. If *element* does not have a name[p191] attribute whose value is an ASCII case-insensitive match for "referrer[p193]", then return.
3. If *element* does not have a content[p191] attribute, or that attribute's value is the empty string, then return.
4. Let *value* be the value of *element*'s content[p191] attribute, converted to ASCII lowercase.
5. If *value* is one of the values given in the first column of the following table, then set *value* to the value given in the second column:

Legacy value	Referrer policy
never	no-referrer
default	the default referrer policy
always	unsafe-url
origin-when-crossorigin	origin-when-cross-origin

6. If *value* is a referrer policy, then set *element*'s node document's policy container[p132]'s referrer policy[p929] to *policy*.

Note

For historical reasons, unlike other standard metadata names, the processing model for `referrer`[p193] is not responsive to element removals, and does not use tree order. Only the most-recently-inserted or most-recently-modified `meta`[p190] element in this state has an effect.

`theme-color`

The value must be a string that matches the CSS <color> production, defining a suggested color that user agents should use to customize the display of the page or of the surrounding user interface. For example, a browser might color the page's title bar with the specified value, or use it as a color highlight in a tab bar or task switcher.

Within an HTML document, the `media`[p191] attribute value must be unique amongst all the `meta`[p190] elements with their `name`[p191] attribute value set to an ASCII case-insensitive match for `theme-color`[p194].

Example

This standard itself uses "WHATWG green" as its theme color:

```
<!DOCTYPE HTML>
<title>HTML Standard</title>
<meta name="theme-color" content="#3c790a">
...
```

The `media`[p191] attribute may be used to describe the context in which the provided color should be used.

Example

If we only wanted to use "WHATWG green" as this standard's theme color in dark mode, we could use the `prefers-color-scheme` media feature:

```
<!DOCTYPE HTML>
<title>HTML Standard</title>
<meta name="theme-color" content="#3c790a" media="(prefers-color-scheme: dark)">
...
```

To obtain a page's theme color, user agents must run the following steps:

1. Let *candidate elements* be the list of all `meta`[p190] elements that meet the following criteria, in tree order:
   - the element is in a document tree;
   - the element has a `name`[p191] attribute, whose value is an ASCII case-insensitive match for `theme-color`[p194]; and
   - the element has a `content`[p191] attribute.
2. For each *element* in *candidate elements*:
   1. If *element* has a `media`[p180] attribute and the value of *element*'s `media`[p191] attribute does not match the environment[p97], then continue.
   2. Let *value* be the result of stripping leading and trailing ASCII whitespace from the value of *element*'s `content`[p191] attribute.
   3. Let *color* be the result of parsing *value*.
   4. If *color* is not failure, then return *color*.
3. Return nothing (the page has no theme color).

If any `meta`[p190] elements are inserted into the document[p47] or removed from the document[p47], or existing `meta`[p190] elements have their `name`[p191], `content`[p191], or `media`[p180] attributes changed, or if the environment changes such that any `meta`[p190] element's `media`[p180] attribute's value may now or may no longer match the environment[p97], user agents must re-run the above algorithm and apply the result to any affected UI.

When using the theme color in UI, user agents may adjust it in implementation-specific ways to make it more suitable for the UI in question. For example, if a user agent intends to use the theme color as a background and display white text over it, it might use a darker variant of the theme color in that part of the UI, to ensure adequate contrast.

`color-scheme`

To aid user agents in rendering the page background with the desired color scheme immediately (rather than waiting for all CSS in the page to load), a 'color-scheme' value can be provided in a `meta`[p190] element.

The value must be a string that matches the syntax for the CSS 'color-scheme' property value. It determines the page's supported color-schemes.

There must not be more than one `meta`[p190] element with its `name`[p191] attribute value set to an ASCII case-insensitive match for `color-scheme`[p195] per document.

Example

The following declaration indicates that the page is aware of and can handle a color scheme with dark background colors and light foreground colors:

```
<meta name="color-scheme" content="dark">
```

To obtain a page's supported color-schemes, user agents must run the following steps:

1. Let *candidate elements* be the list of all `meta`[p190] elements that meet the following criteria, in tree order:
    - the element is in a document tree;
    - the element has a `name`[p191] attribute, whose value is an ASCII case-insensitive match for `color-scheme`[p195]; and
    - the element has a `content`[p191] attribute.
2. For each *element* in *candidate elements*:
    1. Let *parsed* be the result of parsing a list of component values given the value of *element*'s `content`[p191] attribute.
    2. If *parsed* is a valid CSS 'color-scheme' property value, then return *parsed*.
3. Return null.

If any `meta`[p190] elements are inserted into the document[p47] or removed from the document[p47], or existing `meta`[p190] elements have their `name`[p191] or `content`[p191] attributes changed, user agents must re-run the above algorithm.

Note

Because these rules check successive elements until they find a match, an author can provide multiple such values to handle fallback for legacy user agents. Opposite to how CSS fallback works for properties, the multiple meta elements needs to be arranged with the legacy values after the newer values.

4.2.5.2 Other metadata names §[p195]

Anyone can create and use their own **extensions to the predefined set of metadata names**. There is no requirement to register such extensions.

However, a new metadata name should not be created in any of the following cases:

- If either the name is a URL, or the value of its accompanying `content`[p191] attribute is a URL; in those cases, registering it as an extension to the predefined set of link types[p336] is encouraged (rather than creating a new metadata name).
- If the name is for something expected to have processing requirements in user agents; in that case it ought to be standardized.

Also, before creating and using a new metadata name, consulting the WHATWG Wiki MetaExtensions page is encouraged — to avoid choosing a metadata name that's already in use, and to avoid duplicating the purpose of any metadata names that are already in use, and to avoid new standardized names clashing with your chosen name. [WHATWGWIKI][p1502]

Anyone is free to edit the WHATWG Wiki MetaExtensions page at any time to add a metadata name. New metadata names can be specified with the following information:

Keyword

The actual name being defined. The name should not be confusingly similar to any other defined name (e.g. differing only in case).

Brief description

A short non-normative description of what the metadata name's meaning is, including the format the value is required to be in.

Specification

A link to a more detailed description of the metadata name's semantics and requirements. It could be another page on the wiki, or a link to an external page.

Synonyms

A list of other names that have exactly the same processing requirements. Authors should not use the names defined to be synonyms (they are only intended to allow user agents to support legacy content). Anyone may remove synonyms that are not used in practice; only names that need to be processed as synonyms for compatibility with legacy content are to be registered in this way.

Status

One of the following:

Proposed

The name has not received wide peer review and approval. Someone has proposed it and is, or soon will be, using it.

Ratified

The name has received wide peer review and approval. It has a specification that unambiguously defines how to handle pages that use the name, including when they use it in incorrect ways.

Discontinued

The metadata name has received wide peer review and it has been found wanting. Existing pages are using this metadata name, but new pages should avoid it. The "brief description" and "specification" entries will give details of what authors should use instead, if anything.

If a metadata name is found to be redundant with existing values, it should be removed and listed as a synonym for the existing value.

If a metadata name is added in the "proposed" state for a period of a month or more without being used or specified, then it may be removed from the WHATWG Wiki MetaExtensions page.

If a metadata name is added with the "proposed" status and found to be redundant with existing values, it should be removed and listed as a synonym for the existing value. If a metadata name is added with the "proposed" status and found to be harmful, then it should be changed to "discontinued" status.

Anyone can change the status at any time, but should only do so in accordance with the definitions above.

4.2.5.3 Pragma directives §[p19]

When the **http-equiv** attribute is specified on a meta[p190] element, the element is a pragma directive.

The http-equiv[p196] attribute is an enumerated attribute[p77] with the following keywords and states:

Keyword	Conforming	State	Brief description
content-language	No	Content language[p197]	Sets the pragma-set default language[p197].
content-type		Encoding declaration[p197]	An alternative form of setting the charset[p191].
default-style		Default style[p197]	Sets the name of the default CSS style sheet set.
refresh		Refresh[p197]	Acts as a timed redirect.
set-cookie	No	Set-Cookie[p199]	Has no effect.
x-ua-compatible		X-UA-Compatible[p199]	In practice, encourages Internet Explorer to more closely follow the specifications.
content-security-policy		Content security policy[p200]	Enforces a Content Security Policy on a Document[p131].

When a meta[p190] element is inserted into the document[p47], if its http-equiv[p196] attribute is present and represents one of the above states, then the user agent must run the algorithm appropriate for that state, as described in the following list:

Content language state (`http-equiv="content-language"`)

Note

This feature is non-conforming. Authors are encouraged to use the `lang` attribute instead.

This pragma sets the **pragma-set default language**. Until such a pragma is successfully processed, there is no pragma-set default language.

1. If the `meta` element has no `content` attribute, then return.
2. If the element's `content` attribute contains a U+002C COMMA character (,), then return.
3. Let *input* be the value of the element's `content` attribute.
4. Let *position* point at the first character of *input*.
5. Skip ASCII whitespace within *input* given *position*.
6. Collect a sequence of code points that are not ASCII whitespace from *input* given *position*.
7. Let *candidate* be the string that resulted from the previous step.
8. If *candidate* is the empty string, return.
9. Set the pragma-set default language to *candidate*.

Note

If the value consists of multiple space-separated tokens, tokens after the first are ignored.

Note

This pragma is almost, but not quite, entirely unlike the HTTP `Content-Language` header of the same name. [HTTP]

Encoding declaration state (`http-equiv="content-type"`)

The Encoding declaration state is just an alternative form of setting the `charset` attribute: it is a character encoding declaration. This state's user agent requirements are all handled by the parsing section of the specification.

For `meta` elements with an `http-equiv` attribute in the Encoding declaration state, the `content` attribute must have a value that is an ASCII case-insensitive match for a string that consists of: "`text/html;`", optionally followed by any number of ASCII whitespace, followed by "`charset=utf-8`".

A document must not contain both a `meta` element with an `http-equiv` attribute in the Encoding declaration state and a `meta` element with the `charset` attribute present.

The Encoding declaration state may be used in HTML documents, but elements with an `http-equiv` attribute in that state must not be used in XML documents.

Default style state (`http-equiv="default-style"`)

This pragma sets the name of the default CSS style sheet set.

1. If the `meta` element has no `content` attribute, or if that attribute's value is the empty string, then return.
2. Change the preferred CSS style sheet set name with the name being the value of the element's `content` attribute. [CSSOM]

Refresh state (`http-equiv="refresh"`)

This pragma acts as a timed redirect.

A `Document` object has an associated **will declaratively refresh** (a boolean). It is initially false.

1. If the `meta` element has no `content` attribute, or if that attribute's value is the empty string, then return.
2. Let *input* be the value of the element's `content` attribute.
3. Run the shared declarative refresh steps with the `meta` element's node document, *input*, and the `meta` element.

The **shared declarative refresh steps**, given a Document[p131] object *document*, string *input*, and optionally a meta[p190] element *meta*, are as follows:

1. If *document*'s will declaratively refresh[p197] is true, then return.
2. Let *position* point at the first code point of *input*.
3. Skip ASCII whitespace within *input* given *position*.
4. Let *time* be 0.
5. Collect a sequence of code points that are ASCII digits from *input* given *position*, and let *timeString* be the result.
6. If *timeString* is the empty string, then:
    1. If the code point in *input* pointed to by *position* is not U+002E (.), then return.
7. Otherwise, set *time* to the result of parsing *timeString* using the rules for parsing non-negative integers[p78].
8. Collect a sequence of code points that are ASCII digits and U+002E FULL STOP characters (.) from *input* given *position*. Ignore any collected characters.
9. Let *urlRecord* be *document*'s URL.
10. If *position* is not past the end of *input*, then:
    1. If the code point in *input* pointed to by *position* is not U+003B (;), U+002C (,), or ASCII whitespace, then return.
    2. Skip ASCII whitespace within *input* given *position*.
    3. If the code point in *input* pointed to by *position* is U+003B (;) or U+002C (,), then advance *position* to the next code point.
    4. Skip ASCII whitespace within *input* given *position*.
11. If *position* is not past the end of *input*, then:
    1. Let *urlString* be the substring of *input* from the code point at *position* to the end of the string.
    2. If the code point in *input* pointed to by *position* is U+0055 (U) or U+0075 (u), then advance *position* to the next code point. Otherwise, jump to the step labeled *skip quotes*.
    3. If the code point in *input* pointed to by *position* is U+0052 (R) or U+0072 (r), then advance *position* to the next code point. Otherwise, jump to the step labeled *parse*.
    4. If the code point in *input* pointed to by *position* is U+004C (L) or U+006C (l), then advance *position* to the next code point. Otherwise, jump to the step labeled *parse*.
    5. Skip ASCII whitespace within *input* given *position*.
    6. If the code point in *input* pointed to by *position* is U+003D (=), then advance *position* to the next code point. Otherwise, jump to the step labeled *parse*.
    7. Skip ASCII whitespace within *input* given *position*.
    8. *Skip quotes*: If the code point in *input* pointed to by *position* is U+0027 (') or U+0022 ("), then let *quote* be that code point, and advance *position* to the next code point. Otherwise, let *quote* be the empty string.
    9. Set *urlString* to the substring of *input* from the code point at *position* to the end of the string.
    10. If *quote* is not the empty string, and there is a code point in *urlString* equal to *quote*, then truncate *urlString* at that code point, so that it and all subsequent code points are removed.
    11. *Parse*: Set *urlRecord* to the result of encoding-parsing a URL[p98] given *urlString*, relative to *document*.
    12. If *urlRecord* is failure, then return.
12. Set *document*'s will declaratively refresh[p197] to true.
13. Perform one or more of the following steps:
    - After the refresh has come due (as defined below), if the user has not canceled the redirect and, if *meta* is

given, *document*'s active sandboxing flag set[p928] does not have the sandboxed automatic features browsing context flag[p927] set, then navigate[p1028] *document*'s node navigable[p1002] to *urlRecord* using *document*, with *historyHandling*[p1028] set to "replace[p1027]".

For the purposes of the previous paragraph, a refresh is said to have come due as soon as the *later* of the following two conditions occurs:

- At least *time* seconds have elapsed since *document*'s completely loaded time[p1078], adjusted to take into account user or user agent preferences.
- If *meta* is given, at least *time* seconds have elapsed since *meta* was inserted into the document[p47] *document*, adjusted to take into account user or user agent preferences.

Note

It is important to use document *here, and not* meta's *node document, as that might have changed between the initial set of steps and the refresh coming due and* meta *is not always given (in case of the HTTP `Refresh`[p1084] header).*

- Provide the user with an interface that, when selected, navigates[p1028] *document*'s node navigable[p1002] to *urlRecord* using *document*.
- Do nothing.

In addition, the user agent may, as with anything, inform the user of any and all aspects of its operation, including the state of any timers, the destinations of any timed redirects, and so forth.

For meta[p190] elements with an http-equiv[p196] attribute in the Refresh state[p197], the content[p191] attribute must have a value consisting either of:

- just a valid non-negative integer[p78], or
- a valid non-negative integer[p78], followed by a U+003B SEMICOLON character (;), followed by one or more ASCII whitespace, followed by a substring that is an ASCII case-insensitive match for the string "URL", followed by a U+003D EQUALS SIGN character (=), followed by a valid URL string that does not start with a literal U+0027 APOSTROPHE (') or U+0022 QUOTATION MARK (") character.

In the former case, the integer represents a number of seconds before the page is to be reloaded; in the latter case the integer represents a number of seconds before the page is to be replaced by the page at the given URL.

Example

A news organization's front page could include the following markup in the page's head[p174] element, to ensure that the page automatically reloads from the server every five minutes:

```
<meta http-equiv="Refresh" content="300">
```

Example

A sequence of pages could be used as an automated slide show by making each page refresh to the next page in the sequence, using markup such as the following:

```
<meta http-equiv="Refresh" content="20; URL=page4.html">
```

Set-Cookie state **(`http-equiv="set-cookie"`[p196])**

This pragma is non-conforming and has no effect.

User agents are required to ignore this pragma.

X-UA-Compatible state **(`http-equiv="x-ua-compatible"`[p196])**

In practice, this pragma encourages Internet Explorer to more closely follow the specifications.

For meta[p190] elements with an http-equiv[p196] attribute in the X-UA-Compatible state[p199], the content[p191] attribute must have a value that is an ASCII case-insensitive match for the string "IE=edge".

User agents are required to ignore this pragma.

Content security policy state **(`http-equiv="content-security-policy"`)**

This pragma enforces a Content Security Policy on a Document. [CSP]

1. If the `meta` element is not a child of a `head` element, return.
2. If the `meta` element has no `content` attribute, or if that attribute's value is the empty string, then return.
3. Let *policy* be the result of executing Content Security Policy's parse a serialized Content Security Policy algorithm on the `meta` element's `content` attribute's value, with a source of "meta", and a disposition of "enforce".
4. Remove all occurrences of the `report-uri`, `frame-ancestors`, and `sandbox` directives from *policy*.
5. Enforce the policy *policy*.

For `meta` elements with an `http-equiv` attribute in the Content security policy state, the `content` attribute must have a value consisting of a valid Content Security Policy, but must not contain any `report-uri`, `frame-ancestors`, or `sandbox` directives. The Content Security Policy given in the `content` attribute will be enforced upon the current document. [CSP]

Note

At the time of inserting the `meta` element to the document, it is possible that some resources have already been fetched. For example, images might be stored in the list of available images prior to dynamically inserting a `meta` element with an `http-equiv` attribute in the Content security policy state. Resources that have already been fetched are not guaranteed to be blocked by a Content Security Policy that's enforced late.

Example

A page might choose to mitigate the risk of cross-site scripting attacks by preventing the execution of inline JavaScript, as well as blocking all plugin content, using a policy such as the following:

```
<meta http-equiv="Content-Security-Policy" content="script-src 'self'; object-src 'none'">
```

There must not be more than one `meta` element with any particular state in the document at a time.

4.2.5.4 Specifying the document's character encoding

A **character encoding declaration** is a mechanism by which the character encoding used to store or transmit a document is specified.

The Encoding standard requires use of the UTF-8 character encoding and requires use of the "`utf-8`" encoding label to identify it. Those requirements necessitate that the document's character encoding declaration, if it exists, specifies an encoding label using an ASCII case-insensitive match for "`utf-8`". Regardless of whether a character encoding declaration is present or not, the actual character encoding used to encode the document must be UTF-8. [ENCODING]

To enforce the above rules, authoring tools must default to using UTF-8 for newly-created documents.

The following restrictions also apply:

- The character encoding declaration must be serialized without the use of character references or character escapes of any kind.
- The element containing the character encoding declaration must be serialized completely within the first 1024 bytes of the document.

In addition, due to a number of restrictions on `meta` elements, there can only be one `meta`-based character encoding declaration per document.

If an HTML document does not start with a BOM, and its encoding is not explicitly given by Content-Type metadata, and the document is not an `iframe srcdoc` document, then the encoding must be specified using a `meta` element with a `charset` attribute or a `meta` element with an `http-equiv` attribute in the Encoding declaration state.

Note

A character encoding declaration is required (either in the Content-Type metadata[p100] or explicitly in the file) even when all characters are in the ASCII range, because a character encoding is needed to process non-ASCII characters entered by the user in forms, in URLs generated by scripts, and so forth.

Using non-UTF-8 encodings can have unexpected results on form submission and URL encodings, which use the document's character encoding by default.

If the document is an `iframe srcdoc` document[p392], the document must not have a character encoding declaration[p200]. (In this case, the source is already decoded, since it is part of the document that contained the `iframe`[p391].)

In XML, the XML declaration should be used for inline character encoding information, if necessary.

Example

In HTML, to declare that the character encoding is UTF-8, the author could include the following markup near the top of the document (in the `head`[p174] element):

```
<meta charset="utf-8">
```

In XML, the XML declaration would be used instead, at the very top of the markup:

```
<?xml version="1.0" encoding="utf-8"?>
```

4.2.6 The `style` element §[p201]

Categories[p147]:

Metadata content[p150].

Contexts in which this element can be used[p147]:

Where metadata content[p150] is expected.
In a `noscript`[p677] element that is a child of a `head`[p174] element.

Content model[p147]:

Text[p151] that gives a conformant style sheet.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
`media`[p202] — Applicable media
`blocking`[p202] — Whether the element is potentially render-blocking[p105]
Also, the `title`[p202] attribute has special semantics[p202] on this element: CSS style sheet set name

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLStyleElement : HTMLElement {
  [HTMLConstructor] constructor();

  attribute boolean disabled;
  [CEReactions] attribute DOMString media;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList blocking;

  // also has obsolete members
};
```

```
HTMLStyleElement includes LinkStyle;
```

The style[p201] element allows authors to embed CSS style sheets in their documents. The style[p201] element is one of several inputs to the styling processing model. The element does not represent[p142] content for the user.

The **disabled** getter steps are:

1. If this does not have an associated CSS style sheet, return false.
2. If this's associated CSS style sheet's disabled flag is set, return true.
3. Return false.

The disabled[p202] setter steps are:

1. If this does not have an associated CSS style sheet, return.
2. If the given value is true, set this's associated CSS style sheet's disabled flag. Otherwise, unset this's associated CSS style sheet's disabled flag.

Example

Importantly, disabled[p202] attribute assignments only take effect when the style[p201] element has an associated CSS style sheet:

```
const style = document.createElement('style');
style.disabled = true;
style.textContent = 'body { background-color: red; }';
document.body.append(style);
console.log(style.disabled); // false
```

The **media** attribute says which media the styles apply to. The value must be a valid media query list[p97]. The user agent must apply the styles when the media[p202] attribute's value matches the environment[p97] and the other relevant conditions apply, and must not apply them otherwise.

Note

The styles might be further limited in scope, e.g. in CSS with the use of `@media` blocks. This specification does not override such further restrictions or requirements.

The default, if the media[p202] attribute is omitted, is "`all`", meaning that by default styles apply to all media.

The **blocking** attribute is a blocking attribute[p104].

The **title** attribute on style[p201] elements defines CSS style sheet sets. If the style[p201] element has no title[p202] attribute, then it has no title; the title[p158] attribute of ancestors does not apply to the style[p201] element. If the style[p201] element is not in a document tree, then the title[p202] attribute is ignored. [CSSOM][p1495]

Note

The title[p202] attribute on style[p201] elements, like the title[p180] attribute on link[p178] elements, differs from the global title[p158] attribute in that a style[p201] block without a title does not inherit the title of the parent element: it merely has no title.

The child text content of a style[p201] element must be that of a conformant style sheet.

A style[p201] element is implicitly potentially render-blocking[p105] if the element was created by its node document's parser.

The user agent must run the update a style block[p203] algorithm whenever any of the following conditions occur:

- The element is popped off the stack of open elements[p1304] of an HTML parser[p1289] or XML parser[p1402].
- The element is not on the stack of open elements[p1304] of an HTML parser[p1289] or XML parser[p1402], and it becomes connected[p47] or disconnected[p47].

- The element's children changed steps run.

The **update a `style` block** algorithm is as follows:

1. Let *element* be the `style`[p201] element.
2. If *element* has an associated CSS style sheet, remove the CSS style sheet in question.
3. If *element* is not connected, then return.
4. If *element*'s `type`[p1447] attribute is present and its value is neither the empty string nor an ASCII case-insensitive match for "`text/css`[p1492]", then return.

   Note

   In particular, a `type`[p1447] value with parameters, such as "`text/css; charset=utf-8`", will cause this algorithm to return early.

5. If the Should element's inline behavior be blocked by Content Security Policy? algorithm returns "`Blocked`" when executed upon the `style`[p201] element, "`style`", and the `style`[p201] element's child text content, then return. [CSP][p1494]
6. Create a CSS style sheet with the following properties:

   type
   `text/css`[p1492]

   owner node
   element

   media
   The `media`[p202] attribute of *element*.

   Note

   This is a reference to the (possibly absent at this time) attribute, rather than a copy of the attribute's current value. CSSOM defines what happens when the attribute is dynamically set, changed, or removed.

   title
   The `title`[p202] attribute of *element*, if *element* is in a document tree, or the empty string otherwise.

   Note

   Again, this is a reference to the attribute.

   alternate flag
   Unset.

   origin-clean flag
   Set.

   location
   parent CSS style sheet
   owner CSS rule
   null

   disabled flag
   Left at its default value.

   CSS rules
   Left uninitialized.

   This doesn't seem right. Presumably we should be using the element's child text content? Tracked as issue #2997.

7. If *element* contributes a script-blocking style sheet[p205], append *element* to its node document's script-blocking style sheet

set[p205].

8. If *element*'s media[p202] attribute's value matches the environment[p97] and *element* is potentially render-blocking[p105], then block rendering[p135] on *element*.

Once the attempts to obtain the style sheet's critical subresources[p46], if any, are complete, or, if the style sheet has no critical subresources[p46], once the style sheet has been parsed and processed, the user agent must run these steps:

Fetching the critical subresources[p46] is not well-defined; probably issue #968 is the best resolution for that. In the meantime, any critical subresource[p46] request should have its render-blocking set to whether or not the style[p201] element is currently render-blocking[p135].

1. Let *element* be the style[p201] element associated with the style sheet in question.
2. Let *success* be true.
3. If the attempts to obtain any of the style sheet's critical subresources[p46] failed for any reason (e.g., DNS error, HTTP 404 response, a connection being prematurely closed, unsupported Content-Type), set *success* to false.

   Note

   Note that content-specific errors, e.g., CSS parse errors or PNG decoding errors, do not affect success.

4. Queue an element task[p1140] on the networking task source[p1149] given *element* and the following steps:
   1. If *success* is true, fire an event named load[p1490] at *element*.
   2. Otherwise, fire an event named error[p1489] at *element*.
   3. If *element* contributes a script-blocking style sheet[p205]:
      1. Assert: *element*'s node document's script-blocking style sheet set[p205] contains *element*.
      2. Remove *element* from its node document's script-blocking style sheet set[p205].
   4. Unblock rendering[p136] on *element*.

The element must delay the load event[p1377] of the element's node document until all the attempts to obtain the style sheet's critical subresources[p46], if any, are complete.

Note

This specification does not specify a style system, but CSS is expected to be supported by most web browsers. [CSS][p1494]

The **media** and **blocking** IDL attributes must each reflect[p105] the respective content attributes of the same name.

The LinkStyle interface is also implemented by this element. [CSSOM][p1495]

Example

The following document has its stress emphasis styled as bright red text rather than italics text, while leaving titles of works and Latin words in their default italics. It shows how using appropriate elements enables easier restyling of documents.

```
<!DOCTYPE html>
<html lang="en-US">
 <head>
  <title>My favorite book</title>
  <style>
   body { color: black; background: white; }
   em { font-style: normal; color: red; }
  </style>
 </head>
 <body>
  <p>My <em>favorite</em> book of all time has <em>got</em> to be
  <cite>A Cat's Life</cite>. It is a book by P. Rahmel that talks
```

```
  about the <i lang="la">Felis catus</i> in modern human society.</p>
 </body>
</html>
```

4.2.7 Interactions of styling and scripting §[p205]

If the style sheet referenced no other resources (e.g., it was an internal style sheet given by a `style`[p201] element with no `@import` rules), then the style rules must be immediately[p44] made available to script; otherwise, the style rules must only be made available to script once the event loop[p1138] reaches its update the rendering[p1143] step.

An element *el* in the context of a `Document`[p131] of an HTML parser[p1289] or XML parser[p1402] **contributes a script-blocking style sheet** if all of the following are true:

- *el* was created by that `Document`[p131]'s parser.
- *el* is either a `style`[p201] element or a `link`[p178] element that was an external resource link that contributes to the styling processing model[p332] when the *el* was created by the parser.
- *el*'s `media` attribute's value matches the environment[p97].
- *el*'s style sheet was enabled when the element was created by the parser.
- The last time the event loop[p1138] reached step 1[p1141], *el*'s root was that `Document`[p131].
- The user agent hasn't given up on loading that particular style sheet yet. A user agent may give up on loading a style sheet at any time.

> **Note**
>
> *Giving up on a style sheet before the style sheet loads, if the style sheet eventually does still load, means that the script might end up operating with incorrect information. For example, if a style sheet sets the color of an element to green, but a script that inspects the resulting style is executed before the sheet is loaded, the script will find that the element is black (or whatever the default color is), and might thus make poor choices (e.g., deciding to use black as the color elsewhere on the page, instead of green). Implementers have to balance the likelihood of a script using incorrect information with the performance impact of doing nothing while waiting for a slow network request to finish.*

It is expected that counterparts to the above rules also apply to `<?xml-stylesheet?>` PIs. However, this has not yet been thoroughly investigated.

A `Document`[p131] has a **script-blocking style sheet set**, which is an ordered set, initially empty.

A `Document`[p131] *document* **has a style sheet that is blocking scripts** if the following steps return true:

1. If *document*'s script-blocking style sheet set[p205] is not empty, then return true.
2. If *document*'s node navigable[p1002] is null, then return false.
3. Let *containerDocument* be *document*'s node navigable[p1002]'s container document[p1004].
4. If *containerDocument* is non-null and *containerDocument*'s script-blocking style sheet set[p205] is not empty, then return true.
5. Return false.

A `Document`[p131] **has no style sheet that is blocking scripts** if it does not have a style sheet that is blocking scripts[p205].

4.3 Sections §[p206]

4.3.1 The body element §[p206]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As the second element in an html[p173] element.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

A body[p206] element's start tag[p1279] can be omitted if the element is empty, or if the first thing inside the body[p206] element is not ASCII whitespace or a comment[p1288], except if the first thing inside the body[p206] element is a meta[p190], noscript[p677], link[p178], script[p660], style[p201], or template[p679] element.

A body[p206] element's end tag[p1280] can be omitted if the body[p206] element is not immediately followed by a comment[p1288].

Content attributes[p148]:

Global attributes[p155]
onafterprint[p1160]
onbeforeprint[p1160]
onbeforeunload[p1160]
onhashchange[p1160]
onlanguagechange[p1160]
onmessage[p1160]
onmessageerror[p1160]
onoffline[p1160]
ononline[p1160]
onpageswap[p1160]
onpagehide[p1160]
onpagereveal[p1160]
onpageshow[p1160]
onpopstate[p1160]
onrejectionhandled[p1160]
onstorage[p1160]
onunhandledrejection[p1160]
onunload[p1160]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLBodyElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};

HTMLBodyElement includes WindowEventHandlers;
```

The body[p206] element represents[p142] the contents of the document.

In conforming documents, there is only one body[p206] element. The document.body[p137] IDL attribute provides scripts with easy access to a document's body[p206] element.

Note

Some DOM operations (for example, parts of the drag and drop[p879] model) are defined in terms of "the body element[p137]". This refers to a particular element in the DOM, as per the definition of the term, and not any arbitrary body[p206] element.

The body[p206] element exposes as event handler content attributes[p1152] a number of the event handlers[p1151] of the Window[p934] object. It also mirrors their event handler IDL attributes[p1152].

The event handlers[p1151] of the Window[p934] object named by the Window-reflecting body element event handler set[p1160], exposed on the body[p206] element, replace the generic event handlers[p1151] with the same names normally supported by HTML elements[p46].

Example

Thus, for example, a bubbling error[p1489] event dispatched on a child of the body element[p137] of a Document[p131] would first trigger the onerror[p1160] event handler content attributes[p1152] of that element, then that of the root html[p173] element, and only *then* would it trigger the onerror[p1160] event handler content attribute[p1152] on the body[p206] element. This is because the event would bubble from the target, to the body[p206], to the html[p173], to the Document[p131], to the Window[p934], and the event handler[p1151] on the body[p206] is watching the Window[p934] not the body[p206]. A regular event listener attached to the body[p206] using `addEventListener()`, however, would be run when the event bubbled through the body[p206] and not when it reaches the Window[p934] object.

Example

This page updates an indicator to show whether or not the user is online:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>Online or offline?</title>
  <script>
   function update(online) {
     document.getElementById('status').textContent =
       online ? 'Online' : 'Offline';
   }
  </script>
 </head>
 <body ononline="update(true)"
       onoffline="update(false)"
       onload="update(navigator.onLine)">
  <p>You are: <span id="status">(Unknown)</span></p>
 </body>
</html>
```

MDN

4.3.2 The article element §[p207]

Categories[p147]:

Flow content[p150].
Sectioning content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where sectioning content[p150] is expected.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

Uses `HTMLElement`[p143].

The `article`[p207] element represents[p142] a complete, or self-contained, composition in a document, page, application, or site and that is, in principle, independently distributable or reusable, e.g. in syndication. This could be a forum post, a magazine or newspaper article, a blog entry, a user-submitted comment, an interactive widget or gadget, or any other independent item of content.

When `article`[p207] elements are nested, the inner `article`[p207] elements represent articles that are in principle related to the contents of the outer article. For instance, a blog entry on a site that accepts user-submitted comments could represent the comments as `article`[p207] elements nested within the `article`[p207] element for the blog entry.

Author information associated with an `article`[p207] element (q.v. the `address`[p223] element) does not apply to nested `article`[p207] elements.

Note

When used specifically with content to be redistributed in syndication, the `article`[p207] element is similar in purpose to the `entry` element in Atom. [ATOM][p1493]

Note

The schema.org microdata vocabulary can be used to provide the publication date for an `article`[p207] element, using one of the CreativeWork subtypes.

When the main content of the page (i.e. excluding footers, headers, navigation blocks, and sidebars) is all one single self-contained composition, that content may be marked with an `article`[p207], but it is technically redundant in that case (since it's self-evident that the page is a single composition, as it is a single document).

¶[p208] Example

This example shows a blog post using the `article`[p207] element, with some schema.org annotations:

```
<article itemscope itemtype="http://schema.org/BlogPosting">
 <header>
  <h2 itemprop="headline">The Very First Rule of Life</h2>
  <p><time itemprop="datePublished" datetime="2009-10-09">3 days ago</time></p>
  <link itemprop="url" href="?comments=0">
 </header>
 <p>If there's a microphone anywhere near you, assume it's hot and
 sending whatever you're saying to the world. Seriously.</p>
 <p>...</p>
 <footer>
  <a itemprop="discussionUrl" href="?comments=1">Show comments...</a>
 </footer>
</article>
```

Here is that same blog post, but showing some of the comments:

```
<article itemscope itemtype="http://schema.org/BlogPosting">
 <header>
  <h2 itemprop="headline">The Very First Rule of Life</h2>
  <p><time itemprop="datePublished" datetime="2009-10-09">3 days ago</time></p>
  <link itemprop="url" href="?comments=0">
 </header>
 <p>If there's a microphone anywhere near you, assume it's hot and
 sending whatever you're saying to the world. Seriously.</p>
 <p>...</p>
 <section>
```

```
  <h1>Comments</h1>
  <article itemprop="comment" itemscope itemtype="http://schema.org/Comment" id="c1">
   <link itemprop="url" href="#c1">
   <footer>
    <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
     <span itemprop="name">George Washington</span>
    </span></p>
    <p><time itemprop="dateCreated" datetime="2009-10-10">15 minutes ago</time></p>
   </footer>
   <p>Yeah! Especially when talking about your lobbyist friends!</p>
  </article>
  <article itemprop="comment" itemscope itemtype="http://schema.org/Comment" id="c2">
   <link itemprop="url" href="#c2">
   <footer>
    <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
     <span itemprop="name">George Hammond</span>
    </span></p>
    <p><time itemprop="dateCreated" datetime="2009-10-10">5 minutes ago</time></p>
   </footer>
   <p>Hey, you have the same first name as me.</p>
  </article>
 </section>
</article>
```

Notice the use of footer[p221] to give the information for each comment (such as who wrote it and when): the footer[p221] element *can* appear at the start of its section when appropriate, such as in this case. (Using header[p219] in this case wouldn't be wrong either; it's mostly a matter of authoring preference.)

Example

In this example, article[p207] elements are used to host widgets on a portal page. The widgets are implemented as customized built-in elements[p766] in order to get specific styling and scripted behavior.

```
<!DOCTYPE HTML>
<html lang=en>
<title>eHome Portal</title>
<script src="/scripts/widgets.js"></script>
<link rel=stylesheet href="/styles/main.css">
<article is="stock-widget">
 <h2>Stocks</h2>
 <table>
  <thead> <tr> <th> Stock <th> Value <th> Delta
  <tbody> <template> <tr> <td> <td> <td> </template>
 </table>
 <p> <input type=button value="Refresh" onclick="this.parentElement.refresh()">
</article>
<article is="news-widget">
 <h2>News</h2>
 <ul>
  <template>
   <li>
    <p><img> <strong></strong>
    <p>
  </template>
 </ul>
 <p> <input type=button value="Refresh" onclick="this.parentElement.refresh()">
</article>
```

4.3.3 The section element §p210

Categoriesp147**:**

Flow content[p150].
Sectioning content[p150].
Palpable content[p151].

Contexts in which this element can be usedp147**:**

Where sectioning content[p150] is expected.

Content modelp147**:**

Flow content[p150].

Tag omission in text/htmlp148**:**

Neither tag is omissible.

Content attributesp148**:**

Global attributes[p155]

Accessibility considerationsp148**:**

For authors.
For implementers.

DOM interfacep148**:**

Uses HTMLElement[p143].

The section[p210] element represents[p142] a generic section of a document or application. A section, in this context, is a thematic grouping of content, typically with a heading.

Example

Examples of sections would be chapters, the various tabbed pages in a tabbed dialog box, or the numbered sections of a thesis. A web site's home page could be split into sections for an introduction, news items, and contact information.

Note

Authors are encouraged to use the article[p207] element instead of the section[p210] element when it would make sense to syndicate the contents of the element.

¶p210

Note

The section[p210] element is not a generic container element. When an element is needed only for styling purposes or as a convenience for scripting, authors are encouraged to use the div[p257] element instead. A general rule is that the section[p210] element is appropriate only if the element's contents would be listed explicitly in the document's outline[p225].

Example

In the following example, we see an article (part of a larger web page) about apples, containing two short sections.

```
<article>
 <hgroup>
  <h2>Apples</h2>
  <p>Tasty, delicious fruit!</p>
 </hgroup>
 <p>The apple is the pomaceous fruit of the apple tree.</p>
 <section>
  <h3>Red Delicious</h3>
  <p>These bright red apples are the most common found in many
  supermarkets.</p>
 </section>
 <section>
  <h3>Granny Smith</h3>
  <p>These juicy, green apples make a great filling for
  apple pies.</p>
 </section>
```

```
</article>
```

Example

Here is a graduation programme with two sections, one for the list of people graduating, and one for the description of the ceremony. (The markup in this example features an uncommon style sometimes used to minimize the amount of inter-element whitespace[p148].)

```
<!DOCTYPE Html>
<Html Lang=En
 ><Head
   ><Title
     >Graduation Ceremony Summer 2022</Title
   ></Head
 ><Body
   ><H1
     >Graduation</H1
   ><Section
     ><H2
       >Ceremony</H2
     ><P
       >Opening Procession</P
     ><P
       >Speech by Valedictorian</P
     ><P
       >Speech by Class President</P
     ><P
       >Presentation of Diplomas</P
     ><P
       >Closing Speech by Headmaster</P
   ></Section
   ><Section
     ><H2
       >Graduates</H2
     ><Ul
       ><Li
         >Molly Carpenter</Li
       ><Li
         >Anastasia Luccio</Li
       ><Li
         >Ebenezar McCoy</Li
       ><Li
         >Karrin Murphy</Li
       ><Li
         >Thomas Raith</Li
       ><Li
         >Susan Rodriguez</Li
     ></Ul
   ></Section
 ></Body
></Html>
```

Example

In this example, a book author has marked up some sections as chapters and some as appendices, and uses CSS to style the headers in these two classes of section differently.

```
<style>
 section { border: double medium; margin: 2em; }
 section.chapter h2 { font: 2em Roboto, Helvetica Neue, sans-serif; }
```

```
 section.appendix h2 { font: small-caps 2em Roboto, Helvetica Neue, sans-serif; }
</style>
<header>
 <hgroup>
  <h1>My Book</h1>
  <p>A sample with not much content</p>
 </hgroup>
 <p><small>Published by Dummy Publicorp Ltd.</small></p>
</header>
<section class="chapter">
 <h2>My First Chapter</h2>
 <p>This is the first of my chapters. It doesn't say much.</p>
 <p>But it has two paragraphs!</p>
</section>
<section class="chapter">
 <h2>It Continues: The Second Chapter</h2>
 <p>Bla dee bla, dee bla dee bla. Boom.</p>
</section>
<section class="chapter">
 <h2>Chapter Three: A Further Example</h2>
 <p>It's not like a battle between brightness and earthtones would go
 unnoticed.</p>
 <p>But it might ruin my story.</p>
</section>
<section class="appendix">
 <h2>Appendix A: Overview of Examples</h2>
 <p>These are demonstrations.</p>
</section>
<section class="appendix">
 <h2>Appendix B: Some Closing Remarks</h2>
 <p>Hopefully this long example shows that you <em>can</em> style
 sections, so long as they are used to indicate actual sections.</p>
</section>
```

4.3.4 The nav element §[p21]

Categories[p147]:

Flow content[p150].
Sectioning content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where sectioning content[p150] is expected.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The nav element represents a section of a page that links to other pages or to parts within the page: a section with navigation links.

Note

Not all groups of links on a page need to be in a nav element — the element is primarily intended for sections that consist of major navigation blocks. In particular, it is common for footers to have a short list of links to various pages of a site, such as the terms of service, the home page, and a copyright page. The footer element alone is sufficient for such cases; while a nav element can be used in such cases, it is usually unnecessary.

Note

User agents (such as screen readers) that are targeted at users who can benefit from navigation information being omitted in the initial rendering, or who can benefit from navigation information being immediately available, can use this element as a way to determine what content on the page to initially skip or provide on request (or both).

Example

In the following example, there are two nav elements, one for primary navigation around the site, and one for secondary navigation around the page itself.

```
<body>
 <h1>The Wiki Center Of Exampland</h1>
 <nav>
  <ul>
   <li><a href="/">Home</a></li>
   <li><a href="/events">Current Events</a></li>
   ...more...
  </ul>
 </nav>
 <article>
  <header>
   <h2>Demos in Exampland</h2>
   <p>Written by A. N. Other.</p>
  </header>
  <nav>
   <ul>
    <li><a href="#public">Public demonstrations</a></li>
    <li><a href="#destroy">Demolitions</a></li>
    ...more...
   </ul>
  </nav>
  <div>
   <section id="public">
    <h2>Public demonstrations</h2>
    <p>...more...</p>
   </section>
   <section id="destroy">
    <h2>Demolitions</h2>
    <p>...more...</p>
   </section>
   ...more...
  </div>
  <footer>
   <p><a href="?edit">Edit</a> | <a href="?delete">Delete</a> | <a href="?Rename">Rename</a></p>
  </footer>
 </article>
 <footer>
  <p><small>© copyright 1998 Exampland Emperor</small></p>
 </footer>
</body>
```

Example

In the following example, the page has several places where links are present, but only one of those places is considered a navigation section.

```
<body itemscope itemtype="http://schema.org/Blog">
 <header>
  <h1>Wake up sheeple!</h1>
  <p><a href="news.html">News</a> -
     <a href="blog.html">Blog</a> -
     <a href="forums.html">Forums</a></p>
  <p>Last Modified: <span itemprop="dateModified">2009-04-01</span></p>
  <nav>
   <h2>Navigation</h2>
   <ul>
    <li><a href="articles.html">Index of all articles</a></li>
    <li><a href="today.html">Things sheeple need to wake up for today</a></li>
    <li><a href="successes.html">Sheeple we have managed to wake</a></li>
   </ul>
  </nav>
 </header>
 <main>
  <article itemprop="blogPosts" itemscope itemtype="http://schema.org/BlogPosting">
   <header>
    <h2 itemprop="headline">My Day at the Beach</h2>
   </header>
   <div itemprop="articleBody">
    <p>Today I went to the beach and had a lot of fun.</p>
    ...more content...
   </div>
   <footer>
    <p>Posted <time itemprop="datePublished" datetime="2009-10-10">Thursday</time>.</p>
   </footer>
  </article>
  ...more blog posts...
 </main>
 <footer>
  <p>Copyright ©
   <span itemprop="copyrightYear">2010</span>
   <span itemprop="copyrightHolder">The Example Company</span>
  </p>
  <p><a href="about.html">About</a> -
     <a href="policy.html">Privacy Policy</a> -
     <a href="contact.html">Contact Us</a></p>
 </footer>
</body>
```

You can also see microdata annotations in the above example that use the schema.org vocabulary to provide the publication date and other metadata about the blog post.

Example

A nav[p212] element doesn't have to contain a list, it can contain other kinds of content as well. In this navigation block, links are provided in prose:

```
<nav>
 <h1>Navigation</h1>
 <p>You are on my home page. To the north lies <a href="/blog">my
 blog</a>, from whence the sounds of battle can be heard. To the east
 you can see a large mountain, upon which many <a
 href="/school">school papers</a> are littered. Far up thus mountain
 you can spy a little figure who appears to be me, desperately
 scribbling a <a href="/school/thesis">thesis</a>.</p>
```

```
 <p>To the west are several exits. One fun-looking exit is labeled <a
 href="https://games.example.com/">"games"</a>. Another more
 boring-looking exit is labeled <a
 href="https://isp.example.net/">ISP™</a>.</p>
 <p>To the south lies a dark and dank <a href="/about">contacts
 page</a>. Cobwebs cover its disused entrance, and at one point you
 see a rat run quickly out of the page.</p>
</nav>
```

Example

In this example, nav[p212] is used in an email application, to let the user switch folders:

```
<p><input type=button value="Compose" onclick="compose()"></p>
<nav>
 <h1>Folders</h1>
 <ul>
  <li> <a href="/inbox" onclick="return openFolder(this.href)">Inbox</a> <span class=count></span>
  <li> <a href="/sent" onclick="return openFolder(this.href)">Sent</a>
  <li> <a href="/drafts" onclick="return openFolder(this.href)">Drafts</a>
  <li> <a href="/trash" onclick="return openFolder(this.href)">Trash</a>
  <li> <a href="/customers" onclick="return openFolder(this.href)">Customers</a>
 </ul>
</nav>
```

✔ MDN

4.3.5 The aside element §[p215]

Categories[p147]:

Flow content[p150].
Sectioning content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where sectioning content[p150] is expected.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The aside[p215] element represents[p142] a section of a page that consists of content that is tangentially related to the content around the aside[p215] element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography.

The element can be used for typographical effects like pull quotes or sidebars, for advertising, for groups of nav[p212] elements, and for other content that is considered separate from the main content of the page.

Note

It's not appropriate to use the aside[p215] element just for parentheticals, since those are part of the main flow of the document.

Example

The following example shows how an aside is used to mark up background material on Switzerland in a much longer news story on Europe.

```
<aside>
 <h2>Switzerland</h2>
 <p>Switzerland, a land-locked country in the middle of geographic
 Europe, has not joined the geopolitical European Union, though it is
 a signatory to a number of European treaties.</p>
</aside>
```

Example

The following example shows how an aside is used to mark up a pull quote in a longer article.

```
...

<p>He later joined a large company, continuing on the same work.
<q>I love my job. People ask me what I do for fun when I'm not at
work. But I'm paid to do my hobby, so I never know what to
answer. Some people wonder what they would do if they didn't have to
work... but I know what I would do, because I was unemployed for a
year, and I filled that time doing exactly what I do now.</q></p>

<aside>
 <q>People ask me what I do for fun when I'm not at work. But I'm
 paid to do my hobby, so I never know what to answer.</q>
</aside>

<p>Of course his work — or should that be hobby? —
isn't his only passion. He also enjoys other pleasures.</p>

...
```

Example

The following extract shows how aside[p215] can be used for blogrolls and other side content on a blog:

```
<body>
 <header>
  <h1>My wonderful blog</h1>
  <p>My tagline</p>
 </header>
 <aside>
  <!-- this aside contains two sections that are tangentially related
  to the page, namely, links to other blogs, and links to blog posts
  from this blog -->
  <nav>
   <h2>My blogroll</h2>
   <ul>
    <li><a href="https://blog.example.com/">Example Blog</a>
   </ul>
  </nav>
  <nav>
   <h2>Archives</h2>
   <ol reversed>
    <li><a href="/last-post">My last post</a>
    <li><a href="/first-post">My first post</a>
```

```
   </ol>
  </nav>
 </aside>
 <aside>
  <!-- this aside is tangentially related to the page also, it
  contains twitter messages from the blog author -->
  <h1>Twitter Feed</h1>
  <blockquote cite="https://twitter.example.net/t31351234">
   I'm on vacation, writing my blog.
  </blockquote>
  <blockquote cite="https://twitter.example.net/t31219752">
   I'm going to go on vacation soon.
  </blockquote>
 </aside>
 <article>
  <!-- this is a blog post -->
  <h2>My last post</h2>
  <p>This is my last post.</p>
  <footer>
   <p><a href="/last-post" rel=bookmark>Permalink</a>
  </footer>
 </article>
 <article>
  <!-- this is also a blog post -->
  <h2>My first post</h2>
  <p>This is my first post.</p>
  <aside>
   <!-- this aside is about the blog post, since it's inside the
   <article> element; it would be wrong, for instance, to put the
   blogroll here, since the blogroll isn't really related to this post
   specifically, only to the page as a whole -->
   <h2>Posting</h2>
   <p>While I'm thinking about it, I wanted to say something about
   posting. Posting is fun!</p>
  </aside>
  <footer>
   <p><a href="/first-post" rel=bookmark>Permalink</a>
  </footer>
 </article>
 <footer>
  <p><a href="/archives">Archives</a> -
   <a href="/about">About me</a> -
   <a href="/copyright">Copyright</a></p>
 </footer>
</body>
```

4.3.6 The h1, h2, h3, h4, h5, and h6 elements §[p217]

Categories[p147]:

Flow content[p150].
Heading content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

As a child of an hgroup[p219] element.
Where heading content[p151] is expected.

Content model[p147]**:**

Phrasing content[p151].

Tag omission in text/html[p148]**:**

Neither tag is omissible.

Content attributes[p148]**:**

Global attributes[p155]

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLHeadingElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

These elements represent[p142] headings for their sections.

The semantics and meaning of these elements are defined in the section on headings and outlines[p224].

These elements have a heading level[p224] given by the number in their name. The heading level[p224] corresponds to the levels of nested sections. The h1[p217] element is for a top-level section, h2[p217] for a subsection, h3[p217] for a sub-subsection, and so on.

Example

As far as their respective document outlines (their heading and section structures) are concerned, these two snippets are semantically equivalent:

```
<body>
<h1>Let's call it a draw(ing surface)</h1>
<h2>Diving in</h2>
<h2>Simple shapes</h2>
<h2>Canvas coordinates</h2>
<h3>Canvas coordinates diagram</h3>
<h2>Paths</h2>
</body>
```

```
<body>
 <h1>Let's call it a draw(ing surface)</h1>
 <section>
  <h2>Diving in</h2>
 </section>
 <section>
  <h2>Simple shapes</h2>
 </section>
 <section>
  <h2>Canvas coordinates</h2>
  <section>
   <h3>Canvas coordinates diagram</h3>
  </section>
 </section>
 <section>
  <h2>Paths</h2>
 </section>
</body>
```

Authors might prefer the former style for its terseness, or the latter style for its additional styling hooks. Which is best is purely an

issue of preferred authoring style.

4.3.7 The hgroup element §[p219]

Categories[p147]:

Flow content[p150].
Heading content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where heading content[p151] is expected.

Content model[p147]:

Zero or more p[p230] elements, followed by one h1[p217], h2[p217], h3[p217], h4[p217], h5[p217], or h6[p217] element, followed by zero or more p[p230] elements, optionally intermixed with script-supporting elements[p152].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The hgroup[p219] element represents[p142] a heading and related content. The element may be used to group an h1[p217]–h6[p217] element with one or more p[p230] elements containing content representing a subheading, alternative title, or tagline.

Example

Here are some examples of valid headings contained within an hgroup[p219] element.

```
<hgroup>
 <h1>The reality dysfunction</h1>
 <p>Space is not the only void</p>
</hgroup>
```

```
<hgroup>
 <h1>Dr. Strangelove</h1>
 <p>Or: How I Learned to Stop Worrying and Love the Bomb</p>
</hgroup>
```

4.3.8 The header element §[p219]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Flow content[p150], but with no header[p219] or footer[p221] element descendants.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

If there is an ancestor sectioning content[p150] element: for authors; for implementers.
Otherwise: for authors; for implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The header[p219] element represents[p142] a group of introductory or navigational aids.

Note

A header[p219] element is intended to usually contain a heading (an h1[p217]–h6[p217] element or an hgroup[p219] element), but this is not required. The header[p219] element can also be used to wrap a section's table of contents, a search form, or any relevant logos.

Example

Here are some sample headers. This first one is for a game:

```
<header>
 <p>Welcome to...</p>
 <h1>Voidwars!</h1>
</header>
```

The following snippet shows how the element can be used to mark up a specification's header:

```
<header>
 <hgroup>
  <h1>Fullscreen API</h1>
  <p>Living Standard — Last Updated 19 October 2015<p>
 </hgroup>
 <dl>
  <dt>Participate:</dt>
  <dd><a href="https://github.com/whatwg/fullscreen">GitHub whatwg/fullscreen</a></dd>
  <dt>Commits:</dt>
  <dd><a href="https://github.com/whatwg/fullscreen/commits">GitHub whatwg/fullscreen/
commits</a></dd>
 </dl>
</header>
```

Note

The header[p219] element is not sectioning content[p150]; it doesn't introduce a new section.

Example

In this example, the page has a page heading given by the h1[p217] element, and two subsections whose headings are given by h2[p217] elements. The content after the header[p219] element is still part of the last subsection started in the header[p219] element, because the header[p219] element doesn't take part in the outline[p225] algorithm.

```
<body>
 <header>
  <h1>Little Green Guys With Guns</h1>
  <nav>
   <ul>
    <li><a href="/games">Games</a>
    <li><a href="/forum">Forum</a>
    <li><a href="/download">Download</a>
```

```
  </ul>
 </nav>
 <h2>Important News</h2> <!-- this starts a second subsection -->
 <!-- this is part of the subsection entitled "Important News" -->
 <p>To play today's games you will need to update your client.</p>
 <h2>Games</h2> <!-- this starts a third subsection -->
</header>
<p>You have three active games:</p>
<!-- this is still part of the subsection entitled "Games" -->
...
```

4.3.9 The `footer` element §[p22]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Flow content[p150], but with no `header`[p219] or `footer`[p221] element descendants.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

If there is an ancestor sectioning content[p150] element: for authors; for implementers.
Otherwise: for authors; for implementers.

DOM interface[p148]:

Uses `HTMLElement`[p143].

The `footer`[p221] element represents[p142] a footer for its nearest ancestor sectioning content[p150] element, or for the body element[p137] if there is no such ancestor. A footer typically contains information about its section such as who wrote it, links to related documents, copyright data, and the like.

When the `footer`[p221] element contains entire sections, they represent[p142] appendices, indices, long colophons, verbose license agreements, and other such content.

Note

Contact information for the author or editor of a section belongs in an `address`[p223] element, possibly itself inside a `footer`[p221]. Bylines and other information that could be suitable for both a `header`[p219] or a `footer`[p221] can be placed in either (or neither). The primary purpose of these elements is merely to help the author write self-explanatory markup that is easy to maintain and style; they are not intended to impose specific structures on authors.

Footers don't necessarily have to appear at the *end* of a section, though they usually do.

When there is no ancestor sectioning content[p150] element, then it applies to the whole page.

Note

The `footer`[p221] element is not itself sectioning content[p150]; it doesn't introduce a new section.

Example

Here is a page with two footers, one at the top and one at the bottom, with the same content:

```
<body>
 <footer><a href="../">Back to index...</a></footer>
 <hgroup>
  <h1>Lorem ipsum</h1>
  <p>The ipsum of all lorems</p>
 </hgroup>
 <p>A dolor sit amet, consectetur adipisicing elit, sed do eiusmod
 tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
 veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex
 ea commodo consequat. Duis aute irure dolor in reprehenderit in
 voluptate velit esse cillum dolore eu fugiat nulla
 pariatur. Excepteur sint occaecat cupidatat non proident, sunt in
 culpa qui officia deserunt mollit anim id est laborum.</p>
 <footer><a href="../">Back to index...</a></footer>
</body>
```

Example

Here is an example which shows the footer[p221] element being used both for a site-wide footer and for a section footer.

```
<!DOCTYPE HTML>
<HTML LANG="en"><HEAD>

```

Example

Some site designs have what is sometimes referred to as "fat footers" — footers that contain a lot of material, including images, links to other articles, links to pages for sending feedback, special offers... in some ways, a whole "front page" in the footer.

This fragment shows the bottom of a page on a site with a "fat footer":

```
...
 <footer>
  <nav>
   <section>
    <h1>Articles</h1>
    <p><img src="images/somersaults.jpeg" alt=""> Go to the gym with
    our somersaults class! Our teacher Jim takes you through the paces
    in this two-part article. <a href="articles/somersaults/1">Part
    1</a> · <a href="articles/somersaults/2">Part 2</a></p>
    <p><img src="images/kindplus.jpeg"> Tired of walking on the edge of
    a clif<!-- sic -->? Our guest writer Lara shows you how to bumble
    your way through the bars. <a href="articles/kindplus/1">Read
    more...</a></p>
    <p><img src="images/crisps.jpeg"> The chips are down, now all
    that's left is a potato. What can you do with it? <a
    href="articles/crisps/1">Read more...</a></p>
   </section>
   <ul>
    <li> <a href="/about">About us...</a>
    <li> <a href="/feedback">Send feedback!</a>
    <li> <a href="/sitemap">Sitemap</a>
   </ul>
  </nav>
  <p><small>Copyright © 2015 The Snacker —
  <a href="/tos">Terms of Service</a></small></p>
 </footer>
</body>
```

4.3.10 The address element §[p223]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Flow content[p150], but with no heading content[p151] descendants, no sectioning content[p150] descendants, and no header[p219], footer[p221], or address[p223] element descendants.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The address[p223] element represents[p142] the contact information for its nearest article[p207] or body[p206] element ancestor. If that is the body element[p137], then the contact information applies to the document as a whole.

Example

For example, a page at the W3C web site related to HTML might include the following contact information:

```
<ADDRESS>
 <A href="../People/Raggett/">Dave Raggett</A>,
 <A href="../People/Arnaud/">Arnaud Le Hors</A>,
 contact persons for the <A href="Activity">W3C HTML Activity</A>
</ADDRESS>
```

The address element must not be used to represent arbitrary addresses (e.g. postal addresses), unless those addresses are in fact the relevant contact information. (The p element is the appropriate element for marking up postal addresses in general.)

The address element must not contain information other than contact information.

Example

For example, the following is non-conforming use of the address element:

```
<ADDRESS>Last Modified: 1999/12/24 23:37:50</ADDRESS>
```

Typically, the address element would be included along with other information in a footer element.

The contact information for a node *node* is a collection of address elements defined by the first applicable entry from the following list:

↪ **If *node* is an article element**

↪ **If *node* is a body element**

The contact information consists of all the address elements that have *node* as an ancestor and do not have another body or article element ancestor that is a descendant of *node*.

↪ **If *node* has an ancestor element that is an article element**

↪ **If *node* has an ancestor element that is a body element**

The contact information of *node* is the same as the contact information of the nearest article or body element ancestor, whichever is nearest.

↪ **If *node*'s node document has a body element**

The contact information of *node* is the same as the contact information of the body element of the Document.

↪ **Otherwise**

There is no contact information for *node*.

User agents may expose the contact information of a node to the user, or use it for other purposes, such as indexing sections based on the sections' contact information.

Example

In this example the footer contains contact information and a copyright notice.

```
<footer>
 <address>
  For more details, contact
  <a href="mailto:js@example.com">John Smith</a>.
 </address>
 <p><small>© copyright 2038 Example Corp.</small></p>
</footer>
```

4.3.11 Headings and outlines

h1–h6 elements have a **heading level**, which is given by the number in the element's name.

These elements represent[p142] **headings**. The lower a heading[p225]'s heading level[p224] is, the fewer ancestor sections the heading[p225] has.

The **outline** is all headings[p225] in a document, in tree order.

The outline[p225] should be used for generating document outlines, for example when generating tables of contents. When creating an interactive table of contents, entries should jump the user to the relevant heading[p225].

If a document has one or more headings[p225], at least a single heading[p225] within the outline[p225] should have a heading level[p224] of 1.

Each heading[p225] following another heading[p225] *lead* in the outline[p225] must have a heading level[p224] that is less than, equal to, or 1 greater than *lead*'s heading level[p224].

Example

The following example is non-conforming:

```
<body>
 <h1>Apples</h1>
 <p>Apples are fruit.</p>
 <section>
  <h3>Taste</h3>
  <p>They taste lovely.</p>
 </section>
</body>
```

It could be written as follows and then it would be conforming:

```
<body>
 <h1>Apples</h1>
 <p>Apples are fruit.</p>
 <section>
  <h2>Taste</h2>
  <p>They taste lovely.</p>
 </section>
</body>
```

4.3.11.1 Sample outlines §[p225]

Example

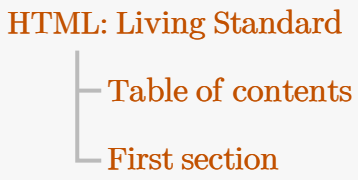
The following markup fragment:

```
<body>
  <hgroup id="document-title">
    <h1>HTML: Living Standard</h1>
    <p>Last Updated 12 August 2016</p>
  </hgroup>
  <p>Some intro to the document.</p>
  <h2>Table of contents</h2>
  <ol id=toc>...</ol>
  <h2>First section</h2>
  <p>Some intro to the first section.</p>
</body>
```

...results in 3 document headings:

1. <h1>HTML: Living Standard</h1>
2. <h2>Table of contents</h2>.
3. <h2>First section</h2>.

A rendered view of the outline[p225] might look like:



Example

First, here is a document, which is a book with very short chapters and subsections:

```
<!DOCTYPE HTML>
<html lang=en>
<title>The Tax Book (all in one page)</title>
<h1>The Tax Book</h1>
<h2>Earning money</h2>
<p>Earning money is good.</p>
<h3>Getting a job</h3>
<p>To earn money you typically need a job.</p>
<h2>Spending money</h2>
<p>Spending is what money is mainly used for.</p>
<h3>Cheap things</h3>
<p>Buying cheap things often not cost-effective.</p>
<h3>Expensive things</h3>
<p>The most expensive thing is often not the most cost-effective either.</p>
<h2>Investing money</h2>
<p>You can lend your money to other people.</p>
<h2>Losing money</h2>
<p>If you spend money or invest money, sooner or later you will lose money.
<h3>Poor judgement</h3>
<p>Usually if you lose money it's because you made a mistake.</p>
```

Its outline[p225] could be presented as follows:

1. The Tax Book
    1. Earning money
        1. Getting a job
    2. Spending money
        1. Cheap things
        2. Expensive things
    3. Investing money
    4. Losing money
        1. Poor judgement

Notice that the `title`[p175] element is not a heading[p225].

Example

A document can contain multiple top-level headings:

```
<!DOCTYPE HTML>
<html lang=en>
<title>Alphabetic Fruit</title>
<h1>Apples</h1>
<p>Pomaceous.</p>
<h1>Bananas</h1>
<p>Edible.</p>
<h1>Carambola</h1>
```

```
<p>Star.</p>
```

The document's outline[p225] could be presented as follows:

1. Apples
2. Bananas
3. Carambola

Example

header[p219] elements do not influence the outline[p225] of a document:

```
<!DOCTYPE HTML>
<html lang="en">
<title>We're adopting a child! — Ray's blog</title>
<h1>Ray's blog</h1>
<article>
 <header>
  <nav>
   <a href="?t=-1d">Yesterday</a>;
   <a href="?t=-7d">Last week</a>;
   <a href="?t=-1m">Last month</a>
  </nav>
  <h2>We're adopting a child!</h2>
 </header>
 <p>As of today, Janine and I have signed the papers to become
 the proud parents of baby Diane! We've been looking forward to
 this day for weeks.</p>
</article>
</html>
```

The document's outline[p225] could be presented as follows:

1. Ray's blog
    1. We're adopting a child!

Example

The following example is conforming, but not encouraged as it has no heading[p225] whose heading level[p224] is 1:

```
<!DOCTYPE HTML>
<html lang=en>
<title>Alphabetic Fruit</title>
<section>
 <h2>Apples</h2>
 <p>Pomaceous.</p>
</section>
<section>
 <h2>Bananas</h2>
 <p>Edible.</p>
</section>
<section>
 <h2>Carambola</h2>
 <p>Star.</p>
</section>
```

The document's outline[p225] could be presented as follows:

1.
    1. Apples
    2. Bananas
    3. Carambola

Example

The following example is conforming, but not encouraged as the first heading[p225]'s heading level[p224] is not 1:

```
<!DOCTYPE HTML>
<html lang=en>
<title>Feathers on The Site of Encyclopedic Knowledge</title>
 <h2>A plea from our caretakers</h2>
 <p>Please, we beg of you, send help! We're stuck in the server room!</p>
<h1>Feathers</h1>
<p>Epidermal growths.</p>
```

The document's outline[p225] could be presented as follows:

1. 1. A plea from our caretakers
2. Feathers

4.3.11.2 Exposing outlines to users §[p228]

User agents are encouraged to expose page outlines[p225] to users to aid in navigation. This is especially true for non-visual media, e.g. screen readers.

Example

For instance, a user agent could map the arrow keys as follows:

Shift + ← Left
Go to previous heading

Shift + → Right
Go to next heading

Shift + ↑ Up
Go to next heading whose level[p224] is one less than the current heading's level

Shift + ↓ Down
Go to next heading whose level[p224] is the same as the current heading's level

4.3.12 Usage summary §[p228]

This section is non-normative.

Element	Purpose Example

body[p206]	The contents of the document.
	`<!DOCTYPE HTML>`
	`<html lang="en">`
	`<head> <title>Steve Hill's Home Page</title> </head>`
	`<body> <p>Hard Trance is My Life.</p> </body>`
	`</html>`

article[p207]	A complete, or self-contained, composition in a document, page, application, or site and that is, in principle, independently distributable or reusable, e.g. in syndication. This could be a forum post, a magazine or newspaper article, a blog entry, a user-submitted comment, an interactive widget or gadget, or any other independent item of content.
	`<article>`
	`<img src="/tumblr_masqy2s5yn1rzfqbpo1_500.jpg" alt="Yellow smiley face with the caption 'masif'">`
	`<p>My fave Masif tee so far!</p>`
	`<footer>Posted 2 days ago</footer>`
	`</article>`
	`<article>`
	`<img src="/tumblr_m9tf6wSr6W1rzfqbpo1_500.jpg" alt="">`
	`<p>Happy 2nd birthday Masif Saturdays!!!</p>`

Element	Purpose Example
	```<footer>Posted 3 weeks ago</footer>```
	```</article>```
section[p210]	A generic section of a document or application. A section, in this context, is a thematic grouping of content, typically with a heading. ``` Biography ```
	```<section>```
	``` The facts ```
	``` 1500+ shows, 14+ countries ```
	```</section>```
	```<section>```
	``` 2010/2011 figures per year ```
	``` 100+ shows, 8+ countries ```
	```</section>```
nav[p212]	A section of a page that links to other pages or to parts within the page: a section with navigation links. ```<nav>```
	```<p>Home```
	```<p>Bio```
	```<p>Discog```
	```</nav>```
aside[p215]	A section of a page that consists of content that is tangentially related to the content around the aside[p215] element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography. ``` Music ```
	``` As any burner can tell you, the event has a lot of trance. ```
	```<aside>You can buy the music we played at our playlist page.</aside>```
	``` This year we played a kind of trance that originated in Belgium, Germany, and the Netherlands in the mid-90s. ```
h1[p217]–h6[p217]	A heading ``` The Guide To Music On The Playa ```
	``` The Main Stage ```
	``` If you want to play on a stage, you should bring one. ```
	``` Amplified Music ```
	``` Amplifiers up to 300W or 90dB are welcome. ```
hgroup[p219]	A heading and related content. The element may be used to group an h1[p217]–h6[p217] element with one or more p[p230] elements containing content representing a subheading, alternative title, or tagline. ```<hgroup>```
	``` Burning Music ```
	``` The Guide To Music On The Playa ```
	```</hgroup>```
	```<section>```
	```<hgroup>```
	``` Main Stage ```
	``` The Fiction Of A Music Festival ```
	```</hgroup>```
	``` If you want to play on a stage, you should bring one. ```
	```</section>```
	```<section>```
	```<hgroup>```
	``` Loudness! ```
	``` Questions About Amplified Music ```
	```</hgroup>```
	``` Amplifiers up to 300W or 90dB are welcome. ```
	```</section>```
header[p219]	A group of introductory or navigational aids. ```<article>```
	```<header>```
	``` Hard Trance is My Life ```
	``` By DJ Steve Hill and Technikal ```
	```</header>```
	``` The album with the amusing punctuation has red artwork. ```
	```</article>```
footer[p221]	A footer for its nearest ancestor sectioning content[p150] element, or for the body element[p137] if there is no such ancestor. A footer typically contains information about its section such as who wrote it, links to related documents, copyright data, and the like. ```<article>```
	``` Hard Trance is My Life ```
	``` The album with the amusing punctuation has red artwork. ```

Element	Purpose Example
	<footer> Artists: DJ Steve Hill and Technikal </footer> </article>

4.3.12.1 Article or section? §[p23]

This section is non-normative.

A section[p210] forms part of something else. An article[p207] is its own thing. But how does one know which is which? Mostly the real answer is "it depends on author intent".

For example, one could imagine a book with a "Granny Smith" chapter that just said "These juicy, green apples make a great filling for apple pies."; that would be a section[p210] because there'd be lots of other chapters on (maybe) other kinds of apples.

On the other hand, one could imagine a tweet or reddit comment or tumblr post or newspaper classified ad that just said "Granny Smith. These juicy, green apples make a great filling for apple pies."; it would then be article[p207]s because that was the whole thing.

A comment on an article is not part of the article[p207] on which it is commenting, therefore it is its own article[p207].

4.4 Grouping content §[p23]

4.4.1 The p element §[p23]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

A p[p230] element's end tag[p1280] can be omitted if the p[p230] element is immediately followed by an address[p223], article[p207], aside[p215], blockquote[p236], details[p641], dialog[p650], div[p257], dl[p245], fieldset[p597], figcaption[p253], figure[p250], footer[p221], form[p515], h1[p217], h2[p217], h3[p217], h4[p217], h5[p217], h6[p217], header[p219], hgroup[p219], hr[p232], main[p254], menu[p241], nav[p212], ol[p239], p[p230], pre[p234], search[p255], section[p210], table[p479], or ul[p240] element, or if there is no more content in the parent element and the parent element is an HTML element[p46] that is not an a[p258], audio[p411], del[p339], ins[p338], map[p471], noscript[p677], or video[p407] element, or an autonomous custom element[p766].

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLParagraphElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

The p[p230] element represents[p142] a paragraph[p153].

Note

While paragraphs are usually represented in visual media by blocks of text that are physically separated from adjacent blocks through blank lines, a style sheet or user agent would be equally justified in presenting paragraph breaks in a different manner, for instance using inline pilcrows (¶).

Example

The following examples are conforming HTML fragments:

```
<p>The little kitten gently seated herself on a piece of
carpet. Later in her life, this would be referred to as the time the
cat sat on the mat.</p>
```

```
<fieldset>
 <legend>Personal information</legend>
 <p>
   <label>Name: <input name="n"></label>
   <label><input name="anon" type="checkbox"> Hide from other users</label>
 </p>
 <p><label>Address: <textarea name="a"></textarea></label></p>
</fieldset>
```

```
<p>There was once an example from Femley,<br>
Whose markup was of dubious quality.<br>
The validator complained,<br>
So the author was pained,<br>
To move the error from the markup to the rhyming.</p>
```

The p[p230] element should not be used when a more specific element is more appropriate.

Example

The following example is technically correct:

```
<section>
 <!-- ... -->
 <p>Last modified: 2001-04-23</p>
 <p>Author: fred@example.com</p>
</section>
```

However, it would be better marked-up as:

```
<section>
 <!-- ... -->
 <footer>Last modified: 2001-04-23</footer>
 <address>Author: fred@example.com</address>
</section>
```

Or:

```
<section>
 <!-- ... -->
 <footer>
  <p>Last modified: 2001-04-23</p>
  <address>Author: fred@example.com</address>
 </footer>
</section>
```

Note

List elements (in particular, ol[p239] and ul[p240] elements) cannot be children of p[p230] elements. When a sentence contains a bulleted list, therefore, one might wonder how it should be marked up.

Example

For instance, this fantastic sentence has bullets relating to

- *wizards,*
- *faster-than-light travel, and*
- *telepathy,*

and is further discussed below.

The solution is to realize that a paragraph[p153], in HTML terms, is not a logical concept, but a structural one. In the fantastic example above, there are actually five paragraphs[p153] as defined by this specification: one before the list, one for each bullet, and one after the list.

Example

The markup for the above example could therefore be:

```
<p>For instance, this fantastic sentence has bullets relating to</p>
<ul>
 <li>wizards,
 <li>faster-than-light travel, and
 <li>telepathy,
</ul>
<p>and is further discussed below.</p>
```

Authors wishing to conveniently style such "logical" paragraphs consisting of multiple "structural" paragraphs can use the div[p257] element instead of the p[p230] element.

Example

Thus for instance the above example could become the following:

```
<div>For instance, this fantastic sentence has bullets relating to
<ul>
 <li>wizards,
 <li>faster-than-light travel, and
 <li>telepathy,
</ul>
and is further discussed below.</div>
```

This example still has five structural paragraphs, but now the author can style just the div[p257] instead of having to consider each part of the example separately.

4.4.2 The hr element §[p232]

Categories[p147]:

Flow content[p150].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.
As a child of a select[p572] element.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLHRElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

The hr[p232] element represents[p142] a paragraph[p153]-level thematic break, e.g., a scene change in a story, or a transition to another topic within a section of a reference book; alternatively, it represents a separator between a set of options of a select[p572] element.

Example

The following fictional extract from a project manual shows two sections that use the hr[p232] element to separate topics within the section.

```
<section>
 <h1>Communication</h1>
 <p>There are various methods of communication. This section
 covers a few of the important ones used by the project.</p>
 <hr>
 <p>Communication stones seem to come in pairs and have mysterious
 properties:</p>
 <ul>
  <li>They can transfer thoughts in two directions once activated
  if used alone.</li>
  <li>If used with another device, they can transfer one's
  consciousness to another body.</li>
  <li>If both stones are used with another device, the
  consciousnesses switch bodies.</li>
 </ul>
 <hr>
 <p>Radios use the electromagnetic spectrum in the meter range and
 longer.</p>
 <hr>
 <p>Signal flares use the electromagnetic spectrum in the
 nanometer range.</p>
</section>
<section>
 <h1>Food</h1>
 <p>All food at the project is rationed:</p>
 <dl>
  <dt>Potatoes</dt>
  <dd>Two per day</dd>
  <dt>Soup</dt>
  <dd>One bowl per day</dd>
 </dl>
 <hr>
 <p>Cooking is done by the chefs on a set rotation.</p>
</section>
```

There is no need for an hr[p232] element between the sections themselves, since the section[p210] elements and the h1[p217] elements

imply thematic changes themselves.

Example

The following extract from *Pandora's Star* by Peter F. Hamilton shows two paragraphs that precede a scene change and the paragraph that follows it. The scene change, represented in the printed book by a gap containing a solitary centered star between the second and third paragraphs, is here represented using the hr[p232] element.

```
<p>Dudley was ninety-two, in his second life, and fast approaching
time for another rejuvenation. Despite his body having the physical
age of a standard fifty-year-old, the prospect of a long degrading
campaign within academia was one he regarded with dread. For a
supposedly advanced civilization, the Intersolar Commonwealth could be
appallingly backward at times, not to mention cruel.</p>
<p><i>Maybe it won't be that bad</i>, he told himself. The lie was
comforting enough to get him through the rest of the night's
shift.</p>
<hr>
<p>The Carlton AllLander drove Dudley home just after dawn. Like the
astronomer, the vehicle was old and worn, but perfectly capable of
doing its job. It had a cheap diesel engine, common enough on a
semi-frontier world like Gralmond, although its drive array was a
thoroughly modern photoneural processor. With its high suspension and
deep-tread tyres it could plough along the dirt track to the
observatory in all weather and seasons, including the metre-deep snow
of Gralmond's winters.</p>
```

Note

The hr[p232] element does not affect the document's outline[p225].

4.4.3 The pre element §[p234]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLPreElement : HTMLElement {
  [HTMLConstructor] constructor();
```

```
  // also has obsolete members
};
```

The pre element represents a block of preformatted text, in which structure is represented by typographic conventions rather than by elements.

Note

In the HTML syntax, a leading newline character immediately following the pre element start tag is stripped.

Some examples of cases where the pre element could be used:

- Including an email, with paragraphs indicated by blank lines, lists indicated by lines prefixed with a bullet, and so on.
- Including fragments of computer code, with structure indicated according to the conventions of that language.
- Displaying ASCII art.

Note

Authors are encouraged to consider how preformatted text will be experienced when the formatting is lost, as will be the case for users of speech synthesizers, braille displays, and the like. For cases like ASCII art, it is likely that an alternative presentation, such as a textual description, would be more universally accessible to the readers of the document.

To represent a block of computer code, the pre element can be used with a code element; to represent a block of computer output the pre element can be used with a samp element. Similarly, the kbd element can be used within a pre element to indicate text that the user is to enter.

Note

This element has rendering requirements involving the bidirectional algorithm.

Example

In the following snippet, a sample of computer code is presented.

```
<p>This is the <code>Panel</code> constructor:</p>
<pre><code>function Panel(element, canClose, closeHandler) {
  this.element = element;
  this.canClose = canClose;
  this.closeHandler = function () { if (closeHandler) closeHandler() };
}</code></pre>
```

Example

In the following snippet, samp and kbd elements are mixed in the contents of a pre element to show a session of Zork I.

```
<pre><samp>You are in an open field west of a big white house with a boarded
front door.
There is a small mailbox here.

></samp> <kbd>open mailbox</kbd>

<samp>Opening the mailbox reveals:
A leaflet.

></samp></pre>
```

Example

The following shows a contemporary poem that uses the pre element to preserve its unusual formatting, which forms an intrinsic part of the poem itself.

```
<pre>                maxling

it is with a           heart
               heavy

that i admit loss of a feline
        so           loved

a friend lost to the
        unknown
                                (night)

~cdr 11dec07</pre>
```

4.4.4 The `blockquote` element §[p236]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
`cite`[p236] — Link to the source of the quotation or more information about the edit

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLQuoteElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute USVString cite;
};
```

Note

The `HTMLQuoteElement`[p236] interface is also used by the `q`[p267] element.

The `blockquote`[p236] element represents[p142] a section that is quoted from another source.

Content inside a `blockquote`[p236] must be quoted from another source, whose address, if it has one, may be cited in the **`cite`** attribute.

If the `cite`[p236] attribute is present, it must be a valid URL potentially surrounded by spaces[p97]. To obtain the corresponding citation link, the value of the attribute must be parsed[p98] relative to the element's node document. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g., by server-side scripts collecting statistics about a site's use of quotations), not for readers.

The content of a blockquote[p236] may be abbreviated or may have context added in the conventional manner for the text's language.

Example

For example, in English this is traditionally done using square brackets. Consider a page with the sentence "Jane ate the cracker. She then said she liked apples and fish."; it could be quoted as follows:

```
<blockquote>
 <p>[Jane] then said she liked [...] fish.</p>
</blockquote>
```

Attribution for the quotation, if any, must be placed outside the blockquote[p236] element.

Example

For example, here the attribution is given in a paragraph after the quote:

```
<blockquote>
 <p>I contend that we are both atheists. I just believe in one fewer
 god than you do. When you understand why you dismiss all the other
 possible gods, you will understand why I dismiss yours.</p>
</blockquote>
<p>— Stephen Roberts</p>
```

The other examples below show other ways of showing attribution.

The **cite** IDL attribute must reflect[p105] the element's `cite` content attribute.

Example

Here a blockquote[p236] element is used in conjunction with a figure[p250] element and its figcaption[p253] to clearly relate a quote to its attribution (which is not part of the quote and therefore doesn't belong inside the blockquote[p236] itself):

```
<figure>
 <blockquote>
  <p>The truth may be puzzling. It may take some work to grapple with.
  It may be counterintuitive. It may contradict deeply held
  prejudices. It may not be consonant with what we desperately want to
  be true. But our preferences do not determine what's true. We have a
  method, and that method helps us to reach not absolute truth, only
  asymptotic approaches to the truth — never there, just closer
  and closer, always finding vast new oceans of undiscovered
  possibilities. Cleverly designed experiments are the key.</p>
 </blockquote>
 <figcaption>Carl Sagan, in "<cite>Wonder and Skepticism</cite>", from
 the <cite>Skeptical Inquirer</cite> Volume 19, Issue 1 (January-February
 1995)</figcaption>
</figure>
```

Example

This next example shows the use of cite[p266] alongside blockquote[p236]:

```
<p>His next piece was the aptly named <cite>Sonnet 130</cite>:</p>
<blockquote cite="https://quotes.example.org/s/sonnet130.html">
  <p>My mistress' eyes are nothing like the sun,<br>
  Coral is far more red, than her lips red,<br>
  ...
```

Example

This example shows how a forum post could use blockquote[p236] to show what post a user is replying to. The article[p207] element is used for each post, to mark up the threading.

```
<article>
 <h1><a href="https://bacon.example.com/?blog=109431">Bacon on a crowbar</a></h1>
 <article>
  <header><strong>t3yw</strong> 12 points 1 hour ago</header>
  <p>I bet a narwhal would love that.</p>
  <footer><a href="?pid=29578">permalink</a></footer>
  <article>
   <header><strong>greg</strong> 8 points 1 hour ago</header>
   <blockquote><p>I bet a narwhal would love that.</p></blockquote>
   <p>Dude narwhals don't eat bacon.</p>
   <footer><a href="?pid=29579">permalink</a></footer>
   <article>
    <header><strong>t3yw</strong> 15 points 1 hour ago</header>
    <blockquote>
     <blockquote><p>I bet a narwhal would love that.</p></blockquote>
     <p>Dude narwhals don't eat bacon.</p>
    </blockquote>
    <p>Next thing you'll be saying they don't get capes and wizard
    hats either!</p>
    <footer><a href="?pid=29580">permalink</a></footer>
    <article>
     <article>
      <header><strong>boing</strong> -5 points 1 hour ago</header>
      <p>narwhals are worse than ceiling cat</p>
      <footer><a href="?pid=29581">permalink</a></footer>
     </article>
    </article>
   </article>
  </article>
  <article>
   <header><strong>fred</strong> 1 points 23 minutes ago</header>
   <blockquote><p>I bet a narwhal would love that.</p></blockquote>
   <p>I bet they'd love to peel a banana too.</p>
   <footer><a href="?pid=29582">permalink</a></footer>
  </article>
 </article>
</article>
```

Example

This example shows the use of a blockquote[p236] for short snippets, demonstrating that one does not have to use p[p230] elements inside blockquote[p236] elements:

```
<p>He began his list of "lessons" with the following:</p>
<blockquote>One should never assume that his side of
the issue will be recognized, let alone that it will
be conceded to have merits.</blockquote>
<p>He continued with a number of similar points, ending with:</p>
<blockquote>Finally, one should be prepared for the threat
of breakdown in negotiations at any given moment and not
be cowed by the possibility.</blockquote>
<p>We shall now discuss these points...
```

Note

Examples of how to represent a conversation[p785] are shown in a later section; it is not appropriate to use the cite[p266] and blockquote[p236] elements for this purpose.

4.4.5 The ol element §[p239]

Categories[p147]:

Flow content[p150].

If the element's children include at least one li[p242] element: Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Zero or more li[p242] and script-supporting[p152] elements.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
reversed[p239] — Number the list backwards
start[p239] — Starting value[p239] of the list
type[p239] — Kind of list marker

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLOListElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute boolean reversed;
  [CEReactions] attribute long start;
  [CEReactions] attribute DOMString type;

  // also has obsolete members
};
```

The ol[p239] element represents[p142] a list of items, where the items have been intentionally ordered, such that changing the order would change the meaning of the document.

The items of the list are the li[p242] element child nodes of the ol[p239] element, in tree order.

The **reversed** attribute is a boolean attribute[p76]. If present, it indicates that the list is a descending list (..., 3, 2, 1). If the attribute is omitted, the list is an ascending list (1, 2, 3, ...).

The **start** attribute, if present, must be a valid integer[p78]. It is used to determine the starting value[p239] of the list.

An ol[p239] element has a **starting value**, which is an integer determined as follows:

1. If the ol[p239] element has a start[p239] attribute, then:
    1. Let *parsed* be the result of parsing the value of the attribute as an integer[p78].
    2. If *parsed* is not an error, then return *parsed*.
2. If the ol[p239] element has a reversed[p239] attribute, then return the number of owned li elements[p243].
3. Return 1.

The **type** attribute can be used to specify the kind of marker to use in the list, in the cases where that matters (e.g. because items are to be referenced[p142] by their number/letter). The attribute, if specified, must have a value that is identical to one of the characters given in the first cell of one of the rows of the following table. The type[p239] attribute represents the state given in the cell in the second column of the row whose first cell matches the attribute's value; if none of the cells match, or if the attribute is omitted, then the attribute represents the decimal[p240] state.

Keyword	State	Description	Examples for values 1-3 and 3999-4001							
1 (U+0031)	**decimal**	Decimal numbers	1.	2.	3.	...	3999.	4000.	4001.	...
a (U+0061)	**lower-alpha**	Lowercase latin alphabet	a.	b.	c.	...	ewu.	ewv.	eww.	...
A (U+0041)	**upper-alpha**	Uppercase latin alphabet	A.	B.	C.	...	EWU.	EWV.	EWW.	...
i (U+0069)	**lower-roman**	Lowercase roman numerals	i.	ii.	iii.	...	mmmcmxcix.	$\overline{\text{iv}}$.	$\overline{\text{iv}}$i.	...
I (U+0049)	**upper-roman**	Uppercase roman numerals	I.	II.	III.	...	MMMCMXCIX.	$\overline{\text{IV}}$.	$\overline{\text{IV}}$I.	...

User agents should render the items of the list in a manner consistent with the state of the type[p239] attribute of the ol[p239] element. Numbers less than or equal to zero should always use the decimal system regardless of the type[p239] attribute.

Note

For CSS user agents, a mapping for this attribute to the 'list-style-type' CSS property is given in the Rendering section[p1414] (the mapping is straightforward: the states above have the same names as their corresponding CSS values).

Note

It is possible to redefine the default CSS list styles used to implement this attribute in CSS user agents; doing so will affect how list items are rendered.

The **reversed** and **type** IDL attributes must reflect[p105] the respective content attributes of the same name.

The **start** IDL attribute must reflect[p105] the content attribute of the same name, with a default value[p108] of 1.

Note

This means that the start[p240] IDL attribute does not necessarily match the list's starting value[p239], in cases where the start[p239] content attribute is omitted and the reversed[p239] content attribute is specified.

Example

The following markup shows a list where the order matters, and where the ol[p239] element is therefore appropriate. Compare this list to the equivalent list in the ul[p240] section to see an example of the same items using the ul[p240] element.

```
<p>I have lived in the following countries (given in the order of when
I first lived there):</p>
<ol>
 <li>Switzerland
 <li>United Kingdom
 <li>United States
 <li>Norway
</ol>
```

Note how changing the order of the list changes the meaning of the document. In the following example, changing the relative order of the first two items has changed the birthplace of the author:

```
<p>I have lived in the following countries (given in the order of when
I first lived there):</p>
<ol>
 <li>United Kingdom
 <li>Switzerland
 <li>United States
 <li>Norway
</ol>
```

4.4.6 The ul element §[p240]

Categories[p147]:

Flow content[p150].

If the element's children include at least one li[p242] element: Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Zero or more li[p242] and script-supporting[p152] elements.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLUListElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

The ul[p240] element represents[p142] a list of items, where the order of the items is not important — that is, where changing the order would not materially change the meaning of the document.

The items of the list are the li[p242] element child nodes of the ul[p240] element.

Example

The following markup shows a list where the order does not matter, and where the ul[p240] element is therefore appropriate. Compare this list to the equivalent list in the ol[p239] section to see an example of the same items using the ol[p239] element.

```
<p>I have lived in the following countries:</p>
<ul>
 <li>Norway
 <li>Switzerland
 <li>United Kingdom
 <li>United States
</ul>
```

Note that changing the order of the list does not change the meaning of the document. The items in the snippet above are given in alphabetical order, but in the snippet below they are given in order of the size of their current account balance in 2007, without changing the meaning of the document whatsoever:

```
<p>I have lived in the following countries:</p>
<ul>
 <li>Switzerland
 <li>Norway
 <li>United Kingdom
 <li>United States
</ul>
```

4.4.7 The menu element §[p241]

Categories[p147]:

Flow content[p150].
If the element's children include at least one li[p242] element: Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Zero or more li[p242] and script-supporting[p152] elements.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLMenuElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

The menu[p241] element represents[p142] a toolbar consisting of its contents, in the form of an unordered list of items (represented by li[p242] elements), each of which represents a command that the user can perform or activate.

Note

The menu[p241] element is simply a semantic alternative to ul[p240] to express an unordered list of commands (a "toolbar").

Example

In this example, a text-editing application uses a menu[p241] element to provide a series of editing commands:

```
<menu>
 <li><button onclick="copy()"><img src="copy.svg" alt="Copy"></button></li>
 <li><button onclick="cut()"><img src="cut.svg" alt="Cut"></button></li>
 <li><button onclick="paste()"><img src="paste.svg" alt="Paste"></button></li>
</menu>
```

Note that the styling to make this look like a conventional toolbar menu is up to the application.

4.4.8 The li element §[p242]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

Inside ol[p239] elements.
Inside ul[p240] elements.
Inside menu[p241] elements.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

An li[p242] element's end tag[p1280] can be omitted if the li[p242] element is immediately followed by another li[p242] element or if there is no more content in the parent element.

Content attributes[p148]:

Global attributes[p155]

If the element is not a child of an `ul`[p240] or `menu`[p241] element: `value`[p243] — Ordinal value[p243] of the list item

Accessibility considerations[p148]:

For authors.

For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLLIElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute long value;

  // also has obsolete members
};
```

The `li`[p242] element represents[p142] a list item. If its parent element is an `ol`[p239], `ul`[p240], or `menu`[p241] element, then the element is an item of the parent element's list, as defined for those elements. Otherwise, the list item has no defined list-related relationship to any other `li`[p242] element.

The **`value`** attribute, if present, must be a valid integer[p78]. It is used to determine the ordinal value[p243] of the list item, when the `li`[p242]'s list owner[p243] is an `ol`[p239] element.

Any element whose computed value of 'display' is 'list-item' has a **list owner**, which is determined as follows:

1. If the element is not being rendered[p1406], return null; the element has no list owner[p243].
2. Let *ancestor* be the element's parent.
3. If the element has an `ol`[p239], `ul`[p240], or `menu`[p241] ancestor, set *ancestor* to the closest such ancestor element.
4. Return the closest inclusive ancestor of *ancestor* that produces a CSS box.

Note

Such an element will always exist, as at the very least the document element will always produce a CSS box.

To determine the **ordinal value** of each element owned by a given list owner[p243] *owner*, perform the following steps:

1. Let *i* be 1.
2. If *owner* is an `ol`[p239] element, let *numbering* be *owner*'s starting value[p239]. Otherwise, let *numbering* be 1.
3. *Loop*: If *i* is greater than the number of list items that *owner* owns[p243], then return; all of *owner*'s owned list items[p243] have been assigned ordinal values[p243].
4. Let *item* be the *i*th of *owner*'s owned list items[p243], in tree order.
5. If *item* is an `li`[p242] element that has a `value`[p243] attribute, then:
    1. Let *parsed* be the result of parsing the value of the attribute as an integer[p78].
    2. If *parsed* is not an error, then set *numbering* to *parsed*.
6. The ordinal value[p243] of *item* is *numbering*.
7. If *owner* is an `ol`[p239] element, and *owner* has a `reversed`[p239] attribute, decrement *numbering* by 1; otherwise, increment *numbering* by 1.
8. Increment *i* by 1.
9. Go to the step labeled *loop*.

The **value** IDL attribute must reflect[p105] the value of the value[p243] content attribute.

Example

The element's value[p244] IDL attribute does not directly correspond to its ordinal value[p243]; it simply reflects[p105] the content attribute. For example, given this list:

```
<ol>
 <li>Item 1
 <li value="3">Item 3
 <li>Item 4
</ol>
```

The ordinal values[p243] are 1, 3, and 4, whereas the value[p244] IDL attributes return 0, 3, 0 on getting.

Example

The following example, the top ten movies are listed (in reverse order). Note the way the list is given a title by using a figure[p250] element and its figcaption[p253] element.

```
<figure>
 <figcaption>The top 10 movies of all time</figcaption>
 <ol>
  <li value="10"><cite>Josie and the Pussycats</cite>, 2001</li>
  <li value="9"><cite lang="sh">Црна мачка, бели мачор</cite>, 1998</li>
  <li value="8"><cite>A Bug's Life</cite>, 1998</li>
  <li value="7"><cite>Toy Story</cite>, 1995</li>
  <li value="6"><cite>Monsters, Inc</cite>, 2001</li>
  <li value="5"><cite>Cars</cite>, 2006</li>
  <li value="4"><cite>Toy Story 2</cite>, 1999</li>
  <li value="3"><cite>Finding Nemo</cite>, 2003</li>
  <li value="2"><cite>The Incredibles</cite>, 2004</li>
  <li value="1"><cite>Ratatouille</cite>, 2007</li>
 </ol>
</figure>
```

The markup could also be written as follows, using the reversed[p239] attribute on the ol[p239] element:

```
<figure>
 <figcaption>The top 10 movies of all time</figcaption>
 <ol reversed>
  <li><cite>Josie and the Pussycats</cite>, 2001</li>
  <li><cite lang="sh">Црна мачка, бели мачор</cite>, 1998</li>
  <li><cite>A Bug's Life</cite>, 1998</li>
  <li><cite>Toy Story</cite>, 1995</li>
  <li><cite>Monsters, Inc</cite>, 2001</li>
  <li><cite>Cars</cite>, 2006</li>
  <li><cite>Toy Story 2</cite>, 1999</li>
  <li><cite>Finding Nemo</cite>, 2003</li>
  <li><cite>The Incredibles</cite>, 2004</li>
  <li><cite>Ratatouille</cite>, 2007</li>
 </ol>
</figure>
```

Note

While it is conforming to include heading elements (e.g. h1[p217]) inside li[p242] elements, it likely does not convey the semantics that the author intended. A heading starts a new section, so a heading in a list implicitly splits the list into spanning multiple sections.

4.4.9 The dl element §[p245]

Categories[p147]:

Flow content[p150].

If the element's children include at least one name-value group: Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Either: Zero or more groups each consisting of one or more dt[p248] elements followed by one or more dd[p249] elements, optionally intermixed with script-supporting elements[p152].

Or: One or more div[p257] elements, optionally intermixed with script-supporting elements[p152].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.

For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLDListElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

The dl[p245] element represents[p142] an association list consisting of zero or more name-value groups (a description list). A name-value group consists of one or more names (dt[p248] elements, possibly as children of a div[p257] element child) followed by one or more values (dd[p249] elements, possibly as children of a div[p257] element child), ignoring any nodes other than dt[p248] and dd[p249] element children, and dt[p248] and dd[p249] elements that are children of div[p257] element children. Within a single dl[p245] element, there should not be more than one dt[p248] element for each name.

Name-value groups may be terms and definitions, metadata topics and values, questions and answers, or any other groups of name-value data.

The values within a group are alternatives; multiple paragraphs forming part of the same value must all be given within the same dd[p249] element.

The order of the list of groups, and of the names and values within each group, may be significant.

In order to annotate groups with microdata[p796] attributes, or other global attributes[p155] that apply to whole groups, or just for styling purposes, each group in a dl[p245] element can be wrapped in a div[p257] element. This does not change the semantics of the dl[p245] element.

The name-value groups of a dl[p245] element *dl* are determined using the following algorithm. A name-value group has a name (a list of dt[p248] elements, initially empty) and a value (a list of dd[p249] elements, initially empty).

1. Let *groups* be an empty list of name-value groups.
2. Let *current* be a new name-value group.
3. Let *seenDd* be false.
4. Let *child* be *dl*'s first child.
5. Let *grandchild* be null.
6. While *child* is not null:
    1. If *child* is a div[p257] element, then:

1. Let *grandchild* be *child*'s first child.
2. While *grandchild* is not null:
    1. Process `dt` or `dd`[p246] for *grandchild*.
    2. Set *grandchild* to *grandchild*'s next sibling.

2. Otherwise, process `dt` or `dd`[p246] for *child*.
3. Set *child* to *child*'s next sibling.

7. If *current* is not empty, then append *current* to *groups*.
8. Return *groups*.

To **process `dt` or `dd`** for a node *node* means to follow these steps:

1. Let *groups*, *current*, and *seenDd* be the same variables as those of the same name in the algorithm that invoked these steps.
2. If *node* is a `dt`[p248] element, then:
    1. If *seenDd* is true, then append *current* to *groups*, set *current* to a new name-value group, and set *seenDd* to false.
    2. Append *node* to *current*'s name.
3. Otherwise, if *node* is a `dd`[p249] element, then append *node* to *current*'s value and set *seenDd* to true.

Note

When a name-value group has an empty list as name or value, it is often due to accidentally using `dd`[p249] elements in the place of `dt`[p248] elements and vice versa. Conformance checkers can spot such mistakes and might be able to advise authors how to correctly use the markup.

Example

In the following example, one entry ("Authors") is linked to two values ("John" and "Luke").

```
<dl>
 <dt> Authors
 <dd> John
 <dd> Luke
 <dt> Editor
 <dd> Frank
</dl>
```

Example

In the following example, one definition is linked to two terms.

```
<dl>
 <dt lang="en-US"> <dfn>color</dfn> </dt>
 <dt lang="en-GB"> <dfn>colour</dfn> </dt>
 <dd> A sensation which (in humans) derives from the ability of
 the fine structure of the eye to distinguish three differently
 filtered analyses of a view. </dd>
</dl>
```

Example

The following example illustrates the use of the `dl`[p245] element to mark up metadata of sorts. At the end of the example, one group has two metadata labels ("Authors" and "Editors") and two values ("Robert Rothman" and "Daniel Jackson"). This example also uses the `div`[p257] element around the groups of `dt`[p248] and `dd`[p249] element, to aid with styling.

```
<dl>
 <div>
```

```
  <dt> Last modified time </dt>
  <dd> 2004-12-23T23:33Z </dd>
 </div>
 <div>
  <dt> Recommended update interval </dt>
  <dd> 60s </dd>
 </div>
 <div>
  <dt> Authors </dt>
  <dt> Editors </dt>
  <dd> Robert Rothman </dd>
  <dd> Daniel Jackson </dd>
 </div>
</dl>
```

Example

The following example shows the dl[p245] element used to give a set of instructions. The order of the instructions here is important (in the other examples, the order of the blocks was not important).

```
<p>Determine the victory points as follows (use the
first matching case):</p>
<dl>
 <dt> If you have exactly five gold coins </dt>
 <dd> You get five victory points </dd>
 <dt> If you have one or more gold coins, and you have one or more silver coins </dt>
 <dd> You get two victory points </dd>
 <dt> If you have one or more silver coins </dt>
 <dd> You get one victory point </dd>
 <dt> Otherwise </dt>
 <dd> You get no victory points </dd>
</dl>
```

Example

The following snippet shows a dl[p245] element being used as a glossary. Note the use of dfn[p269] to indicate the word being defined.

```
<dl>
 <dt><dfn>Apartment</dfn>, n.</dt>
 <dd>An execution context grouping one or more threads with one or
 more COM objects.</dd>
 <dt><dfn>Flat</dfn>, n.</dt>
 <dd>A deflated tire.</dd>
 <dt><dfn>Home</dfn>, n.</dt>
 <dd>The user's login directory.</dd>
</dl>
```

Example

This example uses microdata[p796] attributes in a dl[p245] element, together with the div[p257] element, to annotate the ice cream desserts at a French restaurant.

```
<dl>
 <div itemscope itemtype="http://schema.org/Product">
  <dt itemprop="name">Café ou Chocolat Liégeois
  <dd itemprop="offers" itemscope itemtype="http://schema.org/Offer">
   <span itemprop="price">3.50</span>
   <data itemprop="priceCurrency" value="EUR">€</data>
  <dd itemprop="description">
```

```
   2 boules Café ou Chocolat, 1 boule Vanille, sauce café ou chocolat, chantilly
  </div>

  <div itemscope itemtype="http://schema.org/Product">
   <dt itemprop="name">Américaine
   <dd itemprop="offers" itemscope itemtype="http://schema.org/Offer">
    <span itemprop="price">3.50</span>
    <data itemprop="priceCurrency" value="EUR">€</data>
   <dd itemprop="description">
    1 boule Crème brûlée, 1 boule Vanille, 1 boule Caramel, chantilly
  </div>
 </dl>
```

Without the div[p257] element the markup would need to use the itemref[p802] attribute to link the data in the dd[p249] elements with the item, as follows.

```
<dl>
 <dt itemscope itemtype="http://schema.org/Product" itemref="1-offer 1-description">
  <span itemprop="name">Café ou Chocolat Liégeois</span>
 <dd id="1-offer" itemprop="offers" itemscope itemtype="http://schema.org/Offer">
  <span itemprop="price">3.50</span>
  <data itemprop="priceCurrency" value="EUR">€</data>
 <dd id="1-description" itemprop="description">
  2 boules Café ou Chocolat, 1 boule Vanille, sauce café ou chocolat, chantilly

 <dt itemscope itemtype="http://schema.org/Product" itemref="2-offer 2-description">
  <span itemprop="name">Américaine</span>
 <dd id="2-offer" itemprop="offers" itemscope itemtype="http://schema.org/Offer">
  <span itemprop="price">3.50</span>
  <data itemprop="priceCurrency" value="EUR">€</data>
 <dd id="2-description" itemprop="description">
  1 boule Crème brûlée, 1 boule Vanille, 1 boule Caramel, chantilly
</dl>
```

Note

The dl[p245] element is inappropriate for marking up dialogue. See some examples of how to mark up dialogue[p785].

4.4.10 The dt element §[p248]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

Before dd[p249] or dt[p248] elements inside dl[p245] elements.
Before dd[p249] or dt[p248] elements inside div[p257] elements that are children of a dl[p245] element.

Content model[p147]:

Flow content[p150], but with no header[p219], footer[p221], sectioning content[p150], or heading content[p151] descendants.

Tag omission in text/html[p148]:

A dt[p248] element's end tag[p1280] can be omitted if the dt[p248] element is immediately followed by another dt[p248] element or a dd[p249] element.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.

For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The dt[p248] element represents[p142] the term, or name, part of a term-description group in a description list (dl[p245] element).

Note

The dt[p248] element itself, when used in a dl[p245] element, does not indicate that its contents are a term being defined, but this can be indicated using the dfn[p269] element.

Example

This example shows a list of frequently asked questions (a FAQ) marked up using the dt[p248] element for questions and the dd[p249] element for answers.

```
<article>
 <h1>FAQ</h1>
 <dl>
  <dt>What do we want?</dt>
  <dd>Our data.</dd>
  <dt>When do we want it?</dt>
  <dd>Now.</dd>
  <dt>Where is it?</dt>
  <dd>We are not sure.</dd>
 </dl>
</article>
```

4.4.11 The dd element §[p249]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

After dt[p248] or dd[p249] elements inside dl[p245] elements.
After dt[p248] or dd[p249] elements inside div[p257] elements that are children of a dl[p245] element.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

A dd[p249] element's end tag[p1280] can be omitted if the dd[p249] element is immediately followed by another dd[p249] element or a dt[p248] element, or if there is no more content in the parent element.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The dd[p249] element represents[p142] the description, definition, or value, part of a term-description group in a description list (dl[p245] element).

Example

A dl[p245] can be used to define a vocabulary list, like in a dictionary. In the following example, each entry, given by a dt[p248] with a dfn[p269], has several dd[p249]s, showing the various parts of the definition.

```
<dl>
 <dt><dfn>happiness</dfn></dt>
 <dd class="pronunciation">/'hæpinəs/</dd>
 <dd class="part-of-speech"><i><abbr>n.</abbr></i></dd>
 <dd>The state of being happy.</dd>
 <dd>Good fortune; success. <q>Oh <b>happiness</b>! It worked!</q></dd>
 <dt><dfn>rejoice</dfn></dt>
 <dd class="pronunciation">/rɪ'dʒɔɪs/</dd>
 <dd><i class="part-of-speech"><abbr>v.intr.</abbr></i> To be delighted oneself.</dd>
 <dd><i class="part-of-speech"><abbr>v.tr.</abbr></i> To cause one to be delighted.</dd>
</dl>
```

4.4.12 The figure element §[p250]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Either: one figcaption[p253] element followed by flow content[p150].
Or: flow content[p150] followed by one figcaption[p253] element.
Or: flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The figure[p250] element represents[p142] some flow content[p150], optionally with a caption, that is self-contained (like a complete sentence) and is typically referenced[p142] as a single unit from the main flow of the document.

Note

"Self-contained" in this context does not necessarily mean independent. For example, each sentence in a paragraph is self-contained; an image that is part of a sentence would be inappropriate for figure[p250], but an entire sentence made of images would be fitting.

The element can thus be used to annotate illustrations, diagrams, photos, code listings, etc.

¶[p250] Note

When a figure[p250] is referred to from the main content of the document by identifying it by its caption (e.g., by figure number), it enables such content to be easily moved away from that primary content, e.g., to the side of the page, to dedicated pages, or to an appendix, without affecting the flow of the document.

If a figure[p250] element is referenced[p142] by its relative position, e.g., "in the photograph above" or "as the next figure shows", then moving the figure would disrupt the page's meaning. Authors are encouraged to consider using labels to refer to figures, rather than using such relative references, so that the page can easily be restyled without affecting the page's meaning.

The first figcaption[p253] element child of the element, if any, represents the caption of the figure[p250] element's contents. If there is no child figcaption[p253] element, then there is no caption.

A figure[p250] element's contents are part of the surrounding flow. If the purpose of the page is to display the figure, for example a photograph on an image sharing site, the figure[p250] and figcaption[p253] elements can be used to explicitly provide a caption for that figure. For content that is only tangentially related, or that serves a separate purpose than the surrounding flow, the aside[p215] element should be used (and can itself wrap a figure[p250]). For example, a pull quote that repeats content from an article[p207] would be more appropriate in an aside[p215] than in a figure[p250], because it isn't part of the content, it's a repetition of the content for the purposes of enticing readers or highlighting key topics.

Example

This example shows the figure[p250] element to mark up a code listing.

```
<p>In <a href="#l4">listing 4</a> we see the primary core interface
API declaration.</p>
<figure id="l4">
 <figcaption>Listing 4. The primary core interface API declaration.</figcaption>
 <pre><code>interface PrimaryCore {
 boolean verifyDataLine();
 undefined sendData(sequence&lt;byte> data);
 undefined initSelfDestruct();
}</code></pre>
</figure>
<p>The API is designed to use UTF-8.</p>
```

Example

Here we see a figure[p250] element to mark up a photo that is the main content of the page (as in a gallery).

```
<!DOCTYPE HTML>
<html lang="en">
<title>Bubbles at work — My Gallery™</title>
<figure>
 <img src="bubbles-work.jpeg"
      alt="Bubbles, sitting in his office chair, works on his
           latest project intently.">
 <figcaption>Bubbles at work</figcaption>
</figure>
<nav><a href="19414.html">Prev</a> — <a href="19416.html">Next</a></nav>
```

Example

In this example, we see an image that is *not* a figure, as well as an image and a video that are. The first image is literally part of the example's second sentence, so it's not a self-contained unit, and thus figure[p250] would be inappropriate.

```
<h2>Malinko's comics</h2>

<p>This case centered on some sort of "intellectual property"
infringement related to a comic (see Exhibit A). The suit started
after a trailer ending with these words:

<blockquote>
 <img src="promblem-packed-action.png" alt="ROUGH COPY! Promblem-Packed Action!">
</blockquote>

<p>...was aired. A lawyer, armed with a Bigger Notebook, launched a
preemptive strike using snowballs. A complete copy of the trailer is
included with Exhibit B.

<figure>
 <img src="ex-a.png" alt="Two squiggles on a dirty piece of paper.">
```

```
 <figcaption>Exhibit A. The alleged <cite>rough copy</cite> comic.</figcaption>
</figure>

<figure>
 <video src="ex-b.mov"></video>
 <figcaption>Exhibit B. The <cite>Rough Copy</cite> trailer.</figcaption>
</figure>

<p>The case was resolved out of court.
```

Example

Here, a part of a poem is marked up using figure[p250].

```
<figure>
 <p>'Twas brillig, and the slithy toves<br>
 Did gyre and gimble in the wabe;<br>
 All mimsy were the borogoves,<br>
 And the mome raths outgrabe.</p>
 <figcaption><cite>Jabberwocky</cite> (first verse). Lewis Carroll, 1832-98</figcaption>
</figure>
```

Example

In this example, which could be part of a much larger work discussing a castle, nested figure[p250] elements are used to provide both a group caption and individual captions for each figure in the group:

```
<figure>
 <figcaption>The castle through the ages: 1423, 1858, and 1999 respectively.</figcaption>
 <figure>
  <figcaption>Etching. Anonymous, ca. 1423.</figcaption>
  <img src="castle1423.jpeg" alt="The castle has one tower, and a tall wall around it.">
 </figure>
 <figure>
  <figcaption>Oil-based paint on canvas. Maria Towle, 1858.</figcaption>
  <img src="castle1858.jpeg" alt="The castle now has two towers and two walls.">
 </figure>
 <figure>
  <figcaption>Film photograph. Peter Jankle, 1999.</figcaption>
  <img src="castle1999.jpeg" alt="The castle lies in ruins, the original tower all that remains in
one piece.">
 </figure>
</figure>
```

Example

The previous example could also be more succinctly written as follows (using title[p158] attributes in place of the nested figure[p250]/figcaption[p253] pairs):

```
<figure>
 <img src="castle1423.jpeg" title="Etching. Anonymous, ca. 1423."
      alt="The castle has one tower, and a tall wall around it.">
 <img src="castle1858.jpeg" title="Oil-based paint on canvas. Maria Towle, 1858."
      alt="The castle now has two towers and two walls.">
 <img src="castle1999.jpeg" title="Film photograph. Peter Jankle, 1999."
      alt="The castle lies in ruins, the original tower all that remains in one piece.">
 <figcaption>The castle through the ages: 1423, 1858, and 1999 respectively.</figcaption>
</figure>
```

Example

The figure is sometimes referenced[p142] only implicitly from the content:

```
<article>
 <h1>Fiscal negotiations stumble in Congress as deadline nears</h1>
 <figure>
  <img src="obama-reid.jpeg" alt="Obama and Reid sit together smiling in the Oval Office.">
  <figcaption>Barack Obama and Harry Reid. White House press photograph.</figcaption>
 </figure>
 <p>Negotiations in Congress to end the fiscal impasse sputtered on Tuesday, leaving both chambers
 grasping for a way to reopen the government and raise the country's borrowing authority with a
 Thursday deadline drawing near.</p>
 ...
</article>
```

4.4.13 The figcaption element §[p253]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As the first or last child of a figure[p250] element.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The figcaption[p253] element represents[p142] a caption or legend for the rest of the contents of the figcaption[p253] element's parent figure[p250] element, if any.

Example

The element can contain additional information about the source:

```
<figcaption>
 <p>A duck.</p>
 <p><small>Photograph courtesy of ☆ News.</small></p>
</figcaption>
```

```
<figcaption>
 <p>Average rent for 3-room apartments, excluding non-profit apartments</p>
 <p>Zürich's Statistics Office — <time datetime=2017-11-14>14 November 2017</time></p>
</figcaption>
```

4.4.14 The main element

Categories:

Flow content.
Palpable content.

Contexts in which this element can be used:

Where flow content is expected, but only if it is a hierarchically correct main element.

Content model:

Flow content.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes

Accessibility considerations:

For authors.
For implementers.

DOM interface:

Uses HTMLElement.

The main element represents the dominant contents of the document.

A document must not have more than one main element that does not have the hidden attribute specified.

A **hierarchically correct main element** is one whose ancestor elements are limited to html, body, div, form without an accessible name, and autonomous custom elements. Each main element must be a hierarchically correct main element.

Example

In this example, the author has used a presentation where each component of the page is rendered in a box. To wrap the main content of the page (as opposed to the header, the footer, the navigation bar, and a sidebar), the main element is used.

```
<!DOCTYPE html>
<html lang="en">
<title>RPG System 17</title>
<style>
 header, nav, aside, main, footer {
   margin: 0.5em; border: thin solid; padding: 0.5em;
   background: #EFF; color: black; box-shadow: 0 0 0.25em #033;
 }
 h1, h2, p { margin: 0; }
 nav, main { float: left; }
 aside { float: right; }
 footer { clear: both; }
</style>
<header>
 <h1>System Eighteen</h1>
</header>
<nav>
 <a href="../16/">← System 17</a>
 <a href="../18/">RPXIX →</a>
</nav>
<aside>
 <p>This system has no HP mechanic, so there's no healing.
</aside>
<main>
 <h2>Character creation</h2>
 <p>Attributes (magic, strength, agility) are purchased at the cost of one point per level.</p>
 <h2>Rolls</h2>
```

```
 <p>Each encounter, roll the dice for all your skills. If you roll more than the opponent, you
win.</p>
</main>
<footer>
 <p>Copyright © 2013
</footer>
</html>
```

In the following example, multiple main[p254] elements are used and script is used to make navigation work without a server roundtrip and to set the hidden[p832] attribute on those that are not current:

```
<!doctype html>
<html lang=en-CA>
<meta charset=utf-8>
<title> … </title>
<link rel=stylesheet href=spa.css>
<script src=spa.js async></script>
<nav>
 <a href=/>Home</a>
 <a href=/about>About</a>
 <a href=/contact>Contact</a>
</nav>
<main>
 <h1>Home</h1>
 …
</main>
<main hidden>
 <h1>About</h1>
 …
</main>
<main hidden>
 <h1>Contact</h1>
 …
</main>
<footer>Made with ❤ by <a href=https://example.com/>Example 🐘</a>.</footer>
```

4.4.15 The search element §[p255]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The search[p255] element represents[p142] a part of a document or application that contains a set of form controls or other content related to performing a search or filtering operation. This could be a search of the web site or application; a way of searching or filtering search results on the current web page; or a global or Internet-wide search function.

Note

It's not appropriate to use the search[p255] element just for presenting search results, though suggestions and links as part of "quick search" results can be included as part of a search feature. Rather, a returned web page of search results would instead be expected to be presented as part of the main content of that web page.

Example

In the following example, the author is including a search form within the header[p219] of the web page:

```
<header>
  <h1><a href="/">My fancy blog</a></h1>
  ...
  <search>
    <form action="search.php">
      <label for="query">Find an article</label>
      <input id="query" name="q" type="search">
      <button type="submit">Go!</button>
    </form>
  </search>
</header>
```

Example

In this example, the author has implemented their web application's search functionality entirely with JavaScript. There is no use of the form[p515] element to perform server-side submission, but the containing search[p255] element semantically identifies the purpose of the descendant content as representing search capabilities.

```
<search>
  <label>
    Find and filter your query
    <input type="search" id="query">
  </label>
  <label>
    <input type="checkbox" id="exact-only">
    Exact matches only
  </label>

  <section>
    <h3>Results found:</h3>
    <ul id="results">
      <li>
        <p><a href="services/consulting">Consulting services</a></p>
        <p>
          Find out how can we help you improve your business with our integrated consultants, Bob
and Bob.
        </p>
      </li>
      ...
    </ul>
    <!--
      when a query returns or filters out all results
      render the no results message here
    -->
    <output id="no-results"></output>
```

```
  </section>
</search>
```

Example

In the following example, the page has two search features. The first is located in the web page's header[p219] and serves as a global mechanism to search the web site's content. Its purpose is indicated by its specified title[p175] attribute. The second is included as part of the main content of the page, as it represents a mechanism to search and filter the content of the current page. It contains a heading to indicate its purpose.

```
<body>
  <header>
    ...
    <search title="Website">
      ...
    </search>
  </header>
  <main>
    <h1>Hotels near your location</h1>
     <search>
       <h2>Filter results</h2>
       ...
     </search>
     <article>

```

4.4.16 The div element §[p257]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.
As a child of a dl[p245] element.

Content model[p147]:

If the element is a child of a dl[p245] element: one or more dt[p248] elements followed by one or more dd[p249] elements, optionally intermixed with script-supporting elements[p152].
If the element is not a child of a dl[p245] element: flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLDivElement : HTMLElement {
  [HTMLConstructor] constructor();
```

```
  // also has obsolete members
};
```

The div[p257] element has no special meaning at all. It represents[p142] its children. It can be used with the class[p156], lang[p159], and title[p158] attributes to mark up semantics common to a group of consecutive elements. It can also be used in a dl[p245] element, wrapping groups of dt[p248] and dd[p249] elements.

Note

Authors are strongly encouraged to view the div[p257] element as an element of last resort, for when no other element is suitable. Use of more appropriate elements instead of the div[p257] element leads to better accessibility for readers and easier maintainability for authors.

Example

For example, a blog post would be marked up using article[p207], a chapter using section[p210], a page's navigation aids using nav[p212], and a group of form controls using fieldset[p597].

On the other hand, div[p257] elements can be useful for stylistic purposes or to wrap multiple paragraphs within a section that are all to be annotated in a similar way. In the following example, we see div[p257] elements used as a way to set the language of two paragraphs at once, instead of setting the language on the two paragraph elements separately:

```
<article lang="en-US">
 <h1>My use of language and my cats</h1>
 <p>My cat's behavior hasn't changed much since her absence, except
 that she plays her new physique to the neighbors regularly, in an
 attempt to get pets.</p>
 <div lang="en-GB">
  <p>My other cat, coloured black and white, is a sweetie. He followed
  us to the pool today, walking down the pavement with us. Yesterday
  he apparently visited our neighbours. I wonder if he recognises that
  their flat is a mirror image of ours.</p>
  <p>Hm, I just noticed that in the last paragraph I used British
  English. But I'm supposed to write in American English. So I
  shouldn't say "pavement" or "flat" or "colour"...</p>
 </div>
 <p>I should say "sidewalk" and "apartment" and "color"!</p>
</article>
```

4.5 Text-level semantics §[p258]

4.5.1 The a element §[p258]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
If the element has an href[p304] attribute: Interactive content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Transparent[p152], but there must be no interactive content[p151] descendant, a[p258] element descendant, or descendant with the tabindex[p847] attribute specified.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
href[p304] — Address of the hyperlink[p303]
target[p304] — Navigable[p1001] for hyperlink[p303] navigation[p1028]
download[p304] — Whether to download the resource instead of navigating to it, and its filename if so
ping[p304] — URLs to ping
rel[p304] — Relationship between the location in the document containing the hyperlink[p303] and the destination resource
hreflang[p304] — Language of the linked resource
type[p304] — Hint for the type of the referenced resource
referrerpolicy[p304] — Referrer policy for fetches initiated by the element

Accessibility considerations[p148]:

If the element has an href[p304] attribute: for authors; for implementers.
Otherwise: for authors; for implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLAnchorElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString target;
  [CEReactions] attribute DOMString download;
  [CEReactions] attribute USVString ping;
  [CEReactions] attribute DOMString rel;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList relList;
  [CEReactions] attribute DOMString hreflang;
  [CEReactions] attribute DOMString type;

  [CEReactions] attribute DOMString text;

  [CEReactions] attribute DOMString referrerPolicy;

  // also has obsolete members
};
HTMLAnchorElement includes HTMLHyperlinkElementUtils;
```

If the a[p258] element has an href[p304] attribute, then it represents[p142] a hyperlink[p303] (a hypertext anchor) labeled by its contents.

If the a[p258] element has no href[p304] attribute, then the element represents[p142] a placeholder for where a link might otherwise have been placed, if it had been relevant, consisting of just the element's contents.

The target[p304], download[p304], ping[p304], rel[p304], hreflang[p304], type[p304], and referrerpolicy[p304] attributes must be omitted if the href[p304] attribute is not present.

If the itemprop[p803] attribute is specified on an a[p258] element, then the href[p304] attribute must also be specified.

Example

If a site uses a consistent navigation toolbar on every page, then the link that would normally link to the page itself could be marked up using an a[p258] element:

```
<nav>
 <ul>
  <li> <a href="/">Home</a> </li>
  <li> <a href="/news">News</a> </li>
  <li> <a>Examples</a> </li>
  <li> <a href="/legal">Legal</a> </li>
 </ul>
</nav>
```

The href[p304], target[p304], download[p304], ping[p304], and referrerpolicy[p304] attributes affect what happens when users follow

hyperlinks[p310] or download hyperlinks[p311] created using the a[p258] element. The rel[p304], hreflang[p304], and type[p304] attributes may be used to indicate to the user the likely nature of the target resource before the user follows the link.

For web developers (non-normative)

***a*.text[p260]**

Same as textContent.

The IDL attributes **download**, **ping**, **target**, **rel**, **hreflang**, and **type**, must reflect[p105] the respective content attributes of the same name.

The IDL attribute **relList** must reflect[p105] the rel[p304] content attribute.

The IDL attribute **referrerPolicy** must reflect[p105] the referrerpolicy[p304] content attribute, limited to only known values[p106].

The **text** attribute's getter must return this element's descendant text content.

The text[p260] attribute's setter must string replace all with the given value within this element.

Example

The a[p258] element can be wrapped around entire paragraphs, lists, tables, and so forth, even entire sections, so long as there is no interactive content within (e.g., buttons or other links). This example shows how this can be used to make an entire advertising block into a link:

```
<aside class="advertising">
 <h1>Advertising</h1>
 <a href="https://ad.example.com/?adid=1929&amp;pubid=1422">
  <section>
   <h1>Mellblomatic 9000!</h1>
   <p>Turn all your widgets into mellbloms!</p>
   <p>Only $9.99 plus shipping and handling.</p>
  </section>
 </a>
 <a href="https://ad.example.com/?adid=375&amp;pubid=1422">
  <section>
   <h1>The Mellblom Browser</h1>
   <p>Web browsing at the speed of light.</p>
   <p>No other browser goes faster!</p>
  </section>
 </a>
</aside>
```

Example

The following example shows how a bit of script can be used to effectively make an entire row in a job listing table a hyperlink:

```
<table>
 <tr>
  <th>Position
  <th>Team
  <th>Location
 <tr>
  <td><a href="/jobs/manager">Manager</a>
  <td>Remotees
  <td>Remote
 <tr>
  <td><a href="/jobs/director">Director</a>
  <td>Remotees
  <td>Remote
 <tr>
  <td><a href="/jobs/astronaut">Astronaut</a>
  <td>Architecture
```

```
  <td>Remote
</table>
<script>
document.querySelector("table").onclick = ({ target }) => {
  if (target.parentElement.localName === "tr") {
    const link = target.parentElement.querySelector("a");
    if (link) {
      link.click();
    }
  }
}
</script>
```

4.5.2 The em element §[p26]1

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The em[p261] element represents[p142] stress emphasis of its contents.

The level of stress that a particular piece of content has is given by its number of ancestor em[p261] elements.

The placement of stress emphasis changes the meaning of the sentence. The element thus forms an integral part of the content. The precise way in which stress is used in this way depends on the language.

Example

These examples show how changing the stress emphasis changes the meaning. First, a general statement of fact, with no stress:

```
<p>Cats are cute animals.</p>
```

By emphasizing the first word, the statement implies that the kind of animal under discussion is in question (maybe someone is asserting that dogs are cute):

```
<p><em>Cats</em> are cute animals.</p>
```

Moving the stress to the verb, one highlights that the truth of the entire sentence is in question (maybe someone is saying cats are not cute):

```
<p>Cats <em>are</em> cute animals.</p>
```

By moving it to the adjective, the exact nature of the cats is reasserted (maybe someone suggested cats were *mean* animals):

```
<p>Cats are <em>cute</em> animals.</p>
```

Similarly, if someone asserted that cats were vegetables, someone correcting this might emphasize the last word:

```
<p>Cats are cute <em>animals</em>.</p>
```

By emphasizing the entire sentence, it becomes clear that the speaker is fighting hard to get the point across. This kind of stress emphasis also typically affects the punctuation, hence the exclamation mark here.

```
<p><em>Cats are cute animals!</em></p>
```

Anger mixed with emphasizing the cuteness could lead to markup such as:

```
<p><em>Cats are <em>cute</em> animals!</em></p>
```

Note

The em[p261] element isn't a generic "italics" element. Sometimes, text is intended to stand out from the rest of the paragraph, as if it was in a different mood or voice. For this, the i[p292] element is more appropriate.

The em[p261] element also isn't intended to convey importance; for that purpose, the strong[p262] element is more appropriate.

MDN

4.5.3 The strong element §[p262]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The strong[p262] element represents[p142] strong importance, seriousness, or urgency for its contents.

Importance: the strong[p262] element can be used in a heading, caption, or paragraph to distinguish the part that really matters from other parts that might be more detailed, more jovial, or merely boilerplate. (This is distinct from marking up subheadings, for which the hgroup[p219] element is appropriate.)

Example

For example, the first word of the previous paragraph is marked up with strong[p262] to distinguish it from the more detailed text in the rest of the paragraph.

Seriousness: the strong[p262] element can be used to mark up a warning or caution notice.

Urgency: the strong[p262] element can be used to denote contents that the user needs to see sooner than other parts of the document.

The relative level of importance of a piece of content is given by its number of ancestor strong[p262] elements; each strong[p262] element increases the importance of its contents.

Changing the importance of a piece of text with the strong[p262] element does not change the meaning of the sentence.

Example

Here, the word "chapter" and the actual chapter number are mere boilerplate, and the actual name of the chapter is marked up with strong[p262]:

```
<h1>Chapter 1: <strong>The Praxis</strong></h1>
```

In the following example, the name of the diagram in the caption is marked up with strong[p262], to distinguish it from boilerplate text (before) and the description (after):

```
<figcaption>Figure 1. <strong>Ant colony dynamics</strong>. The ants in this colony are
affected by the heat source (upper left) and the food source (lower right).</figcaption>
```

In this example, the heading is really "Flowers, Bees, and Honey", but the author has added a light-hearted addition to the heading. The strong[p262] element is thus used to mark up the first part to distinguish it from the latter part.

```
<h1><strong>Flowers, Bees, and Honey</strong> and other things I don't understand</h1>
```

Example

Here is an example of a warning notice in a game, with the various parts marked up according to how important they are:

```
<p><strong>Warning.</strong> This dungeon is dangerous.
<strong>Avoid the ducks.</strong> Take any gold you find.
<strong><strong>Do not take any of the diamonds</strong>,
they are explosive and <strong>will destroy anything within
ten meters.</strong></strong> You have been warned.</p>
```

Example

In this example, the strong[p262] element is used to denote the part of the text that the user is intended to read first.

```
<p>Welcome to Remy, the reminder system.</p>
<p>Your tasks for today:</p>
<ul>
 <li><p><strong>Turn off the oven.</strong></p></li>
 <li><p>Put out the trash.</p></li>
 <li><p>Do the laundry.</p></li>
</ul>
```

4.5.4 The small element §[p263]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].

Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses `HTMLElement`[p143].

The `small`[p263] element represents[p142] side comments such as small print.

Note

Small print typically features disclaimers, caveats, legal restrictions, or copyrights. Small print is also sometimes used for attribution, or for satisfying licensing requirements.

Note

The `small`[p263] element does not "de-emphasize" or lower the importance of text emphasized by the `em`[p261] element or marked as important with the `strong`[p262] element. To mark text as not emphasized or important, simply do not mark it up with the `em`[p261] or `strong`[p262] elements respectively.

The `small`[p263] element should not be used for extended spans of text, such as multiple paragraphs, lists, or sections of text. It is only intended for short runs of text. The text of a page listing terms of use, for instance, would not be a suitable candidate for the `small`[p263] element: in such a case, the text is not a side comment, it is the main content of the page.

The `small`[p263] element must not be used for subheadings; for that purpose, use the `hgroup`[p219] element.

Example

In this example, the `small`[p263] element is used to indicate that value-added tax is not included in a price of a hotel room:

Example

```
<dl>
 <dt>Single room
 <dd>199 € <small>breakfast included, VAT not included</small>
 <dt>Double room
 <dd>239 € <small>breakfast included, VAT not included</small>
</dl>
```

Example

In this second example, the `small`[p263] element is used for a side comment in an article.

```
<p>Example Corp today announced record profits for the
second quarter <small>(Full Disclosure: Foo News is a subsidiary of
Example Corp)</small>, leading to speculation about a third quarter
merger with Demo Group.</p>
```

This is distinct from a sidebar, which might be multiple paragraphs long and is removed from the main flow of text. In the following example, we see a sidebar from the same article. This sidebar also has small print, indicating the source of the information in the

sidebar.

```
<aside>
 <h1>Example Corp</h1>
 <p>This company mostly creates small software and Web
 sites.</p>
 <p>The Example Corp company mission is "To provide entertainment
 and news on a sample basis".</p>
 <p><small>Information obtained from <a
 href="https://example.com/about.html">example.com</a> home
 page.</small></p>
</aside>
```

Example

In this last example, the small[p263] element is marked as being *important* small print.

```
<p><strong><small>Continued use of this service will result in a kiss.</small></strong></p>
```

4.5.5 The s element §[p265]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The s[p265] element represents[p142] contents that are no longer accurate or no longer relevant.

Note

The s[p265] element is not appropriate when indicating document edits; to mark a span of text as having been removed from a document, use the del[p339] element.

Example

In this example a recommended retail price has been marked as no longer relevant as the product in question has a new sale price.

```
<p>Buy our Iced Tea and Lemonade!</p>
<p><s>Recommended retail price: $3.99 per bottle</s></p>
```

```
<p><strong>Now selling for just $2.99 a bottle!</strong></p>
```

4.5.6 The cite element §[p266]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The cite[p266] element represents[p142] the title of a work (e.g. a book, a paper, an essay, a poem, a score, a song, a script, a film, a TV show, a game, a sculpture, a painting, a theatre production, a play, an opera, a musical, an exhibition, a legal case report, a computer program, etc.). This can be a work that is being quoted or referenced[p142] in detail (i.e., a citation), or it can just be a work that is mentioned in passing.

A person's name is not the title of a work — even if people call that person a piece of work — and the element must therefore not be used to mark up people's names. (In some cases, the b[p293] element might be appropriate for names; e.g. in a gossip article where the names of famous people are keywords rendered with a different style to draw attention to them. In other cases, if an element is *really* needed, the span[p299] element can be used.)

Example

This next example shows a typical use of the cite[p266] element:

```
<p>My favorite book is <cite>The Reality Dysfunction</cite> by
Peter F. Hamilton. My favorite comic is <cite>Pearls Before
Swine</cite> by Stephan Pastis. My favorite track is <cite>Jive
Samba</cite> by the Cannonball Adderley Sextet.</p>
```

Example

This is correct usage:

```
<p>According to the Wikipedia article <cite>HTML</cite>, as it
stood in mid-February 2008, leaving attribute values unquoted is
unsafe. This is obviously an over-simplification.</p>
```

The following, however, is incorrect usage, as the cite[p266] element here is containing far more than the title of the work:

```
<!-- do not copy this example, it is an example of bad usage! -->
<p>According to <cite>the Wikipedia article on HTML</cite>, as it
```

```
stood in mid-February 2008, leaving attribute values unquoted is
unsafe. This is obviously an over-simplification.</p>
```

Example

The cite[p266] element is a key part of any citation in a bibliography, but it is only used to mark the title:

```
<p><cite>Universal Declaration of Human Rights</cite>, United Nations,
December 1948. Adopted by General Assembly resolution 217 A (III).</p>
```

Note

A citation *is not a* quote *(for which the* q[p267] *element is appropriate).*

Example

This is incorrect usage, because cite[p266] is not for quotes:

```
<p><cite>This is wrong!</cite>, said Ian.</p>
```

This is also incorrect usage, because a person is not a work:

```
<p><q>This is still wrong!</q>, said <cite>Ian</cite>.</p>
```

The correct usage does not use a cite[p266] element:

```
<p><q>This is correct</q>, said Ian.</p>
```

As mentioned above, the b[p293] element might be relevant for marking names as being keywords in certain kinds of documents:

```
<p>And then <b>Ian</b> said <q>this might be right, in a
gossip column, maybe!</q>.</p>
```

4.5.7 The q element §[p267]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
cite[p268] — Link to the source of the quotation or more information about the edit

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLQuoteElement[p236].

The q[p267] element represents[p142] some phrasing content[p151] quoted from another source.

Quotation punctuation (such as quotation marks) that is quoting the contents of the element must not appear immediately before, after, or inside q[p267] elements; they will be inserted into the rendering by the user agent.

Content inside a q[p267] element must be quoted from another source, whose address, if it has one, may be cited in the **cite** attribute. The source may be fictional, as when quoting characters in a novel or screenplay.

If the cite[p268] attribute is present, it must be a valid URL potentially surrounded by spaces[p97]. To obtain the corresponding citation link, the value of the attribute must be parsed[p98] relative to the element's node document. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g., by server-side scripts collecting statistics about a site's use of quotations), not for readers.

The q[p267] element must not be used in place of quotation marks that do not represent quotes; for example, it is inappropriate to use the q[p267] element for marking up sarcastic statements.

The use of q[p267] elements to mark up quotations is entirely optional; using explicit quotation punctuation without q[p267] elements is just as correct.

Example

Here is a simple example of the use of the q[p267] element:

```
<p>The man said <q>Things that are impossible just take
longer</q>. I disagreed with him.</p>
```

Example

Here is an example with both an explicit citation link in the q[p267] element, and an explicit citation outside:

```
<p>The W3C page <cite>About W3C</cite> says the W3C's
mission is <q cite="https://www.w3.org/Consortium/">To lead the
World Wide Web to its full potential by developing protocols and
guidelines that ensure long-term growth for the Web</q>. I
disagree with this mission.</p>
```

Example

In the following example, the quotation itself contains a quotation:

```
<p>In <cite>Example One</cite>, he writes <q>The man
said <q>Things that are impossible just take longer</q>. I
disagreed with him</q>. Well, I disagree even more!</p>
```

Example

In the following example, quotation marks are used instead of the q[p267] element:

```
<p>His best argument was “I disagree”, which
I thought was laughable.</p>
```

Example

In the following example, there is no quote — the quotation marks are used to name a word. Use of the q[p267] element in this case would be inappropriate.

```
<p>The word "ineffable" could have been used to describe the disaster
resulting from the campaign's mismanagement.</p>
```

4.5.8 The dfn element §[p269]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151], but there must be no dfn[p269] element descendants.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
Also, the title[p269] attribute has special semantics[p269] on this element: Full term or expansion of abbreviation

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The dfn[p269] element represents[p142] the defining instance of a term. The paragraph[p153], description list group[p245], or section[p150] that is the nearest ancestor of the dfn[p269] element must also contain the definition(s) for the term[p269] given by the dfn[p269] element.

Defining term: if the dfn[p269] element has a **title** attribute, then the exact value of that attribute is the term being defined. Otherwise, if it contains exactly one element child node and no child Text nodes, and that child element is an abbr[p270] element with a title[p270] attribute, then the exact value of *that* attribute is the term being defined. Otherwise, it is the descendant text content of the dfn[p269] element that gives the term being defined.

If the title[p269] attribute of the dfn[p269] element is present, then it must contain only the term being defined.

Note

The title[p158] attribute of ancestor elements does not affect dfn[p269] elements.

An a[p258] element that links to a dfn[p269] element represents an instance of the term defined by the dfn[p269] element.

Example

In the following fragment, the term "Garage Door Opener" is first defined in the first paragraph, then used in the second. In both cases, its abbreviation is what is actually displayed.

```
<p>The <dfn><abbr title="Garage Door Opener">GDO</abr></dfn>
is a device that allows off-world teams to open the iris.</p>
<!-- ... later in the document: -->
<p>Teal'c activated his <abbr title="Garage Door Opener">GDO</abr>
and so Hammond ordered the iris to be opened.</p>
```

With the addition of an a[p258] element, the reference[p142] can be made explicit:

```
<p>The <dfn id=gdo><abbr title="Garage Door Opener">GDO</abr></dfn>
is a device that allows off-world teams to open the iris.</p>
<!-- ... later in the document: -->
<p>Teal'c activated his <a href=#gdo><abbr title="Garage Door Opener">GDO</abr></a>
and so Hammond ordered the iris to be opened.</p>
```

4.5.9 The abbr element §[p270]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
Also, the title[p270] attribute has special semantics[p270] on this element: Full term or expansion of abbreviation

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The abbr[p270] element represents[p142] an abbreviation or acronym, optionally with its expansion. The **title** attribute may be used to provide an expansion of the abbreviation. The attribute, if specified, must contain an expansion of the abbreviation, and nothing else.

Example

The paragraph below contains an abbreviation marked up with the abbr[p270] element. This paragraph defines the term[p269] "Web Hypertext Application Technology Working Group".

```
<p>The <dfn id=whatwg><abbr
title="Web Hypertext Application Technology Working Group">WHATWG</abbr></dfn>
is a loose unofficial collaboration of web browser manufacturers and
interested parties who wish to develop new technologies designed to
allow authors to write and deploy Applications over the World Wide
Web.</p>
```

An alternative way to write this would be:

```
<p>The <dfn id=whatwg>Web Hypertext Application Technology
Working Group</dfn> (<abbr
title="Web Hypertext Application Technology Working Group">WHATWG</abbr>)
is a loose unofficial collaboration of web browser manufacturers and
interested parties who wish to develop new technologies designed to
allow authors to write and deploy Applications over the World Wide
Web.</p>
```

Example

This paragraph has two abbreviations. Notice how only one is defined; the other, with no expansion associated with it, does not use the abbr[p270] element.

```
<p>The
<abbr title="Web Hypertext Application Technology Working Group">WHATWG</abbr>
started working on HTML5 in 2004.</p>
```

Example

This paragraph links an abbreviation to its definition.

```
<p>The <a href="#whatwg"><abbr
title="Web Hypertext Application Technology Working Group">WHATWG</abbr></a>
community does not have much representation from Asia.</p>
```

Example

This paragraph marks up an abbreviation without giving an expansion, possibly as a hook to apply styles for abbreviations (e.g. smallcaps).

```
<p>Philip` and Dashiva both denied that they were going to
get the issue counts from past revisions of the specification to
backfill the <abbr>WHATWG</abbr> issue graph.</p>
```

If an abbreviation is pluralized, the expansion's grammatical number (plural vs singular) must match the grammatical number of the contents of the element.

Example

Here the plural is outside the element, so the expansion is in the singular:

```
<p>Two <abbr title="Working Group">WG</abbr>s worked on
this specification: the <abbr>WHATWG</abbr> and the
<abbr>HTMLWG</abbr>.</p>
```

Here the plural is inside the element, so the expansion is in the plural:

```
<p>Two <abbr title="Working Groups">WGs</abbr> worked on
this specification: the <abbr>WHATWG</abbr> and the
<abbr>HTMLWG</abbr>.</p>
```

Abbreviations do not have to be marked up using this element. It is expected to be useful in the following cases:

- Abbreviations for which the author wants to give expansions, where using the abbr[p270] element with a title[p158] attribute is an alternative to including the expansion inline (e.g. in parentheses).
- Abbreviations that are likely to be unfamiliar to the document's readers, for which authors are encouraged to either mark up the abbreviation using an abbr[p270] element with a title[p158] attribute or include the expansion inline in the text the first time the abbreviation is used.
- Abbreviations whose presence needs to be semantically annotated, e.g. so that they can be identified from a style sheet and given specific styles, for which the abbr[p270] element can be used without a title[p158] attribute.

Note

Providing an expansion in a title[p158] attribute once will not necessarily cause other abbr[p270] elements in the same document with the same contents but without a title[p158] attribute to behave as if they had the same expansion. Every abbr[p270] element is independent.

4.5.10 The ruby element §[p271]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

See prose.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses `HTMLElement`[p143].

The `ruby`[p271] element allows one or more spans of phrasing content to be marked with ruby annotations. Ruby annotations are short runs of text presented alongside base text, primarily used in East Asian typography as a guide for pronunciation or to include other annotations. In Japanese, this form of typography is also known as *furigana*.

The content model of `ruby`[p271] elements consists of one or more of the following sequences:

1. One or the other of the following:
   - Phrasing content[p151], but with no `ruby`[p271] elements and with no `ruby`[p271] element descendants
   - A single `ruby`[p271] element that itself has no `ruby`[p271] element descendants
2. One or the other of the following:
   - One or more `rt`[p278] elements
   - An `rp`[p278] element followed by one or more `rt`[p278] elements, each of which is itself followed by an `rp`[p278] element

The `ruby`[p271] and `rt`[p278] elements can be used for a variety of kinds of annotations, including in particular (though by no means limited to) those described below. For more details on Japanese Ruby in particular, and how to render Ruby for Japanese, see *Requirements for Japanese Text Layout*. [JLREQ][p1497]

Note

At the time of writing, CSS does not yet provide a way to fully control the rendering of the HTML `ruby`[p271] element. It is hoped that CSS will be extended to support the styles described below in due course.

Mono-ruby for individual base characters in Japanese

One or more hiragana or katakana characters (the ruby annotation) are placed with each ideographic character (the base text). This is used to provide readings of kanji characters.

Example

```
<ruby>B<rt>annotation</ruby>
```

Example

In this example, notice how each annotation corresponds to a single base character.

```
<ruby>君<rt>くん</ruby><ruby>子<rt>し</ruby>は<ruby>和<rt>わ</ruby>して<ruby>同<rt>どう</ruby>ぜず。
```

君くん子しは和わして同どうぜず。

This example can also be written as follows, using one `ruby`[p271] element with two segments of base text and two annotations (one for each) rather than two back-to-back `ruby`[p271] elements each with one base text segment and annotation (as in the markup above):

```
<ruby>君<rt>くん</rt>子<rt>し</ruby>は<ruby>和<rt>わ</ruby>して<ruby>同<rt>どう</ruby>ぜず。
```

Mono-ruby for compound words (jukugo)

This is similar to the previous case: each ideographic character in the compound word (the base text) has its reading given in hiragana or katakana characters (the ruby annotation). The difference is that the base text segments form a compound word rather than being separate from each other.

Example

```
<ruby>B<rt>annotation</rt>B<rt>annotation</ruby>
```

Example

In this example, notice again how each annotation corresponds to a single base character. In this example, each compound word (jukugo) corresponds to a single ruby[p271] element.

The rendering here is expected to be that each annotation be placed over (or next to, in vertical text) the corresponding base character, with the annotations not overhanging any of the adjacent characters.

```
<ruby>鬼<rt>き</rt>門<rt>もん</rt></ruby>の<ruby>方<rt>ほう</rt>角<rt>がく</rt></ruby>を<ruby>凝<rt>ぎょう</rt>視<rt>し</rt></ruby>する
```

鬼き門もんの方ほう角がくを凝ぎょう視しする

Jukugo-ruby

This is semantically identical to the previous case (each individual ideographic character in the base compound word has its reading given in an annotation in hiragana or katakana characters), but the rendering is the more complicated Jukugo Ruby rendering.

Example

This is the same example as above for mono-ruby for compound words. The different rendering is expected to be achieved using different styling (e.g. in CSS), and is not shown here.

```
<ruby>鬼<rt>き</rt>門<rt>もん</rt></ruby>の<ruby>方<rt>ほう</rt>角<rt>がく</rt></ruby>を<ruby>凝<rt>ぎょう</rt>視<rt>し</rt></ruby>する
```

Note

For more details on Jukugo Ruby rendering, see Appendix F in the Requirements for Japanese Text Layout. *[JLREQ][p1497]*

Group ruby for describing meanings

The annotation describes the meaning of the base text, rather than (or in addition to) the pronunciation. As such, both the base text and the annotation can be multiple characters long.

Example

```
<ruby>BASE<rt>annotation</ruby>
```

Example

Here a compound ideographic word has its corresponding katakana given as an annotation.

```
<ruby>境界面<rt>インターフェース</ruby>
```

境界面インターフェース

Example

Here a compound ideographic word has its translation in English provided as an annotation.

```
<ruby lang="ja">編集者<rt lang="en">editor</ruby>
```

編集者editor

Group ruby for Jukuji readings

A phonetic reading that corresponds to multiple base characters, because a one-to-one mapping would be difficult. (In English, the words "Colonel" and "Lieutenant" are examples of words where a direct mapping of pronunciation to individual letters is, in some dialects, rather unclear.)

Example

In this example, the name of a species of flowers has a phonetic reading provided using group ruby:

```
<ruby>紫陽花<rt>あじさい</ruby>
```

紫陽花あじさい

Text with both phonetic and semantic annotations (double-sided ruby)

Sometimes, ruby styles described above are combined.

If this results in two annotations covering the same single base segment, then the annotations can just be placed back to back.

Example

```
<ruby>BASE<rt>annotation 1<rt>annotation 2</ruby>
```

Example

```
<ruby>B<rt>a<rt>a</ruby><ruby>A<rt>a<rt>a</ruby><ruby>S<rt>a<rt>a</ruby><ruby>E<rt>a<rt>a</ruby>
```

Example

In this contrived example, some symbols are given names in English and French.

```
<ruby>
 ♥ <rt> Heart <rt lang=fr> Cœur </rt>
 ☘ <rt> Shamrock <rt lang=fr> Trèfle </rt>
 ✶ <rt> Star <rt lang=fr> Étoile </rt>
</ruby>
```

In more complicated situations such as the following examples, a nested ruby[p271] element is used to give the inner annotations, and then that whole ruby[p271] is then given an annotation at the "outer" level.

Example

```
<ruby><ruby>B<rt>a</rt>A<rt>n</rt>S<rt>t</rt>E<rt>n</rt></ruby><rt>annotation</ruby>
```

Example

Here both a phonetic reading and the meaning are given in ruby annotations. The annotation on the nested ruby[p271] element gives a mono-ruby phonetic annotation for each base character, while the annotation in the rt[p278] element that is a child of the outer ruby[p271] element gives the meaning using hiragana.

```
<ruby><ruby>東<rt>とう</rt>南<rt>なん</rt></ruby><rt>たつみ</rt></ruby>の方角
```

東とう南なんたつみの方角

Example

This is the same example, but the meaning is given in English instead of Japanese:

```
<ruby><ruby>東<rt>とう</rt>南<rt>なん</rt></ruby><rt lang=en>Southeast</rt></ruby>の方角
```

東とう南なんSoutheastの方角

Within a ruby element that does not have a ruby element ancestor, content is segmented and segments are placed into three categories: base text segments, annotation segments, and ignored segments. Ignored segments do not form part of the document's semantics (they consist of some inter-element whitespace and rp elements, the latter of which are used for legacy user agents that do not support ruby at all). Base text segments can overlap (with a limit of two segments overlapping any one position in the DOM, and with any segment having an earlier start point than an overlapping segment also having an equal or later end point, and any segment have a later end point than an overlapping segment also having an equal or earlier start point). Annotation segments correspond to rt elements. Each annotation segment can be associated with a base text segment, and each base text segment can have annotation segments associated with it. (In a conforming document, each base text segment is associated with at least one annotation segment, and each annotation segment is associated with one base text segment.) A ruby element represents the union of the segments of base text it contains, along with the mapping from those base text segments to annotation segments. Segments are described in terms of DOM ranges; annotation segment ranges always consist of exactly one element. [DOM]

At any particular time, the segmentation and categorization of content of a ruby element is the result that would be obtained from running the following algorithm:

1. Let *base text segments* be an empty list of base text segments, each potentially with a list of base text subsegments.
2. Let *annotation segments* be an empty list of annotation segments, each potentially being associated with a base text segment or subsegment.
3. Let *root* be the ruby element for which the algorithm is being run.
4. If *root* has a ruby element ancestor, then jump to the step labeled *end*.
5. Let *current parent* be *root*.
6. Let *index* be 0.
7. Let *start index* be null.
8. Let *saved start index* be null.
9. Let *current base text* be null.
10. *Start mode*: If *index* is greater than or equal to the number of child nodes in *current parent*, then jump to the step labeled *end mode*.
11. If the *index*th node in *current parent* is an rt or rp element, jump to the step labeled *annotation mode*.
12. Set *start index* to the value of *index*.
13. *Base mode*: If the *index*th node in *current parent* is a ruby element, and if *current parent* is the same element as *root*, then push a ruby level and then jump to the step labeled *start mode*.
14. If the *index*th node in *current parent* is an rt or rp element, then set the current base text and then jump to the step labeled *annotation mode*.
15. Increment *index* by one.
16. *Base mode post-increment*: If *index* is greater than or equal to the number of child nodes in *current parent*, then jump to the step labeled *end mode*.
17. Jump back to the step labeled *base mode*.
18. *Annotation mode*: If the *index*th node in *current parent* is an rt element, then push a ruby annotation and jump to the step labeled *annotation mode increment*.
19. If the *index*th node in *current parent* is an rp element, jump to the step labeled *annotation mode increment*.
20. If the *index*th node in *current parent* is not a Text node, or is a Text node that is not inter-element whitespace, then jump

to the step labeled *base mode*.

21. *Annotation mode increment*: Let *lookahead index* be *index* plus one.
22. *Annotation mode white-space skipper*: If *lookahead index* is equal to the number of child nodes in *current parent* then jump to the step labeled *end mode*.
23. If the *lookahead index*th node in *current parent* is an `rt`[p278] element or an `rp`[p278] element, then set *index* to *lookahead index* and jump to the step labeled *annotation mode*.
24. If the *lookahead index*th node in *current parent* is not a `Text` node, or is a `Text` node that is not inter-element whitespace[p148], then jump to the step labeled *base mode* (without further incrementing *index*, so the inter-element whitespace[p148] seen so far becomes part of the next base text segment).
25. Increment *lookahead index* by one.
26. Jump to the step labeled *annotation mode white-space skipper*.
27. *End mode*: If *current parent* is not the same element as *root*, then pop a ruby level[p276] and jump to the step labeled *base mode post-increment*.
28. *End*: Return *base text segments* and *annotation segments*. Any content of the `ruby`[p271] element not described by segments in either of those lists is implicitly in an *ignored segment*.

When the steps above say to **set the current base text**, it means to run the following steps at that point in the algorithm:

1. Let *text range* be a DOM range whose start is the boundary point (*current parent*, *start index*) and whose end is the boundary point (*current parent*, *index*).
2. Let *new text segment* be a base text segment described by the range *text range*.
3. Add *new text segment* to *base text segments*.
4. Let *current base text* be *new text segment*.
5. Let *start index* be null.

When the steps above say to **push a ruby level**, it means to run the following steps at that point in the algorithm:

1. Let *current parent* be the *index*th node in *current parent*.
2. Let *index* be 0.
3. Set *saved start index* to the value of *start index*.
4. Let *start index* be null.

When the steps above say to **pop a ruby level**, it means to run the following steps at that point in the algorithm:

1. Let *index* be the position of *current parent* in *root*.
2. Let *current parent* be *root*.
3. Increment *index* by one.
4. Set *start index* to the value of *saved start index*.
5. Let *saved start index* be null.

When the steps above say to **push a ruby annotation**, it means to run the following steps at that point in the algorithm:

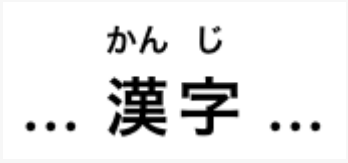
1. Let *rt* be the `rt`[p278] element that is the *index*th node of *current parent*.
2. Let *annotation range* be a DOM range whose start is the boundary point (*current parent*, *index*) and whose end is the boundary point (*current parent*, *index* plus one) (i.e. that contains only *rt*).
3. Let *new annotation segment* be an annotation segment described by the range *annotation range*.
4. If *current base text* is not null, associate *new annotation segment* with *current base text*.
5. Add *new annotation segment* to *annotation segments*.

Example

In this example, each ideograph in the Japanese text 漢字 is annotated with its reading in hiragana.

```
...
<ruby>漢<rt>かん</rt>字<rt>じ</rt></ruby>
...
```

This might be rendered as:



Example

In this example, each ideograph in the traditional Chinese text 漢字 is annotated with its bopomofo reading.

```
<ruby>漢<rt>ㄏㄢˋ</rt>字<rt>ㄗˋ</rt></ruby>
```

This might be rendered as:

Example

In this example, each ideograph in the simplified Chinese text 汉字 is annotated with its pinyin reading.

```
...<ruby>汉<rt>hàn</rt>字<rt>zì</rt></ruby>...
```

This might be rendered as:

Example

In this more contrived example, the acronym "HTML" has four annotations: one for the whole acronym, briefly describing what it is, one for the letters "HT" expanding them to "Hypertext", one for the letter "M" expanding it to "Markup", and one for the letter "L" expanding it to "Language".

```
<ruby>
 <ruby>HT<rt>Hypertext</rt>M<rt>Markup</rt>L<rt>Language</rt></ruby>
 <rt>An abstract language for describing documents and applications
</ruby>
```

4.5.11 The rt element §[p278]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a ruby[p271] element.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

An rt[p278] element's end tag[p1280] can be omitted if the rt[p278] element is immediately followed by an rt[p278] or rp[p278] element, or if there is no more content in the parent element.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The rt[p278] element marks the ruby text component of a ruby annotation. When it is the child of a ruby[p271] element, it doesn't represent[p142] anything itself, but the ruby[p271] element uses it as part of determining what *it* represents[p142].

An rt[p278] element that is not a child of a ruby[p271] element represents[p142] the same thing as its children.

4.5.12 The rp element §[p278]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a ruby[p271] element, either immediately before or immediately after an rt[p278] element.

Content model[p147]:

Text[p151].

Tag omission in text/html[p148]:

An rp[p278] element's end tag[p1280] can be omitted if the rp[p278] element is immediately followed by an rt[p278] or rp[p278] element, or if there is no more content in the parent element.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The rp[p278] element can be used to provide parentheses or other content around a ruby text component of a ruby annotation, to be shown by user agents that don't support ruby annotations.

An rp[p278] element that is a child of a ruby[p271] element represents[p142] nothing. An rp[p278] element whose parent element is not a ruby[p271] element represents[p142] its children.

Example

The example above, in which each ideograph in the text 漢字 is annotated with its phonetic reading, could be expanded to use rp[p278] so that in legacy user agents the readings are in parentheses:

```
...
<ruby>漢<rp>(</rp><rt>かん</rt><rp>)</rp>字<rp>(</rp><rt>じ</rt><rp>)</rp></ruby>
...
```

In conforming user agents the rendering would be as above, but in user agents that do not support ruby, the rendering would be:

```
... 漢(かん)字(じ)...
```

Example

When there are multiple annotations for a segment, rp[p278] elements can also be placed between the annotations. Here is another copy of an earlier contrived example showing some symbols with names given in English and French, but this time with rp[p278] elements as well:

```
<ruby>
♥<rp>: </rp><rt>Heart</rt><rp>, </rp><rt lang=fr>Cœur</rt><rp>.</rp>
♣<rp>: </rp><rt>Shamrock</rt><rp>, </rp><rt lang=fr>Trèfle</rt><rp>.</rp>
⋆<rp>: </rp><rt>Star</rt><rp>, </rp><rt lang=fr>Étoile</rt><rp>.</rp>
</ruby>
```

This would make the example render as follows in non-ruby-capable user agents:

```
♥: Heart, Cœur. ♣: Shamrock, Trèfle. ⋆: Star, Étoile.
```

4.5.13 The data element §[p279]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
value[p280] — Machine-readable value

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLDataElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString value;
};
```

The data element represents its contents, along with a machine-readable form of those contents in the value attribute.

The **value** attribute must be present. Its value must be a representation of the element's contents in a machine-readable format.

Note

When the value is date- or time-related, the more specific time element can be used instead.

The element can be used for several purposes.

When combined with microformats or the microdata attributes defined in this specification, the element serves to provide both a machine-readable value for the purposes of data processors, and a human-readable value for the purposes of rendering in a web browser. In this case, the format to be used in the value attribute is determined by the microformats or microdata vocabulary in use.

The element can also, however, be used in conjunction with scripts in the page, for when a script has a literal value to store alongside a human-readable value. In such cases, the format to be used depends only on the needs of the script. (The data-* attributes can also be useful in such situations.)

The **value** IDL attribute must reflect the content attribute of the same name.

Example

Here, a short table has its numeric values encoded using the data element so that the table sorting JavaScript library can provide a sorting mechanism on each column despite the numbers being presented in textual form in one column and in a decomposed form in another.

```
<script src="sortable.js"></script>
<table class="sortable">
 <thead> <tr> <th> Game <th> Corporations <th> Map Size
 <tbody>
  <tr> <td> 1830 <td> <data value="8">Eight</data> <td> <data value="93">19+74 hexes (93
total)</data>
  <tr> <td> 1856 <td> <data value="11">Eleven</data> <td> <data value="99">12+87 hexes (99
total)</data>
  <tr> <td> 1870 <td> <data value="10">Ten</data> <td> <data value="149">4+145 hexes (149
total)</data>
</table>
```

4.5.14 The time element

Categories:

Flow content.
Phrasing content.
Palpable content.

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:

If the element has a datetime attribute: Phrasing content.
Otherwise: Text, but must match requirements described in prose below.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes
datetime — Machine-readable value

Accessibility considerations:

For authors.

For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLTimeElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString dateTime;
};
```

The time[p280] element represents[p142] its contents, along with a machine-readable form of those contents in the datetime[p281] attribute. The kind of content is limited to various kinds of dates, times, time-zone offsets, and durations, as described below.

The **datetime** attribute may be present. If present, its value must be a representation of the element's contents in a machine-readable format.

A time[p280] element that does not have a datetime[p281] content attribute must not have any element descendants.

The **datetime value** of a time[p280] element is the value of the element's datetime[p281] content attribute, if it has one, otherwise the child text content of the time[p280] element.

The datetime value[p281] of a time[p280] element must match one of the following syntaxes.

A valid month string[p83]

Example

```
<time>2011-11</time>
```

A valid date string[p84]

Example

```
<time>2011-11-18</time>
```

A valid yearless date string[p85]

Example

```
<time>11-18</time>
```

A valid time string[p86]

Example

```
<time>14:54</time>
```

Example

```
<time>14:54:39</time>
```

Example

```
<time>14:54:39.929</time>
```

A valid local date and time string[p87]

Example

```
<time>2011-11-18T14:54</time>
```

Example

```
<time>2011-11-18T14:54:39</time>
```

Example

```
<time>2011-11-18T14:54:39.929</time>
```

Example

```
<time>2011-11-18 14:54</time>
```

Example

```
<time>2011-11-18 14:54:39</time>
```

Example

```
<time>2011-11-18 14:54:39.929</time>
```

Note

Times with dates but without a time zone offset are useful for specifying events that are observed at the same specific time in each time zone, throughout a day. For example, the 2020 new year is celebrated at 2020-01-01 00:00 in each time zone, not at the same precise moment across all time zones. For events that occur at the same time across all time zones, for example a videoconference meeting, a valid global date and time string[p89] is likely more useful.

A valid time-zone offset string[p87]

Example

```
<time>Z</time>
```

Example

```
<time>+0000</time>
```

Example

```
<time>+00:00</time>
```

Example

```
<time>-0800</time>
```

Example

```
<time>-08:00</time>
```

Note

For times without dates (or times referring to events that recur on multiple dates), specifying the geographic location that controls the time is usually more useful than specifying a time zone offset, because geographic locations change time zone offsets with daylight saving time. In some cases, geographic locations even change time zone, e.g. when the boundaries of those time zones are redrawn, as happened with Samoa at the end of 2011. There exists a time zone database that describes

the boundaries of time zones and what rules apply within each such zone, known as the time zone database. *[TZDATABASE]*[p1500]

A valid global date and time string[p89]

Example

```
<time>2011-11-18T14:54Z</time>
```

Example

```
<time>2011-11-18T14:54:39Z</time>
```

Example

```
<time>2011-11-18T14:54:39.929Z</time>
```

Example

```
<time>2011-11-18T14:54+0000</time>
```

Example

```
<time>2011-11-18T14:54:39+0000</time>
```

Example

```
<time>2011-11-18T14:54:39.929+0000</time>
```

Example

```
<time>2011-11-18T14:54+00:00</time>
```

Example

```
<time>2011-11-18T14:54:39+00:00</time>
```

Example

```
<time>2011-11-18T14:54:39.929+00:00</time>
```

Example

```
<time>2011-11-18T06:54-0800</time>
```

Example

```
<time>2011-11-18T06:54:39-0800</time>
```

Example

```
<time>2011-11-18T06:54:39.929-0800</time>
```

Example

```
<time>2011-11-18T06:54-08:00</time>
```

Example

```
<time>2011-11-18T06:54:39-08:00</time>
```

Example

```
<time>2011-11-18T06:54:39.929-08:00</time>
```

Example

```
<time>2011-11-18 14:54Z</time>
```

Example

```
<time>2011-11-18 14:54:39Z</time>
```

Example

```
<time>2011-11-18 14:54:39.929Z</time>
```

Example

```
<time>2011-11-18 14:54+0000</time>
```

Example

```
<time>2011-11-18 14:54:39+0000</time>
```

Example

```
<time>2011-11-18 14:54:39.929+0000</time>
```

Example

```
<time>2011-11-18 14:54+00:00</time>
```

Example

```
<time>2011-11-18 14:54:39+00:00</time>
```

Example

```
<time>2011-11-18 14:54:39.929+00:00</time>
```

Example

```
<time>2011-11-18 06:54-0800</time>
```

Example

```
<time>2011-11-18 06:54:39-0800</time>
```

Example

```
<time>2011-11-18 06:54:39.929-0800</time>
```

Example

```
<time>2011-11-18 06:54-08:00</time>
```

Example

```
<time>2011-11-18 06:54:39-08:00</time>
```

Example

```
<time>2011-11-18 06:54:39.929-08:00</time>
```

Note

Times with dates and a time zone offset are useful for specifying specific events, or recurring virtual events where the time is not anchored to a specific geographic location. For example, the precise time of an asteroid impact, or a particular meeting in a series of meetings held at 1400 UTC every day, regardless of whether any particular part of the world is observing daylight saving time or not. For events where the precise time varies by the local time zone offset of a specific geographic location, a valid local date and time string[p87] combined with that geographic location is likely more useful.

A valid week string[p90]

Example

```
<time>2011-W47</time>
```

Four or more ASCII digits, at least one of which is not U+0030 DIGIT ZERO (0)

Example

```
<time>2011</time>
```

Example

```
<time>0001</time>
```

A valid duration string[p91]

Example

```
<time>PT4H18M3S</time>
```

Example

```
<time>4h 18m 3s</time>
```

The **machine-readable equivalent of the element's contents** must be obtained from the element's datetime value[p281] by using the following algorithm:

1. If parsing a month string[p83] from the element's datetime value[p281] returns a month[p83], that is the machine-readable equivalent; return.
2. If parsing a date string[p84] from the element's datetime value[p281] returns a date[p84], that is the machine-readable equivalent; return.
3. If parsing a yearless date string[p85] from the element's datetime value[p281] returns a yearless date[p85], that is the machine-readable equivalent; return.
4. If parsing a time string[p86] from the element's datetime value[p281] returns a time[p86], that is the machine-readable equivalent; return.

5. If parsing a local date and time string[p87] from the element's datetime value[p281] returns a local date and time[p87], that is the machine-readable equivalent; return.
6. If parsing a time-zone offset string[p88] from the element's datetime value[p281] returns a time-zone offset[p87], that is the machine-readable equivalent; return.
7. If parsing a global date and time string[p90] from the element's datetime value[p281] returns a global date and time[p89], that is the machine-readable equivalent; return.
8. If parsing a week string[p91] from the element's datetime value[p281] returns a week[p90], that is the machine-readable equivalent; return.
9. If the element's datetime value[p281] consists of only ASCII digits, at least one of which is not U+0030 DIGIT ZERO (0), then the machine-readable equivalent is the base-ten interpretation of those digits, representing a year; return.
10. If parsing a duration string[p92] from the element's datetime value[p281] returns a duration[p91], that is the machine-readable equivalent; return.
11. There is no machine-readable equivalent.

Note

The algorithms referenced above are intended to be designed such that for any arbitrary string s, only one of the algorithms returns a value. A more efficient approach might be to create a single algorithm that parses all these data types in one pass; developing such an algorithm is left as an exercise to the reader.

The **dateTime** IDL attribute must reflect[p105] the element's datetime[p281] content attribute.

Example

The time[p280] element can be used to encode dates, for example in microformats. The following shows a hypothetical way of encoding an event using a variant on hCalendar that uses the time[p280] element:

```
<div class="vevent">
 <a class="url" href="http://www.web2con.com/">http://www.web2con.com/</a>
 <span class="summary">Web 2.0 Conference</span>:
 <time class="dtstart" datetime="2005-10-05">October 5</time> -
 <time class="dtend" datetime="2005-10-07">7</time>,
 at the <span class="location">Argent Hotel, San Francisco, CA</span>
</div>
```

Example

Here, a fictional microdata vocabulary based on the Atom vocabulary is used with the time[p280] element to mark up a blog post's publication date.

```
<article itemscope itemtype="https://n.example.org/rfc4287">
 <h1 itemprop="title">Big tasks</h1>
 <footer>Published <time itemprop="published" datetime="2009-08-29">two days ago</time>.</footer>
 <p itemprop="content">Today, I went out and bought a bike for my kid.</p>
</article>
```

Example

In this example, another article's publication date is marked up using time[p280], this time using the schema.org microdata vocabulary:

```
<article itemscope itemtype="http://schema.org/BlogPosting">
 <h1 itemprop="headline">Small tasks</h1>
 <footer>Published <time itemprop="datePublished" datetime="2009-08-30">yesterday</time>.</footer>
 <p itemprop="articleBody">I put a bike bell on her bike.</p>
</article>
```

Example

In the following snippet, the time[p280] element is used to encode a date in the ISO8601 format, for later processing by a script:

```
<p>Our first date was <time datetime="2006-09-23">a Saturday</time>.</p>
```

In this second snippet, the value includes a time:

```
<p>We stopped talking at <time datetime="2006-09-24T05:00-07:00">5am the next morning</time>.</p>
```

A script loaded by the page (and thus privy to the page's internal convention of marking up dates and times using the time[p280] element) could scan through the page and look at all the time[p280] elements therein to create an index of dates and times.

Example

For example, this element conveys the string "Friday" with the additional semantic that the 18th of November 2011 is the meaning that corresponds to "Friday":

```
Today is <time datetime="2011-11-18">Friday</time>.
```

Example

In this example, a specific time in the Pacific Standard Time timezone is specified:

```
Your next meeting is at <time datetime="2011-11-18T15:00-08:00">3pm</time>.
```

✓ MDN

4.5.15 The code element §[p287]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The code[p287] element represents[p142] a fragment of computer code. This could be an XML element name, a filename, a computer program, or any other string that a computer would recognize.

There is no formal way to indicate the language of computer code being marked up. Authors who wish to mark code[p287] elements with the language used, e.g. so that syntax highlighting scripts can use the right rules, can use the class[p156] attribute, e.g. by adding a class prefixed with "`language-`" to the element.

Example

The following example shows how the element can be used in a paragraph to mark up element names and computer code, including punctuation.

```
<p>The <code>code</code> element represents a fragment of computer
code.</p>

<p>When you call the <code>activate()</code> method on the
<code>robotSnowman</code> object, the eyes glow.</p>

<p>The example below uses the <code>begin</code> keyword to indicate
the start of a statement block. It is paired with an <code>end</code>
keyword, which is followed by the <code>.</code> punctuation character
(full stop) to indicate the end of the program.</p>
```

Example

The following example shows how a block of code could be marked up using the pre[p234] and code[p287] elements.

```
<pre><code class="language-pascal">var i: Integer;
begin
   i := 1;
end.</code></pre>
```

A class is used in that example to indicate the language used.

Note

See the pre[p234] element for more details.

4.5.16 The var element §[p288]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The var[p288] element represents[p142] a variable. This could be an actual variable in a mathematical expression or programming context, an identifier representing a constant, a symbol identifying a physical quantity, a function parameter, or just be a term used as a placeholder in prose.

Example

In the paragraph below, the letter "n" is being used as a variable in prose:

```
<p>If there are <var>n</var> pipes leading to the ice
cream factory then I expect at <em>least</em> <var>n</var>
flavors of ice cream to be available for purchase!</p>
```

For mathematics, in particular for anything beyond the simplest of expressions, MathML is more appropriate. However, the var[p288] element can still be used to refer to specific variables that are then mentioned in MathML expressions.

Example

In this example, an equation is shown, with a legend that references the variables in the equation. The expression itself is marked up with MathML, but the variables are mentioned in the figure's legend using var[p288].

```
<figure>
 <math>
  <mi>a</mi>
  <mo>=</mo>
  <msqrt>
   <msup><mi>b</mi><mn>2</mn></msup>
   <mi>+</mi>
   <msup><mi>c</mi><mn>2</mn></msup>
  </msqrt>
 </math>
 <figcaption>
  Using Pythagoras' theorem to solve for the hypotenuse <var>a</var> of
  a triangle with sides <var>b</var> and <var>c</var>
 </figcaption>
</figure>
```

Example

Here, the equation describing mass-energy equivalence is used in a sentence, and the var[p288] element is used to mark the variables and constants in that equation:

```
<p>Then she turned to the blackboard and picked up the chalk. After a few moment's
thought, she wrote <var>E</var> = <var>m</var> <var>c</var><sup>2</sup>. The teacher
looked pleased.</p>
```

4.5.17 The samp element §[p289]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The samp[p289] element represents[p142] sample or quoted output from another program or computing system.

Note

See the pre[p234] and kbd[p290] elements for more details.

Note

This element can be contrasted with the output[p588] element, which can be used to provide immediate output in a web application.

Example

This example shows the samp[p289] element being used inline:

```
<p>The computer said <samp>Too much cheese in tray
two</samp> but I didn't know what that meant.</p>
```

Example

This second example shows a block of sample output from a console program. Nested samp[p289] and kbd[p290] elements allow for the styling of specific elements of the sample output using a style sheet. There's also a few parts of the samp[p289] that are annotated with even more detailed markup, to enable very precise styling. To achieve this, span[p299] elements are used.

```
<pre><samp><span class="prompt">jdoe@mowmow:~$</span> <kbd>ssh demo.example.com</kbd>
Last login: Tue Apr 12 09:10:17 2005 from mowmow.example.com on pts/1
Linux demo 2.6.10-grsec+gg3+e+fhs6b+nfs+gr0501+++p3+c4a+gr2b-reslog-v6.189 #1 SMP Tue Feb 1
11:22:36 PST 2005 i686 unknown

<span class="prompt">jdoe@demo:~$</span> <span class="cursor">_</span></samp></pre>
```

Example

This third example shows a block of input and its respective output. The example uses both code[p287] and samp[p289] elements.

```
<pre>
<code class="language-javascript">console.log(2.3 + 2.4)</code>
<samp>4.699999999999999</samp>
</pre>
```

4.5.18 The kbd element §[p290]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses `HTMLElement`[p143].

The `kbd`[p290] element represents[p142] user input (typically keyboard input, although it may also be used to represent other input, such as voice commands).

When the `kbd`[p290] element is nested inside a `samp`[p289] element, it represents the input as it was echoed by the system.

When the `kbd`[p290] element *contains* a `samp`[p289] element, it represents input based on system output, for example invoking a menu item.

When the `kbd`[p290] element is nested inside another `kbd`[p290] element, it represents an actual key or other single unit of input as appropriate for the input mechanism.

Example

Here the `kbd`[p290] element is used to indicate keys to press:

```
<p>To make George eat an apple, press <kbd><kbd>Shift</kbd> + <kbd>F3</kbd></kbd></p>
```

In this second example, the user is told to pick a particular menu item. The outer `kbd`[p290] element marks up a block of input, with the inner `kbd`[p290] elements representing each individual step of the input, and the `samp`[p289] elements inside them indicating that the steps are input based on something being displayed by the system, in this case menu labels:

```
<p>To make George eat an apple, select
    <kbd><kbd><samp>File</samp></kbd>|<kbd><samp>Eat Apple...</samp></kbd></kbd>
</p>
```

Such precision isn't necessary; the following is equally fine:

```
<p>To make George eat an apple, select <kbd>File | Eat Apple...</kbd></p>
```

4.5.19 The `sub` and `sup` elements §[p291]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

The `sub`[p291] element: for authors; for implementers.
The `sup`[p291] element: for authors; for implementers.

DOM interface[p148]:

Use HTMLElement[p143].

The sup[p291] element represents[p142] a superscript and the sub[p291] element represents[p142] a subscript.

These elements must be used only to mark up typographical conventions with specific meanings, not for typographical presentation for presentation's sake. For example, it would be inappropriate for the sub[p291] and sup[p291] elements to be used in the name of the LaTeX document preparation system. In general, authors should use these elements only if the *absence* of those elements would change the meaning of the content.

In certain languages, superscripts are part of the typographical conventions for some abbreviations.

Example

```
<p>Their names are
<span lang="fr"><abbr>M<sup>lle</sup></abbr> Gwendoline</span> and
<span lang="fr"><abbr>M<sup>me</sup></abbr> Denise</span>.</p>
```

The sub[p291] element can be used inside a var[p288] element, for variables that have subscripts.

Example

Here, the sub[p291] element is used to represent the subscript that identifies the variable in a family of variables:

```
<p>The coordinate of the <var>i</var>th point is
(<var>x<sub><var>i</var></sub></var>, <var>y<sub><var>i</var></sub></var>).
For example, the 10th point has coordinate
(<var>x<sub>10</sub></var>, <var>y<sub>10</sub></var>).</p>
```

Mathematical expressions often use subscripts and superscripts. Authors are encouraged to use MathML for marking up mathematics, but authors may opt to use sub[p291] and sup[p291] if detailed mathematical markup is not desired. [MATHML][p1497]

Example

```
<var>E</var>=<var>m</var><var>c</var><sup>2</sup>
```

```
f(<var>x</var>, <var>n</var>) = log<sub>4</sub><var>x</var><sup><var>n</var></sup>
```

4.5.20 The i element §[p292]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The i[p292] element represents[p142] a span of text in an alternate voice or mood, or otherwise offset from the normal prose in a manner indicating a different quality of text, such as a taxonomic designation, a technical term, an idiomatic phrase from another language, transliteration, a thought, or a ship name in Western texts.

Terms in languages different from the main text should be annotated with lang[p159] attributes (or, in XML, lang attributes in the XML namespace).

Example

The examples below show uses of the i[p292] element:

```
<p>The <i class="taxonomy">Felis silvestris catus</i> is cute.</p>
<p>The term <i>prose content</i> is defined above.</p>
<p>There is a certain <i lang="fr">je ne sais quoi</i> in the air.</p>
```

In the following example, a dream sequence is marked up using i[p292] elements.

```
<p>Raymond tried to sleep.</p>
<p><i>The ship sailed away on Thursday</i>, he
dreamt. <i>The ship had many people aboard, including a beautiful
princess called Carey. He watched her, day-in, day-out, hoping she
would notice him, but she never did.</i></p>
<p><i>Finally one night he picked up the courage to speak with
her—</i></p>
<p>Raymond woke with a start as the fire alarm rang out.</p>
```

Authors can use the class[p156] attribute on the i[p292] element to identify why the element is being used, so that if the style of a particular use (e.g. dream sequences as opposed to taxonomic terms) is to be changed at a later date, the author doesn't have to go through the entire document (or series of related documents) annotating each use.

Authors are encouraged to consider whether other elements might be more applicable than the i[p292] element, for instance the em[p261] element for marking up stress emphasis, or the dfn[p269] element to mark up the defining instance of a term.

Note

Style sheets can be used to format i[p292] elements, just like any other element can be restyled. Thus, it is not the case that content in i[p292] elements will necessarily be italicized.

4.5.21 The b element §[p293]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses `HTMLElement`[p143].

The `b`[p293] element represents[p142] a span of text to which attention is being drawn for utilitarian purposes without conveying any extra importance and with no implication of an alternate voice or mood, such as key words in a document abstract, product names in a review, actionable words in interactive text-driven software, or an article lede.

Example

The following example shows a use of the `b`[p293] element to highlight key words without marking them up as important:

```
<p>The <b>frobonitor</b> and <b>barbinator</b> components are fried.</p>
```

Example

In the following example, objects in a text adventure are highlighted as being special by use of the `b`[p293] element.

```
<p>You enter a small room. Your <b>sword</b> glows
brighter. A <b>rat</b> scurries past the corner wall.</p>
```

Example

Another case where the `b`[p293] element is appropriate is in marking up the lede (or lead) sentence or paragraph. The following example shows how a BBC article about kittens adopting a rabbit as their own could be marked up:

```
<article>
 <h2>Kittens 'adopted' by pet rabbit</h2>
 <p><b class="lede">Six abandoned kittens have found an
 unexpected new mother figure – a pet rabbit.</b></p>
 <p>Veterinary nurse Melanie Humble took the three-week-old
 kittens to her Aberdeen home.</p>
[...]
```

As with the `i`[p292] element, authors can use the `class`[p156] attribute on the `b`[p293] element to identify why the element is being used, so that if the style of a particular use is to be changed at a later date, the author doesn't have to go through annotating each use.

The `b`[p293] element should be used as a last resort when no other element is more appropriate. In particular, headings should use the `h1`[p217] to `h6`[p217] elements, stress emphasis should use the `em`[p261] element, importance should be denoted with the `strong`[p262] element, and text marked or highlighted should use the `mark`[p295] element.

Example

The following would be *incorrect* usage:

```
<p><b>WARNING!</b> Do not frob the barbinator!</p>
```

In the previous example, the correct element to use would have been `strong`[p262], not `b`[p293].

Note

Style sheets can be used to format `b`[p293] elements, just like any other element can be restyled. Thus, it is not the case that content in `b`[p293] elements will necessarily be boldened.

4.5.22 The u element §[p295]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses `HTMLElement`[p143].

The `u`[p295] element represents[p142] a span of text with an unarticulated, though explicitly rendered, non-textual annotation, such as labeling the text as being a proper name in Chinese text (a Chinese proper name mark), or labeling the text as being misspelt.

In most cases, another element is likely to be more appropriate: for marking stress emphasis, the `em`[p261] element should be used; for marking key words or phrases either the `b`[p293] element or the `mark`[p295] element should be used, depending on the context; for marking book titles, the `cite`[p266] element should be used; for labeling text with explicit textual annotations, the `ruby`[p271] element should be used; for technical terms, taxonomic designation, transliteration, a thought, or for labeling ship names in Western texts, the `i`[p292] element should be used.

Note

The default rendering of the `u`[p295] element in visual presentations clashes with the conventional rendering of hyperlinks (underlining). Authors are encouraged to avoid using the `u`[p295] element where it could be confused for a hyperlink.

Example

In this example, a `u`[p295] element is used to mark a word as misspelt:

```
<p>The <u>see</u> is full of fish.</p>
```

4.5.23 The mark element §[p295]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]**:**

Global attributes[p155]

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

Uses `HTMLElement`[p143].

The `mark`[p295] element represents[p142] a run of text in one document marked or highlighted for reference[p142] purposes, due to its relevance in another context. When used in a quotation or other block of text referred to from the prose, it indicates a highlight that was not originally present but which has been added to bring the reader's attention to a part of the text that might not have been considered important by the original author when the block was originally written, but which is now under previously unexpected scrutiny. When used in the main prose of a document, it indicates a part of the document that has been highlighted due to its likely relevance to the user's current activity.

Example

This example shows how the `mark`[p295] element can be used to bring attention to a particular part of a quotation:

```
<p lang="en-US">Consider the following quote:</p>
<blockquote lang="en-GB">
 <p>Look around and you will find, no-one's really
 <mark>colour</mark> blind.</p>
</blockquote>
<p lang="en-US">As we can tell from the <em>spelling</em> of the word,
the person writing this quote is clearly not American.</p>
```

(If the goal was to mark the element as misspelt, however, the `u`[p295] element, possibly with a class, would be more appropriate.)

Example

Another example of the `mark`[p295] element is highlighting parts of a document that are matching some search string. If someone looked at a document, and the server knew that the user was searching for the word "kitten", then the server might return the document with one paragraph modified as follows:

```
<p>I also have some <mark>kitten</mark>s who are visiting me
these days. They're really cute. I think they like my garden! Maybe I
should adopt a <mark>kitten</mark>.</p>
```

Example

In the following snippet, a paragraph of text refers to a specific part of a code fragment.

```
<p>The highlighted part below is where the error lies:</p>
<pre><code>var i: Integer;
begin
   i := <mark>1.1</mark>;
end.</code></pre>
```

This is separate from *syntax highlighting*, for which `span`[p299] is more appropriate. Combining both, one would get:

```
<p>The highlighted part below is where the error lies:</p>
<pre><code><span class=keyword>var</span> <span class=ident>i</span>: <span
class=type>Integer</span>;
<span class=keyword>begin</span>
   <span class=ident>i</span> := <span class=literal><mark>1.1</mark></span>;
<span class=keyword>end</span>.</code></pre>
```

Example

This is another example showing the use of mark[p295] to highlight a part of quoted text that was originally not emphasized. In this example, common typographic conventions have led the author to explicitly style mark[p295] elements in quotes to render in italics.

```
<style>
 blockquote mark, q mark {
   font: inherit; font-style: italic;
   text-decoration: none;
   background: transparent; color: inherit;
 }
 .bubble em {
   font: inherit; font-size: larger;
   text-decoration: underline;
 }
</style>
<article>
 <h1>She knew</h1>
 <p>Did you notice the subtle joke in the joke on panel 4?</p>
 <blockquote>
  <p class="bubble">I didn't <em>want</em> to believe. <mark>Of course
  on some level I realized it was a known-plaintext attack.</mark> But I
  couldn't admit it until I saw for myself.</p>
 </blockquote>
 <p>(Emphasis mine.) I thought that was great. It's so pedantic, yet it
 explains everything neatly.</p>
</article>
```

Note, incidentally, the distinction between the em[p261] element in this example, which is part of the original text being quoted, and the mark[p295] element, which is highlighting a part for comment.

Example

The following example shows the difference between denoting the *importance* of a span of text (strong[p262]) as opposed to denoting the *relevance* of a span of text (mark[p295]). It is an extract from a textbook, where the extract has had the parts relevant to the exam highlighted. The safety warnings, important though they may be, are apparently not relevant to the exam.

```
<h3>Wormhole Physics Introduction</h3>

<p><mark>A wormhole in normal conditions can be held open for a
maximum of just under 39 minutes.</mark> Conditions that can increase
the time include a powerful energy source coupled to one or both of
the gates connecting the wormhole, and a large gravity well (such as a
black hole).</p>

<p><mark>Momentum is preserved across the wormhole. Electromagnetic
radiation can travel in both directions through a wormhole,
but matter cannot.</mark></p>

<p>When a wormhole is created, a vortex normally forms.
<strong>Warning: The vortex caused by the wormhole opening will
annihilate anything in its path.</strong> Vortexes can be avoided when
using sufficiently advanced dialing technology.</p>

<p><mark>An obstruction in a gate will prevent it from accepting a
wormhole connection.</mark></p>
```

4.5.24 The bdi element §[p298]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
Also, the dir[p161] global attribute has special semantics on this element.

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The bdi[p298] element represents[p142] a span of text that is to be isolated from its surroundings for the purposes of bidirectional text formatting. [BIDI][p1493]

Note

The dir[p161] global attribute defaults to auto[p161] on this element (it never inherits from the parent element like with other elements).

Note

This element has rendering requirements involving the bidirectional algorithm[p171].

Example

This element is especially useful when embedding user-generated content with an unknown directionality.

In this example, usernames are shown along with the number of posts that the user has submitted. If the bdi[p298] element were not used, the username of the Arabic user would end up confusing the text (the bidirectional algorithm would put the colon and the number "3" next to the word "User" rather than next to the word "posts").

```
<ul>
 <li>User <bdi>jcranmer</bdi>: 12 posts.
 <li>User <bdi>hober</bdi>: 5 posts.
 <li>User <bdi>إيان</bdi>: 3 posts.
</ul>
```

- User jcranmer: 12 posts.
- User hober: 5 posts.
- User إيان: 3 posts.

When using the bdi[p298] element, the username acts as expected.

- User **jcranmer**: 12 posts.
- User **hober**: 5 posts.
- User 3 :**إيان** posts.

If the bdi[p298] element were to be replaced by a b[p293] element, the username would confuse the bidirectional algorithm and the third

bullet would end up saying "User 3 :", followed by the Arabic name (right-to-left), followed by "posts" and a period.

4.5.25 The bdo element §[p299]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
Also, the dir[p161] global attribute has special semantics on this element.

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The bdo[p299] element represents[p142] explicit text directionality formatting control for its children. It allows authors to override the Unicode bidirectional algorithm by explicitly specifying a direction override. [BIDI][p1493]

Authors must specify the dir[p161] attribute on this element, with the value ltr[p161] to specify a left-to-right override and with the value rtl[p161] to specify a right-to-left override. The auto[p161] value must not be specified.

Note

This element has rendering requirements involving the bidirectional algorithm[p171].

4.5.26 The span element §[p299]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.

For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLSpanElement : HTMLElement {
  [HTMLConstructor] constructor();
};
```

The span[p299] element doesn't mean anything on its own, but can be useful when used together with the global attributes[p155], e.g. class[p156], lang[p159], or dir[p161]. It represents[p142] its children.

Example

In this example, a code fragment is marked up using span[p299] elements and class[p156] attributes so that its keywords and identifiers can be color-coded from CSS:

```
<pre><code class="lang-c"><span class="keyword">for</span> (<span class="ident">j</span> = 0;
<span class="ident">j</span> &lt; 256; <span class="ident">j</span>++) {
  <span class="ident">i_t3</span> = (<span class="ident">i_t3</span> & 0x1ffff) | (<span
class="ident">j</span> &lt;&lt; 17);
  <span class="ident">i_t6</span> = (((((((<span class="ident">i_t3</span> >> 3) ^ <span
class="ident">i_t3</span>) >> 1) ^ <span class="ident">i_t3</span>) >> 8) ^ <span
class="ident">i_t3</span>) >> 5) & 0xff;
  <span class="keyword">if</span> (<span class="ident">i_t6</span> == <span
class="ident">i_t1</span>)
    <span class="keyword">break</span>;
}</code></pre>
```

4.5.27 The br element §[p300]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLBRElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

The br[p300] element represents[p142] a line break.

Note

While line breaks are usually represented in visual media by physically moving subsequent text to a new line, a style sheet or user agent would be equally justified in causing line breaks to be rendered in a different manner, for instance as green dots, or as extra spacing.

br[p300] elements must be used only for line breaks that are actually part of the content, as in poems or addresses.

Example

The following example is correct usage of the br[p300] element:

```
<p>P. Sherman<br>
42 Wallaby Way<br>
Sydney</p>
```

br[p300] elements must not be used for separating thematic groups in a paragraph.

Example

The following examples are non-conforming, as they abuse the br[p300] element:

```
<p><a ...>34 comments.</a><br>
<a ...>Add a comment.</a></p>
```

```
<p><label>Name: <input name="name"></label><br>
<label>Address: <input name="address"></label></p>
```

Here are alternatives to the above, which are correct:

```
<p><a ...>34 comments.</a></p>
<p><a ...>Add a comment.</a></p>
```

```
<p><label>Name: <input name="name"></label></p>
<p><label>Address: <input name="address"></label></p>
```

If a paragraph[p153] consists of nothing but a single br[p300] element, it represents a placeholder blank line (e.g. as in a template). Such blank lines must not be used for presentation purposes.

Any content inside br[p300] elements must not be considered part of the surrounding text.

Note

This element has rendering requirements involving the bidirectional algorithm[p171].

4.5.28 The wbr element §[p301]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses `HTMLElement`[p143].

The `wbr`[p301] element represents[p142] a line break opportunity.

Example

In the following example, someone is quoted as saying something which, for effect, is written as one long word. However, to ensure that the text can be wrapped in a readable fashion, the individual words in the quote are separated using a `wbr`[p301] element.

```
<p>So then she pointed at the tiger and screamed
"there<wbr>is<wbr>no<wbr>way<wbr>you<wbr>are<wbr>ever<wbr>going<wbr>to<wbr>catch<wbr>me"!</p>
```

Any content inside `wbr`[p301] elements must not be considered part of the surrounding text.

Example

```
var wbr = document.createElement("wbr");
wbr.textContent = "This is wrong";
document.body.appendChild(wbr);
```

Note

This element has rendering requirements involving the bidirectional algorithm[p171].

4.5.29 Usage summary §[p302]

This section is non-normative.

Element	Purpose	Example
`a`[p258]	Hyperlinks	`Visit my <a href="drinks.html">drinks</a> page.`
`em`[p261]	Stress emphasis	`I must say I <em>adore</em> lemonade.`
`strong`[p262]	Importance	`This tea is <strong>very hot</strong>.`
`small`[p263]	Side comments	`These grapes are made into wine. <small>Alcohol is addictive.</small>`
`s`[p265]	Inaccurate text	`Price: <s>£4.50</s> £2.00!`
`cite`[p266]	Titles of works	`The case <cite>Hugo v. Danielle</cite> is relevant here.`
`q`[p267]	Quotations	`The judge said <q>You can drink water from the fish tank</q> but advised against it.`
`dfn`[p269]	Defining instance	`The term <dfn>organic food</dfn> refers to food produced without synthetic chemicals.`
`abbr`[p270]	Abbreviations	`Organic food in Ireland is certified by the <abbr title="Irish Organic Farmers and Growers Association">IOFGA</abbr>.`
`ruby`[p271], `rt`[p278], `rp`[p278]	Ruby annotations	`<ruby> OJ <rp>(<rt>Orange Juice<rp>)</ruby>`
`data`[p279]	Machine-readable equivalent	`Available starting today! <data value="UPC:022014640201">North Coast Organic Apple Cider</data>`
`time`[p280]	Machine-readable equivalent of date- or time-related data	`Available starting on <time datetime="2011-11-18">November 18th</time>!`

Element	Purpose	Example
code	Computer code	`The <code>fruitdb</code> program can be used for tracking fruit production.`
var	Variables	`If there are <var>n</var> fruit in the bowl, at least <var>n</var>÷2 will be ripe.`
samp	Computer output	`The computer said <samp>Unknown error -3</samp>.`
kbd	User input	`Hit <kbd>F1</kbd> to continue.`
sub	Subscripts	`Water is H<sub>2</sub>O.`
sup	Superscripts	`The Hydrogen in heavy water is usually <sup>2</sup>H.`
i	Alternative voice	`Lemonade consists primarily of <i>Citrus limon</i>.`
b	Keywords	`Take a <b>lemon</b> and squeeze it with a <b>juicer</b>.`
u	Annotations	`The mixture of apple juice and <u class="spelling">eldeflower</u> juice is very pleasant.`
mark	Highlight	`Elderflower cordial, with one <mark>part</mark> cordial to ten <mark>part</mark>s water, stands a<mark>part</mark> from the rest.`
bdi	Text directionality isolation	`The recommended restaurant is <bdi lang="">My Juice Café (At The Beach)</bdi>.`
bdo	Text directionality formatting	`The proposal is to write English, but in reverse order. "Juice" would become "<bdo dir=rtl>Juice</bdo>">`
span	Other	`In French we call it <span lang="fr">sirop de sureau</span>.`
br	Line break	`Simply Orange Juice Company Apopka, FL 32703 U.S.A.`
wbr	Line breaking opportunity	`www.simply<wbr>orange<wbr>juice.com`

4.6 Links

4.6.1 Introduction

Links are a conceptual construct, created by a, area, form, and link elements, that represent a connection between two resources, one of which is the current Document. There are three kinds of links in HTML:

Links to external resources

These are links to resources that are to be used to augment the current document, generally automatically processed by the user agent. All external resource links have a fetch and process the linked resource algorithm which describes how the resource is obtained.

Hyperlinks

These are links to other resources that are generally exposed to the user by the user agent so that the user can cause the user agent to navigate to those resources, e.g. to visit them in a browser or download them.

Internal resource links

These are links to resources within the current document, used to give those resources special meaning or behavior.

For link elements with an href attribute and a rel attribute, links must be created for the keywords of the rel attribute, as defined for those keywords in the link types section.

Similarly, for a and area elements with an href attribute and a rel attribute, links must be created for the keywords of the rel attribute as defined for those keywords in the link types section. Unlike link elements, however, a and area elements with an href attribute that either do not have a rel attribute, or whose rel attribute has no keywords that are defined as specifying hyperlinks, must also create a hyperlink. This implied hyperlink has no special meaning (it has no link type) beyond linking the element's node document to the resource given by the element's href attribute.

Similarly, for form elements with a rel attribute, links must be created for the keywords of the rel attribute as defined for those keywords in the link types section. form elements that do not have a rel attribute, or whose rel attribute has no

keywords that are defined as specifying hyperlinks[p303], must also create a hyperlink[p303].

A hyperlink[p303] can have one or more **hyperlink annotations** that modify the processing semantics of that hyperlink.

4.6.2 Links created by a[p258] and area[p472] elements §[p304]

The **href** attribute on a[p258] and area[p472] elements must have a value that is a valid URL potentially surrounded by spaces[p97].

Note

The href[p304] *attribute on* a[p258] *and* area[p472] *elements is not required; when those elements do not have* href[p304] *attributes they do not create hyperlinks.*

The **target** attribute, if present, must be a valid navigable target name or keyword[p1009]. It gives the name of the navigable[p1001] that will be used. User agents use this name when following hyperlinks[p310].

The **download** attribute, if present, indicates that the author intends the hyperlink to be used for downloading a resource[p311]. The attribute may have a value; the value, if any, specifies the default filename that the author recommends for use in labeling the resource in a local file system. There are no restrictions on allowed values, but authors are cautioned that most file systems have limitations with regard to what punctuation is supported in filenames, and user agents are likely to adjust filenames accordingly.

The **ping** attribute, if present, gives the URLs of the resources that are interested in being notified if the user follows the hyperlink. The value must be a set of space-separated tokens[p96], each of which must be a valid non-empty URL[p97] whose scheme is an HTTP(S) scheme. The value is used by the user agent for hyperlink auditing[p313].

The **rel** attribute on a[p258] and area[p472] elements controls what kinds of links the elements create. The attribute's value must be an unordered set of unique space-separated tokens[p96]. The allowed keywords and their meanings[p315] are defined below.

rel[p304]'s supported tokens are the keywords defined in HTML link types[p315] which are allowed on a[p258] and area[p472] elements, impact the processing model, and are supported by the user agent. The possible supported tokens are noreferrer[p326], noopener[p326], and opener[p326]. rel[p304]'s supported tokens must only include the tokens from this list that the user agent implements the processing model for.

The rel[p304] attribute has no default value. If the attribute is omitted or if none of the values in the attribute are recognized by the user agent, then the document has no particular relationship with the destination resource other than there being a hyperlink between the two.

The **hreflang** attribute on a[p258] elements that create hyperlinks[p303], if present, gives the language of the linked resource. It is purely advisory. The value must be a valid BCP 47 language tag. [BCP47][p1493] User agents must not consider this attribute authoritative — upon fetching the resource, user agents must use only language information associated with the resource to determine its language, not metadata included in the link to the resource.

The **type** attribute, if present, gives the MIME type of the linked resource. It is purely advisory. The value must be a valid MIME type string. User agents must not consider the type[p304] attribute authoritative — upon fetching the resource, user agents must not use metadata included in the link to the resource to determine its type.

The **referrerpolicy** attribute is a referrer policy attribute[p101]. Its purpose is to set the referrer policy used when following hyperlinks[p310]. [REFERRERPOLICY][p1499]

When an a[p258] or area[p472] element's activation behavior is invoked, the user agent may allow the user to indicate a preference regarding whether the hyperlink is to be used for navigation[p1028] or whether the resource it specifies is to be downloaded.

In the absence of a user preference, the default should be navigation if the element has no download[p304] attribute, and should be to download the specified resource if it does.

The activation behavior of an a[p258] or area[p472] element *element* given an event *event* is:

1. If *element* has no href[p304] attribute, then return.
2. Let *hyperlinkSuffix* be null.

3. If *element* is an a[p258] element, and *event*'s target is an img[p347] with an ismap[p351] attribute specified, then:

    1. Let *x* and *y* be 0.

    2. If *event*'s isTrusted attribute is initialized to true, then set *x* to the distance in CSS pixels from the left edge of the image to the location of the click, and set *y* to the distance in CSS pixels from the top edge of the image to the location of the click.

    3. If *x* is negative, set *x* to 0.

    4. If *y* is negative, set *y* to 0.

    5. Set *hyperlinkSuffix* to the concatenation of U+003F (?), the value of *x* expressed as a base-ten integer using ASCII digits, U+002C (,), and the value of *y* expressed as a base-ten integer using ASCII digits.

4. Let *userInvolvement* be *event*'s user navigation involvement[p1028].

5. If the user has expressed a preference to download the hyperlink, then set *userInvolvement* to "browser UI[p1028]".

    Note

    That is, if the user has expressed a specific preference for downloading, this no longer counts as merely "activation[p1028]".

6. If *element* has a download[p304] attribute, or if the user has expressed a preference to download the hyperlink, then download the hyperlink[p311] created by *element* with *hyperlinkSuffix*[p311] set to *hyperlinkSuffix* and *userInvolvement*[p311] set to *userInvolvement*.

7. Otherwise, follow the hyperlink[p310] created by *element* with *hyperlinkSuffix*[p310] set to *hyperlinkSuffix* and *userInvolvement*[p310] set to *userInvolvement*.

4.6.3 API for a[p258] and area[p472] elements §[p305]

IDL

```
interface mixin HTMLHyperlinkElementUtils {
  [CEReactions] stringifier attribute USVString href;
  readonly attribute USVString origin;
  [CEReactions] attribute USVString protocol;
  [CEReactions] attribute USVString username;
  [CEReactions] attribute USVString password;
  [CEReactions] attribute USVString host;
  [CEReactions] attribute USVString hostname;
  [CEReactions] attribute USVString port;
  [CEReactions] attribute USVString pathname;
  [CEReactions] attribute USVString search;
  [CEReactions] attribute USVString hash;
};
```

For web developers (non-normative)

***hyperlink*.toString()**

***hyperlink*.href[p306]**

Returns the hyperlink's URL.

Can be set, to change the URL.

***hyperlink*.origin[p307]**

Returns the hyperlink's URL's origin.

***hyperlink*.protocol[p307]**

Returns the hyperlink's URL's scheme.

Can be set, to change the URL's scheme.

***hyperlink*.username[p307]**

Returns the hyperlink's URL's username.

Can be set, to change the URL's username.

***hyperlink*.password**[p307]

Returns the hyperlink's URL's password.

Can be set, to change the URL's password.

***hyperlink*.host**[p308]

Returns the hyperlink's URL's host and port (if different from the default port for the scheme).

Can be set, to change the URL's host and port.

***hyperlink*.hostname**[p308]

Returns the hyperlink's URL's host.

Can be set, to change the URL's host.

***hyperlink*.port**[p308]

Returns the hyperlink's URL's port.

Can be set, to change the URL's port.

***hyperlink*.pathname**[p309]

Returns the hyperlink's URL's path.

Can be set, to change the URL's path.

***hyperlink*.search**[p309]

Returns the hyperlink's URL's query (includes leading "?" if non-empty).

Can be set, to change the URL's query (ignores leading "?").

***hyperlink*.hash**[p309]

Returns the hyperlink's URL's fragment (includes leading "#" if non-empty).

Can be set, to change the URL's fragment (ignores leading "#").

An element implementing the HTMLHyperlinkElementUtils[p305] mixin has an associated **url** (null or a URL). It is initially null.

An element implementing the HTMLHyperlinkElementUtils[p305] mixin has an associated **set the url** algorithm, which runs these steps:

1. Set this element's url[p306] to null.
2. If this element's href[p304] content attribute is absent, then return.
3. Let *url* be the result of encoding-parsing a URL[p98] given this element's href[p304] content attribute's value, relative to this element's node document.
4. If *url* is not failure, then set this element's url[p306] to *url*.

When elements implementing the HTMLHyperlinkElementUtils[p305] mixin are created, and whenever those elements have their href[p304] content attribute set, changed, or removed, the user agent must set the url[p306].

Note

This is only observable for `blob:` *URLs as parsing them involves a Blob URL Store lookup.*

An element implementing the HTMLHyperlinkElementUtils[p305] mixin has an associated **reinitialize url** algorithm, which runs these steps:

1. If the element's url[p306] is non-null, its scheme is "`blob`", and it has an opaque path, then terminate these steps.
2. Set the url[p306].

To **update href**, set the element's href[p304] content attribute's value to the element's url[p306], serialized.

The **href** getter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null and this has no `href`[p304] content attribute, return the empty string.
4. Otherwise, if *url* is null, return this's `href`[p304] content attribute's value.
5. Return *url*, serialized.

The `href`[p306] setter steps are to set this's `href`[p304] content attribute's value to the given value.

The **`origin`** getter steps are:

1. Reinitialize url[p306].
2. If this's url[p306] is null, return the empty string.
3. Return the serialization[p909] of this's url[p306]'s origin.

The **`protocol`** getter steps are:

1. Reinitialize url[p306].
2. If this's url[p306] is null, return "`:`".
3. Return this's url[p306]'s scheme, followed by "`:`".

The `protocol`[p307] setter steps are:

1. Reinitialize url[p306].
2. If this's url[p306] is null, then return.
3. Basic URL parse the given value, followed by "`:`", with this's url[p306] as *url* and scheme start state as *state override*.

   Note

   Because the URL parser ignores multiple consecutive colons, providing a value of "`https:`" *(or even* "`https::::`"*) is the same as providing a value of* "`https`"*.*
4. Update `href`[p306].

The **`username`** getter steps are:

1. Reinitialize url[p306].
2. If this's url[p306] is null, return the empty string.
3. Return this's url[p306]'s username.

The `username`[p307] setter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null or *url* cannot have a username/password/port, then return.
4. Set the username, given *url* and the given value.
5. Update `href`[p306].

The **`password`** getter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null, then return the empty string.

4. Return *url*'s password.

The `password`[p307] setter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null or *url* cannot have a username/password/port, then return.
4. Set the password, given *url* and the given value.
5. Update `href`[p306].

The **`host`** getter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* or *url*'s host is null, return the empty string.
4. If *url*'s port is null, return *url*'s host, serialized.
5. Return *url*'s host, serialized, followed by ":" and *url*'s port, serialized.

The `host`[p308] setter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null or *url* has an opaque path, then return.
4. Basic URL parse the given value, with *url* as *url* and host state as *state override*.
5. Update `href`[p306].

The **`hostname`** getter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* or *url*'s host is null, return the empty string.
4. Return *url*'s host, serialized.

The `hostname`[p308] setter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null or *url* has an opaque path, then return.
4. Basic URL parse the given value, with *url* as *url* and hostname state as *state override*.
5. Update `href`[p306].

The **`port`** getter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* or *url*'s port is null, return the empty string.
4. Return *url*'s port, serialized.

The `port`[p308] setter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null or *url* cannot have a username/password/port, then return.
4. If the given value is the empty string, then set *url*'s port to null.
5. Otherwise, basic URL parse the given value, with *url* as *url* and port state as *state override*.
6. Update `href`[p306].

The **`pathname`** getter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null, then return the empty string.
4. Return the result of URL path serializing *url*.

The `pathname`[p309] setter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null or *url* has an opaque path, then return.
4. Set *url*'s path to the empty list.
5. Basic URL parse the given value, with *url* as *url* and path start state as *state override*.
6. Update `href`[p306].

The **`search`** getter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null, or *url*'s query is either null or the empty string, return the empty string.
4. Return "`?`", followed by *url*'s query.

The `search`[p309] setter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null, terminate these steps.
4. If the given value is the empty string, set *url*'s query to null.
5. Otherwise:
    1. Let *input* be the given value with a single leading "`?`" removed, if any.
    2. Set *url*'s query to the empty string.
    3. Basic URL parse *input*, with *url* as *url* and query state as *state override*.
6. Update `href`[p306].

The **`hash`** getter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].

3. If *url* is null, or *url*'s fragment is either null or the empty string, return the empty string.
4. Return "#", followed by *url*'s fragment.

The hash[p309] setter steps are:

1. Reinitialize url[p306].
2. Let *url* be this's url[p306].
3. If *url* is null, then return.
4. If the given value is the empty string, set *url*'s fragment to null.
5. Otherwise:
    1. Let *input* be the given value with a single leading "#" removed, if any.
    2. Set *url*'s fragment to the empty string.
    3. Basic URL parse *input*, with *url* as *url* and fragment state as *state override*.
6. Update href[p306].

4.6.4 Following hyperlinks §[p31]

An element *element* **cannot navigate** if any of the following are true:

- *element*'s node document is not fully active[p1017]; or
- *element* is not an a[p258] element and is not connected.

Note

This is also used by form submission[p633] for the form[p515] element. The exception for a[p258] elements is for compatibility with web content.

To **get an element's noopener**, given an a[p258], area[p472], or form[p515] element *element*, a URL record *url*, and a string *target*, perform the following steps. They return a boolean.

1. If *element*'s link types[p315] include the noopener[p326] or noreferrer[p326] keyword, then return true.
2. If *element*'s link types[p315] do not include the opener[p326] keyword and *target* is an ASCII case-insensitive match for "_blank", then return true.
3. If *url*'s blob URL entry is not null:
    1. Let *blobOrigin* be *url*'s blob URL entry's environment's origin[p1091].
    2. Let *topLevelOrigin* be *element*'s relevant settings object[p1098]'s top-level origin[p1091].
    3. If *blobOrigin* is not same site[p911] with *topLevelOrigin*, then return true.
4. Return false.

To **follow the hyperlink** created by an element *subject*, given an optional ***hyperlinkSuffix*** (default null) and an optional ***userInvolvement*** (default "none[p1028]"):

1. If *subject* cannot navigate[p310], then return.
2. Let *targetAttributeValue* be the empty string.
3. If *subject* is an a[p258] or area[p472] element, then set *targetAttributeValue* to the result of getting an element's target[p177] given *subject*.
4. Let *urlRecord* be the result of encoding-parsing a URL[p98] given *subject*'s href[p304] attribute value, relative to *subject*'s node document.

5. If *urlRecord* is failure, then return.
6. Let *noopener* be the result of getting an element's noopener[p310] with *subject*, *urlRecord*, and *targetAttributeValue*.
7. Let *targetNavigable* be the first return value of applying the rules for choosing a navigable[p1010] given *targetAttributeValue*, *subject*'s node navigable[p1002], and *noopener*.
8. If *targetNavigable* is null, then return.
9. Let *urlString* be the result of applying the URL serializer to *urlRecord*.
10. If *hyperlinkSuffix* is non-null, then append it to *urlString*.
11. Let *referrerPolicy* be the current state of *subject*'s `referrerpolicy` content attribute.
12. If *subject*'s link types[p315] includes the `noreferrer`[p326] keyword, then set *referrerPolicy* to "`no-referrer`".
13. Navigate[p1028] *targetNavigable* to *urlString* using *subject*'s node document, with *referrerPolicy*[p1028] set to *referrerPolicy*, *userInvolvement*[p1028] set to *userInvolvement*, and *sourceElement*[p1028] set to *subject*.

> **Note**
>
> *Unlike many other types of navigations, following hyperlinks does not have special "`replace`[p1027]" behavior for when documents are not completely loaded[p1078]. This is true for both user-initiated instances of following hyperlinks, as well as script-triggered ones via, e.g.,* `aElement.click()`.

4.6.5 Downloading resources §[p311]

In some cases, resources are intended for later use rather than immediate viewing. To indicate that a resource is intended to be downloaded for use later, rather than immediately used, the `download`[p304] attribute can be specified on the `a`[p258] or `area`[p472] element that creates the hyperlink[p303] to that resource.

The attribute can furthermore be given a value, to specify the filename that user agents are to use when storing the resource in a file system. This value can be overridden by the `Content-Disposition` HTTP header's filename parameters. [RFC6266][p1499]

In cross-origin situations, the `download`[p304] attribute has to be combined with the `Content-Disposition` HTTP header, specifically with the `attachment` disposition type, to avoid the user being warned of possibly nefarious activity. (This is to protect users from being made to download sensitive personal or confidential information without their full understanding.)

To **download the hyperlink** created by an element *subject*, given an optional ***hyperlinkSuffix*** (default null) and an optional ***userInvolvement*** (default "`none`[p1028]"):

1. If *subject* cannot navigate[p310], then return.
2. If *subject*'s node document's active sandboxing flag set[p928] has the sandboxed downloads browsing context flag[p927] set, then return.
3. Let *urlString* be the result of encoding-parsing-and-serializing a URL[p99] given *subject*'s `href`[p304] attribute value, relative to *subject*'s node document.
4. If *urlString* is failure, then return.
5. If *hyperlinkSuffix* is non-null, then append it to *urlString*.
6. If *userInvolvement* is not "`browser UI`[p1028]", then:
    1. Assert: *subject* has a `download`[p304] attribute.
    2. Let *navigation* be *subject*'s relevant global object[p1098]'s navigation API[p964].
    3. Let *filename* be the value of *subject*'s `download`[p304] attribute.
    4. Let *continue* be the result of firing a download request `navigate` event[p987] at *navigation* with *destinationURL*[p987] set to *urlString*, *userInvolvement*[p987] set to *userInvolvement*, *sourceElement*[p987] set to *subject*, and *filename*[p987] set to *filename*.

5. If *continue* is false, then return.

7. Run these steps in parallel[p44]:

    1. Optionally, the user agent may abort these steps, if it believes doing so would safeguard the user from a potentially hostile download.

    2. Let *request* be a new request whose URL is *urlString*, client is entry settings object[p1095], initiator is "`download`", destination is the empty string, and whose synchronous flag and use-URL-credentials flag are set.

    3. Handle as a download[p312] the result of fetching *request*.

To **handle as a download** a response *response*:

1. Let *suggestedFilename* be the result of getting the suggested filename[p312] for *response*.

2. Provide the user with a way to save *response* for later use. If the user agent needs a filename, it should use *suggestedFilename*. Report any problems downloading the file to the user.

3. Return *suggestedFilename*.

To **get the suggested filename** for a response *response*:

⚠Warning!

This algorithm is intended to mitigate security dangers involved in downloading files from untrusted sites, and user agents are strongly urged to follow it.

1. Let *filename* be the undefined value.

2. If *response* has a `Content-Disposition` header, that header specifies the `attachment` disposition type, and the header includes filename information, then let *filename* have the value specified by the header, and jump to the step labeled *sanitize* below. [RFC6266][p1499]

3. Let *interface origin* be the origin of the `Document`[p131] in which the download[p311] or navigate[p1028] action resulting in the download was initiated, if any.

4. Let *response origin* be the origin[p909] of the URL of *response*, unless that URL's scheme component is `data`, in which case let *response origin* be the same as the *interface origin*, if any.

5. If there is no *interface origin*, then let *trusted operation* be true. Otherwise, let *trusted operation* be true if *response origin* is the same origin[p910] as *interface origin*, and false otherwise.

6. If *trusted operation* is true and *response* has a `Content-Disposition` header and that header includes filename information, then let *filename* have the value specified by the header, and jump to the step labeled *sanitize* below. [RFC6266][p1499]

7. If the download was not initiated from a hyperlink[p303] created by an `a`[p258] or `area`[p472] element, or if the element of the hyperlink[p303] from which it was initiated did not have a `download`[p304] attribute when the download was initiated, or if there was such an attribute but its value when the download was initiated was the empty string, then jump to the step labeled *no proposed filename*.

8. Let *proposed filename* have the value of the `download`[p304] attribute of the element of the hyperlink[p303] that initiated the download at the time the download was initiated.

9. If *trusted operation* is true, let *filename* have the value of *proposed filename*, and jump to the step labeled *sanitize* below.

10. If *response* has a `Content-Disposition` header and that header specifies the `attachment` disposition type, let *filename* have the value of *proposed filename*, and jump to the step labeled *sanitize* below. [RFC6266][p1499]

11. *No proposed filename*: If *trusted operation* is true, or if the user indicated a preference for having the response in question downloaded, let *filename* have a value derived from the URL of *response* in an implementation-defined manner, and jump to the step labeled *sanitize* below.

12. Let *filename* be set to the user's preferred filename or to a filename selected by the user agent, and jump to the step labeled *sanitize* below.

    ⚠Warning!

If the algorithm reaches this step, then a download was begun from a different origin than* response*, and the origin did not mark the file as suitable for downloading, and the download was not initiated by the user. This could be because a* download[p304] *attribute was used to trigger the download, or because* response *is not of a type that the user agent supports.

This could be dangerous, because, for instance, a hostile server could be trying to get a user to unknowingly download private information and then re-upload it to the hostile server, by tricking the user into thinking the data is from the hostile server.

Thus, it is in the user's interests that the user be somehow notified that* response *comes from quite a different source, and to prevent confusion, any suggested filename from the potentially hostile* interface origin *should be ignored.

13. *Sanitize*: Optionally, allow the user to influence *filename*. For example, a user agent could prompt the user for a filename, potentially providing the value of *filename* as determined above as a default value.

14. Adjust *filename* to be suitable for the local file system.

    Example

    For example, this could involve removing characters that are not legal in filenames, or trimming leading and trailing whitespace.

15. If the platform conventions do not in any way use extensions[p313] to determine the types of file on the file system, then return *filename* as the filename.

16. Let *claimed type* be the type given by *response*'s Content-Type metadata[p100], if any is known. Let *named type* be the type given by *filename*'s extension[p313], if any is known. For the purposes of this step, a *type* is a mapping of a MIME type to an extension[p313].

17. If *named type* is consistent with the user's preferences (e.g., because the value of *filename* was determined by prompting the user), then return *filename* as the filename.

18. If *claimed type* and *named type* are the same type (i.e., the type given by *response*'s Content-Type metadata[p100] is consistent with the type given by *filename*'s extension[p313]), then return *filename* as the filename.

19. If the *claimed type* is known, then alter *filename* to add an extension[p313] corresponding to *claimed type*.

    Otherwise, if *named type* is known to be potentially dangerous (e.g. it will be treated by the platform conventions as a native executable, shell script, HTML application, or executable-macro-capable document), then optionally alter *filename* to add a known-safe extension[p313] (e.g. "`.txt`").

    Note

    This last step would make it impossible to download executables, which might not be desirable. As always, implementers are forced to balance security and usability in this matter.

20. Return *filename* as the filename.

For the purposes of this algorithm, a file **extension** consists of any part of the filename that platform conventions dictate will be used for identifying the type of the file. For example, many operating systems use the part of the filename following the last dot ("`.`") in the filename to determine the type of the file, and from that the manner in which the file is to be opened or executed.

User agents should ignore any directory or path information provided by the response itself, its URL, and any download[p304] attribute, in deciding where to store the resulting file in the user's file system.

4.6.6 Hyperlink auditing §[p313]

If a hyperlink[p303] created by an a[p258] or area[p472] element has a ping[p304] attribute, and the user follows the hyperlink, and the value of the element's href[p304] attribute can be parsed[p98], relative to the element's node document, without failure, then the user agent must take the ping[p304] attribute's value, split that string on ASCII whitespace, parse[p98] each resulting token, relative to the element's node document, and then run these steps for each resulting URL *ping URL*, ignoring when parsing returns failure:

1. If *ping URL*'s scheme is not an HTTP(S) scheme, then return.

2. Optionally, return. (For example, the user agent might wish to ignore any or all ping URLs in accordance with the user's expressed preferences.)

3. Let *settingsObject* be the element's node document's relevant settings object[p1098].

4. Let *request* be a new request whose URL is *ping URL*, method is `POST`, header list is « (`Content-Type`[p100], `text/ping`[p1465]) », body is `PING`, client is *settingsObject*, destination is the empty string, credentials mode is "include", referrer is "no-referrer", and whose use-URL-credentials flag is set, and whose initiator type is "ping".

5. Let *target URL* be the result of encoding-parsing-and-serializing a URL[p99] given the element's `href`[p304] attribute's value, relative to the element's node document, and then:

   ↪ **If the URL of the `Document`[p131] object containing the hyperlink being audited and *ping URL* have the same origin[p910]**

   ↪ **If the origins are different, but the scheme of the URL of the `Document`[p131] containing the hyperlink being audited is not "`https`"**

   request must include a `Ping-From`[p314] header with, as its value, the URL of the document containing the hyperlink, and a `Ping-To`[p314] HTTP header with, as its value, the *target URL*.

   ↪ **Otherwise**

   request must include a `Ping-To`[p314] HTTP header with, as its value, *target URL*. Note request *does not include a `Ping-From`[p314] header.*

6. Fetch *request*.

This may be done in parallel[p44] with the primary fetch, and is independent of the result of that fetch.

User agents should allow the user to adjust this behavior, for example in conjunction with a setting that disables the sending of HTTP `Referer` (sic) headers. Based on the user's preferences, UAs may either ignore[p46] the `ping`[p304] attribute altogether, or selectively ignore URLs in the list (e.g. ignoring any third-party URLs); this is explicitly accounted for in the steps above.

User agents must ignore any entity bodies returned in the responses. User agents may close the connection prematurely once they start receiving a response body.

An `a`[p258] or `area`[p472] element that creates a hyperlink[p303] and has the `ping`[p304] attribute is present, user agents may indicate to the user that following the hyperlink will also cause secondary requests to be sent in the background, possibly including listing the actual target URLs.

Example

For example, a visual user agent could include the hostnames of the target ping URLs along with the hyperlink's actual URL in a status bar or tooltip.

Note

The `ping`[p304] attribute is redundant with pre-existing technologies like HTTP redirects and JavaScript in allowing web pages to track which off-site links are most popular or allowing advertisers to track click-through rates.

However, the `ping`[p304] attribute provides these advantages to the user over those alternatives:

- *It allows the user to see the final target URL unobscured.*
- *It allows the UA to inform the user about the out-of-band notifications.*
- *It allows the UA to optimize the use of available network bandwidth so that the target page loads faster.*

4.6.6.1 The `Ping-From`[p314] and `Ping-To`[p314] headers §[p31 4]

The **`Ping-From`** and **`Ping-To`** HTTP request headers are included in hyperlink auditing[p313] requests. Their value is a URL, serialized.

4.6.7 Link types §[p315]

The following table summarizes the link types that are defined by this specification, by their corresponding keywords. This table is non-normative; the actual definitions for the link types are given in the next few sections.

In this section, the term *referenced document* refers to the resource identified by the element representing the link, and the term *current document* refers to the resource within which the element representing the link finds itself.

To determine which link types apply to a `link`[p178], `a`[p258], `area`[p472], or `form`[p515] element, the element's `rel` attribute must be split on ASCII whitespace. The resulting tokens are the keywords for the link types that apply to that element.

Except where otherwise specified, a keyword must not be specified more than once per `rel`[p304] attribute.

Some of the sections that follow the table below list synonyms for certain keywords. The indicated synonyms are to be handled as specified by user agents, but must not be used in documents (for example, the keyword "`copyright`").

Keywords are always ASCII case-insensitive, and must be compared as such.

Example

Thus, `rel="next"` is the same as `rel="NEXT"`.

Keywords that are **body-ok** affect whether `link`[p178] elements are allowed in the body[p180]. The body-ok[p315] keywords are `dns-prefetch`[p318], `modulepreload`[p324], `pingback`[p327], `preconnect`[p327], `prefetch`[p328], `preload`[p329], and `stylesheet`[p332].

New link types that are to be implemented by web browsers are to be added to this standard. The remainder can be registered as extensions[p336].

Link type	Effect on...			body-ok[p315]	Has `Link` processing	Brief description
	`link`[p178]	`a`[p258] and `area`[p472]	`form`[p515]			
`alternate`[p316]	Hyperlink[p303]		*not allowed*	·	·	Gives alternate representations of the current document.
`canonical`[p318]	Hyperlink[p303]	*not allowed*		·	·	Gives the preferred URL for the current document.
`author`[p317]	Hyperlink[p303]		*not allowed*	·	·	Gives a link to the author of the current document or article.
`bookmark`[p318]	*not allowed*	Hyperlink[p303]	*not allowed*	·	·	Gives the permalink for the nearest ancestor section.
`dns-prefetch`[p318]	External Resource[p303]	*not allowed*		Yes	·	Specifies that the user agent should preemptively perform DNS resolution for the target resource's origin[p909].
`expect`[p319]	Internal Resource[p303]	*not allowed*		·	·	Expect an element with the target ID to appear in the current document.
`external`[p320]	*not allowed*	Annotation[p304]		·	·	Indicates that the referenced document is not part of the same site as the current document.
`help`[p320]	Hyperlink[p303]			·	·	Provides a link to context-sensitive help.
`icon`[p321]	External Resource[p303]	*not allowed*		·	·	Imports an icon to represent the current document.
`manifest`[p323]	External Resource[p303]	*not allowed*		·	·	Imports or links to an application manifest. [MANIFEST][p1497]
`modulepreload`[p324]	External Resource[p303]	*not allowed*		Yes	·	Specifies that the user agent must preemptively fetch the module script[p1106] and store it in the document's module map[p132] for later evaluation. Optionally, the module's dependencies can be fetched as well.
`license`[p322]	Hyperlink[p303]			·	·	Indicates that the main content of the current document is covered by the copyright license described by the referenced document.
`next`[p336]	Hyperlink[p303]			·	·	Indicates that the current document is a part of a series, and that the next document in the series is the referenced document.
`nofollow`[p326]	*not allowed*	Annotation[p304]		·	·	Indicates that the current document's original author or publisher does not endorse the referenced document.
`noopener`[p326]	*not allowed*	Annotation[p304]		·	·	Creates a top-level traversable[p1003] with a non-auxiliary browsing context[p1012] if the hyperlink would otherwise create one that was auxiliary (i.e., has an appropriate `target`[p304] attribute value).
`noreferrer`[p326]	*not allowed*	Annotation[p304]		·	·	No `Referer` (sic) header will be included. Additionally, has the same effect as `noopener`[p326].
`opener`[p326]	*not allowed*	Annotation[p304]		·	·	Creates an auxiliary browsing context[p1012] if the hyperlink would otherwise create a top-level traversable[p1003] with a non-auxiliary browsing context[p1012] (i.e., has

Link type	Effect on...			body-ok[p315]	Has `Link` processing	Brief description
	link[p178]	a[p258] and area[p472]	form[p515]			
						"_blank" as target[p304] attribute value).
pingback[p327]	External Resource[p303]	*not allowed*		Yes	·	Gives the address of the pingback server that handles pingbacks to the current document.
preconnect[p327]	External Resource[p303]	*not allowed*		Yes	Yes	Specifies that the user agent should preemptively connect to the target resource's origin[p909].
prefetch[p328]	External Resource[p303]	*not allowed*		Yes	·	Specifies that the user agent should preemptively fetch and cache the target resource as it is likely to be required for a followup navigation[p1028].
preload[p329]	External Resource[p303]	*not allowed*		Yes	Yes	Specifies that the user agent must preemptively fetch and cache the target resource for current navigation[p1028] according to the potential destination given by the as[p182] attribute (and the priority associated with the corresponding destination).
prev[p336]	Hyperlink[p303]			·	·	Indicates that the current document is a part of a series, and that the previous document in the series is the referenced document.
privacy-policy[p332]	Hyperlink[p303]		*not allowed*	·	·	Gives a link to information about the data collection and usage practices that apply to the current document.
search[p332]	Hyperlink[p303]			·	·	Gives a link to a resource that can be used to search through the current document and its related pages.
stylesheet[p332]	External Resource[p303]	*not allowed*		Yes	·	Imports a style sheet.
tag[p335]	*not allowed*	Hyperlink[p303]	*not allowed*	·	·	Gives a tag (identified by the given address) that applies to the current document.
terms-of-service[p336]	Hyperlink[p303]		*not allowed*	·	·	Gives a link to information about the agreements between the current document's provider and users who wish to use the current document.

4.6.7.1 Link type "alternate" §[p316]

The alternate[p316] keyword may be used with link[p178], a[p258], and area[p472] elements.

The meaning of this keyword depends on the values of the other attributes.

↪ **If the element is a link[p178] element and the rel[p179] attribute also contains the keyword stylesheet[p332]**

The alternate[p316] keyword modifies the meaning of the stylesheet[p332] keyword in the way described for that keyword. The alternate[p316] keyword does not create a link of its own.

Example

Here, a set of link[p178] elements provide some style sheets:

```
<!-- a persistent style sheet -->
<link rel="stylesheet" href="default.css">

<!-- the preferred alternate style sheet -->
<link rel="stylesheet" href="green.css" title="Green styles">

<!-- some alternate style sheets -->
<link rel="alternate stylesheet" href="contrast.css" title="High contrast">
<link rel="alternate stylesheet" href="big.css" title="Big fonts">
<link rel="alternate stylesheet" href="wide.css" title="Wide screen">
```

↪ **If the alternate[p316] keyword is used with the type[p304] attribute set to the value `application/rss+xml` or the value `application/atom+xml`**

The keyword creates a hyperlink[p303] referencing a syndication feed (though not necessarily syndicating exactly the same content as the current page).

For the purposes of feed autodiscovery, user agents should consider all link[p178] elements in the document with the alternate[p316] keyword used and with their type[p304] attribute set to the value `application/rss+xml` or the value `application/atom+xml`. If the user agent has the concept of a default syndication feed, the first such element (in tree order) should be used as the default.

Example

The following link[p178] elements give syndication feeds for a blog:

```
<link rel="alternate" type="application/atom+xml" href="posts.xml" title="Cool Stuff Blog">
<link rel="alternate" type="application/atom+xml" href="posts.xml?category=robots" title="Cool
Stuff Blog: robots category">
<link rel="alternate" type="application/atom+xml" href="comments.xml" title="Cool Stuff Blog:
Comments">
```

Such link[p178] elements would be used by user agents engaged in feed autodiscovery, with the first being the default (where applicable).

The following example offers various different syndication feeds to the user, using a[p258] elements:

```
<p>You can access the planets database using Atom feeds:</p>
<ul>
 <li><a href="recently-visited-planets.xml" rel="alternate" type="application/
atom+xml">Recently Visited Planets</a></li>
 <li><a href="known-bad-planets.xml" rel="alternate" type="application/atom+xml">Known Bad
Planets</a></li>
 <li><a href="unexplored-planets.xml" rel="alternate" type="application/atom+xml">Unexplored
Planets</a></li>
</ul>
```

These links would not be used in feed autodiscovery.

↪ **Otherwise**

The keyword creates a hyperlink[p303] referencing an alternate representation of the current document.

The nature of the referenced document is given by the hreflang[p304], and type[p304] attributes.

If the alternate[p316] keyword is used with the hreflang[p304] attribute, and that attribute's value differs from the document element's language[p159], it indicates that the referenced document is a translation.

If the alternate[p316] keyword is used with the type[p304] attribute, it indicates that the referenced document is a reformulation of the current document in the specified format.

The hreflang[p304] and type[p304] attributes can be combined when specified with the alternate[p316] keyword.

Example

The following example shows how you can specify versions of the page that use alternative formats, are aimed at other languages, and that are intended for other media:

```
<link rel=alternate href="/en/html" hreflang=en type=text/html title="English HTML">
<link rel=alternate href="/fr/html" hreflang=fr type=text/html title="French HTML">
<link rel=alternate href="/en/html/print" hreflang=en type=text/html media=print
title="English HTML (for printing)">
<link rel=alternate href="/fr/html/print" hreflang=fr type=text/html media=print title="French
HTML (for printing)">
<link rel=alternate href="/en/pdf" hreflang=en type=application/pdf title="English PDF">
<link rel=alternate href="/fr/pdf" hreflang=fr type=application/pdf title="French PDF">
```

This relationship is transitive — that is, if a document links to two other documents with the link type "alternate[p316]", then, in addition to implying that those documents are alternative representations of the first document, it is also implying that those two documents are alternative representations of each other.

4.6.7.2 Link type "author" §[p317]

The author[p317] keyword may be used with link[p178], a[p258], and area[p472] elements. This keyword creates a hyperlink[p303].

For a[p258] and area[p472] elements, the author[p317] keyword indicates that the referenced document provides further information about the author of the nearest article[p207] element ancestor of the element defining the hyperlink, if there is one, or of the page as a whole, otherwise.

For link[p178] elements, the author[p317] keyword indicates that the referenced document provides further information about the author for the page as a whole.

Note

The "referenced document" can be, and often is, a mailto: URL giving the email address of the author. [MAILTO][p1497]

Synonyms: For historical reasons, user agents must also treat link[p178], a[p258], and area[p472] elements that have a rev attribute with the value "made" as having the author[p317] keyword specified as a link relationship.

4.6.7.3 Link type "bookmark" §[p318]

The bookmark[p318] keyword may be used with a[p258] and area[p472] elements. This keyword creates a hyperlink[p303].

The bookmark[p318] keyword gives a permalink for the nearest ancestor article[p207] element of the linking element in question, or of the section the linking element is most closely associated with, if there are no ancestor article[p207] elements.

Example

The following snippet has three permalinks. A user agent could determine which permalink applies to which part of the spec by looking at where the permalinks are given.

```
...
<body>
 <h1>Example of permalinks</h1>
 <div id="a">
  <h2>First example</h2>
  <p><a href="a.html" rel="bookmark">This permalink applies to
  only the content from the first H2 to the second H2</a>. The DIV isn't
  exactly that section, but it roughly corresponds to it.</p>
 </div>
 <h2>Second example</h2>
 <article id="b">
  <p><a href="b.html" rel="bookmark">This permalink applies to
  the outer ARTICLE element</a> (which could be, e.g., a blog post).</p>
  <article id="c">
   <p><a href="c.html" rel="bookmark">This permalink applies to
   the inner ARTICLE element</a> (which could be, e.g., a blog comment).</p>
  </article>
 </article>
</body>
...
```

4.6.7.4 Link type "canonical" §[p318]

The canonical[p318] keyword may be used with link[p178] element. This keyword creates a hyperlink[p303].

The canonical[p318] keyword indicates that URL given by the href[p179] attribute is the preferred URL for the current document. That helps search engines reduce duplicate content, as described in more detail in *The Canonical Link Relation*. [RFC6596][p1499]

4.6.7.5 Link type "dns-prefetch" §[p318]

The dns-prefetch[p318] keyword may be used with link[p178] elements. This keyword creates an external resource link[p303]. This keyword is body-ok[p315].

The dns-prefetch keyword indicates that preemptively performing DNS resolution for the origin of the specified resource is likely to be beneficial, as it is highly likely that the user will require resources located at that origin, and the user experience would be improved by preempting the latency costs associated with DNS resolution.

There is no default type for resources given by the dns-prefetch keyword.

The appropriate times to fetch and process this type of link are:

- When the external resource link is created on a link element that is already browsing-context connected.
- When the external resource link's link element becomes browsing-context connected.
- When the href attribute of the link element of an external resource link that is already browsing-context connected is changed.

The fetch and process the linked resource steps for this type of linked resource, given a link element *el*, are:

1. Let *url* be the result of encoding-parsing a URL given *el*'s href attribute's value, relative to *el*'s node document.
2. If *url* is failure, then return.
3. Let *partitionKey* be the result of determining the network partition key given *el*'s node document's relevant settings object.
4. The user agent should resolve an origin given *partitionKey* and *url*'s origin.

> **Note**
> *As the results of this algorithm can be cached, future fetches could be faster.*

4.6.7.6 Link type "expect" §9

The expect keyword may be used with link elements. This keyword creates an internal resource link.

An internal resource link created by the expect keyword can be used to block rendering until the element that it indicates is connected to the document and fully parsed.

There is no default type for resources given by the expect keyword.

Whenever any of the following conditions occur for a link element *el*:

- the expect internal resource link is created on *el* that is already browsing-context connected;
- an expect internal resource link has been created on *el* and *el* becomes browsing-context connected;
- an expect internal resource link has been created on *el*, *el* is already browsing-context connected, and *el*'s href attribute is set, changed, or removed; or
- an expect internal resource link has been created on *el*, *el* is already browsing-context connected, and *el*'s media attribute is set, changed, or removed,

then process *el*.

To **process internal resource link** given a link element *el*, run these steps:

1. Let *doc* be *el*'s node document.
2. Let *url* be the result of encoding-parsing a URL given *el*'s href attribute's value, relative to *doc*.
3. If this fails, or if *url* does not equal *doc*'s URL with *exclude fragments* set to false, then unblock rendering on *el* and return.
4. Let *indicatedElement* be the result of selecting the indicated part given *doc* and *url*.
5. If all of the following are true:
    - *doc*'s current document readiness is "loading";

- *el* creates an internal resource link[p303];
- *el* is browsing-context connected[p47];
- *el*'s `rel`[p179] attribute contains `expect`[p319];
- *el* is potentially render-blocking[p105];
- *el*'s `media`[p180] attribute matches the environment[p97]; and
- *indicatedElement* is not an element, or is on a stack of open elements[p1304] of an HTML parser[p1289] whose associated `Document`[p131] is *doc*,

then block rendering[p135] on *el*.

6. Otherwise, unblock rendering[p136] on *el*.

To **process internal resource links** given a `Document`[p131] *doc*:

1. For each `expect`[p319] `link`[p178] element *link* in *doc*'s render-blocking element set[p135], process[p319] *link*.

The following attribute change steps, given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used to ensure `expect`[p319] `link`[p178] elements respond to dynamic `id`[p156] and `name`[p1445] changes:

1. If *namespace* is not null, then return.
2. If *element* is in a stack of open elements[p1304] of an HTML parser[p1289], then return.
3. If any of the following is true:
   - *localName* is `id`[p156]; or
   - *localName* is `name`[p1445] and *element* is an `a`[p258] element,

   then process internal resource links[p320] given *element*'s node document.

4.6.7.7 Link type "external" §[p32]

The `external`[p320] keyword may be used with `a`[p258], `area`[p472], and `form`[p515] elements. This keyword does not create a hyperlink[p303], but annotates[p304] any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The `external`[p320] keyword indicates that the link is leading to a document that is not part of the site that the current document forms a part of.

4.6.7.8 Link type "help" §[p32]

The `help`[p320] keyword may be used with `link`[p178], `a`[p258], `area`[p472], and `form`[p515] elements. This keyword creates a hyperlink[p303].

For `a`[p258], `area`[p472], and `form`[p515] elements, the `help`[p320] keyword indicates that the referenced document provides further help information for the parent of the element defining the hyperlink, and its children.

Example

In the following example, the form control has associated context-sensitive help. The user agent could use this information, for example, displaying the referenced document if the user presses the "Help" or "F1" key.

```
<p><label> Topic: <input name=topic> <a href="help/topic.html" rel="help">(Help)</a></label></p>
```

For `link`[p178] elements, the `help`[p320] keyword indicates that the referenced document provides help for the page as a whole.

For `a`[p258] and `area`[p472] elements, on some browsers, the `help`[p320] keyword causes the link to use a different cursor.

4.6.7.9 Link type "icon" §[p32]

The icon[p321] keyword may be used with link[p178] elements. This keyword creates an external resource link[p303].

The specified resource is an icon representing the page or site, and should be used by the user agent when representing the page in the user interface.

Icons could be auditory icons, visual icons, or other kinds of icons. If multiple icons are provided, the user agent must select the most appropriate icon according to the type[p180], media[p180], and sizes[p181] attributes. If there are multiple equally appropriate icons, user agents must use the last one declared in tree order at the time that the user agent collected the list of icons. If the user agent tries to use an icon but that icon is determined, upon closer examination, to in fact be inappropriate (e.g. because it uses an unsupported format), then the user agent must try the next-most-appropriate icon as determined by the attributes.

Note

User agents are not required to update icons when the list of icons changes, but are encouraged to do so.

There is no default type for resources given by the icon[p321] keyword. However, for the purposes of determining the type of the resource[p183], user agents must expect the resource to be an image.

The sizes[p181] keywords represent icon sizes in raw pixels (as opposed to CSS pixels).

Note

An icon that is 50 CSS pixels wide intended for displays with a device pixel density of two device pixels per CSS pixel (2x, 192dpi) would have a width of 100 raw pixels. This feature does not support indicating that a different resource is to be used for small high-resolution icons vs large low-resolution icons (e.g. 50×50 2x vs 100×100 1x).

To parse and process the attribute's value, the user agent must first split the attribute's value on ASCII whitespace, and must then parse each resulting keyword to determine what it represents.

The **any** keyword represents that the resource contains a scalable icon, e.g. as provided by an SVG image.

Other keywords must be further parsed as follows to determine what they represent:

1. If the keyword doesn't contain exactly one U+0078 LATIN SMALL LETTER X or U+0058 LATIN CAPITAL LETTER X character, then this keyword doesn't represent anything. Return for that keyword.
2. Let *width string* be the string before the "`x`" or "`X`".
3. Let *height string* be the string after the "`x`" or "`X`".
4. If either *width string* or *height string* start with a U+0030 DIGIT ZERO (0) character or contain any characters other than ASCII digits, then this keyword doesn't represent anything. Return for that keyword.
5. Apply the rules for parsing non-negative integers[p78] to *width string* to obtain *width*.
6. Apply the rules for parsing non-negative integers[p78] to *height string* to obtain *height*.
7. The keyword represents that the resource contains a bitmap icon with a width of *width* device pixels and a height of *height* device pixels.

The keywords specified on the sizes[p181] attribute must not represent icon sizes that are not actually available in the linked resource.

The linked resource fetch setup steps[p184] for this type of linked resource, given a link[p178] element *el* and request *request*, are:

1. Set *request*'s destination to "`image`".
2. Return true.

The process a link header[p185] steps for this type of linked resource are to do nothing.

In the absence of a link[p178] with the icon[p321] keyword, for Document[p131] objects whose URL's scheme is an HTTP(S) scheme, user agents may instead run these steps in parallel[p44]:

1. Let *request* be a new request whose URL is the URL record obtained by resolving the URL "`/favicon.ico`" against the Document[p131] object's URL, client is the Document[p131] object's relevant settings object[p1098], destination is "`image`", synchronous

flag is set, credentials mode is "include", and whose use-URL-credentials flag is set.

2. Let *response* be the result of fetching *request*.

3. Use *response*'s unsafe response[p99] as an icon as if it had been declared using the icon[p321] keyword.

Example

The following snippet shows the top part of an application with several icons.

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>lsForums — Inbox</title>
  <link rel=icon href=favicon.png sizes="16x16" type="image/png">
  <link rel=icon href=windows.ico sizes="32x32 48x48" type="image/vnd.microsoft.icon">
  <link rel=icon href=mac.icns sizes="128x128 512x512 8192x8192 32768x32768">
  <link rel=icon href=iphone.png sizes="57x57" type="image/png">
  <link rel=icon href=gnome.svg sizes="any" type="image/svg+xml">
  <link rel=stylesheet href=lsforums.css>
  <script src=lsforums.js></script>
  <meta name=application-name content="lsForums">
 </head>
 <body>
  ...
```

For historical reasons, the icon[p321] keyword may be preceded by the keyword "shortcut". If the "shortcut" keyword is present, the rel[p304] attribute's entire value must be an ASCII case-insensitive match for the string "shortcut icon" (with a single U+0020 SPACE character between the tokens and no other ASCII whitespace).

4.6.7.10 Link type "license" §[p32]

The license[p322] keyword may be used with link[p178], a[p258], area[p472], and form[p515] elements. This keyword creates a hyperlink[p303].

The license[p322] keyword indicates that the referenced document provides the copyright license terms under which the main content of the current document is provided.

This specification does not specify how to distinguish between the main content of a document and content that is not deemed to be part of that main content. The distinction should be made clear to the user.

Example

Consider a photo sharing site. A page on that site might describe and show a photograph, and the page might be marked up as follows:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>Exampl Pictures: Kissat</title>
  <link rel="stylesheet" href="/style/default">
 </head>
 <body>
  <h1>Kissat</h1>
  <nav>
   <a href="../">Return to photo index</a>
  </nav>
  <figure>
   <img src="/pix/39627052_fd8dcd98b5.jpg">
   <figcaption>Kissat</figcaption>
  </figure>
  <p>One of them has six toes!</p>
```

```
  <p><small><a rel="license" href="http://www.opensource.org/licenses/mit-license.php">MIT
Licensed</a></small></p>
  <footer>
   <a href="/">Home</a> | <a href="../">Photo index</a>
   <p><small>© copyright 2009 Exampl Pictures. All Rights Reserved.</small></p>
  </footer>
 </body>
</html>
```

In this case the `license`[p322] applies to just the photo (the main content of the document), not the whole document. In particular not the design of the page itself, which is covered by the copyright given at the bottom of the document. This could be made clearer in the styling (e.g. making the license link prominently positioned near the photograph, while having the page copyright in light small text at the foot of the page).

Synonyms: For historical reasons, user agents must also treat the keyword "`copyright`" like the `license`[p322] keyword.

4.6.7.11 Link type "`manifest`" §[p323]

The `manifest`[p323] keyword may be used with `link`[p178] elements. This keyword creates an external resource link[p303].

The `manifest`[p323] keyword indicates the manifest file that provides metadata associated with the current document.

There is no default type for resources given by the `manifest`[p323] keyword.

When a web application is not installed, the appropriate time to fetch and process the linked resource[p184] for this link type is when the user agent deems it necessary. For example, when the user chooses to install the web application.

For an installed web application, the appropriate times to fetch and process the linked resource[p184] for this link type are:

- When the external resource link[p303] is created on a `link`[p178] element that is already browsing-context connected[p47].
- When the external resource link[p303]'s `link`[p178] element becomes browsing-context connected[p47].
- When the `href`[p179] attribute of the `link`[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is changed.

In any case, only the first `link`[p178] element in tree order whose `rel`[p179] attribute contains the token `manifest`[p323] may be used.

A user agent must not delay the load event[p1377] for this link type.

The linked resource fetch setup steps[p184] for this type of linked resource, given a `link`[p178] element *el* and request *request*, are:

1. Let *navigable* be *el*'s node document's node navigable[p1002].
2. If *navigable* is null, then return false.
3. If *navigable* is not a top-level traversable[p1003], then return false.
4. Set *request*'s initiator to "`manifest`".
5. Set *request*'s destination to "`manifest`".
6. Set *request*'s mode to "`cors`".
7. Set *request*'s credentials mode to the CORS settings attribute credentials mode[p101] for *el*'s `crossorigin`[p180] content attribute.
8. Return true.

To process this type of linked resource[p185] given a `link`[p178] element *el*, boolean *success*, response *response*, and byte sequence *bodyBytes*:

1. If *response*'s Content-Type metadata[p100] is not a JSON MIME type, then set *success* to false.

2. If *success* is true:

    1. Let *document URL* be *el*'s node document's URL.

    2. Let *manifest URL* be *response*'s URL.

    3. Process the manifest given *document URL*, *manifest URL*, and *bodyBytes*. [MANIFEST]

The process a link header steps for this type of linked resource are to do nothing.

MDN

4.6.7.12 Link type "modulepreload"

The `modulepreload` keyword may be used with `link` elements. This keyword creates an external resource link. This keyword is body-ok.

The `modulepreload` keyword is a specialized alternative to the `preload` keyword, with a processing model geared toward preloading module scripts. In particular, it uses the specific fetch behavior for module scripts (including, e.g., a different interpretation of the `crossorigin` attribute), and places the result into the appropriate module map for later evaluation. In contrast, a similar external resource link using the `preload` keyword would place the result in the preload cache, without affecting the document's module map.

Additionally, implementations can take advantage of the fact that module scripts declare their dependencies in order to fetch the specified module's dependency as well. This is intended as an optimization opportunity, since the user agent knows that, in all likelihood, those dependencies will also be needed later. It will not generally be observable without using technology such as service workers, or monitoring on the server side. Notably, the appropriate `load` or `error` events will occur after the specified module is fetched, and will not wait for any dependencies.

A user agent must not delay the load event for this link type.

The appropriate times to fetch and process the linked resource for such a link are:

- When the external resource link is created on a `link` element that is already browsing-context connected.
- When the external resource link's `link` element becomes browsing-context connected.
- When the `href` attribute of the `link` element of an external resource link that is already browsing-context connected is changed.

Note

Unlike some other link relations, changing the relevant attributes (such as `as`, `crossorigin`, and `referrerpolicy`) of such a `link` does not trigger a new fetch. This is because the document's module map has already been populated by a previous fetch, and so re-fetching would be pointless.

The fetch and process the linked resource algorithm for `modulepreload` links, given a `link` element *el*, is as follows:

1. If *el*'s `href` attribute's value is the empty string, then return.
2. Let *destination* be the current state of *el*'s `as` attribute (a destination), or "`script`" if it is in no state.
3. If *destination* is not script-like, then queue an element task on the networking task source given *el* to fire an event named `error` at *el*, and return.
4. Let *url* be the result of encoding-parsing a URL given *el*'s `href` attribute's value, relative to *el*'s node document.
5. If *url* is failure, then return.
6. Let *settings object* be *el*'s node document's relevant settings object.
7. Let *credentials mode* be the CORS settings attribute credentials mode for *el*'s `crossorigin` attribute.
8. Let *cryptographic nonce* be *el*.[[CryptographicNonce]].
9. Let *integrity metadata* be the value of *el*'s `integrity` attribute, if it is specified, or the empty string otherwise.
10. If *el* does not have an `integrity` attribute, then set *integrity metadata* to the result of resolving a module integrity

metadata[p1101] with *url* and *settings object*.

11. Let *referrer policy* be the current state of *el*'s `referrerpolicy`[p180] attribute.

12. Let *fetch priority* be the current state of *el*'s `fetchpriority`[p182] attribute.

13. Let *options* be a script fetch options[p1101] whose cryptographic nonce[p1101] is *cryptographic nonce*, integrity metadata[p1101] is *integrity metadata*, parser metadata[p1101] is "`not-parser-inserted`", credentials mode[p1101] is *credentials mode*, referrer policy[p1101] is *referrer policy*, and fetch priority[p1101] is *fetch priority*.

14. Fetch a modulepreload module script graph[p1104] given *url*, *destination*, *settings object*, *options*, and with the following steps given *result*:

    1. If *result* is null, then fire an event named `error`[p1489] at *el*, and return.

    2. Fire an event named `load`[p1490] at *el*.

The process a link header[p185] steps for this type of linked resource are to do nothing.

¶[p325] **Example**

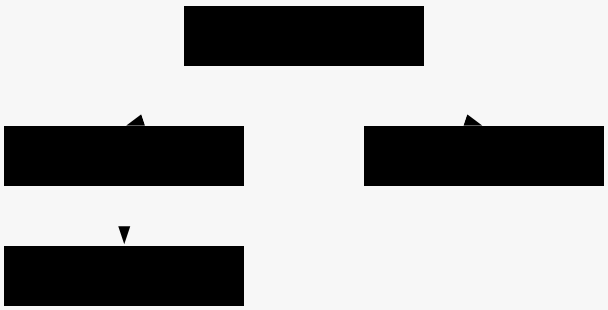
The following snippet shows the top part of an application with several modules preloaded:

```
<!DOCTYPE html>
<html lang="en">
<title>IRCFog</title>

<link rel="modulepreload" href="app.mjs">
<link rel="modulepreload" href="helpers.mjs">
<link rel="modulepreload" href="irc.mjs">
<link rel="modulepreload" href="fog-machine.mjs">

<script type="module" src="app.mjs">
...
```

Assume that the module graph for the application is as follows:



Here we see the application developer has used `modulepreload`[p324] to declare all of the modules in their module graph, ensuring that the user agent initiates fetches for them all. Without such preloading, the user agent might need to go through multiple network roundtrips before discovering `helpers.mjs`, if technologies such as HTTP/2 Server Push are not in play. In this way, `modulepreload`[p324] `link`[p178] elements can be used as a sort of "manifest" of the application's modules.

¶[p325] **Example**

The following code shows how `modulepreload`[p324] links can be used in conjunction with `import()` to ensure network fetching is done ahead of time, so that when `import()` is called, the module is already ready (but not evaluated) in the module map[p1134]:

```
<link rel="modulepreload" href="awesome-viewer.mjs">

<button onclick="import('./awesome-viewer.mjs').then(m => m.view())">
  View awesome thing
</button>
```

4.6.7.13 Link type "nofollow" §p32 6

The nofollow p326 keyword may be used with a p258, area p472, and form p515 elements. This keyword does not create a hyperlink p303, but annotates p304 any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The nofollow p326 keyword indicates that the link is not endorsed by the original author or publisher of the page, or that the link to the referenced document was included primarily because of a commercial relationship between people affiliated with the two pages.

✔ MDN

4.6.7.14 Link type "noopener" §p32 6

The noopener p326 keyword may be used with a p258, area p472, and form p515 elements. This keyword does not create a hyperlink p303, but annotates p304 any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The keyword indicates that any newly created top-level traversable p1003 which results from following the hyperlink p303 will not contain an auxiliary browsing context p1012. E.g., the resulting Window p934's opener p942 getter will return null.

Note

See also the processing model p1011.

Example

This typically creates a top-level traversable p1003 with an auxiliary browsing context p1012 (assuming there is no existing navigable p1001 whose target name p1002 is "example"):

```
<a href=help.html target=example>Help!</a>
```

This creates a top-level traversable p1003 with a non-auxiliary browsing context p1012 (assuming the same thing):

```
<a href=help.html target=example rel=noopener>Help!</a>
```

These are equivalent and only navigate the parent navigable p1001:

```
<a href=index.html target=_parent>Home</a>
```

```
<a href=index.html target=_parent rel=noopener>Home</a>
```

✔ MDN

4.6.7.15 Link type "noreferrer" §p32 6

The noreferrer p326 keyword may be used with a p258, area p472, and form p515 elements. This keyword does not create a hyperlink p303, but annotates p304 any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

It indicates that no referrer information is to be leaked when following the link and also implies the noopener p326 keyword behavior under the same conditions.

Note

See also the processing model p311 where referrer is directly manipulated.

Example

`<a href="..." rel="noreferrer" target="_blank">` has the same behavior as `<a href="..." rel="noreferrer noopener" target="_blank">`.

4.6.7.16 Link type "opener" §p32 6

The opener p326 keyword may be used with a p258, area p472, and form p515 elements. This keyword does not create a hyperlink p303, but

annotates[p304] any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The keyword indicates that any newly created top-level traversable[p1003] which results from following the hyperlink[p303] will contain an auxiliary browsing context[p1012].

Note

See also the processing model[p310].

Example

In the following example the opener[p326] is used to allow the help page popup to navigate its opener, e.g., in case what the user is looking for can be found elsewhere. An alternative might be to use a named target, rather than `_blank`, but this has the potential to clash with existing names.

```
<a href="..." rel=opener target=_blank>Help!</a>
```

4.6.7.17 Link type "pingback" §[p327]

The pingback[p327] keyword may be used with link[p178] elements. This keyword creates an external resource link[p303]. This keyword is body-ok[p315].

For the semantics of the pingback[p327] keyword, see *Pingback 1.0*. [PINGBACK][p1498]

4.6.7.18 Link type "preconnect" §[p327]

The preconnect[p327] keyword may be used with link[p178] elements. This keyword creates an external resource link[p303]. This keyword is body-ok[p315].

The preconnect[p327] keyword indicates that preemptively initiating a connection to the origin[p909] of the specified resource is likely to be beneficial, as it is highly likely that the user will require resources located at that origin[p909], and the user experience would be improved by preempting the latency costs associated with establishing the connection.

There is no default type for resources given by the preconnect[p327] keyword.

A user agent must not delay the load event[p1377] for this link type.

The appropriate times to fetch and process[p184] this type of link are:

- When the external resource link[p303] is created on a link[p178] element that is already browsing-context connected[p47].
- When the external resource link[p303]'s link[p178] element becomes browsing-context connected[p47].
- When the href[p179] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is changed.
- When the crossorigin[p180] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is set, changed, or removed.

The fetch and process the linked resource[p184] steps for this type of linked resource, given a link[p178] element *el*, are to create link options[p186] from *el* and to preconnect[p327] given the result.

The process a link header[p185] step for this type of linked resource given a link processing options[p185] *options* are to preconnect[p327] given *options*.

To **preconnect** given a link processing options[p185] *options*:

1. If *options*'s href[p186] is an empty string, return.
2. Let *url* be the result of encoding-parsing a URL[p98] given *options*'s href[p186], relative to *options*'s base URL[p186].

Passing the base URL instead of a document or environment is tracked by issue #9715.

3. If *url* is failure, then return.
4. If *url*'s scheme is not an HTTP(S) scheme, then return.
5. Let *partitionKey* be the result of determining the network partition key given *options*'s environment[p186].
6. Let *useCredentials* be true.
7. If *options*'s crossorigin[p186] is Anonymous[p101] and *options*'s origin[p186] does not have the same origin[p910] as *url*'s origin, then set *useCredentials* to false.
8. The user agent should obtain a connection given *partitionKey*, *url*'s origin, and *useCredentials*.

Note

This connection is obtained but not used directly. It will remain in the connection pool for subsequent use.

The user agent should attempt to initiate a preconnect and perform the full connection handshake (DNS+TCP for HTTP, and DNS+TCP+TLS for HTTPS origins) whenever possible, but is allowed to elect to perform a partial handshake (DNS only for HTTP, and DNS or DNS+TCP for HTTPS origins), or skip it entirely, due to resource constraints or other reasons.

The optimal number of connections per origin is dependent on the negotiated protocol, users current connectivity profile, available device resources, global connection limits, and other context specific variables. As a result, the decision for how many connections should be opened is deferred to the user agent.

MDN

4.6.7.19 Link type "prefetch" §p328

The prefetch[p328] keyword may be used with link[p178] elements. This keyword creates an external resource link[p303]. This keyword is body-ok[p315].

The prefetch[p328] keyword indicates that preemptively fetching and caching the specified resource or same-site document is likely to be beneficial, as it is highly likely that the user will require this resource for future navigations.

There is no default type for resources given by the prefetch[p328] keyword.

The appropriate times to fetch and process[p184] this type of link are:

- When the external resource link[p303] is created on a link[p178] element that is already browsing-context connected[p47].
- When the external resource link[p303]'s link[p178] element becomes browsing-context connected[p47].
- When the href[p179] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is changed.
- When the crossorigin[p180] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is set, changed, or removed.

The fetch and process the linked resource[p184] algorithm for prefetch[p328] links, given a link[p178] element *el*, is as follows:

1. If *el*'s href[p179] attribute's value is the empty string, then return.
2. Let *options* be the result of creating link options[p186] from *el*.
3. Set *options*'s destination[p186] to the empty string.
4. Let *request* be the result of creating a link request[p185] given *options*.
5. If *request* is null, then return.
6. Set *request*'s initiator to "prefetch".
7. Let *processPrefetchResponse* be the following steps given a response *response* and null, failure, or a byte sequence *bytesOrNull*:

    1. If *response* is a network error, fire an event named error[p1489] at *el*.

2. Otherwise, fire an event named load at *el*.

8. The user agent should fetch *request*, with *processResponseConsumeBody* set to *processPrefetchResponse*. User agents may delay the fetching of *request* to prioritize other requests that are necessary for the current document.

The process a link header steps for this type of linked resource are to do nothing.

4.6.7.20 Link type "preload" §

The preload keyword may be used with link elements. This keyword creates an external resource link. This keyword is body-ok.

The preload keyword indicates that the user agent will preemptively fetch and cache the specified resource according to the potential destination given by the as attribute, and the priority given by the fetchpriority attribute, as it is highly likely that the user will require this resource for the current navigation.

Note

User-agents might perform additional operations when a resource is loaded, such as preemptively decoding images or creating stylesheets. However, these additional operations cannot have observable effects.

There is no default type for resources given by the preload keyword.

A user agent must not delay the load event for this link type.

The appropriate times to fetch and process the linked resource for such a link are:

- When the external resource link is created on a link element that is already browsing-context connected.
- When the external resource link's link element becomes browsing-context connected.
- When the href attribute of the link element of an external resource link that is already browsing-context connected is changed.
- When the as attribute of the link element of an external resource link that is already browsing-context connected is changed.
- When the type attribute of the link element of an external resource link that is already browsing-context connected, but was previously not obtained due to the type attribute specifying an unsupported type for the request destination, is set, removed, or changed.
- When the media attribute of the link element of an external resource link that is already browsing-context connected, but was previously not obtained due to the media attribute not matching the environment, is changed or removed.

A Document has a **map of preloaded resources**, which is an ordered map, initially empty.

A **preload key** is a struct. It has the following items:

URL
A URL

destination
A string

mode
A request mode, either "`same-origin`", "`cors`", or "`no-cors`"

credentials mode
A credentials mode

A **preload entry** is a struct. It has the following items:

integrity metadata
A string

response

Null or a response

on response available

Null, or an algorithm accepting a response or null

To **consume a preloaded resource** for `Window`[p934] *window*, given a URL *url*, a string *destination*, a string *mode*, a string *credentialsMode*, a string *integrityMetadata*, and *onResponseAvailable*, which is an algorithm accepting a response:

1. Let *key* be a preload key[p329] whose URL[p329] is *url*, destination[p329] is *destination*, mode[p329] is *mode*, and credentials mode[p329] is *credentialsMode*.
2. Let *preloads* be *window*'s associated `Document`[p935]'s map of preloaded resources[p329].
3. If *key* does not exist in *preloads*, then return false.
4. Let *entry* be *preloads*[*key*].
5. Let *consumerIntegrityMetadata* be the result of parsing *integrityMetadata*.
6. Let *preloadIntegrityMetadata* be the result of parsing *entry*'s integrity metadata[p329].
7. If none of the following conditions apply:
    - *consumerIntegrityMetadata* is `no metadata`;
    - *consumerIntegrityMetadata* is equal to *preloadIntegrityMetadata*; or

    > This comparison would ignore unknown integrity options. See issue #116.

    then return false.

    > **Note**
    > *A mismatch in integrity metadata between the preload and the consumer, even if both match the data, would lead to an additional fetch from the network.*

    > **Note**
    > *It is important that network errors are added to the preload cache so that if a preload request results in an error, the erroneous response isn't re-requested from the network later. This also has security implications; consider the case where a developer specifies subresource integrity metadata on a preload request, but not the following resource request. If the preload request fails subresource integrity verification and is discarded, the resource request will fetch and consume a potentially-malicious response from the network without verifying its integrity. [SRI][p1500]*
8. Remove *preloads*[*key*].
9. If *entry*'s response[p330] is null, then set *entry*'s on response available[p330] to *onResponseAvailable*.
10. Otherwise, call *onResponseAvailable* with *entry*'s response[p330].
11. Return true.

For the purposes of this section, a string *type* **matches** a string *destination* if the following algorithm returns true:

1. If *type* is an empty string, then return true.
2. If *destination* is "`fetch`", then return true.
3. Let *mimeTypeRecord* be the result of parsing *type*.
4. If *mimeTypeRecord* is failure, then return false.
5. If *mimeTypeRecord* is not supported by the user agent, then return false.
6. If any of the following are true:
    - *destination* is "`audio`" or "`video`", and *mimeTypeRecord* is an audio or video MIME type;
    - *destination* is a script-like destination and *mimeTypeRecord* is a JavaScript MIME type;

- *destination* is "`image`" and *mimeTypeRecord* is an image MIME type;
- *destination* is "`font`" and *mimeTypeRecord* is a font MIME type;
- *destination* is "`json`" and *mimeTypeRecord* is a JSON MIME type;
- *destination* is "`style`" and *mimeTypeRecord*'s essence is `text/css`[p1492]; or
- *destination* is "`track`" and *mimeTypeRecord*'s essence is `text/vtt`[p1492],

then return true.

7. Return false.

To **create a preload key** for a request *request*, return a new preload key[p329] whose URL[p329] is *request*'s URL, destination[p329] is *request*'s destination, mode[p329] is *request*'s mode, and credentials mode[p329] is *request*'s credentials mode.

To **translate a preload destination** given a string *destination*:

1. If *destination* is not "`fetch`", "`font`", "`image`", "`script`", "`style`", or "`track`", then return null.
2. Return the result of translating *destination*.

To **preload** given a link processing options[p185] *options* and an optional *processResponse*, which is an algorithm accepting a response:

1. If *options*'s type[p186] doesn't match[p330] *options*'s destination[p186], then return.
2. If *options*'s destination[p186] is "`image`" and *options*'s source set[p186] is not null, then set *options*'s href[p186] to the result of selecting an image source[p372] from *options*'s source set[p186].
3. Let *request* be the result of creating a link request[p185] given *options*.
4. If *request* is null, then return.
5. Let *unsafeEndTime* be 0.
6. Let *entry* be a new preload entry[p329] whose integrity metadata[p329] is *options*'s integrity[p186].
7. Let *key* be the result of creating a preload key[p331] given *request*.
8. If *options*'s document[p186] is null, then set *request*'s initiator type to "`early hint`".
9. Let *controller* be null.
10. Let *reportTiming* given a `Document`[p131] *document* be to report timing for *controller* given *document*'s relevant global object[p1098].
11. Set *controller* to the result of fetching *request*, with *processResponseConsumeBody* set to the following steps given a response *response* and null, failure, or a byte sequence *bodyBytes*:
    1. If *bodyBytes* is a byte sequence, then set *response*'s body to *bodyBytes* as a body.

       Note

       By using processResponseConsumeBody, we have extracted the entire body. This is necessary to ensure the preloader loads the entire body from the network, regardless of whether the preload will be consumed (which is uncertain at this point). This step then resets the request's body to a new body containing the same bytes, so that other specifications can read from it at the time of actual consumption, despite us having already done so once.
    2. Otherwise, set *response* to a network error.
    3. Set *unsafeEndTime* to the unsafe shared current time.
    4. If *options*'s document[p186] is not null, then call *reportTiming* given *options*'s document[p186].
    5. If *entry*'s on response available[p330] is null, then set *entry*'s response[p330] to *response*; otherwise call *entry*'s on response available[p330] given *response*.
    6. If *processResponse* is given, then call *processResponse* with *response*.

12. Let *commit* be the following steps given a Document[p131] *document*:

    1. If *entry*'s response[p330] is not null, then call *reportTiming* given *document*.

    2. Set *document*'s map of preloaded resources[p329][*key*] to *entry*.

13. If *options*'s document[p186] is null, then set *options*'s on document ready[p186] to *commit*. Otherwise, call *commit* with *options*'s document[p186].

The fetch and process the linked resource[p184] steps for this type of linked resource, given a link[p178] element *el*, are:

1. Update the source set[p373] for *el*.

2. Let *options* be the result of creating link options[p186] from *el*.

3. Preload[p331] *options*, with the following steps given a response *response*:

    1. If *response* is a network error, fire an event named error[p1489] at *el*. Otherwise, fire an event named load[p1490] at *el*.

> The actual browsers' behavior is different from the spec here, and the feasibility of changing the behavior has not yet been investigated. See issue #1142.

The process a link header[p185] step for this type of link given a link processing options[p185] *options* is to preload[p331] *options*.

4.6.7.21 Link type "privacy-policy" §[p33]

The privacy-policy[p332] keyword may be used with link[p178], a[p258], and area[p472] elements. This keyword creates a hyperlink[p303].

The privacy-policy[p332] keyword indicates that the referenced document contains information about the data collection and usage practices that apply to the current document, as described in more detail in *Additional Link Relation Types*. The referenced document may be a standalone privacy policy, or a specific section of some more general document. [RFC6903][p1499]

4.6.7.22 Link type "search" §[p33]

The search[p332] keyword may be used with link[p178], a[p258], area[p472], and form[p515] elements. This keyword creates a hyperlink[p303].

The search[p332] keyword indicates that the referenced document provides an interface specifically for searching the document and its related resources.

Note

OpenSearch description documents can be used with link[p178] *elements and the* search[p332] *link type to enable user agents to autodiscover search interfaces. [OPENSEARCH][p1498]*

4.6.7.23 Link type "stylesheet" §[p33]

The stylesheet[p332] keyword may be used with link[p178] elements. This keyword creates an external resource link[p303] that contributes to the styling processing model. This keyword is body-ok[p315].

The specified resource is a CSS style sheet that describes how to present the document.

If the alternate[p316] keyword is also specified on the link[p178] element, then **the link is an alternative style sheet**; in this case, the title[p158] attribute must be specified on the link[p178] element, with a non-empty value.

The default type for resources given by the stylesheet[p332] keyword is text/css[p1492].

A link[p178] element of this type is implicitly potentially render-blocking[p105] if the element was created by its node document's parser.

When the disabled[p182] attribute of a link[p178] element with a stylesheet[p332] keyword is set, disable the associated CSS style sheet.

The appropriate times to fetch and process[p184] this type of link are:

- When the external resource link[p303] is created on a link[p178] element that is already browsing-context connected[p47].
- When the external resource link[p303]'s link[p178] element becomes browsing-context connected[p47].
- When the href[p179] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is changed.
- When the disabled[p182] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is set, changed, or removed.
- When the crossorigin[p180] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is set, changed, or removed.
- When the type[p180] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47] is set or changed to a value that does not or no longer matches the Content-Type metadata[p100] of the previous obtained external resource, if any.
- When the type[p180] attribute of the link[p178] element of an external resource link[p303] that is already browsing-context connected[p47], but was previously not obtained due to the type[p180] attribute specifying an unsupported type, is removed or changed.
- When the external resource link[p303] that is already browsing-context connected[p47] changes from being an alternative style sheet[p332] to not being one, or vice versa.

Quirk: If the document has been set to quirks mode, has the same origin[p910] as the URL of the external resource, and the Content-Type metadata[p100] of the external resource is not a supported style sheet type, the user agent must instead assume it to be text/css[p1492].

The linked resource fetch setup steps[p184] for this type of linked resource, given a link[p178] element *el* and request *request*, are:

1. If *el*'s disabled[p182] attribute is set, then return false.
2. If *el* contributes a script-blocking style sheet[p205], append *el* to its node document's script-blocking style sheet set[p205].
3. If *el*'s media[p180] attribute's value matches the environment[p97] and *el* is potentially render-blocking[p105], then block rendering[p135] on *el*.
4. If *el* is currently render-blocking[p135], then set *request*'s render-blocking to true.
5. Return true.

See issue #968 for plans to use the CSSOM fetch a CSS style sheet algorithm instead of the default fetch and process the linked resource[p184] algorithm. In the meantime, any critical subresource[p46] request should have its render-blocking set to whether or not the link[p178] element is currently render-blocking[p135].

To process this type of linked resource[p185] given a link[p178] element *el*, boolean *success*, response *response*, and byte sequence *bodyBytes*:

1. If the resource's Content-Type metadata[p100] is not text/css[p1492], then set *success* to false.
2. If *el* no longer creates an external resource link[p303] that contributes to the styling processing model, or if, since the resource in question was fetched[p184], it has become appropriate to fetch[p184] it again, then:
    1. Remove *el* from *el*'s node document's script-blocking style sheet set[p205].
    2. Return.
3. If *el* has an associated CSS style sheet, remove the CSS style sheet.
4. If *success* is true, then:
    1. Create a CSS style sheet with the following properties:

        type
        text/css[p1492]

location

response's URL list[0]

> We provide a URL here on the assumption that w3c/csswg-drafts issue #9316 will be fixed.

owner node

el

media

The `media`[p180] attribute of *el*.

> **Note**
> *This is a reference to the (possibly absent at this time) attribute, rather than a copy of the attribute's current value. CSSOM defines what happens when the attribute is dynamically set, changed, or removed.*

title

The `title`[p180] attribute of *el*, if *el* is in a document tree, or the empty string otherwise.

> **Note**
> *This is similarly a reference to the attribute, rather than a copy of the attribute's current value.*

alternate flag

Set if the link is an alternative style sheet[p332] and *el*'s explicitly enabled[p182] is false; unset otherwise.

origin-clean flag

Set if the resource is CORS-same-origin[p99]; unset otherwise.

parent CSS style sheet

owner CSS rule

null

disabled flag

Left at its default value.

CSS rules

Left uninitialized.

> This doesn't seem right. Presumably we should be using *bodyBytes*? Tracked as issue #2997.

The CSS environment encoding is the result of running the following steps: [CSSSYNTAX][p1495]

1. If *el* has a `charset`[p1445] attribute, get an encoding from that attribute's value. If that succeeds, return the resulting encoding. [ENCODING][p1496]
2. Otherwise, return the document's character encoding. [DOM][p1496]

2. Fire an event named `load`[p1490] at *el*.

5. Otherwise, fire an event named `error`[p1489] at *el*.
6. If *el* contributes a script-blocking style sheet[p205], then:
    1. Assert: *el*'s node document's script-blocking style sheet set[p205] contains *el*.
    2. Remove *el* from its node document's script-blocking style sheet set[p205].
7. Unblock rendering[p136] on *el*.

The process a link header[p185] steps for this type of linked resource are to do nothing.

4.6.7.24 Link type "tag" §[p335]

The tag[p335] keyword may be used with a[p258] and area[p472] elements. This keyword creates a hyperlink[p303].

The tag[p335] keyword indicates that the *tag* that the referenced document represents applies to the current document.

Note

Since it indicates that the tag applies to the current document*, it would be inappropriate to use this keyword in the markup of a tag cloud[p784], which lists the popular tags across a set of pages.*

Example

This document is about some gems, and so it is *tagged* with "https://en.wikipedia.org/wiki/Gemstone" to unambiguously categorize it as applying to the "jewel" kind of gems, and not to, say, the towns in the US, the Ruby package format, or the Swiss locomotive class:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>My Precious</title>
 </head>
 <body>
  <header><h1>My precious</h1> <p>Summer 2012</p></header>
  <p>Recently I managed to dispose of a red gem that had been
  bothering me. I now have a much nicer blue sapphire.</p>
  <p>The red gem had been found in a bauxite stone while I was digging
  out the office level, but nobody was willing to haul it away. The
  same red gem stayed there for literally years.</p>
  <footer>
   Tags: <a rel=tag href="https://en.wikipedia.org/wiki/Gemstone">Gemstone</a>
  </footer>
 </body>
</html>
```

Example

In *this* document, there are two articles. The "tag[p335]" link, however, applies to the whole page (and would do so wherever it was placed, including if it was within the article[p207] elements).

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>Gem 4/4</title>
 </head>
 <body>
  <article>
   <h1>801: Steinbock</h1>
   <p>The number 801 Gem 4/4 electro-diesel has an ibex and was rebuilt in 2002.</p>
  </article>
  <article>
   <h1>802: Murmeltier</h1>
   <figure>
    <img src="https://upload.wikimedia.org/wikipedia/commons/b/b0/
Trains_de_la_Bernina_en_hiver_2.jpg"
         alt="The 802 was red with pantographs and tall vents on the side.">
    <figcaption>The 802 in the 1980s, above Lago Bianco.</figcaption>
   </figure>
   <p>The number 802 Gem 4/4 electro-diesel has a marmot and was rebuilt in 2003.</p>
  </article>
  <p class="topic"><a rel=tag href="https://en.wikipedia.org/wiki/Rhaetian_Railway_Gem_4/4">Gem
4/4</a></p>
 </body>
```

```
</html>
```

4.6.7.25 Link Type "terms-of-service" §p336

The terms-of-servicep336 keyword may be used with linkp178, ap258, and areap472 elements. This keyword creates a hyperlinkp303.

The terms-of-servicep336 keyword indicates that the referenced document contains information about the agreements between the current document's provider and users who wish to use the current document, as described in more detail in *Additional Link Relation Types*. [RFC6903]p1499

4.6.7.26 Sequential link types §p336

Some documents form part of a sequence of documents.

A sequence of documents is one where each document can have a *previous sibling* and a *next sibling*. A document with no previous sibling is the start of its sequence, a document with no next sibling is the end of its sequence.

A document may be part of multiple sequences.

4.6.7.26.1 Link type "next" §p336

The nextp336 keyword may be used with linkp178, ap258, areap472, and formp515 elements. This keyword creates a hyperlinkp303.

The nextp336 keyword indicates that the document is part of a sequence, and that the link is leading to the document that is the next logical document in the sequence.

When the nextp336 keyword is used with a linkp178 element, user agents should process such links as if they were using one of the dns-prefetchp318, preconnectp327, or prefetchp328 keywords. Which keyword the user agent wishes to use is implementation-dependent; for example, a user agent may wish to use the less-costly preconnectp327 processing model when trying to conserve data, battery power, or processing power, or may wish to pick a keyword depending on heuristic analysis of past user behavior in similar scenarios.

4.6.7.26.2 Link type "prev" §p336

The prevp336 keyword may be used with linkp178, ap258, areap472, and formp515 elements. This keyword creates a hyperlinkp303.

The prevp336 keyword indicates that the document is part of a sequence, and that the link is leading to the document that is the previous logical document in the sequence.

Synonyms: For historical reasons, user agents must also treat the keyword "previous" like the prevp336 keyword.

4.6.7.27 Other link types §p336

Extensions to the predefined set of link types may be registered on the microformats page for existing rel values. [MFREL]p1498

Anyone is free to edit the microformats page for existing rel values at any time to add a type. Extension types must be specified with the following information:

Keyword

The actual value being defined. The value should not be confusingly similar to any other defined value (e.g. differing only in case).

If the value contains a U+003A COLON character (:), it must also be an absolute URL.

Effect on... link[p178]

One of the following:

Not allowed
The keyword must not be specified on link[p178] elements.

Hyperlink
The keyword may be specified on a link[p178] element; it creates a hyperlink[p303].

External Resource
The keyword may be specified on a link[p178] element; it creates an external resource link[p303].

Effect on... a[p258] and area[p472]

One of the following:

Not allowed
The keyword must not be specified on a[p258] and area[p472] elements.

Hyperlink
The keyword may be specified on a[p258] and area[p472] elements; it creates a hyperlink[p303].

External Resource
The keyword may be specified on a[p258] and area[p472] elements; it creates an external resource link[p303].

Hyperlink Annotation
The keyword may be specified on a[p258] and area[p472] elements; it annotates[p304] other hyperlinks[p303] created by the element.

Effect on... form[p515]

One of the following:

Not allowed
The keyword must not be specified on form[p515] elements.

Hyperlink
The keyword may be specified on form[p515] elements; it creates a hyperlink[p303].

External Resource
The keyword may be specified on form[p515] elements; it creates an external resource link[p303].

Hyperlink Annotation
The keyword may be specified on form[p515] elements; it annotates[p304] other hyperlinks[p303] created by the element.

Brief description

A short non-normative description of what the keyword's meaning is.

Specification

A link to a more detailed description of the keyword's semantics and requirements. It could be another page on the wiki, or a link to an external page.

Synonyms

A list of other keyword values that have exactly the same processing requirements. Authors should not use the values defined to be synonyms, they are only intended to allow user agents to support legacy content. Anyone may remove synonyms that are not used in practice; only names that need to be processed as synonyms for compatibility with legacy content are to be registered in this way.

Status

One of the following:

Proposed
The keyword has not received wide peer review and approval. Someone has proposed it and is, or soon will be, using it.

Ratified
The keyword has received wide peer review and approval. It has a specification that unambiguously defines how to handle pages that use the keyword, including when they use it in incorrect ways.

Discontinued
The keyword has received wide peer review and it has been found wanting. Existing pages are using this keyword, but new pages should avoid it. The "brief description" and "specification" entries will give details of what authors should use instead, if anything.

If a keyword is found to be redundant with existing values, it should be removed and listed as a synonym for the existing value.

If a keyword is registered in the "proposed" state for a period of a month or more without being used or specified, then it may be

removed from the registry.

If a keyword is added with the "proposed" status and found to be redundant with existing values, it should be removed and listed as a synonym for the existing value. If a keyword is added with the "proposed" status and found to be harmful, then it should be changed to "discontinued" status.

Anyone can change the status at any time, but should only do so in accordance with the definitions above.

Conformance checkers must use the information given on the microformats page for existing rel values to establish if a value is allowed or not: values defined in this specification or marked as "proposed" or "ratified" must be accepted when used on the elements for which they apply as described in the "Effect on..." field, whereas values marked as "discontinued" or not listed in either this specification or on the aforementioned page must be rejected as invalid. Conformance checkers may cache this information (e.g. for performance reasons or to avoid the use of unreliable network connectivity).

When an author uses a new type not defined by either this specification or the wiki page, conformance checkers should offer to add the value to the wiki, with the details described above, with the "proposed" status.

Types defined as extensions in the microformats page for existing rel values with the status "proposed" or "ratified" may be used with the `rel` attribute on `link`[p178], `a`[p258], and `area`[p472] elements in accordance to the "Effect on..." field. [MFREL][p1498]

4.7 Edits §[p33] 8

The `ins`[p338] and `del`[p339] elements represent edits to the document.

4.7.1 The `ins` element §[p33] 8

Categories[p147]**:**

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]**:**

Where phrasing content[p151] is expected.

Content model[p147]**:**

Transparent[p152].

Tag omission in text/html[p148]**:**

Neither tag is omissible.

Content attributes[p148]**:**

Global attributes[p155]
`cite`[p340] — Link to the source of the quotation or more information about the edit
`datetime`[p340] — Date and (optionally) time of the change

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

Uses `HTMLModElement`[p341].

The `ins`[p338] element represents[p142] an addition to the document.

Example

The following represents the addition of a single paragraph:

```
<aside>
```

```
 <ins>
  <p> I like fruit. </p>
 </ins>
</aside>
```

As does the following, because everything in the aside[p215] element here counts as phrasing content[p151] and therefore there is just one paragraph[p153]:

```
<aside>
 <ins>
  Apples are <em>tasty</em>.
 </ins>
 <ins>
  So are pears.
 </ins>
</aside>
```

ins[p338] elements should not cross implied paragraph[p153] boundaries.

Example

The following example represents the addition of two paragraphs, the second of which was inserted in two parts. The first ins[p338] element in this example thus crosses a paragraph boundary, which is considered poor form.

```
<aside>
 <!-- don't do this -->
 <ins datetime="2005-03-16 00:00Z">
  <p> I like fruit. </p>
  Apples are <em>tasty</em>.
 </ins>
 <ins datetime="2007-12-19 00:00Z">
  So are pears.
 </ins>
</aside>
```

Here is a better way of marking this up. It uses more elements, but none of the elements cross implied paragraph boundaries.

```
<aside>
 <ins datetime="2005-03-16 00:00Z">
  <p> I like fruit. </p>
 </ins>
 <ins datetime="2005-03-16 00:00Z">
  Apples are <em>tasty</em>.
 </ins>
 <ins datetime="2007-12-19 00:00Z">
  So are pears.
 </ins>
</aside>
```

4.7.2 The del element §[p339]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Transparent[p152].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
`cite`[p340] — Link to the source of the quotation or more information about the edit
`datetime`[p340] — Date and (optionally) time of the change

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses `HTMLModElement`[p341].

The `del`[p339] element represents[p142] a removal from the document.

`del`[p339] elements should not cross implied paragraph[p153] boundaries.

Example

The following shows a "to do" list where items that have been done are crossed-off with the date and time of their completion.

```
<h1>To Do</h1>
<ul>
 <li>Empty the dishwasher</li>
 <li><del datetime="2009-10-11T01:25-07:00">Watch Walter Lewin's lectures</del></li>
 <li><del datetime="2009-10-10T23:38-07:00">Download more tracks</del></li>
 <li>Buy a printer</li>
</ul>
```

4.7.3 Attributes common to `ins`[p338] and `del`[p339] elements §[p340]

The **`cite`** attribute may be used to specify the URL of a document that explains the change. When that document is long, for instance the minutes of a meeting, authors are encouraged to include a fragment pointing to the specific part of that document that discusses the change.

If the `cite`[p340] attribute is present, it must be a valid URL potentially surrounded by spaces[p97] that explains the change. To obtain the corresponding citation link, the value of the attribute must be parsed[p98] relative to the element's node document. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g., by server-side scripts collecting statistics about a site's edits), not for readers.

The **`datetime`** attribute may be used to specify the time and date of the change.

If present, the `datetime`[p340] attribute's value must be a valid date string with optional time[p94].

User agents must parse the `datetime`[p340] attribute according to the parse a date or time string[p94] algorithm. If that doesn't return a date[p84] or a global date and time[p89], then the modification has no associated timestamp (the value is non-conforming; it is not a valid date string with optional time[p94]). Otherwise, the modification is marked as having been made at the given date[p84] or global date and time[p89]. If the given value is a global date and time[p89] then user agents should use the associated time-zone offset information to determine which time zone to present the given datetime in.

This value may be shown to the user, but it is primarily intended for private use.

The `ins`[p338] and `del`[p339] elements must implement the `HTMLModElement`[p341] interface:

IDL

```
[Exposed=Window]
interface HTMLModElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute USVString cite;
  [CEReactions] attribute DOMString dateTime;
};
```

The **cite** IDL attribute must reflect[p105] the element's cite[p340] content attribute. The **dateTime** IDL attribute must reflect[p105] the element's datetime[p340] content attribute.

4.7.4 Edits and paragraphs §[p34] 1

This section is non-normative.

Since the ins[p338] and del[p339] elements do not affect paragraphing[p153], it is possible, in some cases where paragraphs are implied[p153] (without explicit p[p230] elements), for an ins[p338] or del[p339] element to span both an entire paragraph or other non-phrasing content[p151] elements and part of another paragraph. For example:

```
<section>
 <ins>
  <p>
   This is a paragraph that was inserted.
  </p>
  This is another paragraph whose first sentence was inserted
  at the same time as the paragraph above.
 </ins>
 This is a second sentence, which was there all along.
</section>
```

By only wrapping some paragraphs in p[p230] elements, one can even get the end of one paragraph, a whole second paragraph, and the start of a third paragraph to be covered by the same ins[p338] or del[p339] element (though this is very confusing, and not considered good practice):

```
<section>
 This is the first paragraph. <ins>This sentence was
 inserted.
 <p>This second paragraph was inserted.</p>
 This sentence was inserted too.</ins> This is the
 third paragraph in this example.
 <!-- (don't do this) -->
</section>
```

However, due to the way implied paragraphs[p153] are defined, it is not possible to mark up the end of one paragraph and the start of the very next one using the same ins[p338] or del[p339] element. You instead have to use one (or two) p[p230] element(s) and two ins[p338] or del[p339] elements, as for example:

```
<section>
 <p>This is the first paragraph. <del>This sentence was
 deleted.</del></p>
 <p><del>This sentence was deleted too.</del> That
 sentence needed a separate &lt;del&gt; element.</p>
</section>
```

Partly because of the confusion described above, authors are strongly encouraged to always mark up all paragraphs with the p[p230] element, instead of having ins[p338] or del[p339] elements that cross implied paragraphs[p153] boundaries.

4.7.5 Edits and lists §p342

This section is non-normative.

The content models of the ol[p239] and ul[p240] elements do not allow ins[p338] and del[p339] elements as children. Lists always represent all their items, including items that would otherwise have been marked as deleted.

To indicate that an item is inserted or deleted, an ins[p338] or del[p339] element can be wrapped around the contents of the li[p242] element. To indicate that an item has been replaced by another, a single li[p242] element can have one or more del[p339] elements followed by one or more ins[p338] elements.

Example

In the following example, a list that started empty had items added and removed from it over time. The bits in the example that have been emphasized show the parts that are the "current" state of the list. The list item numbers don't take into account the edits, though.

```
<h1>Stop-ship bugs</h1>
<ol>
 <li><ins datetime="2008-02-12T15:20Z">Bug 225:
 Rain detector doesn't work in snow</ins></li>
 <li><del datetime="2008-03-01T20:22Z"><ins datetime="2008-02-14T12:02Z">Bug 228:
 Water buffer overflows in April</ins></del></li>
 <li><ins datetime="2008-02-16T13:50Z">Bug 230:
 Water heater doesn't use renewable fuels</ins></li>
 <li><del datetime="2008-02-20T21:15Z"><ins datetime="2008-02-16T14:25Z">Bug 232:
 Carbon dioxide emissions detected after startup</ins></del></li>
</ol>
```

Example

In the following example, a list that started with just fruit was replaced by a list with just colors.

```
<h1>List of <del>fruits</del><ins>colors</ins></h1>
<ul>
 <li><del>Lime</del><ins>Green</ins></li>
 <li><del>Apple</del></li>
 <li>Orange</li>
 <li><del>Pear</del></li>
 <li><ins>Teal</ins></li>
 <li><del>Lemon</del><ins>Yellow</ins></li>
 <li>Olive</li>
 <li><ins>Purple</ins></li>
</ul>
```

4.7.6 Edits and tables §p342

This section is non-normative.

The elements that form part of the table model have complicated content model requirements that do not allow for the ins[p338] and del[p339] elements, so indicating edits to a table can be difficult.

To indicate that an entire row or an entire column has been added or removed, the entire contents of each cell in that row or column can be wrapped in ins[p338] or del[p339] elements (respectively).

Example

Here, a table's row has been added:

```
<table>
```

```
 <thead>
  <tr> <th> Game name           <th> Game publisher   <th> Verdict
 <tbody>
  <tr> <td> Diablo 2            <td> Blizzard         <td> 8/10
  <tr> <td> Portal              <td> Valve            <td> 10/10
  <tr> <td> <ins>Portal 2</ins> <td> <ins>Valve</ins> <td> <ins>10/10</ins>
</table>
```

Here, a column has been removed (the time at which it was removed is given also, as is a link to the page explaining why):

```
<table>
 <thead>
  <tr> <th> Game name           <th> Game publisher   <th> <del cite="/edits/r192"
datetime="2011-05-02 14:23Z">Verdict</del>
 <tbody>
  <tr> <td> Diablo 2            <td> Blizzard         <td> <del cite="/edits/r192"
datetime="2011-05-02 14:23Z">8/10</del>
  <tr> <td> Portal              <td> Valve            <td> <del cite="/edits/r192"
datetime="2011-05-02 14:23Z">10/10</del>
  <tr> <td> Portal 2            <td> Valve            <td> <del cite="/edits/r192"
datetime="2011-05-02 14:23Z">10/10</del>
</table>
```

Generally speaking, there is no good way to indicate more complicated edits (e.g. that a cell was removed, moving all subsequent cells up or to the left).

4.8 Embedded content §[p34]

4.8.1 The `picture` element §[p34]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Embedded content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where embedded content[p151] is expected.

Content model[p147]:

Zero or more `source`[p344] elements, followed by one `img`[p347] element, optionally intermixed with script-supporting elements[p152].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLPictureElement : HTMLElement {
  [HTMLConstructor] constructor();
};
```

The picture[p343] element is a container which provides multiple sources to its contained img[p347] element to allow authors to declaratively control or give hints to the user agent about which image resource to use, based on the screen pixel density, viewport size, image format, and other factors. It represents[p142] its children.

Note

The picture[p343] element is somewhat different from the similar-looking video[p407] and audio[p411] elements. While all of them contain source[p344] elements, the source[p344] element's src[p345] attribute has no meaning when the element is nested within a picture[p343] element, and the resource selection algorithm is different. Also, the picture[p343] element itself does not display anything; it merely provides a context for its contained img[p347] element that enables it to choose from multiple URLs.

4.8.2 The source element §[p344]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a picture[p343] element, before the img[p347] element.
As a child of a media element[p415], before any flow content[p150] or track[p412] elements.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]
type[p344] — Type of embedded resource
media[p344] — Applicable media
src[p345] (in audio[p411] or video[p407]) — Address of the resource
srcset[p345] (in picture[p343]) — Images to use in different situations, e.g., high-resolution displays, small monitors, etc.
sizes[p345] (in picture[p343]) — Image sizes for different page layouts
width[p478] (in picture[p343]) — Horizontal dimension
height[p478] (in picture[p343]) — Vertical dimension

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLSourceElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute USVString src;
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute USVString srcset;
  [CEReactions] attribute DOMString sizes;
  [CEReactions] attribute DOMString media;
  [CEReactions] attribute unsigned long width;
  [CEReactions] attribute unsigned long height;
};
```

The source[p344] element allows authors to specify multiple alternative source sets[p365] for img[p347] elements or multiple alternative media resources[p416] for media elements[p415]. It does not represent[p142] anything on its own.

The **type** attribute may be present. If present, the value must be a valid MIME type string.

The **media** attribute may also be present. If present, the value must contain a valid media query list[p97]. The user agent will skip to the next source[p344] element if the value does not match the environment[p97].

Note

The media attribute is only evaluated once during the resource selection algorithm for media elements. In contrast, when using the picture element, the user agent will react to changes in the environment.

The remainder of the requirements depend on whether the parent is a picture element or a media element:

↪ **The source element's parent is a picture element**

The **srcset** attribute must be present, and is a srcset attribute.

The srcset attribute contributes the image sources to the source set, if the source element is selected.

If the srcset attribute has any image candidate strings using a width descriptor, the sizes attribute may also be present. If, additionally, the following sibling img element does not allow auto-sizes, the sizes attribute must be present. The **sizes** attribute is a sizes attribute, which contributes the source size to the source set, if the source element is selected.

Note

If the img element allows auto-sizes, then the sizes attribute can be omitted on previous sibling source elements. In such cases, it is equivalent to specifying auto.

The source element supports dimension attributes. The img element can use the width and height attributes of a source element, instead of those on the img element itself, to determine its rendered dimensions and aspect-ratio, as defined in the Rendering section.

The type attribute gives the type of the images in the source set, to allow the user agent to skip to the next source element if it does not support the given type.

Note

If the type attribute is not *specified, the user agent will not select a different source element if it finds that it does not support the image format after fetching it.*

When a source element has a following sibling source element or img element with a srcset attribute specified, it must have at least one of the following:

- A media attribute specified with a value that, after stripping leading and trailing ASCII whitespace, is not the empty string and is not an ASCII case-insensitive match for the string "`all`".
- A type attribute specified.

The src attribute must not be present.

↪ **The source element's parent is a media element**

The **src** attribute gives the URL of the media resource. The value must be a valid non-empty URL potentially surrounded by spaces. This attribute must be present.

The type attribute gives the type of the media resource, to help the user agent determine if it can play this media resource before fetching it. The `codecs` parameter, which certain MIME types define, might be necessary to specify exactly how the resource is encoded. [RFC6381]

Note

Dynamically modifying a source element's src or type attribute when the element is already inserted in a video or audio element will have no effect. To change what is playing, just use the src attribute on the media element directly, possibly making use of the canPlayType() method to pick from amongst available resources. Generally, manipulating source elements manually after the document has been parsed is an unnecessarily complicated approach.

Example

The following list shows some examples of how to use the `codecs=` MIME parameter in the type attribute.

H.264 Constrained baseline profile video (main and extended video compatible) level 3 and Low-Complexity

AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="avc1.42E01E, mp4a.40.2"'>
```

H.264 Extended profile video (baseline-compatible) level 3 and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="avc1.58A01E, mp4a.40.2"'>
```

H.264 Main profile video level 3 and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="avc1.4D401E, mp4a.40.2"'>
```

H.264 'High' profile video (incompatible with main, baseline, or extended profiles) level 3 and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="avc1.64001E, mp4a.40.2"'>
```

MPEG-4 Visual Simple Profile Level 0 video and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="mp4v.20.8, mp4a.40.2"'>
```

MPEG-4 Advanced Simple Profile Level 0 video and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="mp4v.20.240, mp4a.40.2"'>
```

MPEG-4 Visual Simple Profile Level 0 video and AMR audio in 3GPP container

```
<source src='video.3gp' type='video/3gpp; codecs="mp4v.20.8, samr"'>
```

Theora video and Vorbis audio in Ogg container

```
<source src='video.ogv' type='video/ogg; codecs="theora, vorbis"'>
```

Theora video and Speex audio in Ogg container

```
<source src='video.ogv' type='video/ogg; codecs="theora, speex"'>
```

Vorbis audio alone in Ogg container

```
<source src='audio.ogg' type='audio/ogg; codecs=vorbis'>
```

Speex audio alone in Ogg container

```
<source src='audio.spx' type='audio/ogg; codecs=speex'>
```

FLAC audio alone in Ogg container

```
<source src='audio.oga' type='audio/ogg; codecs=flac'>
```

Dirac video and Vorbis audio in Ogg container

```
<source src='video.ogv' type='video/ogg; codecs="dirac, vorbis"'>
```

The srcset[p345] and sizes[p345] attributes must not be present.

The source[p344] HTML element insertion steps[p46], given *insertedNode*, are:

1. Let *parent* be *insertedNode*'s parent.
2. If *parent* is a media element[p415] that has no src[p417] attribute and whose networkState[p419] has the value NETWORK_EMPTY[p419], then invoke that media element[p415]'s resource selection algorithm[p421].
3. If *parent* is a picture[p343] element, then for each *child* of *parent*'s children, if *child* is an img[p347] element, then count this as a relevant mutation[p366] for *child*.

The source[p344] HTML element moving steps[p46], given *movedNode* and *oldParent*, are:

1. If *oldParent* is a picture[p343] element, then for each *child* of *oldParent*'s children, if *child* is an img[p347] element, then count this as a relevant mutation[p366] for *child*.

The source[p344] HTML element removing steps[p46], given *removedNode* and *oldParent*, are:

1. If *oldParent* is a picture[p343] element, then for each *child* of *oldParent*'s children, if *child* is an img[p347] element, then count this as a relevant mutation[p366] for *child*.

The IDL attributes **src**, **type**, **srcset**, **sizes**, and **media** must reflect[p105] the respective content attributes of the same name.

Example

If the author isn't sure if user agents will all be able to render the media resources provided, the author can listen to the error[p1489] event on the last source[p344] element and trigger fallback behavior:

```
<script>
 function fallback(video) {
   // replace <video> with its contents
   while (video.hasChildNodes()) {
     if (video.firstChild instanceof HTMLSourceElement)
       video.removeChild(video.firstChild);
     else
       video.parentNode.insertBefore(video.firstChild, video);
   }
   video.parentNode.removeChild(video);
 }
</script>
<video controls autoplay>
 <source src='video.mp4' type='video/mp4; codecs="avc1.42E01E, mp4a.40.2"'>
 <source src='video.ogv' type='video/ogg; codecs="theora, vorbis"'
         onerror="fallback(parentNode)">
 ...
</video>
```

4.8.3 The img element §[p347]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Embedded content[p151].
Form-associated element[p514].
If the element has a usemap[p474] attribute: Interactive content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where embedded content[p151] is expected.
As a child of a picture[p343] element, after all source[p344] elements.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]
alt[p348] — Replacement text for use when images are not available
src[p348] — Address of the resource
srcset[p348] — Images to use in different situations, e.g., high-resolution displays, small monitors, etc.
sizes[p349] — Image sizes for different page layouts
crossorigin[p349] — How the element handles crossorigin requests
usemap[p474] — Name of image map[p474] to use
ismap[p351] — Whether the image is a server-side image map
width[p478] — Horizontal dimension

`height`[p478] — Vertical dimension
`referrerpolicy`[p349] — Referrer policy for fetches initiated by the element
`decoding`[p349] — Decoding hint to use when processing this image for presentation
`loading`[p349] — Used when determining loading deferral
`fetchpriority`[p349] — Sets the priority for fetches initiated by the element

Accessibility considerations[p148]**:**

If the element has a non-empty `alt`[p348] attribute: for authors; for implementers.
Otherwise: for authors; for implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window,
 LegacyFactoryFunction=Image(optional unsigned long width, optional unsigned long height)]
interface HTMLImageElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString alt;
  [CEReactions] attribute USVString src;
  [CEReactions] attribute USVString srcset;
  [CEReactions] attribute DOMString sizes;
  [CEReactions] attribute DOMString? crossOrigin;
  [CEReactions] attribute DOMString useMap;
  [CEReactions] attribute boolean isMap;
  [CEReactions] attribute unsigned long width;
  [CEReactions] attribute unsigned long height;
  readonly attribute unsigned long naturalWidth;
  readonly attribute unsigned long naturalHeight;
  readonly attribute boolean complete;
  readonly attribute USVString currentSrc;
  [CEReactions] attribute DOMString referrerPolicy;
  [CEReactions] attribute DOMString decoding;
  [CEReactions] attribute DOMString loading;
  [CEReactions] attribute DOMString fetchPriority;

  Promise<undefined> decode();

  // also has obsolete members
};
```

An `img`[p347] element represents an image.

An `img`[p347] element has a **dimension attribute source**, initially set to the element itself.

The image given by the **`src`** and **`srcset`** attributes, and any previous sibling `source`[p344] elements' `srcset`[p345] attributes if the parent is a `picture`[p343] element, is the embedded content; the value of the **`alt`** attribute provides equivalent content for those who cannot process images or who have image loading disabled (i.e., it is the `img`[p347] element's fallback content[p151]).

The requirements on the `alt`[p348] attribute's value are described in a separate section[p379].

At least one of the `src`[p348] and `srcset`[p348] attributes must be present.

If the `src`[p348] attribute is present, it must contain a valid non-empty URL potentially surrounded by spaces[p97] referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.

Note

The requirements above imply that images can be static bitmaps (e.g. PNGs, GIFs, JPEGs), single-page vector documents (single-page PDFs, XML files with an SVG document element), animated bitmaps (APNGs, animated GIFs), animated vector graphics (XML files with an SVG document element that use declarative SMIL animation), and so forth. However, these definitions preclude SVG files with script, multipage PDF files, interactive MNG files, HTML documents, plain text documents, and the like. [PNG][p1498] [GIF][p1496] [JPEG][p1497] [PDF][p1498] [XML][p1502] [APNG][p1493] [SVG][p1500] [MNG][p1498]

The srcset attribute is a srcset attribute.

The srcset attribute and the src attribute (if width descriptors are not used) contribute the image sources to the source set (if no source element was selected).

If the srcset attribute is present and has any image candidate strings using a width descriptor, the sizes attribute must also be present. If the srcset attribute is *not* specified, and the loading attribute is in the Lazy state, the sizes attribute may be specified with the value "auto" (ASCII case-insensitive). The **sizes** attribute is a sizes attribute, which contributes the source size to the source set (if no source element was selected).

An img element **allows auto-sizes** if:

- its loading attribute is in the Lazy state, and
- its sizes attribute's value is "auto" (ASCII case-insensitive), or starts with "auto," (ASCII case-insensitive).

The **crossorigin** attribute is a CORS settings attribute. Its purpose is to allow images from third-party sites that allow cross-origin access to be used with canvas.

The **referrerpolicy** attribute is a referrer policy attribute. Its purpose is to set the referrer policy used when fetching the image. [REFERRERPOLICY]

The **decoding** attribute indicates the preferred method to decode this image. The attribute, if present, must be an image decoding hint. This attribute's *missing value default* and *invalid value default* are both the Auto state.

The **fetchpriority** attribute is a fetch priority attribute. Its purpose is to set the priority used when fetching the image.

The **loading** attribute is a lazy loading attribute. Its purpose is to indicate the policy for loading images that are outside the viewport.

When the loading attribute's state is changed to the Eager state, the user agent must run these steps:

1. Let *resumptionSteps* be the img element's lazy load resumption steps.
2. If *resumptionSteps* is null, then return.
3. Set the img's lazy load resumption steps to null.
4. Invoke *resumptionSteps*.

Example

```
<img src="1.jpeg" alt="1">
<img src="2.jpeg" loading=eager alt="2">
<img src="3.jpeg" loading=lazy alt="3">
<div id=very-large></div> <!-- Everything after this div is below the viewport -->
<img src="4.jpeg" alt="4">
<img src="5.jpeg" loading=lazy alt="5">
```

In the example above, the images load as follows:

↪ **1.jpeg**, **2.jpeg**, **4.jpeg**
The images load eagerly and delay the window's load event.

↪ **3.jpeg**
The image loads when layout is known, due to being in the viewport, however it does not delay the window's load event.

↪ **5.jpeg**
The image loads only once scrolled into the viewport, and does not delay the window's load event.

Note

Developers are encouraged to specify a preferred aspect ratio via width and height attributes on lazy loaded images, even if CSS sets the image's width and height properties, to prevent the page layout from shifting around after the image loads.

The img HTML element insertion steps, given *insertedNode*, are:

1. If *insertedNode*'s parent is a picture element, then, count this as a relevant mutation for *insertedNode*.

The img HTML element moving steps, given *movedNode* and *oldParent*, are:

1. If *oldParent* is a picture element, then, count this as a relevant mutation for *movedNode*.

The img HTML element removing steps, given *removedNode* and *oldParent*, are:

1. If *oldParent* is a picture element, then, count this as a relevant mutation for *removedNode*.

The img element must not be used as a layout tool. In particular, img elements should not be used to display transparent images, as such images rarely convey meaning and rarely add anything useful to the document.

What an img element represents depends on the src attribute and the alt attribute.

↪ **If the src attribute is set and the alt attribute is set to the empty string**

The image is either decorative or supplemental to the rest of the content, redundant with some other information in the document.

If the image is available and the user agent is configured to display that image, then the element represents the element's image data.

Otherwise, the element represents nothing, and may be omitted completely from the rendering. User agents may provide the user with a notification that an image is present but has been omitted from the rendering.

↪ **If the src attribute is set and the alt attribute is set to a value that isn't empty**

The image is a key part of the content; the alt attribute gives a textual equivalent or replacement for the image.

If the image is available and the user agent is configured to display that image, then the element represents the element's image data.

Otherwise, the element represents the text given by the alt attribute. User agents may provide the user with a notification that an image is present but has been omitted from the rendering.

↪ **If the src attribute is set and the alt attribute is not**

The image might be a key part of the content, and there is no textual equivalent of the image available.

Note

In a conforming document, the absence of the alt attribute indicates that the image is a key part of the content but that a textual replacement for the image was not available when the image was generated.

If the image is available and the user agent is configured to display that image, then the element represents the element's image data.

If the image has a src attribute whose value is the empty string, then the element represents nothing.

Otherwise, the user agent should display some sort of indicator that there is an image that is not being rendered, and may, if requested by the user, or if so configured, or when required to provide contextual information in response to navigation, provide caption information for the image, derived as follows:

1. If the image has a title attribute whose value is not the empty string, then return the value of that attribute.
2. If the image is a descendant of a figure element that has a child figcaption element, and, ignoring the figcaption element and its descendants, the figure element has no flow content descendants other than inter-element whitespace and the img element, then return the contents of the first such figcaption element.
3. Return nothing. (There is no caption information.)

↪ **If the src attribute is not set and either the alt attribute is set to the empty string or the alt attribute is**

not set at all

The element represents[p142] nothing.

↪ **Otherwise**

The element represents[p142] the text given by the `alt`[p348] attribute.

The `alt`[p348] attribute does not represent advisory information. User agents must not present the contents of the `alt`[p348] attribute in the same way as content of the `title`[p158] attribute.

User agents may always provide the user with the option to display any image, or to prevent any image from being displayed. User agents may also apply heuristics to help the user make use of the image when the user is unable to see it, e.g. due to a visual disability or because they are using a text terminal with no graphics capabilities. Such heuristics could include, for instance, optical character recognition (OCR) of text found within the image.

⚠Warning!

While user agents are encouraged to repair cases of missing `alt`[p348] attributes, authors must not rely on such behavior. Requirements for providing text to act as an alternative for images[p379] are described in detail below.

The *contents* of `img`[p347] elements, if any, are ignored for the purposes of rendering.

The `usemap`[p474] attribute, if present, can indicate that the image has an associated image map[p474].

The **`ismap`** attribute, when used on an element that is a descendant of an `a`[p258] element with an `href`[p304] attribute, indicates by its presence that the element provides access to a server-side image map. This affects how events are handled on the corresponding `a`[p258] element.

The `ismap`[p351] attribute is a boolean attribute[p76]. The attribute must not be specified on an element that does not have an ancestor `a`[p258] element with an `href`[p304] attribute.

Note

The `usemap`[p474] and `ismap`[p351] attributes can result in confusing behavior when used together with `source`[p344] elements with the `media`[p344] attribute specified in a `picture`[p343] element.

The `img`[p347] element supports dimension attributes[p478].

The **`alt`**, **`src`**, **`srcset`**, and **`sizes`** IDL attributes must reflect[p105] the respective content attributes of the same name.

The **`crossOrigin`** IDL attribute must reflect[p105] the `crossorigin`[p349] content attribute, limited to only known values[p106].

The **`useMap`** IDL attribute must reflect[p105] the `usemap`[p474] content attribute.

The **`isMap`** IDL attribute must reflect[p105] the `ismap`[p351] content attribute.

The **`referrerPolicy`** IDL attribute must reflect[p105] the `referrerpolicy`[p349] content attribute, limited to only known values[p106].

The **`decoding`** IDL attribute must reflect[p105] the `decoding`[p349] content attribute, limited to only known values[p106].

The **`loading`** IDL attribute must reflect[p105] the `loading`[p349] content attribute, limited to only known values[p106].

The **`fetchPriority`** IDL attribute must reflect[p105] the `fetchpriority`[p349] content attribute, limited to only known values[p106].

For web developers (non-normative)

***image*.`width`[p352] `[ = value ]`**

***image*.`height`[p352] `[ = value ]`**

These attributes return the actual rendered dimensions of the image, or 0 if the dimensions are not known.

They can be set, to change the corresponding content attributes.

***image*.`naturalWidth`[p352]**

***image*.`naturalHeight`[p352]**

These attributes return the natural dimensions of the image, or 0 if the dimensions are not known.

***image*.complete**[p352]

Returns true if the image has been completely downloaded or if no image is specified; otherwise, returns false.

***image*.currentSrc**[p352]

Returns the image's absolute URL.

***image*.decode()**[p352]

This method causes the user agent to decode[p367] the image in parallel[p44], returning a promise that fulfills when decoding is complete.

The promise will be rejected with an "EncodingError" DOMException if the image cannot be decoded.

***image* = new Image**[p354]**([*width* [, *height*]])**

Returns a new img[p347] element, with the width[p478] and height[p478] attributes set to the values passed in the relevant arguments, if applicable.

The IDL attributes **width** and **height** must return the rendered width and height of the image, in CSS pixels, if the image is being rendered[p1406]; or else the density-corrected natural width and height[p365] of the image, in CSS pixels, if the image has density-corrected natural width and height[p365] and is *available*[p365] but is not being rendered[p1406]; or else 0, if the image is not *available*[p365] or does not have density-corrected natural width and height[p365]. [CSS][p1494]

On setting, they must act as if they reflected[p105] the respective content attributes of the same name.

The IDL attributes **naturalWidth** and **naturalHeight** must return the density-corrected natural width and height[p365] of the image, in CSS pixels, if the image has density-corrected natural width and height[p365] and is *available*[p365], or else 0. [CSS][p1494]

Note

Since the density-corrected natural width and height[p365] of an image take into account any orientation specified in its metadata, naturalWidth[p352] and naturalHeight[p352] reflect the dimensions after applying any rotation needed to correctly orient the image, regardless of the value of the 'image-orientation' property.

The **complete** getter steps are:

1. If any of the following are true:
    - both the src[p348] attribute and the srcset[p348] attribute are omitted;
    - the srcset[p348] attribute is omitted and the src[p348] attribute's value is the empty string;
    - the img[p347] element's current request[p364]'s state[p364] is completely available[p365] and its pending request[p364] is null; or
    - the img[p347] element's current request[p364]'s state[p364] is broken[p365] and its pending request[p364] is null,

    then return true.
2. Return false.

The **currentSrc** IDL attribute must return the img[p347] element's current request[p364]'s current URL[p364].

The **decode()** method, when invoked, must perform the following steps:

1. Let *promise* be a new promise.
2. Queue a microtask[p1140] to perform the following steps:

    Note

    This is done because updating the image data[p368] takes place in a microtask as well. Thus, to make code such as

    ```
    img.src = "stars.jpg";
    img.decode();
    ```

    properly decode `stars.jpg`*, we need to delay any processing by one microtask.*

1. Let *global* be this's relevant global object[p1098].

2. If any of the following are true:

   - this's node document is not fully active[p1017]; or
   - this's current request[p364]'s state[p364] is broken[p365],

   then reject *promise* with an "EncodingError" DOMException.

3. Otherwise, in parallel[p44], wait for one of the following cases to occur, and perform the corresponding actions:

   ↪ **This img[p347] element's node document stops being fully active[p1017]**
   ↪ **This img[p347] element's current request[p364] changes or is mutated**
   ↪ **This img[p347] element's current request[p364]'s state[p364] becomes broken[p365]**
   Queue a global task[p1140] on the DOM manipulation task source[p1149] with *global* to reject *promise* with an "EncodingError" DOMException.

   ↪ **This img[p347] element's current request[p364]'s state[p364] becomes completely available[p365]**
   Decode[p367] the image.

   If decoding does not need to be performed for this image (for example because it is a vector graphic) or the decoding process completes successfully, then queue a global task[p1140] on the DOM manipulation task source[p1149] with *global* to resolve *promise* with undefined.

   If decoding fails (for example due to invalid image data), then queue a global task[p1140] on the DOM manipulation task source[p1149] with *global* to reject *promise* with an "EncodingError" DOMException.

   User agents should ensure that the decoded media data stays readily available until at least the end of the next successful update the rendering[p1143] step in the event loop[p1138]. This is an important part of the API contract, and should not be broken if at all possible. (Typically, this would only be violated in low-memory situations that require evicting decoded image data, or when the image is too large to keep in decoded form for this period of time.)

Note

Animated images will become completely available[p365] only after all their frames are loaded. Thus, even though an implementation could decode the first frame before that point, the above steps will not do so, instead waiting until all frames are available.

3. Return *promise*.

Example

Without the decode()[p352] method, the process of loading an img[p347] element and then displaying it might look like the following:

```
const img = new Image();
img.src = "nebula.jpg";
img.onload = () => {
    document.body.appendChild(img);
};
img.onerror = () => {
    document.body.appendChild(new Text("Could not load the nebula :("));
};
```

However, this can cause notable dropped frames, as the paint that occurs after inserting the image into the DOM causes a synchronous decode on the main thread.

This can instead be rewritten using the decode()[p352] method:

```
const img = new Image();
img.src = "nebula.jpg";
img.decode().then(() => {
```

```
    document.body.appendChild(img);
}).catch(() => {
    document.body.appendChild(new Text("Could not load the nebula :("));
});
```

This latter form avoids the dropped frames of the original, by allowing the user agent to decode the image in parallel[p44], and only inserting it into the DOM (and thus causing it to be painted) once the decoding process is complete.

Example

Because the `decode()`[p352] method attempts to ensure that the decoded image data is available for at least one frame, it can be combined with the `requestAnimationFrame()`[p1205] API. This means it can be used with coding styles or frameworks that ensure that all DOM modifications are batched together as animation frame callbacks[p1205]:

```
const container = document.querySelector("#container");

const { containerWidth, containerHeight } = computeDesiredSize();
requestAnimationFrame(() => {
 container.style.width = containerWidth;
 container.style.height = containerHeight;
});

// ...

const img = new Image();
img.src = "supernova.jpg";
img.decode().then(() => {
    requestAnimationFrame(() => container.appendChild(img));
});
```

A legacy factory function is provided for creating `HTMLImageElement`[p348] objects (in addition to the factory methods from DOM such as `createElement()`): **`Image(width, height)`**. When invoked, the legacy factory function must perform the following steps:

1. Let *document* be the current global object[p1098]'s associated `Document`[p935].
2. Let *img* be the result of creating an element given *document*, "`img`", and the HTML namespace.
3. If *width* is given, then set an attribute value for *img* using "`width`[p478]" and *width*.
4. If *height* is given, then set an attribute value for *img* using "`height`[p478]" and *height*.
5. Return *img*.

Example

A single image can have different appropriate alternative text depending on the context.

In each of the following cases, the same image is used, yet the `alt`[p348] text is different each time. The image is the coat of arms of the Carouge municipality in the canton Geneva in Switzerland.

Here it is used as a supplementary icon:

```
<p>I lived in <img src="carouge.svg" alt=""> Carouge.</p>
```

Here it is used as an icon representing the town:

```
<p>Home town: <img src="carouge.svg" alt="Carouge"></p>
```

Here it is used as part of a text on the town:

```
<p>Carouge has a coat of arms.</p>
<p><img src="carouge.svg" alt="The coat of arms depicts a lion, sitting in front of a tree."></p>
<p>It is used as decoration all over the town.</p>
```

Here it is used as a way to support a similar text where the description is given as well as, instead of as an alternative to, the image:

```
<p>Carouge has a coat of arms.</p>
<p><img src="carouge.svg" alt=""></p>
<p>The coat of arms depicts a lion, sitting in front of a tree.
It is used as decoration all over the town.</p>
```

Here it is used as part of a story:

```
<p>She picked up the folder and a piece of paper fell out.</p>
<p><img src="carouge.svg" alt="Shaped like a shield, the paper had a
red background, a green tree, and a yellow lion with its tongue
hanging out and whose tail was shaped like an S."></p>
<p>She stared at the folder. S! The answer she had been looking for all
this time was simply the letter S! How had she not seen that before? It all
came together now. The phone call where Hector had referred to a lion's tail,
the time Maria had stuck her tongue out...</p>
```

Here it is not known at the time of publication what the image will be, only that it will be a coat of arms of some kind, and thus no replacement text can be provided, and instead only a brief caption for the image is provided, in the title[p158] attribute:

```
<p>The last user to have uploaded a coat of arms uploaded this one:</p>
<p><img src="last-uploaded-coat-of-arms.cgi" title="User-uploaded coat of arms."></p>
```

Ideally, the author would find a way to provide real replacement text even in this case, e.g. by asking the previous user. Not providing replacement text makes the document more difficult to use for people who are unable to view images, e.g. blind users, or users or very low-bandwidth connections or who pay by the byte, or users who are forced to use a text-only web browser.

Example

Here are some more examples showing the same picture used in different contexts, with different appropriate alternate texts each time.

```
<article>
 <h1>My cats</h1>
 <h2>Fluffy</h2>
 <p>Fluffy is my favorite.</p>
 <img src="fluffy.jpg" alt="She likes playing with a ball of yarn.">
 <p>She's just too cute.</p>
 <h2>Miles</h2>
 <p>My other cat, Miles just eats and sleeps.</p>
</article>
```

```
<article>
 <h1>Photography</h1>
 <h2>Shooting moving targets indoors</h2>
 <p>The trick here is to know how to anticipate; to know at what speed and
 what distance the subject will pass by.</p>
 <img src="fluffy.jpg" alt="A cat flying by, chasing a ball of yarn, can be
 photographed quite nicely using this technique.">
 <h2>Nature by night</h2>
 <p>To achieve this, you'll need either an extremely sensitive film, or
 immense flash lights.</p>
</article>
```

```
<article>
 <h1>About me</h1>
 <h2>My pets</h2>
 <p>I've got a cat named Fluffy and a dog named Miles.</p>
 <img src="fluffy.jpg" alt="Fluffy, my cat, tends to keep itself busy.">
 <p>My dog Miles and I like go on long walks together.</p>
 <h2>music</h2>
 <p>After our walks, having emptied my mind, I like listening to Bach.</p>
</article>
```

```
<article>
 <h1>Fluffy and the Yarn</h1>
 <p>Fluffy was a cat who liked to play with yarn. She also liked to jump.</p>
 <aside><img src="fluffy.jpg" alt="" title="Fluffy"></aside>
 <p>She would play in the morning, she would play in the evening.</p>
</article>
```

4.8.4 Images §p356

4.8.4.1 Introduction §p356

This section is non-normative.

To embed an image in HTML, when there is only a single image resource, use the img[p347] element and its src[p348] attribute.

Example

```
<h2>From today's featured article</h2>
<img src="/uploads/100-marie-lloyd.jpg" alt="" width="100" height="150">
<p><b><a href="/wiki/Marie_Lloyd">Marie Lloyd</a></b> (1870–1922)
was an English <a href="/wiki/Music_hall">music hall</a> singer, ...
```

However, there are a number of situations for which the author might wish to use multiple image resources that the user agent can choose from:

- Different users might have different environmental characteristics:
  - The users' physical screen size might be different from one another.

    Example

    A mobile phone's screen might be 4 inches diagonally, while a laptop's screen might be 14 inches diagonally.

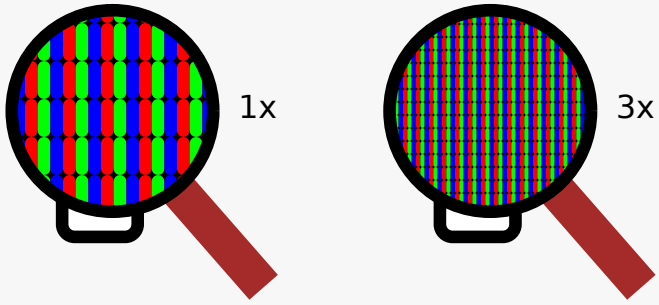
    
    Note

    This is only relevant when an image's rendered size depends on the viewport size.

- The users' screen pixel density might be different from one another.

  Example

  A mobile phone's screen might have three times as many physical pixels per inch compared to another mobile phone's screen, regardless of their physical screen size.

- The users' zoom level might be different from one another, or might change for a single user over time.

  Example

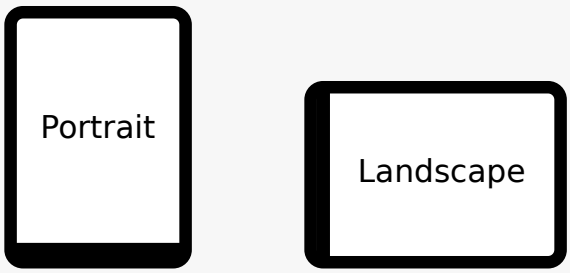
  A user might zoom in to a particular image to be able to get a more detailed look.

  The zoom level and the screen pixel density (the previous point) can both affect the number of physical screen pixels per CSS pixel. This ratio is usually referred to as **device-pixel-ratio**.

- The users' screen orientation might be different from one another, or might change for a single user over time.

  Example

  A tablet can be held upright or rotated 90 degrees, so that the screen is either "portrait" or "landscape".

- The users' network speed, network latency and bandwidth cost might be different from one another, or might change for a single user over time.

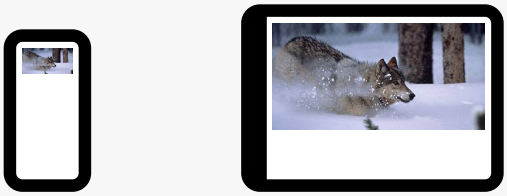
  Example

  A user might be on a fast, low-latency and constant-cost connection while at work, on a slow, low-latency and constant-cost connection while at home, and on a variable-speed, high-latency and variable-cost connection anywhere else.

- Authors might want to show the same image content but with different rendered size depending on, usually, the width of the viewport. This is usually referred to as **viewport-based selection**.

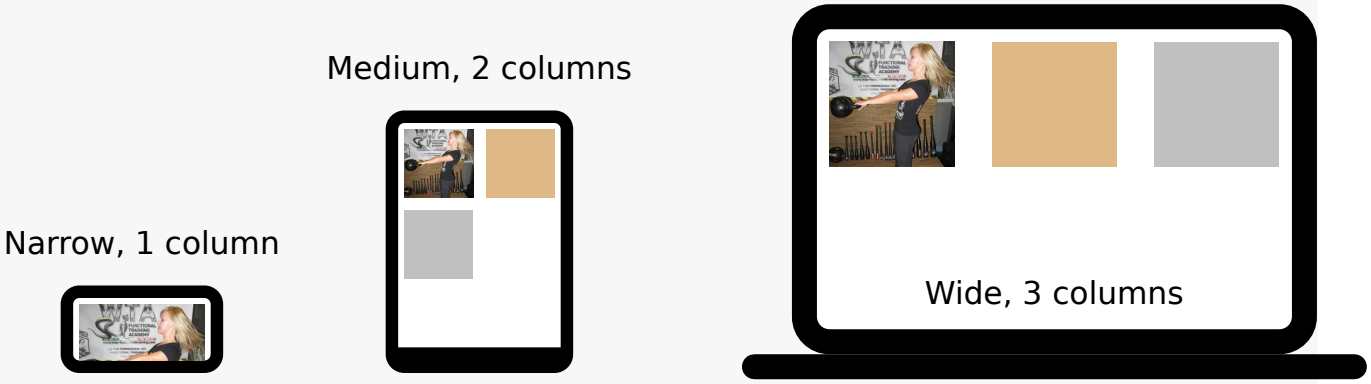
  Example

  A web page might have a banner at the top that always spans the entire viewport width. In this case, the rendered size of the image depends on the physical size of the screen (assuming a maximised browser window).



Example

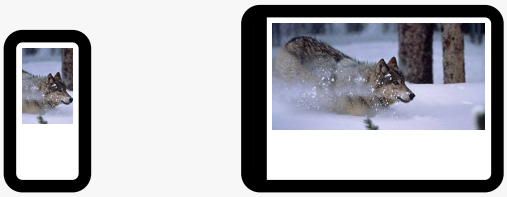
Another web page might have images in columns, with a single column for screens with a small physical size, two columns for screens with medium physical size, and three columns for screens with big physical size, with the images varying in rendered size in each case to fill up the viewport. In this case, the rendered size of an image might be *bigger* in the one-column layout compared to the two-column layout, despite the screen being smaller.



- Authors might want to show different image content depending on the rendered size of the image. This is usually referred to as **art direction**.

Example

When a web page is viewed on a screen with a large physical size (assuming a maximised browser window), the author might wish to include some less relevant parts surrounding the critical part of the image. When the same web page is viewed on a screen with a small physical size, the author might wish to show only the critical part of the image.



- Authors might want to show the same image content but using different image formats, depending on which image formats the user agent supports. This is usually referred to as **image format-based selection**.

Example

A web page might have some images in the JPEG, WebP and JPEG XR image formats, with the latter two having better compression abilities compared to JPEG. Since different user agents can support different image formats, with some formats offering better compression ratios, the author would like to serve the better formats to user agents that support them, while providing JPEG fallback for user agents that don't.

The above situations are not mutually exclusive. For example, it is reasonable to combine different resources for different device-pixel-

ratio[p357] with different resources for art direction[p358].

While it is possible to solve these problems using scripting, doing so introduces some other problems:

- Some user agents aggressively download images specified in the HTML markup, before scripts have had a chance to run, so that web pages complete loading sooner. If a script changes which image to download, the user agent will potentially start two separate downloads, which can instead cause worse page loading performance.
- If the author avoids specifying any image in the HTML markup and instead instantiates a single download from script, that avoids the double download problem above but then no image will be downloaded at all for users with scripting disabled and the aggressive image downloading optimization will also be disabled.

With this in mind, this specification introduces a number of features to address the above problems in a declarative manner.

Device-pixel-ratio[p357]-based selection when the rendered size of the image is fixed

The src[p348] and srcset[p348] attributes on the img[p347] element can be used, using the `x` descriptor, to provide multiple images that only vary in their size (the smaller image is a scaled-down version of the bigger image).

Note

The `x` descriptor is not appropriate when the rendered size of the image depends on the viewport width (viewport-based selection[p357]), but can be used together with art direction[p358].

Example

```
<h2>From today's featured article</h2>
<img src="/uploads/100-marie-lloyd.jpg"
     srcset="/uploads/150-marie-lloyd.jpg 1.5x, /uploads/200-marie-lloyd.jpg 2x"
     alt="" width="100" height="150">
<p><b><a href="/wiki/Marie_Lloyd">Marie Lloyd</a></b> (1870–1922)
was an English <a href="/wiki/Music_hall">music hall</a> singer, ...
```

The user agent can choose any of the given resources depending on the user's screen's pixel density, zoom level, and possibly other factors such as the user's network conditions.

For backwards compatibility with older user agents that don't yet understand the srcset[p348] attribute, one of the URLs is specified in the img[p347] element's src[p348] attribute. This will result in something useful (though perhaps lower-resolution than the user would like) being displayed even in older user agents. For new user agents, the src[p348] attribute participates in the resource selection, as if it was specified in srcset[p348] with a `1x` descriptor.

The image's rendered size is given in the width[p478] and height[p478] attributes, which allows the user agent to allocate space for the image before it is downloaded.

Viewport-based selection[p357]

The srcset[p348] and sizes[p349] attributes can be used, using the `w` descriptor, to provide multiple images that only vary in their size (the smaller image is a scaled-down version of the bigger image).

Example

In this example, a banner image takes up the entire viewport width (using appropriate CSS).

```
<h1><img sizes="100vw" srcset="wolf-400.jpg 400w, wolf-800.jpg 800w, wolf-1600.jpg 1600w"
     src="wolf-400.jpg" alt="The rad wolf"></h1>
```

The user agent will calculate the effective pixel density of each image from the specified `w` descriptors and the specified rendered size in the sizes[p349] attribute. It can then choose any of the given resources depending on the user's screen's pixel density, zoom level, and possibly other factors such as the user's network conditions.

If the user's screen is 320 CSS pixels wide, this is equivalent to specifying `wolf-400.jpg 1.25x, wolf-800.jpg 2.5x, wolf-1600.jpg 5x`. On the other hand, if the user's screen is 1200 CSS pixels wide, this is equivalent to specifying `wolf-400.jpg 0.33x, wolf-800.jpg 0.67x, wolf-1600.jpg 1.33x`. By using the `w` descriptors and the sizes[p349] attribute, the user agent can choose the correct image source to download regardless of how large the user's device is.

For backwards compatibility, one of the URLs is specified in the img[p347] element's src[p348] attribute. In new user agents, the

src[p348] attribute is ignored when the srcset[p348] attribute uses w descriptors.

Example

In this example, the web page has three layouts depending on the width of the viewport. The narrow layout has one column of images (the width of each image is about 100%), the middle layout has two columns of images (the width of each image is about 50%), and the widest layout has three columns of images, and some page margin (the width of each image is about 33%). It breaks between these layouts when the viewport is 30em wide and 50em wide, respectively.

```
<img sizes="(max-width: 30em) 100vw, (max-width: 50em) 50vw, calc(33vw - 100px)"
     srcset="swing-200.jpg 200w, swing-400.jpg 400w, swing-800.jpg 800w, swing-1600.jpg 1600w"
     src="swing-400.jpg" alt="Kettlebell Swing">
```

The sizes[p349] attribute sets up the layout breakpoints at 30em and 50em, and declares the image sizes between these breakpoints to be 100vw, 50vw, or calc(33vw - 100px). These sizes do not necessarily have to match up exactly with the actual image width as specified in the CSS.

The user agent will pick a width from the sizes[p349] attribute, using the first item with a <media-condition> (the part in parentheses) that evaluates to true, or using the last item (calc(33vw - 100px)) if they all evaluate to false.

For example, if the viewport width is 29em, then (max-width: 30em) evaluates to true and 100vw is used, so the image size, for the purpose of resource selection, is 29em. If the viewport width is instead 32em, then (max-width: 30em) evaluates to false, but (max-width: 50em) evaluates to true and 50vw is used, so the image size, for the purpose of resource selection, is 16em (half the viewport width). Notice that the slightly wider viewport results in a smaller image because of the different layout.

The user agent can then calculate the effective pixel density and choose an appropriate resource similarly to the previous example.

Example

This example is the same as the previous example, but the image is lazy-loaded[p102]. In this case, the sizes[p349] attribute can use the auto[p364] keyword, and the user agent will use the width[p478] attribute (or the width specified in CSS) for the source size[p365].

```
<img loading="lazy" width="200" height="200" sizes="auto"
     srcset="swing-200.jpg 200w, swing-400.jpg 400w, swing-800.jpg 800w, swing-1600.jpg 1600w"
     src="swing-400.jpg" alt="Kettlebell Swing">
```

For better backwards-compatibility with legacy user agents that don't support the auto[p364] keyword, fallback sizes can be specified if desired.

```
<img loading="lazy" width="200" height="200"
     sizes="auto, (max-width: 30em) 100vw, (max-width: 50em) 50vw, calc(33vw - 100px)"
     srcset="swing-200.jpg 200w, swing-400.jpg 400w, swing-800.jpg 800w, swing-1600.jpg 1600w"
     src="swing-400.jpg" alt="Kettlebell Swing">
```

Art direction[p358]-based selection

The picture[p343] element and the source[p344] element, together with the media[p344] attribute, can be used to provide multiple images that vary the image content (for instance the smaller image might be a cropped version of the bigger image).

Example

```
<picture>
  <source media="(min-width: 45em)" srcset="large.jpg">
  <source media="(min-width: 32em)" srcset="med.jpg">
  <img src="small.jpg" alt="The wolf runs through the snow.">
</picture>
```

The user agent will choose the first source[p344] element for which the media query in the media[p344] attribute matches, and then choose an appropriate URL from its srcset[p345] attribute.

The rendered size of the image varies depending on which resource is chosen. To specify dimensions that the user agent can

use before having downloaded the image, CSS can be used.

CSS
```
img { width: 300px; height: 300px }
@media (min-width: 32em) { img { width: 500px; height:300px } }
@media (min-width: 45em) { img { width: 700px; height:400px } }
```

Example

This example combines art direction[p358]- and device-pixel-ratio[p357]-based selection. A banner that takes half the viewport is provided in two versions, one for wide screens and one for narrow screens.

```
<h1>
 <picture>
  <source media="(max-width: 500px)" srcset="banner-phone.jpeg, banner-phone-HD.jpeg 2x">
  <img src="banner.jpeg" srcset="banner-HD.jpeg 2x" alt="The Breakfast Combo">
 </picture>
</h1>
```

Image format-based selection[p358]

The type[p344] attribute on the source[p344] element can be used to provide multiple images in different formats.

Example

```
<h2>From today's featured article</h2>
<picture>
 <source srcset="/uploads/100-marie-lloyd.webp" type="image/webp">
 <source srcset="/uploads/100-marie-lloyd.jxr" type="image/vnd.ms-photo">
 <img src="/uploads/100-marie-lloyd.jpg" alt="" width="100" height="150">
</picture>
<p><b><a href="/wiki/Marie_Lloyd">Marie Lloyd</a></b> (1870–1922)
was an English <a href="/wiki/Music_hall">music hall</a> singer, ...
```

In this example, the user agent will choose the first source that has a type[p344] attribute with a supported MIME type. If the user agent supports WebP images, the first source[p344] element will be chosen. If not, but the user agent does support JPEG XR images, the second source[p344] element will be chosen. If neither of those formats are supported, the img[p347] element will be chosen.

4.8.4.1.1 Adaptive images §[p361]

This section is non-normative.

CSS and media queries can be used to construct graphical page layouts that adapt dynamically to the user's environment, in particular to different viewport dimensions and pixel densities. For content, however, CSS does not help; instead, we have the img[p347] element's srcset[p348] attribute and the picture[p343] element. This section walks through a sample case showing how to use these features.

Consider a situation where on wide screens (wider than 600 CSS pixels) a 300×150 image named `a-rectangle.png` is to be used, but on smaller screens (600 CSS pixels and less), a smaller 100×100 image called `a-square.png` is to be used. The markup for this would look like this:

```
<figure>
 <picture>
  <source srcset="a-square.png" media="(max-width: 600px)">
  <img src="a-rectangle.png" alt="Barney Frank wears a suit and glasses.">
 </picture>
 <figcaption>Barney Frank, 2011</figcaption>
</figure>
```

Note

For details on what to put in the alt attribute, see the Requirements for providing text to act as an alternative for images section.

The problem with this is that the user agent does not necessarily know what dimensions to use for the image when the image is loading. To avoid the layout having to be reflowed multiple times as the page is loading, CSS and CSS media queries can be used to provide the dimensions:

```
<style>
 #a { width: 300px; height: 150px; }
 @media (max-width: 600px) { #a { width: 100px; height: 100px; } }
</style>
<figure>
 <picture>
  <source srcset="a-square.png" media="(max-width: 600px)">
  <img src="a-rectangle.png" alt="Barney Frank wears a suit and glasses." id="a">
 </picture>
 <figcaption>Barney Frank, 2011</figcaption>
</figure>
```

Alternatively, the width and height attributes can be used on the source and img elements to provide the width and height:

```
<figure>
 <picture>
  <source srcset="a-square.png" media="(max-width: 600px)" width="100" height="100">
  <img src="a-rectangle.png" width="300" height="150"
  alt="Barney Frank wears a suit and glasses.">
 </picture>
 <figcaption>Barney Frank, 2011</figcaption>
</figure>
```

The img element is used with the src attribute, which gives the URL of the image to use for legacy user agents that do not support the picture element. This leads to a question of which image to provide in the src attribute.

If the author wants the biggest image in legacy user agents, the markup could be as follows:

```
<picture>
 <source srcset="pear-mobile.jpeg" media="(max-width: 720px)">
 <source srcset="pear-tablet.jpeg" media="(max-width: 1280px)">
 <img src="pear-desktop.jpeg" alt="The pear is juicy.">
</picture>
```

However, if legacy mobile user agents are more important, one can list all three images in the source elements, overriding the src attribute entirely.

```
<picture>
 <source srcset="pear-mobile.jpeg" media="(max-width: 720px)">
 <source srcset="pear-tablet.jpeg" media="(max-width: 1280px)">
 <source srcset="pear-desktop.jpeg">
 <img src="pear-mobile.jpeg" alt="The pear is juicy.">
</picture>
```

Since at this point the src attribute is actually being ignored entirely by picture-supporting user agents, the src attribute can default to any image, including one that is neither the smallest nor biggest:

```
<picture>
 <source srcset="pear-mobile.jpeg" media="(max-width: 720px)">
 <source srcset="pear-tablet.jpeg" media="(max-width: 1280px)">
```

```
 <source srcset="pear-desktop.jpeg">
 <img src="pear-tablet.jpeg" alt="The pear is juicy.">
</picture>
```

Above the `max-width` media feature is used, giving the maximum (viewport) dimensions that an image is intended for. It is also possible to use `min-width` instead.

```
<picture>
 <source srcset="pear-desktop.jpeg" media="(min-width: 1281px)">
 <source srcset="pear-tablet.jpeg" media="(min-width: 721px)">
 <img src="pear-mobile.jpeg" alt="The pear is juicy.">
</picture>
```

4.8.4.2 Attributes common to source[p344], img[p347], and link[p178] elements §[p363]

4.8.4.2.1 Srcset attributes §[p363]

A **srcset attribute** is an attribute with requirements defined in this section.

If present, its value must consist of one or more image candidate strings[p363], each separated from the next by a U+002C COMMA character (,). If an image candidate string[p363] contains no descriptors and no ASCII whitespace after the URL, the following image candidate string[p363], if there is one, must begin with one or more ASCII whitespace.

An **image candidate string** consists of the following components, in order, with the further restrictions described below this list:

1. Zero or more ASCII whitespace.
2. A valid non-empty URL[p97] that does not start or end with a U+002C COMMA character (,), referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.
3. Zero or more ASCII whitespace.
4. Zero or one of the following:
    - A **width descriptor**, consisting of: ASCII whitespace, a valid non-negative integer[p78] giving a number greater than zero representing the **width descriptor value**, and a U+0077 LATIN SMALL LETTER W character.
    - A **pixel density descriptor**, consisting of: ASCII whitespace, a valid floating-point number[p78] giving a number greater than zero representing the **pixel density descriptor value**, and a U+0078 LATIN SMALL LETTER X character.
5. Zero or more ASCII whitespace.

There must not be an image candidate string[p363] for an element that has the same width descriptor value[p363] as another image candidate string[p363]'s width descriptor value[p363] for the same element.

There must not be an image candidate string[p363] for an element that has the same pixel density descriptor value[p363] as another image candidate string[p363]'s pixel density descriptor value[p363] for the same element. For the purpose of this requirement, an image candidate string[p363] with no descriptors is equivalent to an image candidate string[p363] with a `1x` descriptor.

If an image candidate string[p363] for an element has the width descriptor[p363] specified, all other image candidate strings[p363] for that element must also have the width descriptor[p363] specified.

The specified width in an image candidate string[p363]'s width descriptor[p363] must match the natural width in the resource given by the image candidate string[p363]'s URL, if it has a natural width.

If an element has a sizes attribute[p364] present, all image candidate strings[p363] for that element must have the width descriptor[p363] specified.

4.8.4.2.2 Sizes attributes

A **sizes attribute** is an attribute with requirements defined in this section.

If present, the value must be a valid source size list.

A **valid source size list** is a string that matches the following grammar: [CSSVALUES] [MQ]

```
<source-size-list> = <source-size>#? , <source-size-value>
<source-size> = <media-condition> <source-size-value> | auto
<source-size-value> = <length> | auto
```

A <source-size-value> that is a <length> must not be negative, and must not use CSS functions other than the math functions.

The keyword **auto** is a width that is computed in parse a sizes attribute. If present, it must be the first entry and the entire <source-size-list> value must either be the string "auto" (ASCII case-insensitive) or start with the string "auto," (ASCII case-insensitive).

Note

If the img element that initiated the image loading (with the update the image data or react to environment changes algorithms) allows auto-sizes and is being rendered, then auto is the concrete object size width. Otherwise, the auto value is ignored and the next source size is used instead, if any.

The auto keyword may be specified in the sizes attribute of source elements and sizes attribute of img elements, if the following conditions are met. Otherwise, auto must not be specified.

- The element is a source element with a following sibling img element.
- The element is an img element.
- The img element referenced in either condition above allows auto-sizes.

Note

In addition, it is strongly encouraged to specify dimensions using the width and height attributes or with CSS. Without specified dimensions, the image will likely render with 300x150 dimensions because `sizes="auto"` *implies* `contain-intrinsic-size: 300px 150px` *in the Rendering section.*

The <source-size-value> gives the intended layout width of the image. The author can specify different widths for different environments with <media-condition>s.

Note

Percentages are not allowed in a <source-size-value>, to avoid confusion about what it would be relative to. The 'vw' unit can be used for sizes relative to the viewport width.

4.8.4.3 Processing model

An img element has a **current request** and a **pending request**. The current request is initially set to a new image request. The pending request is initially set to null.

An **image request** has a **state**, **current URL**, and **image data**.

An image request's state is one of the following:

Unavailable

The user agent hasn't obtained any image data, or has obtained some or all of the image data but hasn't yet decoded enough of the image to get the image dimensions.

Partially available

The user agent has obtained some of the image data and at least the image dimensions are available.

Completely available

The user agent has obtained all of the image data and at least the image dimensions are available.

Broken

The user agent has obtained all of the image data that it can, but it cannot even decode the image enough to get the image dimensions (e.g. the image is corrupted, or the format is not supported, or no data could be obtained).

An image request's current URL is initially the empty string.

An image request's image data is the decoded image data.

When an image request's state is either partially available or completely available, the image request is said to be **available**.

When an `img` element's current request's state is completely available and the user agent can decode the media data without errors, then the `img` element is said to be **fully decodable**.

An image request's state is initially unavailable.

When an `img` element's current request is available, the `img` element provides a paint source whose width is the image's density-corrected natural width (if any), whose height is the image's density-corrected natural height (if any), and whose appearance is the natural appearance of the image.

An `img` element is said to **use `srcset` or `picture`** if it has a `srcset` attribute specified or if it has a parent that is a `picture` element.

Each `img` element has a **last selected source**, which must initially be null.

Each image request has a **current pixel density**, which must initially be 1.

Each image request has **preferred density-corrected dimensions**, which is either a struct consisting of a width and a height or is null. It must initially be null.

To determine the **density-corrected natural width and height** of an `img` element *img*:

1. Let *dim* be *img*'s current request's preferred density-corrected dimensions.

   Note

   The preferred density-corrected dimensions are set in the prepare an image for presentation algorithm based on meta information in the image.

2. If *dim* is null, set *dim* to *img*'s natural dimensions.
3. Set *dim*'s width to *dim*'s width divided by *img*'s current request's current pixel density.
4. Set *dim*'s height to *dim*'s height divided by *img*'s current request's current pixel density.
5. Return *dim*.

Example

For example, if the current pixel density is 3.125, that means that there are 300 device pixels per CSS inch, and thus if the image data is 300x600, it has density-corrected natural width and height of 96 CSS pixels by 192 CSS pixels.

All `img` and `link` elements are associated with a source set.

A **source set** is an ordered set of zero or more image sources and a source size.

An **image source** is a URL, and optionally either a pixel density descriptor, or a width descriptor.

A **source size** is a <source-size-value>. When a source size has a unit relative to the viewport, it must be interpreted relative to the `img` element's node document's viewport. Other units must be interpreted the same as in Media Queries. [MQ]

A **parse error** for algorithms in this section indicates a non-fatal mismatch between input and requirements. User agents are encouraged to expose parse error[p366]s somehow.

Whether the image is fetched successfully or not (e.g. whether the response status was an ok status) must be ignored when determining the image's type and whether it is a valid image.

Note

This allows servers to return images with error responses, and have them displayed.

The user agent should apply the image sniffing rules to determine the type of the image, with the image's associated Content-Type headers[p100] giving the *official type*. If these rules are not applied, then the type of the image must be the type given by the image's associated Content-Type headers[p100].

User agents must not support non-image resources with the `img`[p347] element (e.g. XML files whose document element is an HTML element). User agents must not run executable code (e.g. scripts) embedded in the image resource. User agents must only display the first page of a multipage resource (e.g. a PDF file). User agents must not allow the resource to act in an interactive fashion, but should honour any animation in the resource.

This specification does not specify which image types are to be supported.

4.8.4.3.1 When to obtain images §[p366]

By default, images are obtained immediately. User agents may provide users with the option to instead obtain them on-demand. (The on-demand option might be used by bandwidth-constrained users, for example.)

When obtaining images immediately, the user agent must synchronously update the image data[p368] of the `img`[p347] element, with the *restart animation* flag set if so stated, whenever that element is created or has experienced relevant mutations[p366].

When obtaining images on demand, the user agent must update the image data[p368] of an `img`[p347] element whenever it needs the image data (i.e., on demand), but only if the `img`[p347] element's current request[p364]'s state[p364] is unavailable[p364]. When an `img`[p347] element has experienced relevant mutations[p366], if the user agent only obtains images on demand, the `img`[p347] element's current request[p364]'s state[p364] must return to unavailable[p364].

4.8.4.3.2 Reacting to DOM mutations §[p366]

The **relevant mutations** for an `img`[p347] element are as follows:

- The element's `src`[p348], `srcset`[p348], `width`[p478], or `sizes`[p349] attributes are set, changed, or removed.
- The element's `src`[p348] attribute is set to the same value as the previous value. This must set the *restart animation* flag for the update the image data[p368] algorithm.
- The element's `crossorigin`[p349] attribute's state is changed.
- The element's `referrerpolicy`[p349] attribute's state is changed.
- The `img`[p347] or `source`[p344] HTML element insertion steps[p46], HTML element removing steps[p46], and HTML element moving steps[p46] count the mutation as a relevant mutation[p366].
- The element's parent is a `picture`[p343] element and a `source`[p344] element that is a previous sibling has its `srcset`[p345], `sizes`[p345], `media`[p344], `type`[p344], `width`[p478] or `height`[p478] attributes set, changed, or removed.
- The element's adopting steps are run.
- If the element allows auto-sizes[p349]: the element starts or stops being rendered[p1406], or its concrete object size width changes. This must set the *maybe omit events* flag for the update the image data[p368] algorithm.

4.8.4.3.3 The list of available images §[p367]

Each Document[p131] object must have a **list of available images**. Each image in this list is identified by a tuple consisting of an absolute URL, a CORS settings attribute[p101] mode, and, if the mode is not No CORS[p101], an origin[p909]. Each image furthermore has an **ignore higher-layer caching** flag. User agents may copy entries from one Document[p131] object's list of available images[p367] to another at any time (e.g. when the Document[p131] is created, user agents can add to it all the images that are loaded in other Document[p131]s), but must not change the keys of entries copied in this way when doing so, and must unset the ignore higher-layer caching[p367] flag for the copied entry. User agents may also remove images from such lists at any time (e.g. to save memory). User agents must remove entries in the list of available images[p367] as appropriate given higher-layer caching semantics for the resource (e.g. the HTTP `Cache-Control` response header) when the ignore higher-layer caching[p367] flag is unset.

Note

The list of available images[p367] is intended to enable synchronous switching when changing the src[p348] attribute to a URL that has previously been loaded, and to avoid re-downloading images in the same document even when they don't allow caching per HTTP. It is not used to avoid re-downloading the same image while the previous image is still loading.

Note

The user agent can also store the image data separately from the list of available images[p367].

Example

For example, if a resource has the HTTP response header `Cache-Control: must-revalidate`, and its ignore higher-layer caching[p367] flag is unset, the user agent would remove it from the list of available images[p367] but could keep the image data separately, and use that if the server responds with a `304 Not Modified` status.

4.8.4.3.4 Decoding images §[p367]

Image data is usually encoded in order to reduce file size. This means that in order for the user agent to present the image to the screen, the data needs to be decoded. **Decoding** is the process which converts an image's media data into a bitmap form, suitable for presentation to the screen. Note that this process can be slow relative to other processes involved in presenting content. Thus, the user agent can choose when to perform decoding, in order to create the best user experience.

Image decoding is said to be synchronous if it prevents presentation of other content until it is finished. Typically, this has an effect of atomically presenting the image and any other content at the same time. However, this presentation is delayed by the amount of time it takes to perform the decode.

Image decoding is said to be asynchronous if it does not prevent presentation of other content. This has an effect of presenting non-image content faster. However, the image content is missing on screen until the decode finishes. Once the decode is finished, the screen is updated with the image.

In both synchronous and asynchronous decoding modes, the final content is presented to screen after the same amount of time has elapsed. The main difference is whether the user agent presents non-image content ahead of presenting the final content.

In order to aid the user agent in deciding whether to perform synchronous or asynchronous decode, the decoding[p349] attribute can be set on img[p347] elements. The possible values of the decoding[p349] attribute are the following **image decoding hint** keywords:

Keyword	State	Description
sync	**Sync**	Indicates a preference to decode[p367] this image synchronously for atomic presentation with other content.
async	**Async**	Indicates a preference to decode[p367] this image asynchronously to avoid delaying presentation of other content.
auto	**Auto**	Indicates no preference in decoding mode (the default).

When decoding[p367] an image, the user agent should respect the preference indicated by the decoding[p349] attribute's state. If the state indicated is Auto[p367], then the user agent is free to choose any decoding behavior.

Note

It is also possible to control the decoding behavior using the decode()[p352] method. Since the decode()[p352] method performs decoding[p367] independently from the process responsible for presenting content to screen, it is unaffected by the decoding[p349] attribute.

4.8.4.3.5 Updating the image data §[p368]

Note

This algorithm cannot be called from steps running in parallel[p44]. If a user agent needs to call this algorithm from steps running in parallel[p44], it needs to queue[p1139] a task to do so.

When the user agent is to **update the image data** of an `img`[p347] element, optionally with the *restart animations* flag set, optionally with the *maybe omit events* flag set, it must run the following steps:

1. If the element's node document is not fully active[p1017], then:
    1. Continue running this algorithm in parallel[p44].
    2. Wait until the element's node document is fully active[p1017].
    3. If another instance of this algorithm for this `img`[p347] element was started after this instance (even if it aborted and is no longer running), then return.
    4. Queue a microtask[p1140] to continue this algorithm.
2. If the user agent cannot support images, or its support for images has been disabled, then abort the image request[p371] for the current request[p364] and the pending request[p364], set the current request[p364]'s state[p364] to unavailable[p364], set the pending request[p364] to null, and return.
3. Let *previousURL* be the current request[p364]'s current URL[p364].
4. Let *selected source* be null and *selected pixel density* be undefined.
5. If the element does not use `srcset` or `picture`[p365] and it has a `src`[p348] attribute specified whose value is not the empty string, then set *selected source* to the value of the element's `src`[p348] attribute and set *selected pixel density* to 1.0.
6. Set the element's last selected source[p365] to *selected source*.
7. If *selected source* is not null, then:
    1. Let *urlString* be the result of encoding-parsing-and-serializing a URL[p99] given *selected source*, relative to the element's node document.
    2. If *urlString* is failure, then abort this inner set of steps.
    3. Let *key* be a tuple consisting of *urlString*, the `img`[p347] element's `crossorigin`[p349] attribute's mode, and, if that mode is not No CORS[p101], the node document's origin.
    4. If the list of available images[p367] contains an entry for *key*, then:
        1. Set the ignore higher-layer caching[p367] flag for that entry.
        2. Abort the image request[p371] for the current request[p364] and the pending request[p364].
        3. Set the pending request[p364] to null.
        4. Set the current request[p364] to a new image request[p364] whose image data[p364] is that of the entry and whose state[p364] is completely available[p365].
        5. Prepare the current request for presentation[p372] given the `img`[p347] element.
        6. Set the current request[p364]'s current pixel density[p365] to *selected pixel density*.
        7. Queue an element task[p1140] on the DOM manipulation task source[p1149] given the `img`[p347] element and the following steps:
            1. If *restart animation* is set, then restart the animation[p1427].
            2. Set the current request[p364]'s current URL[p364] to *urlString*.
            3. If *maybe omit events* is not set or *previousURL* is not equal to *urlString*, then fire an event named `load`[p1490] at the `img`[p347] element.
        8. Abort the update the image data[p368] algorithm.

8. Queue a microtask[p1140] to perform the rest of this algorithm, allowing the task[p1139] that invoked this algorithm to continue.

9. If another instance of this algorithm for this `img`[p347] element was started after this instance (even if it aborted and is no longer running), then return.

   Note

   Only the last instance takes effect, to avoid multiple requests when, for example, the `src`[p348], `srcset`[p348], and `crossorigin`[p349] attributes are all set in succession.

10. Let *selected source* and *selected pixel density* be the URL and pixel density that results from selecting an image source[p372], respectively.

11. If *selected source* is null, then:

    1. Set the current request[p364]'s state[p364] to broken[p365], abort the image request[p371] for the current request[p364] and the pending request[p364], and set the pending request[p364] to null.

    2. Queue an element task[p1140] on the DOM manipulation task source[p1149] given the `img`[p347] element and the following steps:

       1. Change the current request[p364]'s current URL[p364] to the empty string.

       2. If all of the following are true:

          - the element has a `src`[p348] attribute or it uses `srcset` or `picture`[p365]; and
          - *maybe omit events* is not set or *previousURL* is not the empty string,

          then fire an event named `error`[p1489] at the `img`[p347] element.

    3. Return.

12. Let *urlString* be the result of encoding-parsing-and-serializing a URL[p99] given *selected source*, relative to the element's node document.

13. If *urlString* is failure, then:

    1. Abort the image request[p371] for the current request[p364] and the pending request[p364].

    2. Set the current request[p364]'s state[p364] to broken[p365].

    3. Set the pending request[p364] to null.

    4. Queue an element task[p1140] on the DOM manipulation task source[p1149] given the `img`[p347] element and the following steps:

       1. Change the current request[p364]'s current URL[p364] to *selected source*.

       2. If *maybe omit events* is not set or *previousURL* is not equal to *selected source*, then fire an event named `error`[p1489] at the `img`[p347] element.

    5. Return.

14. If the pending request[p364] is not null and *urlString* is the same as the pending request[p364]'s current URL[p364], then return.

15. If *urlString* is the same as the current request[p364]'s current URL[p364] and the current request[p364]'s state[p364] is partially available[p364], then abort the image request[p371] for the pending request[p364], queue an element task[p1140] on the DOM manipulation task source[p1149] given the `img`[p347] element to restart the animation[p1427] if *restart animation* is set, and return.

16. Abort the image request[p371] for the pending request[p364].

17. Set *image request* to a new image request[p364] whose current URL[p364] is *urlString*.

18. If the current request[p364]'s state[p364] is unavailable[p364] or broken[p365], then set the current request[p364] to *image request*. Otherwise, set the pending request[p364] to *image request*.

19. Let *request* be the result of creating a potential-CORS request[p99] given *urlString*, "`image`", and the current state of the element's `crossorigin`[p349] content attribute.

20. Set *request*'s client to the element's node document's relevant settings object[p1098].

21. If the element uses srcset or picture[p365], set *request*'s initiator to "imageset".

22. Set *request*'s referrer policy to the current state of the element's referrerpolicy[p349] attribute.

23. Set *request*'s priority to the current state of the element's fetchpriority[p349] attribute.

24. Let *delay load event* be true if the img[p347]'s lazy loading attribute[p102] is in the Eager[p102] state, or if scripting is disabled[p1099] for the img[p347], and false otherwise.

25. If the will lazy load element steps[p103] given the img[p347] return true, then:

    1. Set the img[p347]'s lazy load resumption steps[p103] to the rest of this algorithm starting with the step labeled *fetch the image*.

    2. Start intersection-observing a lazy loading element[p103] for the img[p347] element.

    3. Return.

26. *Fetch the image*: Fetch *request*. Return from this algorithm, and run the remaining steps as part of the fetch's *processResponse* for the response *response*.

    The resource obtained in this fashion, if any, is *image request*'s image data[p364]. It can be either CORS-same-origin[p99] or CORS-cross-origin[p99]; this affects the image's interaction with other APIs (e.g., when used on a canvas[p684]).

    When *delay load event* is true, fetching the image must delay the load event[p1377] of the element's node document until the task[p1139] that is queued[p1139] by the networking task source[p1149] once the resource has been fetched (defined below[p371]) has been run.

    ⚠Warning!

    This, unfortunately, can be used to perform a rudimentary port scan of the user's local network (especially in conjunction with scripting, though scripting isn't actually necessary to carry out such an attack). User agents may implement cross-origin[p909] access control policies that are stricter than those described above to mitigate this attack, but unfortunately such policies are typically not compatible with existing web content.

27. As soon as possible, jump to the first applicable entry from the following list:

    ↪ **If the resource type is multipart/x-mixed-replace[p1463]**

    The next task[p1139] that is queued[p1139] by the networking task source[p1149] while the image is being fetched must run the following steps:

    1. If *image request* is the pending request[p364] and at least one body part has been completely decoded, abort the image request[p371] for the current request[p364], and upgrade the pending request to the current request[p372].

    2. Otherwise, if *image request* is the pending request[p364] and the user agent is able to determine that *image request*'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, abort the image request[p371] for the current request[p364], upgrade the pending request to the current request[p372], and set the current request[p364]'s state[p364] to broken[p365].

    3. Otherwise, if *image request* is the current request[p364], its state[p364] is unavailable[p364], and the user agent is able to determine *image request*'s image's width and height, set the current request[p364]'s state[p364] to partially available[p364].

    4. Otherwise, if *image request* is the current request[p364], its state[p364] is unavailable[p364], and the user agent is able to determine that *image request*'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, set the current request[p364]'s state[p364] to broken[p365].

    Each task[p1139] that is queued[p1139] by the networking task source[p1149] while the image is being fetched must update the presentation of the image, but as each new body part comes in, if the user agent is able to determine the image's width and height, it must prepare the img element's current request for presentation[p372] given the img[p347] element and replace the previous image. Once one body part has been completely decoded, perform the following steps:

    1. Set the img[p347] element's current request[p364]'s state[p364] to completely available[p365].

    2. If *maybe omit events* is not set or *previousURL* is not equal to *urlString*, then queue an element task[p1140] on the DOM manipulation task source[p1149] given the img[p347] element to fire an event named load[p1490] at the

`img`[p347] element.

↪ **If the resource type and data corresponds to a supported image format, as described below**[p366]

The next task[p1139] that is queued[p1139] by the networking task source[p1149] while the image is being fetched must run the following steps:

1. If the user agent is able to determine *image request*'s image's width and height, and *image request* is the pending request[p364], set *image request*'s state[p364] to partially available[p364].
2. Otherwise, if the user agent is able to determine *image request*'s image's width and height, and *image request* is the current request[p364], prepare *image request* for presentation[p372] given the `img`[p347] element and set *image request*'s state[p364] to partially available[p364].
3. Otherwise, if the user agent is able to determine that *image request*'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, and *image request* is the pending request[p364]:
    1. Abort the image request[p371] for the current request[p364] and the pending request[p364].
    2. Upgrade the pending request to the current request[p372].
    3. Set the current request[p364]'s state[p364] to broken[p365].
    4. Fire an event named `error`[p1489] at the `img`[p347] element.
4. Otherwise, if the user agent is able to determine that *image request*'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, and *image request* is the current request[p364]:
    1. Abort the image request[p371] for *image request*.
    2. If *maybe omit events* is not set or *previousURL* is not equal to *urlString*, then fire an event named `error`[p1489] at the `img`[p347] element.

That task[p1139], and each subsequent task[p1139], that is queued[p1139] by the networking task source[p1149] while the image is being fetched, if *image request* is the current request[p364], must update the presentation of the image appropriately (e.g., if the image is a progressive JPEG, each packet can improve the resolution of the image).

Furthermore, the last task[p1139] that is queued[p1139] by the networking task source[p1149] once the resource has been fetched must additionally run these steps:

1. If *image request* is the pending request[p364], abort the image request[p371] for the current request[p364], upgrade the pending request to the current request[p372], and prepare *image request* for presentation[p372] given the `img`[p347] element.
2. Set *image request* to the completely available[p365] state.
3. Add the image to the list of available images[p367] using the key *key*, with the ignore higher-layer caching[p367] flag set.
4. If *maybe omit events* is not set or *previousURL* is not equal to *urlString*, then fire an event named `load`[p1490] at the `img`[p347] element.

↪ **Otherwise**

The image data is not in a supported file format; the user agent must set *image request*'s state[p364] to broken[p365], abort the image request[p371] for the current request[p364] and the pending request[p364], upgrade the pending request to the current request[p372] if *image request* is the pending request[p364], and then, if *maybe omit events* is not set or *previousURL* is not equal to *urlString*, queue an element task[p1140] on the DOM manipulation task source[p1149] given the `img`[p347] element to fire an event named `error`[p1489] at the `img`[p347] element.

While a user agent is running the above algorithm for an element *x*, there must be a strong reference from the element's node document to the element *x*, even if that element is not connected.

To **abort the image request** for an image request[p364] or null *image request* means to run the following steps:

1. If *image request* is null, then return.
2. Forget *image request*'s image data[p364], if any.
3. Abort any instance of the fetching algorithm for *image request*, discarding any pending tasks generated by that algorithm.

To **upgrade the pending request to the current request** for an `img` element means to run the following steps:

1. Set the `img` element's current request to the pending request.
2. Set the `img` element's pending request to null.

4.8.4.3.6 Preparing an image for presentation

To **prepare an image for presentation** for an image request *req* given image element *img*:

1. Let *exifTagMap* be the EXIF tags obtained from *req*'s image data, as defined by the relevant codec. [EXIF]
2. Let *physicalWidth* and *physicalHeight* be the width and height obtained from *req*'s image data, as defined by the relevant codec.
3. Let *dimX* be the value of *exifTagMap*'s tag `0xA002` (`PixelXDimension`).
4. Let *dimY* be the value of *exifTagMap*'s tag `0xA003` (`PixelYDimension`).
5. Let *resX* be the value of *exifTagMap*'s tag `0x011A` (`XResolution`).
6. Let *resY* be the value of *exifTagMap*'s tag `0x011B` (`YResolution`).
7. Let *resUnit* be the value of *exifTagMap*'s tag `0x0128` (`ResolutionUnit`).
8. If either *dimX* or *dimY* is not a positive integer, then return.
9. If either *resX* or *resY* is not a positive floating-point number, then return.
10. If *resUnit* is not equal to `2` (`Inch`), then return.
11. Let *widthFromDensity* be the value of *physicalWidth*, multiplied by 72 and divided by *resX*.
12. Let *heightFromDensity* be the value of *physicalHeight*, multiplied by 72 and divided by *resY*.
13. If *widthFromDensity* is not equal to *dimX* or *heightFromDensity* is not equal to *dimY*, then return.
14. If *req*'s image data is CORS-cross-origin, then set *img*'s natural dimensions to *dimX* and *dimY*, scale *img*'s pixel data accordingly, and return.
15. Set *req*'s preferred density-corrected dimensions to a struct with its width set to *dimX* and its height set to *dimY*.
16. Update *req*'s `img` element's presentation appropriately.

Note

Resolution in EXIF is equivalent to CSS points per inch, therefore 72 is the base for computing size from resolution.

It is not yet specified what would be the case if EXIF arrives after the image is already presented. See issue #4929.

4.8.4.3.7 Selecting an image source

To **select an image source** given an `img` element *el*:

1. Update the source set for *el*.
2. If *el*'s source set is empty, return null as the URL and undefined as the pixel density.
3. Return the result of selecting an image from *el*'s source set.

To **select an image source from a source set** given a source set *sourceSet*:

1. If an entry *b* in *sourceSet* has the same associated pixel density descriptor as an earlier entry *a* in *sourceSet*, then remove entry *b*. Repeat this step until none of the entries in *sourceSet* have the same associated pixel density descriptor

as an earlier entry.

2. In an implementation-defined manner, choose one image source[p365] from *sourceSet*. Let *selectedSource* be this choice.
3. Return *selectedSource* and its associated pixel density.

4.8.4.3.8 Creating a source set from attributes §[p37 3]

When asked to **create a source set** given a string *default source*, a string *srcset*, a string *sizes*, and an element or null *img*:

1. Let *source set* be an empty source set[p365].
2. If *srcset* is not an empty string, then set *source set* to the result of parsing[p374] *srcset*.
3. Set *source set*'s source size[p365] to the result of parsing[p376] *sizes* with *img*.
4. If *default source* is not the empty string and *source set* does not contain an image source[p365] with a pixel density descriptor[p363] value of 1, and no image source[p365] with a width descriptor[p363], append *default source* to *source set*.
5. Normalize the source densities[p377] of *source set*.
6. Return *source set*.

4.8.4.3.9 Updating the source set §[p37 3]

When asked to **update the source set** for a given `img`[p347] or `link`[p178] element *el*, user agents must do the following:

1. Set *el*'s source set[p365] to an empty source set[p365].
2. Let *elements* be « *el* ».
3. If *el* is an `img`[p347] element whose parent node is a `picture`[p343] element, then replace the contents of *elements* with *el*'s parent node's child elements, retaining relative order.
4. Let *img* be *el* if *el* is an `img`[p347] element, otherwise null.
5. For each *child* in *elements*:
    1. If *child* is *el*:
        1. Let *default source* be the empty string.
        2. Let *srcset* be the empty string.
        3. Let *sizes* be the empty string.
        4. If *el* is an `img`[p347] element that has a `srcset`[p348] attribute, then set *srcset* to that attribute's value.
        5. Otherwise, if *el* is a `link`[p178] element that has an `imagesrcset`[p181] attribute, then set *srcset* to that attribute's value.
        6. If *el* is an `img`[p347] element that has a `sizes`[p349] attribute, then set *sizes* to that attribute's value.
        7. Otherwise, if *el* is a `link`[p178] element that has an `imagesizes`[p181] attribute, then set *sizes* to that attribute's value.
        8. If *el* is an `img`[p347] element that has a `src`[p348] attribute, then set *default source* to that attribute's value.
        9. Otherwise, if *el* is a `link`[p178] element that has an `href`[p179] attribute, then set *default source* to that attribute's value.
        10. Set *el*'s source set[p365] to the result of creating a source set[p373] given *default source*, *srcset*, *sizes*, and *img*.
        11. Return.

Note

If el *is a* link *element, then* elements *contains only* el*, so this step will be reached immediately and the rest of the algorithm will not run.*

2. If *child* is not a source element, then continue.
3. If *child* does not have a srcset attribute, continue to the next child.
4. Parse *child*'s srcset attribute and let *source set* be the returned source set.
5. If *source set* has zero image sources, continue to the next child.
6. If *child* has a media attribute, and its value does not match the environment, continue to the next child.
7. Parse *child*'s sizes attribute with *img*, and let *source set*'s source size be the returned value.
8. If *child* has a type attribute, and its value is an unknown or unsupported MIME type, continue to the next child.
9. If *child* has width or height attributes, set *el*'s dimension attribute source to *child*. Otherwise, set *el*'s dimension attribute source to *el*.
10. Normalize the source densities of *source set*.
11. Set *el*'s source set to *source set*.
12. Return.

Note

Each img *element independently considers its previous sibling* source *elements plus the* img *element itself for selecting an image source, ignoring any other (invalid) elements, including other* img *elements in the same* picture *element, or* source *elements that are following siblings of the relevant* img *element.*

4.8.4.3.10 Parsing a srcset attribute

When asked to **parse a srcset attribute** from an element, parse the value of the element's srcset attribute as follows:

1. Let *input* be the value passed to this algorithm.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *candidates* be an initially empty source set.
4. *Splitting loop*: Collect a sequence of code points that are ASCII whitespace or U+002C COMMA characters from *input* given *position*. If any U+002C COMMA characters were collected, that is a parse error.
5. If *position* is past the end of *input*, return *candidates*.
6. Collect a sequence of code points that are not ASCII whitespace from *input* given *position*, and let *url* be the result.
7. Let *descriptors* be a new empty list.
8. If *url* ends with U+002C (,), then:
    1. Remove all trailing U+002C COMMA characters from *url*. If this removed more than one character, that is a parse error.

    Otherwise:

    1. *Descriptor tokenizer*: Skip ASCII whitespace within *input* given *position*.
    2. Let *current descriptor* be the empty string.
    3. Let *state* be *in descriptor*.
    4. Let *c* be the character at *position*. Do the following depending on the value of *state*. For the purpose of this step, "EOF" is a special character representing that *position* is past the end of *input*.

↪ ***In descriptor***

Do the following, depending on the value of *c*:

↪ **ASCII whitespace**

If *current descriptor* is not empty, append *current descriptor* to *descriptors* and let *current descriptor* be the empty string. Set *state* to *after descriptor*.

↪ **U+002C COMMA (,)**

Advance *position* to the next character in *input*. If *current descriptor* is not empty, append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

↪ **U+0028 LEFT PARENTHESIS (()**

Append *c* to *current descriptor*. Set *state* to *in parens*.

↪ **EOF**

If *current descriptor* is not empty, append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

↪ **Anything else**

Append *c* to *current descriptor*.

↪ ***In parens***

Do the following, depending on the value of *c*:

↪ **U+0029 RIGHT PARENTHESIS ())**

Append *c* to *current descriptor*. Set *state* to *in descriptor*.

↪ **EOF**

Append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

↪ **Anything else**

Append *c* to *current descriptor*.

↪ ***After descriptor***

Do the following, depending on the value of *c*:

↪ **ASCII whitespace**

Stay in this state.

↪ **EOF**

Jump to the step labeled *descriptor parser*.

↪ **Anything else**

Set *state* to *in descriptor*. Set *position* to the *previous* character in *input*.

Advance *position* to the next character in *input*. Repeat this step.

Note

In order to be compatible with future additions, this algorithm supports multiple descriptors and descriptors with parens.

9. *Descriptor parser*: Let *error* be *no*.
10. Let *width* be *absent*.
11. Let *density* be *absent*.
12. Let *future-compat-h* be *absent*.
13. For each descriptor in *descriptors*, run the appropriate set of steps from the following list:

↪ **If the descriptor consists of a valid non-negative integer[p78] followed by a U+0077 LATIN SMALL LETTER W character**

1. If the user agent does not support the `sizes`[p349] attribute, let *error* be *yes*.

Note

A conforming user agent will support the `sizes`[p349] *attribute. However, user agents typically implement and ship features in an incremental manner in practice.*

2. If *width* and *density* are not both *absent*, then let *error* be *yes*.

3. Apply the rules for parsing non-negative integers[p78] to the descriptor. If the result is 0, let *error* be *yes*. Otherwise, let *width* be the result.

↪ **If the descriptor consists of a valid floating-point number[p78] followed by a U+0078 LATIN SMALL LETTER X character**

1. If *width*, *density* and *future-compat-h* are not all *absent*, then let *error* be *yes*.

2. Apply the rules for parsing floating-point number values[p79] to the descriptor. If the result is less than 0, let *error* be *yes*. Otherwise, let *density* be the result.

Note

If density *is 0, the natural dimensions will be infinite. User agents are expected to have limits in how big images can be rendered.*

↪ **If the descriptor consists of a valid non-negative integer[p78] followed by a U+0068 LATIN SMALL LETTER H character**

This is a parse error[p366].

1. If *future-compat-h* and *density* are not both *absent*, then let *error* be *yes*.

2. Apply the rules for parsing non-negative integers[p78] to the descriptor. If the result is 0, let *error* be *yes*. Otherwise, let *future-compat-h* be the result.

↪ **Anything else**

Let *error* be *yes*.

14. If *future-compat-h* is not *absent* and *width* is *absent*, let *error* be *yes*.

15. If *error* is still *no*, then append a new image source[p365] to *candidates* whose URL is *url*, associated with a width *width* if not *absent* and a pixel density *density* if not *absent*. Otherwise, there is a parse error[p366].

16. Return to the step labeled *splitting loop*.

4.8.4.3.11 Parsing a sizes attribute §[p37 6]

When asked to **parse a sizes attribute** from an element *element*, with an `img`[p347] element or null *img*:

1. Let *unparsed sizes list* be the result of parsing a comma-separated list of component values from the value of *element*'s sizes attribute[p364] (or the empty string, if the attribute is absent). [CSSSYNTAX][p1495]

2. Let *size* be null.

3. For each *unparsed size* in *unparsed sizes list*:

    1. Remove all consecutive <whitespace-token>s from the end of *unparsed size*. If *unparsed size* is now empty, then that is a parse error[p366]; continue.

    2. If the last component value in *unparsed size* is a valid non-negative <source-size-value>[p364], then set *size* to its value and remove the component value from *unparsed size*. Any CSS function other than the math functions is invalid. Otherwise, there is a parse error[p366]; continue.

    3. If *size* is `auto`[p364], and *img* is not null, and *img* is being rendered[p1406], and *img* allows auto-sizes[p349], then set *size* to the concrete object size width of *img*, in CSS pixels.

    Note

    If size *is still* `auto`[p364]*, then it will be ignored.*

    4. Remove all consecutive <whitespace-token>s from the end of *unparsed size*. If *unparsed size* is now empty:

1. If this was not the last item in *unparsed sizes list*, that is a parse error[p366].
2. If *size* is not `auto`[p364], then return *size*. Otherwise, continue.

5. Parse the remaining component values in *unparsed size* as a <media-condition>. If it does not parse correctly, or it does parse correctly but the <media-condition> evaluates to false, continue. [MQ][p1498]
6. If *size* is not `auto`[p364], then return *size*. Otherwise, continue.

4. Return `100vw`.

Note

It is invalid to use a bare <source-size-value>[p364] that is a <length> (without an accompanying <media-condition>) as an entry in the <source-size-list>[p364] that is not the last entry. However, the parsing algorithm allows it at any point in the <source-size-list>[p364], and will accept it immediately as the size if the preceding entries in the list weren't used. This is to enable future extensions, and protect against simple author errors such as a final trailing comma. A bare `auto`[p364] keyword is allowed to have other entries following it to provide a fallback for legacy user agents.

4.8.4.3.12 Normalizing the source densities §[p37]

An image source[p365] can have a pixel density descriptor[p363], a width descriptor[p363], or no descriptor at all accompanying its URL. Normalizing a source set[p365] gives every image source[p365] a pixel density descriptor[p363].

When asked to **normalize the source densities** of a source set[p365] *source set*, the user agent must do the following:

1. Let *source size* be *source set*'s source size[p365].
2. For each image source[p365] in *source set*:
    1. If the image source[p365] has a pixel density descriptor[p363], continue to the next image source[p365].
    2. Otherwise, if the image source[p365] has a width descriptor[p363], replace the width descriptor[p363] with a pixel density descriptor[p363] with a value[p363] of the width descriptor value[p363] divided by *source size* and a unit of `x`.

        Note

        If the source size[p365] is 0, then the density would be infinity, which results in the natural dimensions being 0 by 0.

    3. Otherwise, give the image source[p365] a pixel density descriptor[p363] of `1x`.

4.8.4.3.13 Reacting to environment changes §[p37]

The user agent may at any time run the following algorithm to update an `img`[p347] element's image in order to **react to changes in the environment**. (User agents are *not required* to ever run this algorithm; for example, if the user is not looking at the page any more, the user agent might want to wait until the user has returned to the page before determining which image to use, in case the environment changes again in the meantime.)

Note

User agents are encouraged to run this algorithm in particular when the user changes the viewport's size (e.g. by resizing the window or changing the page zoom), and when an `img`[p347] element is inserted into a document[p47], so that the density-corrected natural width and height[p365] match the new viewport, and so that the correct image is chosen when art direction[p358] is involved.

1. Await a stable state[p1146]. The synchronous section[p1146] consists of all the remaining steps of this algorithm until the algorithm says the synchronous section[p1146] has ended. (Steps in synchronous sections[p1146] are marked with ⌛.)
2. ⌛ If the `img`[p347] element does not use `srcset` or `picture`[p365], its node document is not fully active[p1017], it has image data whose resource type is `multipart/x-mixed-replace`[p1463], or its pending request[p364] is not null, then return.
3. ⌛ Let *selected source* and *selected pixel density* be the URL and pixel density that results from selecting an image source[p372], respectively.

4. ⌛ If *selected source* is null, then return.
5. ⌛ If *selected source* and *selected pixel density* are the same as the element's last selected source[p365] and current pixel density[p365], then return.
6. ⌛ Let *urlString* be the result of encoding-parsing-and-serializing a URL[p99] given *selected source*, relative to the element's node document.
7. ⌛ If *urlString* is failure, then return.
8. ⌛ Let *corsAttributeState* be the state of the element's `crossorigin`[p349] content attribute.
9. ⌛ Let *origin* be the `img`[p347] element's node document's origin.
10. ⌛ Let *client* be the `img`[p347] element's node document's relevant settings object[p1098].
11. ⌛ Let *key* be a tuple consisting of *urlString*, *corsAttributeState*, and, if *corsAttributeState* is not No CORS[p101], *origin*.
12. ⌛ Let *image request* be a new image request[p364] whose current URL[p364] is *urlString*.
13. ⌛ Set the element's pending request[p364] to *image request*.
14. End the synchronous section[p1146], continuing the remaining steps in parallel[p44].
15. If the list of available images[p367] contains an entry for *key*, then set *image request*'s image data[p364] to that of the entry. Continue to the next step.

    Otherwise:

    1. Let *request* be the result of creating a potential-CORS request[p99] given *urlString*, "`image`", and *corsAttributeState*.
    2. Set *request*'s client to *client*, set *request*'s initiator to "`imageset`", and set *request*'s synchronous flag.
    3. Set *request*'s referrer policy to the current state of the element's `referrerpolicy`[p349] attribute.
    4. Set *request*'s priority to the current state of the element's `fetchpriority`[p349] attribute.
    5. Let *response* be the result of fetching *request*.
    6. If *response*'s unsafe response[p99] is a network error or if the image format is unsupported (as determined by applying the image sniffing rules, again as mentioned earlier), or if the user agent is able to determine that *image request*'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, or if the resource type is `multipart/x-mixed-replace`[p1463], then set the pending request[p364] to null and abort these steps.
    7. Otherwise, *response*'s unsafe response[p99] is *image request*'s image data[p364]. It can be either CORS-same-origin[p99] or CORS-cross-origin[p99]; this affects the image's interaction with other APIs (e.g., when used on a `canvas`[p684]).
16. Queue an element task[p1140] on the DOM manipulation task source[p1149] given the `img`[p347] element and the following steps:

    1. If the `img`[p347] element has experienced relevant mutations[p366] since this algorithm started, then set the pending request[p364] to null and abort these steps.
    2. Set the `img`[p347] element's last selected source[p365] to *selected source* and the `img`[p347] element's current pixel density[p365] to *selected pixel density*.
    3. Set the *image request*'s state[p364] to completely available[p365].
    4. Add the image to the list of available images[p367] using the key *key*, with the ignore higher-layer caching[p367] flag set.
    5. Upgrade the pending request to the current request[p372].
    6. Prepare *image request* for presentation[p372] given the `img`[p347] element.
    7. Fire an event named `load`[p1490] at the `img`[p347] element.

4.8.4.4 Requirements for providing text to act as an alternative for images §p37 9

4.8.4.4.1 General guidelines §p37 9

Except where otherwise specified, the alt[p348] attribute must be specified and its value must not be empty; the value must be an appropriate replacement for the image. The specific requirements for the alt[p348] attribute depend on what the image is intended to represent, as described in the following sections.

The most general rule to consider when writing alternative text is the following: **the intent is that replacing every image with the text of its alt[p348] attribute does not change the meaning of the page**.

So, in general, alternative text can be written by considering what one would have written had one not been able to include the image.

A corollary to this is that the alt[p348] attribute's value should never contain text that could be considered the image's *caption*, *title*, or *legend*. It is supposed to contain replacement text that could be used by users *instead* of the image; it is not meant to supplement the image. The title[p158] attribute can be used for supplemental information.

Another corollary is that the alt[p348] attribute's value should not repeat information that is already provided in the prose next to the image.

Note

One way to think of alternative text is to think about how you would read the page containing the image to someone over the phone, without mentioning that there is an image present. Whatever you say instead of the image is typically a good start for writing the alternative text.

4.8.4.4.2 A link or button containing nothing but the image §p37 9

When an a[p258] element that creates a hyperlink[p303], or a button[p567] element, has no textual content but contains one or more images, the alt[p348] attributes must contain text that together convey the purpose of the link or button.

Example

In this example, a user is asked to pick their preferred color from a list of three. Each color is given by an image, but for users who have configured their user agent not to display images, the color names are used instead:

```
<h1>Pick your color</h1>
<ul>
 <li><a href="green.html"><img src="green.jpeg" alt="Green"></a></li>
 <li><a href="blue.html"><img src="blue.jpeg" alt="Blue"></a></li>
 <li><a href="red.html"><img src="red.jpeg" alt="Red"></a></li>
</ul>
```

Example

In this example, each button has a set of images to indicate the kind of color output desired by the user. The first image is used in each case to give the alternative text.

```
<button name="rgb"><img src="red" alt="RGB"><img src="green" alt=""><img src="blue"
alt=""></button>
<button name="cmyk"><img src="cyan" alt="CMYK"><img src="magenta" alt=""><img src="yellow"
alt=""><img src="black" alt=""></button>
```

Since each image represents one part of the text, it could also be written like this:

```
<button name="rgb"><img src="red" alt="R"><img src="green" alt="G"><img src="blue"
alt="B"></button>
<button name="cmyk"><img src="cyan" alt="C"><img src="magenta" alt="M"><img src="yellow"
alt="Y"><img src="black" alt="K"></button>
```

However, with other alternative text, this might not work, and putting all the alternative text into one image in each case might

make more sense:

```
<button name="rgb"><img src="red" alt="sRGB profile"><img src="green" alt=""><img src="blue"
alt=""></button>
<button name="cmyk"><img src="cyan" alt="CMYK profile"><img src="magenta" alt=""><img src="yellow"
alt=""><img src="black" alt=""></button>
```

4.8.4.4.3 A phrase or paragraph with an alternative graphical representation: charts, diagrams, graphs, maps, illustrations §[p38]

Sometimes something can be more clearly stated in graphical form, for example as a flowchart, a diagram, a graph, or a simple map showing directions. In such cases, an image can be given using the img[p347] element, but the lesser textual version must still be given, so that users who are unable to view the image (e.g. because they have a very slow connection, or because they are using a text-only browser, or because they are listening to the page being read out by a hands-free automobile voice web browser, or simply because they are blind) are still able to understand the message being conveyed.

The text must be given in the alt[p348] attribute, and must convey the same message as the image specified in the src[p348] attribute.

It is important to realize that the alternative text is a *replacement* for the image, not a description of the image.

Example

In the following example we have a flowchart in image form, with text in the alt[p348] attribute rephrasing the flowchart in prose form:

```
<p>In the common case, the data handled by the tokenization stage
comes from the network, but it can also come from script.</p>
<p><img src="images/parsing-model-overview.svg" alt="The Network
passes data to the Input Stream Preprocessor, which passes it to the
Tokenizer, which passes it to the Tree Construction stage. From there,
data goes to both the DOM and to Script Execution. Script Execution is
linked to the DOM, and, using document.write(), passes data to the
Tokenizer."></p>
```

Example

Here's another example, showing a good solution and a bad solution to the problem of including an image in a description.

First, here's the good solution. This sample shows how the alternative text should just be what you would have put in the prose if the image had never existed.

```
<!-- This is the correct way to do things. -->
<p>
 You are standing in an open field west of a house.
 <img src="house.jpeg" alt="The house is white, with a boarded front door.">
 There is a small mailbox here.
</p>
```

Second, here's the bad solution. In this incorrect way of doing things, the alternative text is simply a description of the image, instead of a textual replacement for the image. It's bad because when the image isn't shown, the text doesn't flow as well as in the first example.

```
<!-- This is the wrong way to do things. -->
<p>
 You are standing in an open field west of a house.
 <img src="house.jpeg" alt="A white house, with a boarded front door.">
 There is a small mailbox here.
```

```
</p>
```

Text such as "Photo of white house with boarded door" would be equally bad alternative text (though it could be suitable for the title[p158] attribute or in the figcaption[p253] element of a figure[p250] with this image).

4.8.4.4.4 A short phrase or label with an alternative graphical representation: icons, logos §[p38] 1

A document can contain information in iconic form. The icon is intended to help users of visual browsers to recognize features at a glance.

In some cases, the icon is supplemental to a text label conveying the same meaning. In those cases, the alt[p348] attribute must be present but must be empty.

Example

Here the icons are next to text that conveys the same meaning, so they have an empty alt[p348] attribute:

```
<nav>
 <p><a href="/help/"><img src="/icons/help.png" alt=""> Help</a></p>
 <p><a href="/configure/"><img src="/icons/configuration.png" alt="">
 Configuration Tools</a></p>
</nav>
```

In other cases, the icon has no text next to it describing what it means; the icon is supposed to be self-explanatory. In those cases, an equivalent textual label must be given in the alt[p348] attribute.

Example

Here, posts on a news site are labeled with an icon indicating their topic.

```
<body>
 <article>
  <header>
   <h1>Ratatouille wins <i>Best Movie of the Year</i> award</h1>
   <p><img src="movies.png" alt="Movies"></p>
  </header>
  <p>Pixar has won yet another <i>Best Movie of the Year</i> award,
  making this its 8th win in the last 12 years.</p>
 </article>
 <article>
  <header>
   <h1>Latest TWiT episode is online</h1>
   <p><img src="podcasts.png" alt="Podcasts"></p>
  </header>
  <p>The latest TWiT episode has been posted, in which we hear
  several tech news stories as well as learning much more about the
  iPhone. This week, the panelists compare how reflective their
  iPhones' Apple logos are.</p>
 </article>
</body>
```

Many pages include logos, insignia, flags, or emblems, which stand for a particular entity such as a company, organization, project, band, software package, country, or some such.

If the logo is being used to represent the entity, e.g. as a page heading, the alt[p348] attribute must contain the name of the entity being represented by the logo. The alt[p348] attribute must *not* contain text like the word "logo", as it is not the fact that it is a logo that is being conveyed, it's the entity itself.

If the logo is being used next to the name of the entity that it represents, then the logo is supplemental, and its alt[p348] attribute must instead be empty.

If the logo is merely used as decorative material (as branding, or, for example, as a side image in an article that mentions the entity to which the logo belongs), then the entry below on purely decorative images applies. If the logo is actually being discussed, then it is being used as a phrase or paragraph (the description of the logo) with an alternative graphical representation (the logo itself), and the first entry above applies.

Example

In the following snippets, all four of the above cases are present. First, we see a logo used to represent a company:

```
<h1><img src="XYZ.gif" alt="The XYZ company"></h1>
```

Next, we see a paragraph which uses a logo right next to the company name, and so doesn't have any alternative text:

```
<article>
 <h2>News</h2>
 <p>We have recently been looking at buying the <img src="alpha.gif"
 alt=""> AΒΓ company, a small Greek company
 specializing in our type of product.</p>
```

In this third snippet, we have a logo being used in an aside, as part of the larger article discussing the acquisition:

```
<aside><p><img src="alpha-large.gif" alt=""></p></aside>
 <p>The AΒΓ company has had a good quarter, and our
 pie chart studies of their accounts suggest a much bigger blue slice
 than its green and orange slices, which is always a good sign.</p>
</article>
```

Finally, we have an opinion piece talking about a logo, and the logo is therefore described in detail in the alternative text.

```
<p>Consider for a moment their logo:</p>

<p><img src="/images/logo" alt="It consists of a green circle with a
green question mark centered inside it."></p>

<p>How unoriginal can you get? I mean, oooooh, a question mark, how
<em>revolutionary</em>, how utterly <em>ground-breaking</em>, I'm
sure everyone will rush to adopt those specifications now! They could
at least have tried for some sort of, I don't know, sequence of
rounded squares with varying shades of green and bold white outlines,
at least that would look good on the cover of a blue book.</p>
```

This example shows how the alternative text should be written such that if the image isn't *available*[p365], and the text is used instead, the text flows seamlessly into the surrounding text, as if the image had never been there in the first place.

4.8.4.4.5 Text that has been rendered to a graphic for typographical effect §[p382]

Sometimes, an image just consists of text, and the purpose of the image is not to highlight the actual typographic effects used to render the text, but just to convey the text itself.

In such cases, the alt[p348] attribute must be present but must consist of the same text as written in the image itself.

Example

Consider a graphic containing the text "Earth Day", but with the letters all decorated with flowers and plants. If the text is merely being used as a heading, to spice up the page for graphical users, then the correct alternative text is just the same text "Earth Day", and no mention need be made of the decorations:

```
<h1><img src="earthdayheading.png" alt="Earth Day"></h1>
```

Example

An illuminated manuscript might use graphics for some of its images. The alternative text in such a situation is just the character that the image represents.

```
<p><img src="initials/o.svg" alt="O">nce upon a time and a long long time ago, late at
night, when it was dark, over the hills, through the woods, across a great ocean, in a land far
away, in a small house, on a hill, under a full moon...
```

When an image is used to represent a character that cannot otherwise be represented in Unicode, for example gaiji, itaiji, or new characters such as novel currency symbols, the alternative text should be a more conventional way of writing the same thing, e.g. using the phonetic hiragana or katakana to give the character's pronunciation.

Example

In this example from 1997, a new-fangled currency symbol that looks like a curly E with two bars in the middle instead of one is represented using an image. The alternative text gives the character's pronunciation.

```
<p>Only <img src="euro.png" alt="euro ">5.99!
```

An image should not be used if characters would serve an identical purpose. Only when the text cannot be directly represented using text, e.g., because of decorations or because there is no appropriate character (as in the case of gaiji), would an image be appropriate.

Note

If an author is tempted to use an image because their default system font does not support a given character, then web fonts are a better solution than images.

4.8.4.4.6 A graphical representation of some of the surrounding text §[p38 3]

In many cases, the image is actually just supplementary, and its presence merely reinforces the surrounding text. In these cases, the `alt`[p348] attribute must be present but its value must be the empty string.

In general, an image falls into this category if removing the image doesn't make the page any less useful, but including the image makes it a lot easier for users of visual browsers to understand the concept.

Example

A flowchart that repeats the previous paragraph in graphical form:

```
<p>The Network passes data to the Input Stream Preprocessor, which
passes it to the Tokenizer, which passes it to the Tree Construction
stage. From there, data goes to both the DOM and to Script Execution.
Script Execution is linked to the DOM, and, using document.write(),
passes data to the Tokenizer.</p>
<p><img src="images/parsing-model-overview.svg" alt=""></p>
```

In these cases, it would be wrong to include alternative text that consists of just a caption. If a caption is to be included, then either the `title`[p158] attribute can be used, or the `figure`[p250] and `figcaption`[p253] elements can be used. In the latter case, the image would in fact be a phrase or paragraph with an alternative graphical representation, and would thus require alternative text.

```
<!-- Using the title="" attribute -->
<p>The Network passes data to the Input Stream Preprocessor, which
passes it to the Tokenizer, which passes it to the Tree Construction
stage. From there, data goes to both the DOM and to Script Execution.
```

```
Script Execution is linked to the DOM, and, using document.write(),
passes data to the Tokenizer.</p>
<p><img src="images/parsing-model-overview.svg" alt=""
        title="Flowchart representation of the parsing model."></p>
```

```
<!-- Using <figure> and <figcaption> -->
<p>The Network passes data to the Input Stream Preprocessor, which
passes it to the Tokenizer, which passes it to the Tree Construction
stage. From there, data goes to both the DOM and to Script Execution.
Script Execution is linked to the DOM, and, using document.write(),
passes data to the Tokenizer.</p>
<figure>
 <img src="images/parsing-model-overview.svg" alt="The Network leads to
 the Input Stream Preprocessor, which leads to the Tokenizer, which
 leads to the Tree Construction stage. The Tree Construction stage
 leads to two items. The first is Script Execution, which leads via
 document.write() back to the Tokenizer. The second item from which
 Tree Construction leads is the DOM. The DOM is related to the Script
 Execution.">
 <figcaption>Flowchart representation of the parsing model.</figcaption>
</figure>
```

```
<!-- This is WRONG. Do not do this. Instead, do what the above examples do. -->
<p>The Network passes data to the Input Stream Preprocessor, which
passes it to the Tokenizer, which passes it to the Tree Construction
stage. From there, data goes to both the DOM and to Script Execution.
Script Execution is linked to the DOM, and, using document.write(),
passes data to the Tokenizer.</p>
<p><img src="images/parsing-model-overview.svg"
        alt="Flowchart representation of the parsing model."></p>
<!-- Never put the image's caption in the alt="" attribute! -->
```

Example

A graph that repeats the previous paragraph in graphical form:

```
<p>According to a study covering several billion pages,
about 62% of documents on the web in 2007 triggered the Quirks
rendering mode of web browsers, about 30% triggered the Almost
Standards mode, and about 9% triggered the Standards mode.</p>
<p><img src="rendering-mode-pie-chart.png" alt=""></p>
```

4.8.4.4.7 Ancillary images §[p384]

Sometimes, an image is not critical to the content, but is nonetheless neither purely decorative nor entirely redundant with the text. In these cases, the `alt`[p348] attribute must be present, and its value should either be the empty string, or a textual representation of the information that the image conveys. If the image has a caption giving the image's title, then the `alt`[p348] attribute's value must not be empty (as that would be quite confusing for non-visual readers).

Example

Consider a news article about a political figure, in which the individual's face was shown in an image. The image is not purely decorative, as it is relevant to the story. The image is not entirely redundant with the story either, as it shows what the politician looks like. Whether any alternative text need be provided is an authoring decision, decided by whether the image influences the interpretation of the prose.

In this first variant, the image is shown without context, and no alternative text is provided:

```
<p><img src="president.jpeg" alt=""> Ahead of today's referendum,
the President wrote an open letter to all registered voters. In it, she admitted that the country
was
divided.</p>
```

If the picture is just a face, there might be no value in describing it. It's of no interest to the reader whether the individual has red hair or blond hair, whether the individual has white skin or black skin, whether the individual has one eye or two eyes.

However, if the picture is more dynamic, for instance showing the politician as angry, or particularly happy, or devastated, some alternative text would be useful in setting the tone of the article, a tone that might otherwise be missed:

```
<p><img src="president.jpeg" alt="The President is sad.">
Ahead of today's referendum, the President wrote an open letter to all
registered voters. In it, she admitted that the country was divided.
</p>
```

```
<p><img src="president.jpeg" alt="The President is happy!">
Ahead of today's referendum, the President wrote an open letter to all
registered voters. In it, she admitted that the country was divided.
</p>
```

Whether the individual was "sad" or "happy" makes a difference to how the rest of the paragraph is to be interpreted: is she likely saying that she is unhappy with the country being divided, or is she saying that the prospect of a divided country is good for her political career? The interpretation varies based on the image.

Example

If the image has a caption, then including alternative text avoids leaving the non-visual user confused as to what the caption refers to.

```
<p>Ahead of today's referendum, the President wrote an open letter to
all registered voters. In it, she admitted that the country was divided.</p>
<figure>
 <img src="president.jpeg"
      alt="A high forehead, cheerful disposition, and dark hair round out the President's face.">
 <figcaption> The President of Ruritania. Photo © 2014 PolitiPhoto. </figcaption>
</figure>
```

4.8.4.4.8 A purely decorative image that doesn't add any information §[p385]

If an image is decorative but isn't especially page-specific — for example an image that forms part of a site-wide design scheme — the image should be specified in the site's CSS, not in the markup of the document.

However, a decorative image that isn't discussed by the surrounding text but still has some relevance can be included in a page using the `img`[p347] element. Such images are decorative, but still form part of the content. In these cases, the `alt`[p348] attribute must be present but its value must be the empty string.

Example

Examples where the image is purely decorative despite being relevant would include things like a photo of the Black Rock City landscape in a blog post about an event at Burning Man, or an image of a painting inspired by a poem, on a page reciting that poem. The following snippet shows an example of the latter case (only the first verse is included in this snippet):

```
<h1>The Lady of Shalott</h1>
<p><img src="shalott.jpeg" alt=""></p>
<p>On either side the river lie<br>
Long fields of barley and of rye,<br>
That clothe the wold and meet the sky;<br>
```

```
And through the field the road run by<br>
To many-tower'd Camelot;<br>
And up and down the people go,<br>
Gazing where the lilies blow<br>
Round an island there below,<br>
The island of Shalott.</p>
```

4.8.4.4.9 A group of images that form a single larger picture with no links §p386

When a picture has been sliced into smaller image files that are then displayed together to form the complete picture again, one of the images must have its alt p348 attribute set as per the relevant rules that would be appropriate for the picture as a whole, and then all the remaining images must have their alt p348 attribute set to the empty string.

Example

In the following example, a picture representing a company logo for XYZ Corp has been split into two pieces, the first containing the letters "XYZ" and the second with the word "Corp". The alternative text ("XYZ Corp") is all in the first image.

```
<h1><img src="logo1.png" alt="XYZ Corp"><img src="logo2.png" alt=""></h1>
```

Example

In the following example, a rating is shown as three filled stars and two empty stars. While the alternative text could have been "★★★☆☆", the author has instead decided to more helpfully give the rating in the form "3 out of 5". That is the alternative text of the first image, and the rest have blank alternative text.

```
<p>Rating: <meter max=5 value=3><img src="1" alt="3 out of 5"
  ><img src="1" alt=""><img src="1" alt=""><img src="0" alt=""
  ><img src="0" alt=""></meter></p>
```

4.8.4.4.10 A group of images that form a single larger picture with links §p386

Generally, image maps p474 should be used instead of slicing an image for links.

However, if an image is indeed sliced and any of the components of the sliced picture are the sole contents of links, then one image per link must have alternative text in its alt p348 attribute representing the purpose of the link.

Example

In the following example, a picture representing the flying spaghetti monster emblem, with each of the left noodly appendages and the right noodly appendages in different images, so that the user can pick the left side or the right side in an adventure.

```
<h1>The Church</h1>
<p>You come across a flying spaghetti monster. Which side of His
Noodliness do you wish to reach out for?</p>
<p><a href="?go=left" ><img src="fsm-left.png"  alt="Left side. "></a
  ><img src="fsm-middle.png" alt=""
  ><a href="?go=right"><img src="fsm-right.png" alt="Right side."></a></p>
```

4.8.4.4.11 A key part of the content §p386

In some cases, the image is a critical part of the content. This could be the case, for instance, on a page that is part of a photo gallery. The image is the whole *point* of the page containing it.

How to provide alternative text for an image that is a key part of the content depends on the image's provenance.

The general case

When it is possible for detailed alternative text to be provided, for example if the image is part of a series of screenshots in a magazine review, or part of a comic strip, or is a photograph in a blog entry about that photograph, text that can serve as a substitute for the image must be given as the contents of the alt[p348] attribute.

Example

A screenshot in a gallery of screenshots for a new OS, with some alternative text:

```
<figure>
 <img src="KDE%20Light%20desktop.png"
      alt="The desktop is blue, with icons along the left hand side in
           two columns, reading System, Home, K-Mail, etc. A window is
           open showing that menus wrap to a second line if they
           cannot fit in the window. The window has a list of icons
           along the top, with an address bar below it, a list of
           icons for tabs along the left edge, a status bar on the
           bottom, and two panes in the middle. The desktop has a bar
           at the bottom of the screen with a few buttons, a pager, a
           list of open applications, and a clock.">
 <figcaption>Screenshot of a KDE desktop.</figcaption>
</figure>
```

Example

A graph in a financial report:

```
<img src="sales.gif"
     title="Sales graph"
     alt="From 1998 to 2005, sales increased by the following percentages
     with each year: 624%, 75%, 138%, 40%, 35%, 9%, 21%">
```

Note that "sales graph" would be inadequate alternative text for a sales graph. Text that would be a good *caption* is not generally suitable as replacement text.

Images that defy a complete description

In certain cases, the nature of the image might be such that providing thorough alternative text is impractical. For example, the image could be indistinct, or could be a complex fractal, or could be a detailed topographical map.

In these cases, the alt[p348] attribute must contain some suitable alternative text, but it may be somewhat brief.

Example

Sometimes there simply is no text that can do justice to an image. For example, there is little that can be said to usefully describe a Rorschach inkblot test. However, a description, even if brief, is still better than nothing:

```
<figure>
 <img src="/commons/a/a7/Rorschach1.jpg" alt="A shape with left-right
 symmetry with indistinct edges, with a small gap in the center, two
 larger gaps offset slightly from the center, with two similar gaps
 under them. The outline is wider in the top half than the bottom
 half, with the sides extending upwards higher than the center, and
 the center extending below the sides.">
 <figcaption>A black outline of the first of the ten cards
 in the Rorschach inkblot test.</figcaption>
</figure>
```

Note that the following would be a very bad use of alternative text:

```
<!-- This example is wrong. Do not copy it. -->
```

```
<figure>
 <img src="/commons/a/a7/Rorschach1.jpg" alt="A black outline
 of the first of the ten cards in the Rorschach inkblot test.">
 <figcaption>A black outline of the first of the ten cards
 in the Rorschach inkblot test.</figcaption>
</figure>
```

Including the caption in the alternative text like this isn't useful because it effectively duplicates the caption for users who don't have images, taunting them twice yet not helping them any more than if they had only read or heard the caption once.

Example

Another example of an image that defies full description is a fractal, which, by definition, is infinite in detail.

The following example shows one possible way of providing alternative text for the full view of an image of the Mandelbrot set.

```
<img src="ms1.jpeg" alt="The Mandelbrot set appears as a cardioid with
its cusp on the real axis in the positive direction, with a smaller
bulb aligned along the same center line, touching it in the negative
direction, and with these two shapes being surrounded by smaller bulbs
of various sizes.">
```

Example

Similarly, a photograph of a person's face, for example in a biography, can be considered quite relevant and key to the content, but it can be hard to fully substitute text for:

```
<section class="bio">
 <h1>A Biography of Isaac Asimov</h1>
 <p>Born <b>Isaak Yudovich Ozimov</b> in 1920, Isaac was a prolific author.</p>
 <p><img src="headpics/asimov.jpeg" alt="Isaac Asimov had dark hair, a tall forehead, and wore
glasses.
 Later in life, he wore long white sideburns."></p>
 <p>Asimov was born in Russia, and moved to the US when he was three years old.</p>
 <p>...</p>
</section>
```

In such cases it is unnecessary (and indeed discouraged) to include a reference to the presence of the image itself in the alternative text, since such text would be redundant with the browser itself reporting the presence of the image. For example, if the alternative text was "A photo of Isaac Asimov", then a conforming user agent might read that out as "(Image) A photo of Isaac Asimov" rather than the more useful "(Image) Isaac Asimov had dark hair, a tall forehead, and wore glasses...".

Images whose contents are not known

In some unfortunate cases, there might be no alternative text available at all, either because the image is obtained in some automated fashion without any associated alternative text (e.g., a webcam), or because the page is being generated by a script using user-provided images where the user did not provide suitable or usable alternative text (e.g. photograph sharing sites), or because the author does not themself know what the images represent (e.g. a blind photographer sharing an image on their blog).

In such cases, the `alt` attribute may be omitted, but one of the following conditions must be met as well:

- The `img` element is in a `figure` element that contains a `figcaption` element that contains content other than inter-element whitespace, and, ignoring the `figcaption` element and its descendants, the `figure` element has no flow content descendants other than inter-element whitespace and the `img` element.
- The `title` attribute is present and has a non-empty value.

Note

Relying on the `title` attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

Note

Such cases are to be kept to an absolute minimum. If there is even the slightest possibility of the author having the ability to provide real alternative text, then it would not be acceptable to omit the alt[p348] attribute.

Example

A photo on a photo-sharing site, if the site received the image with no metadata other than the caption, could be marked up as follows:

```
<figure>
 <img src="1100670787_6a7c664aef.jpg">
 <figcaption>Bubbles traveled everywhere with us.</figcaption>
</figure>
```

It would be better, however, if a detailed description of the important parts of the image obtained from the user and included on the page.

Example

A blind user's blog in which a photo taken by the user is shown. Initially, the user might not have any idea what the photo they took shows:

```
<article>
 <h1>I took a photo</h1>
 <p>I went out today and took a photo!</p>
 <figure>
  <img src="photo2.jpeg">
  <figcaption>A photograph taken blindly from my front porch.</figcaption>
 </figure>
</article>
```

Eventually though, the user might obtain a description of the image from their friends and could then include alternative text:

```
<article>
 <h1>I took a photo</h1>
 <p>I went out today and took a photo!</p>
 <figure>
  <img src="photo2.jpeg" alt="The photograph shows my squirrel
  feeder hanging from the edge of my roof. It is half full, but there
  are no squirrels around. In the background, out-of-focus trees fill the
  shot. The feeder is made of wood with a metal grate, and it contains
  peanuts. The edge of the roof is wooden too, and is painted white
  with light blue streaks.">
  <figcaption>A photograph taken blindly from my front porch.</figcaption>
 </figure>
</article>
```

Example

Sometimes the entire point of the image is that a textual description is not available, and the user is to provide the description. For instance, the point of a CAPTCHA image is to see if the user can literally read the graphic. Here is one way to mark up a CAPTCHA (note the title[p158] attribute):

```
<p><label>What does this image say?
<img src="captcha.cgi?id=8934" title="CAPTCHA">
<input type=text name=captcha></label>
(If you cannot see the image, you can use an <a
href="?audio">audio</a> test instead.)</p>
```

Another example would be software that displays images and asks for alternative text precisely for the purpose of then writing a page with correct alternative text. Such a page could have a table of images, like this:

```
<table>
 <thead>
  <tr> <th> Image <th> Description
 <tbody>
  <tr>
   <td> <img src="2421.png" title="Image 640 by 100, filename 'banner.gif'">
   <td> <input name="alt2421">
  <tr>
   <td> <img src="2422.png" title="Image 200 by 480, filename 'ad3.gif'">
   <td> <input name="alt2422">
</table>
```

Notice that even in this example, as much useful information as possible is still included in the `title`[p158] attribute.

Note

Since some users cannot use images at all (e.g. because they have a very slow connection, or because they are using a text-only browser, or because they are listening to the page being read out by a hands-free automobile voice web browser, or simply because they are blind), the `alt`[p348] attribute is only allowed to be omitted rather than being provided with replacement text when no alternative text is available and none can be made available, as in the above examples. Lack of effort from the part of the author is not an acceptable reason for omitting the `alt`[p348] attribute.

4.8.4.4.12 An image not intended for the user §[p39]

Generally authors should avoid using `img`[p347] elements for purposes other than showing images.

If an `img`[p347] element is being used for purposes other than showing an image, e.g. as part of a service to count page views, then the `alt`[p348] attribute must be the empty string.

In such cases, the `width`[p478] and `height`[p478] attributes should both be set to zero.

4.8.4.4.13 An image in an email or private document intended for a specific person who is known to be able to view images §[p39]

This section does not apply to documents that are publicly accessible, or whose target audience is not necessarily personally known to the author, such as documents on a web site, emails sent to public mailing lists, or software documentation.

When an image is included in a private communication (such as an HTML email) aimed at a specific person who is known to be able to view images, the `alt`[p348] attribute may be omitted. However, even in such cases authors are strongly urged to include alternative text (as appropriate according to the kind of image involved, as described in the above entries), so that the email is still usable should the user use a mail client that does not support images, or should the document be forwarded on to other users whose abilities might not include easily seeing images.

4.8.4.4.14 Guidance for markup generators §[p39]

Markup generators (such as WYSIWYG authoring tools) should, wherever possible, obtain alternative text from their users. However, it is recognized that in many cases, this will not be possible.

For images that are the sole contents of links, markup generators should examine the link target to determine the title of the target, or the URL of the target, and use information obtained in this manner as the alternative text.

For images that have captions, markup generators should use the `figure`[p250] and `figcaption`[p253] elements, or the `title`[p158] attribute, to provide the image's caption.

As a last resort, implementers should either set the `alt`[p348] attribute to the empty string, under the assumption that the image is a purely decorative image that doesn't add any information but is still specific to the surrounding content, or omit the `alt`[p348] attribute altogether, under the assumption that the image is a key part of the content.

Markup generators may specify a **generator-unable-to-provide-required-alt** attribute on img[p347] elements for which they have been unable to obtain alternative text and for which they have therefore omitted the alt[p348] attribute. The value of this attribute must be the empty string. Documents containing such attributes are not conforming, but conformance checkers will silently ignore[p391] this error.

Note

This is intended to avoid markup generators from being pressured into replacing the error of omitting the alt[p348] attribute with the even more egregious error of providing phony alternative text, because state-of-the-art automated conformance checkers cannot distinguish phony alternative text from correct alternative text.

Markup generators should generally avoid using the image's own filename as the alternative text. Similarly, markup generators should avoid generating alternative text from any content that will be equally available to presentation user agents (e.g., web browsers).

Note

This is because once a page is generated, it will typically not be updated, whereas the browsers that later read the page can be updated by the user, therefore the browser is likely to have more up-to-date and finely-tuned heuristics than the markup generator did when generating the page.

4.8.4.4.15 Guidance for conformance checkers §[p39] 1

A conformance checker must report the lack of an alt[p348] attribute as an error unless one of the conditions listed below applies:

- The img[p347] element is in a figure[p250] element that satisfies the conditions described above[p388].
- The img[p347] element has a title[p158] attribute with a value that is not the empty string (also as described above[p388]).
- The conformance checker has been configured to assume that the document is an email or document intended for a specific person who is known to be able to view images.
- The img[p347] element has a (non-conforming) generator-unable-to-provide-required-alt[p391] attribute whose value is the empty string. A conformance checker that is not reporting the lack of an alt[p348] attribute as an error must also not report the presence of the empty generator-unable-to-provide-required-alt[p391] attribute as an error. (This case does not represent a case where the document is conforming, only that the generator could not determine appropriate alternative text — validators are not required to show an error in this case, because such an error might encourage markup generators to include bogus alternative text purely in an attempt to silence validators. Naturally, conformance checkers *may* report the lack of an alt[p348] attribute as an error even in the presence of the generator-unable-to-provide-required-alt[p391] attribute; for example, there could be a user option to report *all* conformance errors even those that might be the more or less inevitable result of using a markup generator.)

4.8.5 The iframe element §[p39] 1

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Embedded content[p151].
Interactive content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where embedded content[p151] is expected.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

`src`[p392] — Address of the resource
`srcdoc`[p392] — A document to render in the `iframe`[p391]
`name`[p396] — Name of content navigable[p1004]
`sandbox`[p396] — Security rules for nested content
`allow`[p398] — Permissions policy to be applied to the `iframe`[p391]'s contents
`allowfullscreen`[p398] — Whether to allow the `iframe`[p391]'s contents to use `requestFullscreen()`
`width`[p478] — Horizontal dimension
`height`[p478] — Vertical dimension
`referrerpolicy`[p399] — Referrer policy for fetches initiated by the element
`loading`[p399] — Used when determining loading deferral

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLIFrameElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute USVString src;
  [CEReactions] attribute (TrustedHTML or DOMString) srcdoc;
  [CEReactions] attribute DOMString name;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList sandbox;
  [CEReactions] attribute DOMString allow;
  [CEReactions] attribute boolean allowFullscreen;
  [CEReactions] attribute DOMString width;
  [CEReactions] attribute DOMString height;
  [CEReactions] attribute DOMString referrerPolicy;
  [CEReactions] attribute DOMString loading;
  readonly attribute Document? contentDocument;
  readonly attribute WindowProxy? contentWindow;
  Document? getSVGDocument();

  // also has obsolete members
};
```

The `iframe`[p391] element represents[p142] its content navigable[p1004].

The **`src`** attribute gives the URL of a page that the element's content navigable[p1004] is to contain. The attribute, if present, must be a valid non-empty URL potentially surrounded by spaces[p97]. If the `itemprop`[p803] attribute is specified on an `iframe`[p391] element, then the `src`[p392] attribute must also be specified.

The **`srcdoc`** attribute gives the content of the page that the element's content navigable[p1004] is to contain. The value of the attribute is used to construct[p1046] **an `iframe srcdoc` document**, which is a `Document`[p131] whose URL matches `about:srcdoc`[p98].

The `srcdoc`[p392] attribute, if present, must have a value using the HTML syntax[p1277] that consists of the following syntactic components, in the given order:

1. Any number of comments[p1288] and ASCII whitespace.
2. Optionally, a DOCTYPE[p1277].
3. Any number of comments[p1288] and ASCII whitespace.
4. The document element, in the form of an `html`[p173] element[p1278].
5. Any number of comments[p1288] and ASCII whitespace.

Note

The above requirements apply in XML documents as well.

Example

Here a blog uses the srcdoc attribute in conjunction with the sandbox attribute described below to provide users of user agents that support this feature with an extra layer of protection from script injection in the blog post comments:

```
<article>
 <h1>I got my own magazine!</h1>
 <p>After much effort, I've finally found a publisher, and so now I
 have my own magazine! Isn't that awesome?! The first issue will come
 out in September, and we have articles about getting food, and about
 getting in boxes, it's going to be great!</p>
 <footer>
  <p>Written by <a href="/users/cap">cap</a>, 1 hour ago.
 </footer>
 <article>
  <footer> Thirteen minutes ago, <a href="/users/ch">ch</a> wrote: </footer>
  <iframe sandbox srcdoc="<p>did you get a cover picture yet?"></iframe>
 </article>
 <article>
  <footer> Nine minutes ago, <a href="/users/cap">cap</a> wrote: </footer>
  <iframe sandbox srcdoc="<p>Yeah, you can see it <a
href=&quot;/gallery?mode=cover&amp;amp;page=1&quot;>in my gallery</a>."></iframe>
 </article>
 <article>
  <footer> Five minutes ago, <a href="/users/ch">ch</a> wrote: </footer>
  <iframe sandbox srcdoc="<p>hey that's earl's table.
<p>you should get earl&amp;amp;me on the next cover."></iframe>
 </article>
```

Notice the way that quotes have to be escaped (otherwise the srcdoc attribute would end prematurely), and the way raw ampersands (e.g. in URLs or in prose) mentioned in the sandboxed content have to be *doubly* escaped — once so that the ampersand is preserved when originally parsing the srcdoc attribute, and once more to prevent the ampersand from being misinterpreted when parsing the sandboxed content.

Furthermore, notice that since the DOCTYPE is optional in iframe srcdoc documents, and the html, head, and body elements have optional start and end tags, and the title element is also optional in iframe srcdoc documents, the markup in a srcdoc attribute can be relatively succinct despite representing an entire document, since only the contents of the body element need appear literally in the syntax. The other elements are still present, but only by implication.

Note

In the HTML syntax, authors need only remember to use U+0022 QUOTATION MARK characters (") to wrap the attribute contents and then to escape all U+0026 AMPERSAND (&) and U+0022 QUOTATION MARK (") characters, and to specify the sandbox attribute, to ensure safe embedding of content. (And remember to escape ampersands before quotation marks, to ensure quotation marks become " and not ".)

Note

In XML the U+003C LESS-THAN SIGN character (<) needs to be escaped as well. In order to prevent attribute-value normalization, some of XML's whitespace characters — specifically U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), and U+000D CARRIAGE RETURN (CR) — also need to be escaped. [XML]

Note

If the src attribute and the srcdoc attribute are both specified together, the srcdoc attribute takes priority. This allows authors to provide a fallback URL for legacy user agents that do not support the srcdoc attribute.

The iframe HTML element post-connection steps, given *insertedNode*, are:

1. Create a new child navigable for *insertedNode*.
2. If *insertedNode* has a sandbox attribute, then parse the sandboxing directive given the attribute's value and

insertedNode's iframe sandboxing flag set[p928].

3. Process the iframe attributes[p394] for *insertedNode*, with *initialInsertion*[p394] set to true.

The iframe[p391] HTML element removing steps[p46], given *removedNode*, are to destroy a child navigable[p1007] given *removedNode*.

Note

This happens without any unload[p1491] events firing (the element's content document[p1004] is destroyed[p1007], not unloaded[p1079]).

Although iframe[p391]s are processed while in a shadow tree, per the above, several other aspects of their behavior are not well-defined with regards to shadow trees. See issue #763 for more detail.

Whenever an iframe[p391] element with a non-null content navigable[p1004] has its srcdoc[p392] attribute set, changed, or removed, the user agent must process the iframe attributes[p394].

Similarly, whenever an iframe[p391] element with a non-null content navigable[p1004] but with no srcdoc[p392] attribute specified has its src[p392] attribute set, changed, or removed, the user agent must process the iframe attributes[p394].

To **process the iframe attributes** for an element *element*, with an optional boolean ***initialInsertion*** (default false):

1. If *element*'s srcdoc[p392] attribute is specified, then:
    1. Set *element*'s current navigation was lazy loaded[p396] boolean to false.
    2. If the will lazy load element steps[p103] given *element* return true, then:
        1. Set *element*'s lazy load resumption steps[p103] to the rest of this algorithm starting with the step labeled *navigate to the srcdoc resource*.
        2. Set *element*'s current navigation was lazy loaded[p396] boolean to true.
        3. Start intersection-observing a lazy loading element[p103] for *element*.
        4. Return.
    3. *Navigate to the srcdoc resource*: Navigate an iframe or frame[p395] given *element*, about:srcdoc[p97], the empty string, and the value of *element*'s srcdoc[p392] attribute.

       The resulting Document[p131] must be considered an iframe srcdoc document[p392].
2. Otherwise:
    1. Let *url* be the result of running the shared attribute processing steps for iframe and frame elements[p395] given *element* and *initialInsertion*.
    2. If *url* is null, then return.
    3. If *url* matches about:blank[p98] and *initialInsertion* is true, then:
        1. Run the iframe load event steps[p395] given *element*.
        2. Return.
    4. Let *referrerPolicy* be the current state of *element*'s referrerpolicy[p399] content attribute.
    5. Set *element*'s current navigation was lazy loaded[p396] boolean to false.
    6. If the will lazy load element steps[p103] given *element* return true, then:
        1. Set *element*'s lazy load resumption steps[p103] to the rest of this algorithm starting with the step labeled *navigate*.
        2. Set *element*'s current navigation was lazy loaded[p396] boolean to true.
        3. Start intersection-observing a lazy loading element[p103] for *element*.
        4. Return.

7. *Navigate*: Navigate an `iframe` or `frame`[p395] given *element*, *url*, and *referrerPolicy*.

The **shared attribute processing steps for `iframe` and `frame` elements**, given an element *element* and a boolean *initialInsertion*, are:

1. Let *url* be the URL record `about:blank`[p54].
2. If *element* has a `src`[p392] attribute specified, and its value is not the empty string, then:
    1. Let *maybeURL* be the result of encoding-parsing a URL[p98] given that attribute's value, relative to *element*'s node document.
    2. If *maybeURL* is not failure, then set *url* to *maybeURL*.
3. If the inclusive ancestor navigables[p1007] of *element*'s node navigable[p1002] contains a navigable[p1001] whose active document[p1002]'s URL equals *url* with *exclude fragments* set to true, then return null.
4. If *url* matches `about:blank`[p98] and *initialInsertion* is true, then perform the URL and history update steps[p1042] given *element*'s content navigable[p1004]'s active document[p1002] and *url*.

    Note

    This is necessary in case url *is something like* `about:blank?foo`*. If* url *is just plain* `about:blank`*, this will do nothing.*
5. Return *url*.

To **navigate an `iframe` or `frame`** given an element *element*, a URL *url*, a referrer policy *referrerPolicy*, an optional string-or-null *srcdocString* (default null), and an optional boolean *initialInsertion* (default false):

1. Let *historyHandling* be "`auto`[p1027]".
2. If *element*'s content navigable[p1004]'s active document[p1002] is not completely loaded[p1078], then set *historyHandling* to "`replace`[p1027]".
3. If *element* is an `iframe`[p391], then set *element*'s pending resource-timing start time[p396] to the current high resolution time given *element*'s node document's relevant global object[p1098].
4. Navigate[p1028] *element*'s content navigable[p1004] to *url* using *element*'s node document, with *historyHandling*[p1028] set to *historyHandling*, *referrerPolicy*[p1028] set to *referrerPolicy*, *documentResource*[p1028] set to *srcdocString*, and *initialInsertion*[p1028] set to *initialInsertion*.

Each `Document`[p131] has an **iframe load in progress** flag and a **mute iframe load** flag. When a `Document`[p131] is created, these flags must be unset for that `Document`[p131].

To run the **iframe load event steps**, given an `iframe`[p391] element *element*:

1. Assert: *element*'s content navigable[p1004] is not null.
2. Let *childDocument* be *element*'s content navigable[p1004]'s active document[p1002].
3. If *childDocument* has its mute iframe load[p395] flag set, then return.
4. If *element*'s pending resource-timing start time[p396] is not null, then:
    1. Let *global* be *element*'s node document's relevant global object[p1098].
    2. Let *fallbackTimingInfo* be a new fetch timing info whose start time is *element*'s pending resource-timing start time[p396] and whose response end time is the current high resolution time given *global*.
    3. Mark resource timing given *fallbackTimingInfo*, *url*, "`iframe`[p391]", *global*, the empty string, a new response body info, and 0.
    4. Set *element*'s pending resource-timing start time[p396] to null.
5. Set *childDocument*'s iframe load in progress[p395] flag.
6. Fire an event named `load`[p1490] at *element*.
7. Unset *childDocument*'s iframe load in progress[p395] flag.

⚠Warning!

This, in conjunction with scripting, can be used to probe the URL space of the local network's HTTP servers. User agents may implement cross-origin[p909] access control policies that are stricter than those described above to mitigate this attack, but unfortunately such policies are typically not compatible with existing web content.

If an element type **potentially delays the load event**, then for each element *element* of that type, the user agent must delay the load event[p1377] of *element*'s node document if *element*'s content navigable[p1004] is non-null and any of the following are true:

- *element*'s content navigable[p1004]'s active document[p1002] is not ready for post-load tasks[p1377];
- *element*'s content navigable[p1004]'s is delaying load events[p1001] is true; or
- anything is delaying the load event[p1377] of *element*'s content navigable[p1004]'s active document[p1002].

Note

If, during the handling of the load[p1490] event, element's *content navigable[p1004] is again navigated[p1028], that will further delay the load event[p1377].*

Each iframe[p391] element has an associated **current navigation was lazy loaded** boolean, initially false. It is set and unset in the process the iframe attributes[p394] algorithm.

An iframe[p391] element whose current navigation was lazy loaded[p396] boolean is false potentially delays the load event[p396].

Each iframe[p391] element has an associated null or DOMHighResTimeStamp **pending resource-timing start time**, initially set to null.

Note

If, when the element is created, the srcdoc[p392] attribute is not set, and the src[p392] attribute is either also not set or set but its value cannot be parsed[p98], the element's content navigable[p1004] will remain at the initial about:blank[p132] Document[p131].

Note

If the user navigates[p1028] away from this page, the iframe[p391]'s content navigable[p1004]'s active WindowProxy[p1002] object will proxy new Window[p934] objects for new Document[p131] objects, but the src[p392] attribute will not change.

The **name** attribute, if present, must be a valid navigable target name[p1008]. The given value is used to name the element's content navigable[p1004] if present when that is created[p1005].

The **sandbox** attribute, when specified, enables a set of extra restrictions on any content hosted by the iframe[p391]. Its value must be an unordered set of unique space-separated tokens[p96] that are ASCII case-insensitive. The allowed values are:

- allow-downloads[p928]
- allow-forms[p928]
- allow-modals[p928]
- allow-orientation-lock[p928]
- allow-pointer-lock[p928]
- allow-popups[p928]
- allow-popups-to-escape-sandbox[p928]
- allow-presentation[p928]
- allow-same-origin[p928]
- allow-scripts[p928]
- allow-top-navigation[p928]
- allow-top-navigation-by-user-activation[p928]
- allow-top-navigation-to-custom-protocols[p928]

When the attribute is set, the content is treated as being from a unique opaque origin[p909], forms, scripts, and various potentially annoying APIs are disabled, and links are prevented from targeting other navigables[p1001]. The allow-same-origin[p928] keyword causes the content to be treated as being from its real origin instead of forcing it into an opaque origin[p909]; the allow-top-navigation[p928] keyword allows the content to navigate[p1028] its traversable navigable[p1003]; the allow-top-navigation-by-user-activation[p928] keyword behaves similarly but allows such navigation[p1028] only when the browsing context's active window[p1002] has transient activation[p838]; the allow-top-navigation-to-custom-protocols[p928] reenables navigations toward non fetch scheme to be handed off to external software[p1038]; and the allow-forms[p928], allow-modals[p928], allow-orientation-lock[p928], allow-pointer-lock[p928], allow-popups[p928], allow-presentation[p928], allow-scripts[p928], and allow-popups-to-escape-sandbox[p928] keywords re-enable forms, modal

dialogs, screen orientation lock, the pointer lock API, popups, the presentation API, scripts, and the creation of unsandboxed auxiliary browsing contexts[p1012] respectively. The `allow-downloads`[p928] keyword allows content to perform downloads. [POINTERLOCK][p1499] [SCREENORIENTATION][p1500] [PRESENTATION][p1499]

The `allow-top-navigation`[p928] and `allow-top-navigation-by-user-activation`[p928] keywords must not both be specified, as doing so is redundant; only `allow-top-navigation`[p928] will have an effect in such non-conformant markup.

Similarly, the `allow-top-navigation-to-custom-protocols`[p928] keyword must not be specified if either `allow-top-navigation`[p928] or `allow-popups`[p928] are specified, as doing so is redundant.

Note

To allow `alert()`[p1183], `confirm()`[p1183], and `prompt()`[p1183] inside sandboxed content, both the `allow-modals`[p928] and `allow-same-origin`[p928] keywords need to be specified, and the loaded URL needs to be same origin[p910] with the top-level origin[p1091]. Without the `allow-same-origin`[p928] keyword, the content is always treated as cross-origin, and cross-origin content cannot show simple dialogs[p1184].

⚠Warning!

Setting both the `allow-scripts`[p928] and `allow-same-origin`[p928] keywords together when the embedded page has the same origin[p910] as the page containing the `iframe`[p391] allows the embedded page to simply remove the `sandbox`[p396] attribute and then reload itself, effectively breaking out of the sandbox altogether.

⚠Warning!

These flags only take effect when the content navigable[p1004] of the `iframe`[p391] element is navigated[p1028]. Removing them, or removing the entire `sandbox`[p396] attribute, has no effect on an already-loaded page.

⚠Warning!

Potentially hostile files should not be served from the same server as the file containing the `iframe`[p391] element. Sandboxing hostile content is of minimal help if an attacker can convince the user to just visit the hostile content directly, rather than in the `iframe`[p391]. To limit the damage that can be caused by hostile HTML content, it should be served from a separate dedicated domain. Using a different domain ensures that scripts in the files are unable to attack the site, even if the user is tricked into visiting those pages directly, without the protection of the `sandbox`[p396] attribute.

When an `iframe`[p391] element's `sandbox`[p396] attribute is set or changed while it has a non-null content navigable[p1004], the user agent must parse the sandboxing directive[p927] given the attribute's value and the `iframe`[p391] element's iframe sandboxing flag set[p928].

When an `iframe`[p391] element's `sandbox`[p396] attribute is removed while it has a non-null content navigable[p1004], the user agent must empty the `iframe`[p391] element's iframe sandboxing flag set[p928].

Example

In this example, some completely-unknown, potentially hostile, user-provided HTML content is embedded in a page. Because it is served from a separate domain, it is affected by all the normal cross-site restrictions. In addition, the embedded page has scripting disabled, plugins disabled, forms disabled, and it cannot navigate any frames or windows other than itself (or any frames or windows it itself embeds).

```
<p>We're not scared of you! Here is your content, unedited:</p>
<iframe sandbox src="https://usercontent.example.net/getusercontent.cgi?id=12193"></iframe>
```

⚠Warning!

It is important to use a separate domain so that if the attacker convinces the user to visit that page directly, the page doesn't run in the context of the site's origin, which would make the user vulnerable to any attack found in the page.

Example

In this example, a gadget from another site is embedded. The gadget has scripting and forms enabled, and the origin sandbox restrictions are lifted, allowing the gadget to communicate with its originating server. The sandbox is still useful, however, as it

disables plugins and popups, thus reducing the risk of the user being exposed to malware and other annoyances.

```
<iframe sandbox="allow-same-origin allow-forms allow-scripts"
        src="https://maps.example.com/embedded.html"></iframe>
```

Example

Suppose a file A contained the following fragment:

```
<iframe sandbox="allow-same-origin allow-forms" src=B></iframe>
```

Suppose that file B contained an iframe also:

```
<iframe sandbox="allow-scripts" src=C></iframe>
```

Further, suppose that file C contained a link:

```
<a href=D>Link</a>
```

For this example, suppose all the files were served as text/html[p1462].

Page C in this scenario has all the sandboxing flags set. Scripts are disabled, because the iframe[p391] in A has scripts disabled, and this overrides the allow-scripts[p928] keyword set on the iframe[p391] in B. Forms are also disabled, because the inner iframe[p391] (in B) does not have the allow-forms[p928] keyword set.

Suppose now that a script in A removes all the sandbox[p396] attributes in A and B. This would change nothing immediately. If the user clicked the link in C, loading page D into the iframe[p391] in B, page D would now act as if the iframe[p391] in B had the allow-same-origin[p928] and allow-forms[p928] keywords set, because that was the state of the content navigable[p1004] in the iframe[p391] in A when page B was loaded.

Generally speaking, dynamically removing or changing the sandbox[p396] attribute is ill-advised, because it can make it quite hard to reason about what will be allowed and what will not.

The **allow** attribute, when specified, determines the container policy that will be used when the permissions policy[p132] for a Document[p131] in the iframe[p391]'s content navigable[p1004] is initialized. Its value must be a serialized permissions policy. [PERMISSIONSPOLICY][p1498]

Example

In this example, an iframe[p391] is used to embed a map from an online navigation service. The allow[p398] attribute is used to enable the Geolocation API within the nested context.

```
<iframe src="https://maps.example.com/" allow="geolocation"></iframe>
```

The **allowfullscreen** attribute is a boolean attribute[p76]. When specified, it indicates that Document[p131] objects in the iframe[p391] element's content navigable[p1004] will be initialized with a permissions policy[p132] which allows the "fullscreen" feature to be used from any origin[p909]. This is enforced by the process permissions policy attributes algorithm. [PERMISSIONSPOLICY][p1498]

Example

Here, an iframe[p391] is used to embed a player from a video site. The allowfullscreen[p398] attribute is needed to enable the player to show its video fullscreen.

```
<article>
 <header>
  <p><img src="/usericons/1627591962735"> <b>Fred Flintstone</b></p>
  <p><a href="/posts/3095182851" rel=bookmark>12:44</a> — <a href="#acl-3095182851">Private
Post</a></p>
```

```
  </header>
  <p>Check out my new ride!</p>
  <iframe src="https://video.example.com/embed?id=92469812" allowfullscreen></iframe>
</article>
```

Note

Neither allow[p398] nor allowfullscreen[p398] can grant access to a feature in an iframe[p391] element's content navigable[p1004] if the element's node document is not already allowed to use that feature.

To determine whether a Document[p131] object *document* is **allowed to use** the policy-controlled-feature *feature*, run these steps:

1. If *document*'s browsing context[p1012] is null, then return false.
2. If *document* is not fully active[p1017], then return false.
3. If the result of running is feature enabled in document for origin on *feature*, *document*, and *document*'s origin is "Enabled", then return true.
4. Return false.

⚠Warning!

Because they only influence the permissions policy[p132] of the content navigable[p1004]'s active document[p1002], the allow[p398] and allowfullscreen[p398] attributes only take effect when the content navigable[p1004] of the iframe[p391] is navigated[p1028]. Adding or removing them has no effect on an already-loaded document.

The iframe[p391] element supports dimension attributes[p478] for cases where the embedded content has specific dimensions (e.g. ad units have well-defined dimensions).

An iframe[p391] element never has fallback content[p151], as it will always create a new child navigable[p1005], regardless of whether the specified initial contents are successfully used.

The **referrerpolicy** attribute is a referrer policy attribute[p101]. Its purpose is to set the referrer policy used when processing the iframe attributes[p394]. [REFERRERPOLICY][p1499]

The **loading** attribute is a lazy loading attribute[p102]. Its purpose is to indicate the policy for loading iframe[p391] elements that are outside the viewport.

When the loading[p399] attribute's state is changed to the Eager[p102] state, the user agent must run these steps:

1. Let *resumptionSteps* be the iframe[p391] element's lazy load resumption steps[p103].
2. If *resumptionSteps* is null, then return.
3. Set the iframe[p391]'s lazy load resumption steps[p103] to null.
4. Invoke *resumptionSteps*.

Descendants of iframe[p391] elements represent nothing. (In legacy user agents that do not support iframe[p391] elements, the contents would be parsed as markup that could act as fallback content.)

Note

The HTML parser[p1289] treats markup inside iframe[p391] elements as text.

The IDL attributes **src**, **name**, **sandbox**, and **allow** must reflect[p105] the respective content attributes of the same name.

The **srcdoc** getter steps are:

1. Let *attribute* be the result of running get an attribute by namespace and local name given null, `srcdoc`[p392]'s local name, and this.
2. If *attribute* is null, then return the empty string.
3. Return *attribute*'s value.

The `srcdoc`[p399] setter steps are:

1. Let *compliantString* be the result of invoking the Get Trusted Type compliant string algorithm with `TrustedHTML`, this's relevant global object[p1098], the given value, "`HTMLIFrameElement srcdoc`", and "`script`".
2. Set an attribute value given this, `srcdoc`[p392]'s local name, and *compliantString*.

The supported tokens for `sandbox`[p399]'s `DOMTokenList` are the allowed values defined in the `sandbox`[p396] attribute and supported by the user agent.

The **`allowFullscreen`** IDL attribute must reflect[p105] the `allowfullscreen`[p398] content attribute.

The **`referrerPolicy`** IDL attribute must reflect[p105] the `referrerpolicy`[p399] content attribute, limited to only known values[p106].

The **`loading`** IDL attribute must reflect[p105] the `loading`[p399] content attribute, limited to only known values[p106].

The **`contentDocument`** getter steps are to return this's content document[p1004].

The **`contentWindow`** getter steps are to return this's content window[p1005].

Example

Here is an example of a page using an `iframe`[p391] to include advertising from an advertising broker:

```
<iframe src="https://ads.example.com/?customerid=923513721&amp;format=banner"
        width="468" height="60"></iframe>
```

4.8.6 The `embed` element §[p400]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Embedded content[p151].
Interactive content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where embedded content[p151] is expected.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]
`src`[p401] — Address of the resource
`type`[p401] — Type of embedded resource
`width`[p478] — Horizontal dimension
`height`[p478] — Vertical dimension
Any other attribute that has no namespace (see prose).

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLEmbedElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute USVString src;
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute DOMString width;
  [CEReactions] attribute DOMString height;
  Document? getSVGDocument();

  // also has obsolete members
};
```

The embed[p400] element provides an integration point for an external application or interactive content.

The **src** attribute gives the URL of the resource being embedded. The attribute, if present, must contain a valid non-empty URL potentially surrounded by spaces[p97].

If the itemprop[p803] attribute is specified on an embed[p400] element, then the src[p401] attribute must also be specified.

The **type** attribute, if present, gives the MIME type by which the plugin to instantiate is selected. The value must be a valid MIME type string. If both the type[p401] attribute and the src[p401] attribute are present, then the type[p401] attribute must specify the same type as the explicit Content-Type metadata[p100] of the resource given by the src[p401] attribute.

While any of the following conditions are occurring, any plugin[p48] instantiated for the element must be removed, and the embed[p400] element represents[p142] nothing:

- The element has neither a src[p401] attribute nor a type[p401] attribute.
- The element has a media element[p415] ancestor.
- The element has an ancestor object[p403] element that is *not* showing its fallback content[p151].

An embed[p400] element is said to be **potentially active** when the following conditions are all met simultaneously:

- The element is in a document or was in a document the last time the event loop[p1138] reached step 1[p1141].
- The element's node document is fully active[p1017].
- The element has either a src[p401] attribute set or a type[p401] attribute set (or both).
- The element's src[p401] attribute is either absent or its value is not the empty string.
- The element is not a descendant of a media element[p415].
- The element is not a descendant of an object[p403] element that is not showing its fallback content[p151].
- The element is being rendered[p1406], or was being rendered[p1406] the last time the event loop[p1138] reached step 1[p1141].

Whenever an embed[p400] element that was not potentially active[p401] becomes potentially active[p401], and whenever a potentially active[p401] embed[p400] element that is remaining potentially active[p401] has its src[p401] attribute set, changed, or removed or its type[p401] attribute set, changed, or removed, the user agent must queue an element task[p1140] on the **embed task source** given the element to run the embed element setup steps[p401] for that element.

The embed element setup steps for a given embed[p400] element *element* are as follows:

1. If another task[p1139] has since been queued to run the embed element setup steps[p401] for *element*, then return.
2. If *element* has a src[p401] attribute set, then:
    1. Let *url* be the result of encoding-parsing a URL[p98] given *element*'s src[p401] attribute's value, relative to *element*'s node document.
    2. If *url* is failure, then return.

3. Let *request* be a new request whose URL is *url*, client is *element*'s node document's relevant settings object[p1098], destination is "`embed`", credentials mode is "`include`", mode is "`navigate`", initiator type is "`embed`", and whose use-URL-credentials flag is set.

4. Fetch *request*, with *processResponse* set to the following steps given response *response*:

    1. If another task[p1139] has since been queued to run the `embed` element setup steps[p401] for *element*, then return.

    2. If *response* is a network error, then fire an event named `load`[p1490] at *element*, and return.

    3. Let *type* be the result of determining the type of content[p402] given *element* and *response*.

    4. Switch on *type*:

        ↪ **null**

            1. Display no plugin[p402] for *element*.

        ↪ **Otherwise**

            1. If *element*'s content navigable[p1004] is null, then create a new child navigable[p1005] for *element*.

            2. Navigate[p1028] *element*'s content navigable[p1004] to *response*'s URL using *element*'s node document, with *response*[p1028] set to *response*, and *historyHandling*[p1028] set to "`replace`[p1027]".

            Note

            element's `src`[p401] *attribute does not get updated if the content navigable*[p1004] *gets further navigated to other locations.*

            3. *element* now represents[p142] its content navigable[p1004].

    Fetching the resource must delay the load event[p1377] of *element*'s node document.

3. Otherwise, display no plugin[p402] for *element*.

To determine the **type of the content** given an `embed`[p400] element *element* and a response *response*, run the following steps:

1. If *element* has a `type`[p401] attribute, and that attribute's value is a type that a plugin[p48] supports, then return the value of the `type`[p401] attribute.

2. If the path component of *response*'s url matches a pattern that a plugin[p48] supports, then return the type that that plugin can handle.

    Example

    For example, a plugin might say that it can handle URLs with path components that end with the four character string "`.swf`".

3. If *response* has explicit Content-Type metadata[p100], and that value is a type that a plugin[p48] supports, then return that value.

4. Return null.

Note

It is intentional that the above algorithm allows response *to have a non-ok status. This allows servers to return data for plugins even with error responses (e.g., HTTP 500 Internal Server Error codes can still contain plugin data).*

To **display no plugin** for an `embed`[p400] element *element*:

1. Destroy a child navigable[p1007] given *element*.

2. Display an indication that no plugin[p48] could be found for *element*, as the contents of *element*.

3. *element* now represents[p142] nothing.

Note

The embed element has no fallback content; its descendants are ignored.

Whenever an embed element that was potentially active stops being potentially active, any plugin that had been instantiated for that element must be unloaded.

The embed element potentially delays the load event.

The embed element supports dimension attributes.

The IDL attributes **src** and **type** each must reflect the respective content attributes of the same name.

4.8.7 The object element

Categories:

Flow content.
Phrasing content.
Embedded content.
Listed form-associated element.
Palpable content.

Contexts in which this element can be used:

Where embedded content is expected.

Content model:

Transparent.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes
data — Address of the resource
type — Type of embedded resource
name — Name of content navigable
form — Associates the element with a form element
width — Horizontal dimension
height — Vertical dimension

Accessibility considerations:

For authors.
For implementers.

DOM interface:

IDL

```
[Exposed=Window]
interface HTMLObjectElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute USVString data;
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute DOMString name;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute DOMString width;
  [CEReactions] attribute DOMString height;
  readonly attribute Document? contentDocument;
  readonly attribute WindowProxy? contentWindow;
  Document? getSVGDocument();

  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
```

```
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  undefined setCustomValidity(DOMString error);

  // also has obsolete members
};
```

Depending on the type of content instantiated by the object[p403] element, the node also supports other interfaces.

The object[p403] element can represent an external resource, which, depending on the type of the resource, will either be treated as an image or as a child navigable[p1004].

The **data** attribute specifies the URL of the resource. It must be present, and must contain a valid non-empty URL potentially surrounded by spaces[p97].

The **type** attribute, if present, specifies the type of the resource. If present, the attribute must be a valid MIME type string.

The **name** attribute, if present, must be a valid navigable target name[p1008]. The given value is used to name the element's content navigable[p1004], if applicable, and if present when the element's content navigable[p1004] is created[p1005].

Whenever one of the following conditions occur:

- the element is created,
- the element is popped off the stack of open elements[p1304] of an HTML parser[p1289] or XML parser[p1402],
- the element is not on the stack of open elements[p1304] of an HTML parser[p1289] or XML parser[p1402], and it is either inserted into a document[p47] or removed from a document[p47],
- the element's node document changes whether it is fully active[p1017],
- one of the element's ancestor object[p403] elements changes to or from showing its fallback content[p151],
- the element's classid[p1447] attribute is set, changed, or removed,
- the element's classid[p1447] attribute is not present, and its data[p404] attribute is set, changed, or removed,
- neither the element's classid[p1447] attribute nor its data[p404] attribute are present, and its type[p404] attribute is set, changed, or removed,
- the element changes from being rendered[p1406] to not being rendered, or vice versa,

...the user agent must queue an element task[p1140] on the DOM manipulation task source[p1149] given the object[p403] element to run the following steps to (re)determine what the object[p403] element represents. This task[p1139] being queued[p1139] or actively running must delay the load event[p1377] of the element's node document.

1. If the user has indicated a preference that this object[p403] element's fallback content[p151] be shown instead of the element's usual behavior, then jump to the step below labeled *fallback*.

   Note

   For example, a user could ask for the element's fallback content[p151] to be shown because that content uses a format that the user finds more accessible.

2. If the element has an ancestor media element[p415], or has an ancestor object[p403] element that is *not* showing its fallback content[p151], or if the element is not in a document whose browsing context[p1012] is non-null, or if the element's node document is not fully active[p1017], or if the element is still in the stack of open elements[p1304] of an HTML parser[p1289] or XML parser[p1402], or if the element is not being rendered[p1406], then jump to the step below labeled *fallback*.

3. If the data[p404] attribute is present and its value is not the empty string, then:

   1. If the type[p404] attribute is present and its value is not a type that the user agent supports, then the user agent may jump to the step below labeled *fallback* without fetching the content to examine its real type.

   2. Let *url* be the result of encoding-parsing a URL[p98] given the data[p404] attribute's value, relative to the element's

node document.

3. If *url* is failure, then fire an event named `error`[p1489] at the element and jump to the step below labeled *fallback*.

4. Let *request* be a new request whose URL is *url*, client is the element's node document's relevant settings object[p1098], destination is "`object`", credentials mode is "`include`", mode is "`navigate`", initiator type is "`object`", and whose use-URL-credentials flag is set.

5. Fetch *request*.

   Fetching the resource must delay the load event[p1377] of the element's node document until the task[p1139] that is queued[p1139] by the networking task source[p1149] once the resource has been fetched (defined next) has been run.

6. If the resource is not yet available (e.g. because the resource was not available in the cache, so that loading the resource required making a request over the network), then jump to the step below labeled *fallback*. The task[p1139] that is queued[p1139] by the networking task source[p1149] once the resource is available must restart this algorithm from this step. Resources can load incrementally; user agents may opt to consider a resource "available" whenever enough data has been obtained to begin processing the resource.

7. If the load failed (e.g. there was an HTTP 404 error, there was a DNS error), fire an event named `error`[p1489] at the element, then jump to the step below labeled *fallback*.

8. Determine the *resource type*, as follows:

   1. Let the *resource type* be unknown.

   2. If the user agent is configured to strictly obey Content-Type headers for this resource, and the resource has associated Content-Type metadata[p100], then let the *resource type* be the type specified in the resource's Content-Type metadata[p100], and jump to the step below labeled *handler*.

      ⚠Warning!

      This can introduce a vulnerability, wherein a site is trying to embed a resource that uses a particular type, but the remote site overrides that and instead furnishes the user agent with a resource that triggers a different type of content with different security characteristics.

   3. Run the appropriate set of steps from the following list:

      ↪ **If the resource has associated Content-Type metadata[p100]**

      1. Let *binary* be false.

      2. If the type specified in the resource's Content-Type metadata[p100] is "`text/plain`", and the result of applying the rules for distinguishing if a resource is text or binary to the resource is that the resource is not `text/plain`, then set *binary* to true.

      3. If the type specified in the resource's Content-Type metadata[p100] is "`application/octet-stream`", then set *binary* to true.

      4. If *binary* is false, then let the *resource type* be the type specified in the resource's Content-Type metadata[p100], and jump to the step below labeled *handler*.

      5. If there is a `type`[p404] attribute present on the `object`[p403] element, and its value is not `application/octet-stream`, then run the following steps:

         1. If the attribute's value is a type that starts with "`image/`" that is not also an XML MIME type, then let the *resource type* be the type specified in that `type`[p404] attribute.

         2. Jump to the step below labeled *handler*.

      ↪ **Otherwise, if the resource does not have associated Content-Type metadata[p100]**

      1. If there is a `type`[p404] attribute present on the `object`[p403] element, then let the *tentative type* be the type specified in that `type`[p404] attribute.

         Otherwise, let *tentative type* be the computed type of the resource.

      2. If *tentative type* is *not* `application/octet-stream`, then let *resource type* be *tentative*

type and jump to the step below labeled *handler*.

4. If applying the URL parser algorithm to the URL of the specified resource (after any redirects) results in a URL record whose path component matches a pattern that a plugin[p48] supports, then let *resource type* be the type that that plugin can handle.

   Example

   For example, a plugin might say that it can handle resources with path components that end with the four character string "`.swf`".

Note

It is possible for this step to finish, or for one of the substeps above to jump straight to the next step, with resource type *still being unknown. In both cases, the next step will trigger fallback.*

9. *Handler*: Handle the content as given by the first of the following cases that matches:

   ↪ **If the *resource type* is an XML MIME type, or if the *resource type* does not start with "`image/`"**

   If the `object`[p403] element's content navigable[p1004] is null, then create a new child navigable[p1005] for the element.

   Let *response* be the response from fetch.

   If *response*'s URL does not match about:blank[p98], then navigate[p1028] the element's content navigable[p1004] to *response*'s URL using the element's node document, with *historyHandling*[p1028] set to "`replace`[p1027]".

   Note

   The `data`[p404] attribute of the `object`[p403] element doesn't get updated if the content navigable[p1004] gets further navigated[p1028] to other locations.

   The `object`[p403] element represents[p142] its content navigable[p1004].

   ↪ **If the *resource type* starts with "`image/`", and support for images has not been disabled**

   Destroy a child navigable[p1007] given the `object`[p403] element.

   Apply the image sniffing rules to determine the type of the image.

   The `object`[p403] element represents[p142] the specified image.

   If the image cannot be rendered, e.g. because it is malformed or in an unsupported format, jump to the step below labeled *fallback*.

   ↪ **Otherwise**

   The given *resource type* is not supported. Jump to the step below labeled *fallback*.

   Note

   If the previous step ended with the resource type *being unknown, this is the case that is triggered.*

10. The element's contents are not part of what the `object`[p403] element represents.

11. If the `object`[p403] element does not represent its content navigable[p1004], then once the resource is completely loaded, queue an element task[p1140] on the DOM manipulation task source[p1149] given the `object`[p403] element to fire an event named `load`[p1490] at the element.

    Note

    If the element does *represent its content navigable[p1004], then an analogous task will be queued when the created `Document`[p131] is completely finished loading[p1078].*

12. Return.

4. *Fallback*: The `object`[p403] element represents[p142] the element's children. This is the element's fallback content[p151]. Destroy a child navigable[p1007] given the element.

Due to the algorithm above, the contents of object elements act as fallback content, used only when referenced resources can't be shown (e.g. because it returned a 404 error). This allows multiple object elements to be nested inside each other, targeting multiple user agents with different capabilities, with the user agent picking the first one it supports.

The object element potentially delays the load event.

The form attribute is used to explicitly associate the object element with its form owner.

The object element supports dimension attributes.

The IDL attributes **data**, **type**, and **name** each must reflect the respective content attributes of the same name.

The **contentDocument** getter steps are to return this's content document.

The **contentWindow** getter steps are to return this's content window.

The willValidate, validity, and validationMessage attributes, and the checkValidity(), reportValidity(), and setCustomValidity() methods, are part of the constraint validation API. The form IDL attribute is part of the element's forms API.

Example

In this example, an HTML page is embedded in another using the object element.

```
<figure>
 <object data="clock.html"></object>
 <figcaption>My HTML Clock</figcaption>
</figure>
```

4.8.8 The video element §

Categories:

Flow content.
Phrasing content.
Embedded content.
If the element has a controls attribute: Interactive content.
Palpable content.

Contexts in which this element can be used:

Where embedded content is expected.

Content model:

If the element has a src attribute: zero or more track elements, then transparent, but with no media element descendants.
If the element does not have a src attribute: zero or more source elements, then zero or more track elements, then transparent, but with no media element descendants.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes
src — Address of the resource
crossorigin — How the element handles crossorigin requests
poster — Poster frame to show prior to video playback
preload — Hints how much buffering the media resource will likely need
autoplay — Hint that the media resource can be started automatically when the page is loaded
playsinline — Encourage the user agent to display video content within the element's playback area
loop — Whether to loop the media resource
muted — Whether to mute the media resource by default
controls — Show user agent controls
width — Horizontal dimension

height[p478] — Vertical dimension

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLVideoElement : HTMLMediaElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute unsigned long width;
  [CEReactions] attribute unsigned long height;
  readonly attribute unsigned long videoWidth;
  readonly attribute unsigned long videoHeight;
  [CEReactions] attribute USVString poster;
  [CEReactions] attribute boolean playsInline;
};
```

A video[p407] element is used for playing videos or movies, and audio files with captions.

Content may be provided inside the video[p407] element. User agents should not show this content to the user; it is intended for older web browsers which do not support video[p407], so that text can be shown to the users of these older browsers informing them of how to access the video contents.

Note

In particular, this content is not intended to address accessibility concerns. To make video content accessible to the partially sighted, the blind, the hard-of-hearing, the deaf, and those with other physical or cognitive disabilities, a variety of features are available. Captions can be provided, either embedded in the video stream or as external files using the track[p412] element. Sign-language tracks can be embedded in the video stream. Audio descriptions can be embedded in the video stream or in text form using a WebVTT file referenced using the track[p412] element and synthesized into speech by the user agent. WebVTT can also be used to provide chapter titles. For users who would rather not use a media element at all, transcripts or other textual alternatives can be provided by simply linking to them in the prose near the video[p407] element. [WEBVTT][p1502]

The video[p407] element is a media element[p415] whose media data[p416] is ostensibly video data, possibly with associated audio data.

The src[p417], crossorigin[p418], preload[p430], autoplay[p436], loop[p434], muted[p466], and controls[p465] attributes are the attributes common to all media elements[p416].

The **poster** attribute gives the URL of an image file that the user agent can show while no video data is available. The attribute, if present, must contain a valid non-empty URL potentially surrounded by spaces[p97].

If the specified resource is to be used, then, when the element is created or when the poster[p408] attribute is set, changed, or removed, the user agent must run the following steps to determine the element's **poster frame** (regardless of the value of the element's show poster flag[p433]):

1. If there is an existing instance of this algorithm running for this video[p407] element, abort that instance of this algorithm without changing the poster frame[p408].
2. If the poster[p408] attribute's value is the empty string or if the attribute is absent, then there is no poster frame[p408]; return.
3. Let *url* be the result of encoding-parsing a URL[p98] given the poster[p408] attribute's value, relative to the element's node document.
4. If *url* is failure, then return. Note *There is no poster frame[p408].*
5. Let *request* be a new request whose URL is *url*, client is the element's node document's relevant settings object[p1098], destination is "`image`", initiator type is "`video`", credentials mode is "`include`", and whose use-URL-credentials flag is set.
6. Fetch *request*. This must delay the load event[p1377] of the element's node document.
7. If an image is thus obtained, the poster frame[p408] is that image. Otherwise, there is no poster frame[p408].

Note

The image given by the poster[p408] attribute, the poster frame[p408], is intended to be a representative frame of the video (typically one of the first non-blank frames) that gives the user an idea of what the video is like.

The **playsinline** attribute is a boolean attribute[p76]. If present, it serves as a hint to the user agent that the video ought to be displayed "inline" in the document by default, constrained to the element's playback area, instead of being displayed fullscreen or in an independent resizable window.

Note

The absence of the playsinline[p409] attribute does not imply that the video will display fullscreen by default. Indeed, most user agents have chosen to play all videos inline by default, and in such user agents the playsinline[p409] attribute has no effect.

A video[p407] element represents what is given for the first matching condition in the list below:

↪ **When no video data is available (the element's readyState[p436] attribute is either HAVE_NOTHING[p434], or HAVE_METADATA[p434] but no video data has yet been obtained at all, or the element's readyState[p436] attribute is any subsequent value but the media resource[p416] does not have a video channel)**

The video[p407] element represents[p142] its poster frame[p408], if any, or else transparent black with no natural dimensions.

↪ **When the video[p407] element is paused[p437], the current playback position[p433] is the first frame of video, and the element's show poster flag[p433] is set**

The video[p407] element represents[p142] its poster frame[p408], if any, or else the first frame of the video.

↪ **When the video[p407] element is paused[p437], and the frame of video corresponding to the current playback position[p433] is not available (e.g. because the video is seeking or buffering)**

↪ **When the video[p407] element is neither potentially playing[p437] nor paused[p437] (e.g. when seeking or stalled)**

The video[p407] element represents[p142] the last frame of the video to have been rendered.

↪ **When the video[p407] element is paused[p437]**

The video[p407] element represents[p142] the frame of video corresponding to the current playback position[p433].

↪ **Otherwise (the video[p407] element has a video channel and is potentially playing[p437])**

The video[p407] element represents[p142] the frame of video at the continuously increasing "current" position[p433]. When the current playback position[p433] changes such that the last frame rendered is no longer the frame corresponding to the current playback position[p433] in the video, the new frame must be rendered.

Frames of video must be obtained from the video track that was selected[p449] when the event loop[p1138] last reached step 1[p1141].

Note

Which frame in a video stream corresponds to a particular playback position is defined by the video stream's format.

The video[p407] element also represents[p142] any text track cues[p452] whose text track cue active flag[p453] is set and whose text track[p450] is in the showing[p451] mode, and any audio from the media resource[p416], at the current playback position[p433].

Any audio associated with the media resource[p416] must, if played, be played synchronized with the current playback position[p433], at the element's effective media volume[p466]. The user agent must play the audio from audio tracks that were enabled[p449] when the event loop[p1138] last reached step 1.

In addition to the above, the user agent may provide messages to the user (such as "buffering", "no video loaded", "error", or more detailed information) by overlaying text or icons on the video or other areas of the element's playback area, or in another appropriate manner.

User agents that cannot render the video may instead make the element represent[p142] a link to an external video playback utility or to the video data itself.

When a video[p407] element's media resource[p416] has a video channel, the element provides a paint source whose width is the media resource[p416]'s natural width[p410], whose height is the media resource[p416]'s natural height[p410], and whose appearance is the frame of video corresponding to the current playback position[p433], if that is available, or else (e.g. when the video is seeking or buffering) its previous appearance, if any, or else (e.g. because the video is still loading the first frame) blackness.

For web developers (non-normative)

***video*.videoWidth**[p410]

***video*.videoHeight**[p410]

These attributes return the natural dimensions of the video, or 0 if the dimensions are not known.

The **natural width** and **natural height** of the media resource[p416] are the dimensions of the resource in CSS pixels after taking into account the resource's dimensions, aspect ratio, clean aperture, resolution, and so forth, as defined for the format used by the resource. If an anamorphic format does not define how to apply the aspect ratio to the video data's dimensions to obtain the "correct" dimensions, then the user agent must apply the ratio by increasing one dimension and leaving the other unchanged.

The **videoWidth** IDL attribute must return the natural width[p410] of the video in CSS pixels. The **videoHeight** IDL attribute must return the natural height[p410] of the video in CSS pixels. If the element's readyState[p436] attribute is HAVE_NOTHING[p434], then the attributes must return 0.

Whenever the natural width[p410] or natural height[p410] of the video changes (including, for example, because the selected video track[p449] was changed), if the element's readyState[p436] attribute is not HAVE_NOTHING[p434], the user agent must queue a media element task[p416] given the media element[p415] to fire an event named resize[p469] at the media element[p415].

The video[p407] element supports dimension attributes[p478].

In the absence of style rules to the contrary, video content should be rendered inside the element's playback area such that the video content is shown centered in the playback area at the largest possible size that fits completely within it, with the video content's aspect ratio being preserved. Thus, if the aspect ratio of the playback area does not match the aspect ratio of the video, the video will be shown letterboxed or pillarboxed. Areas of the element's playback area that do not contain the video represent nothing.

Note

In user agents that implement CSS, the above requirement can be implemented by using the style rule suggested in the Rendering section[p1426].

The natural width of a video[p407] element's playback area is the natural width of the poster frame[p408], if that is available and the element currently represents[p142] its poster frame; otherwise, it is the natural width[p410] of the video resource, if that is available; otherwise the natural width is missing.

The natural height of a video[p407] element's playback area is the natural height of the poster frame[p408], if that is available and the element currently represents[p142] its poster frame; otherwise it is the natural height[p410] of the video resource, if that is available; otherwise the natural height is missing.

The default object size is a width of 300 CSS pixels and a height of 150 CSS pixels. [CSSIMAGES][p1494]

User agents should provide controls to enable or disable the display of closed captions, audio description tracks, and other additional data associated with the video stream, though such features should, again, not interfere with the page's normal rendering.

User agents may allow users to view the video content in manners more suitable to the user, such as fullscreen or in an independent resizable window. User agents may even trigger such a viewing mode by default upon playing a video, although they should not do so when the playsinline[p409] attribute is specified. As with the other user interface features, controls to enable this should not interfere with the page's normal rendering unless the user agent is exposing a user interface[p465]. In such an independent viewing mode, however, user agents may make full user interfaces visible, even if the controls[p465] attribute is absent.

User agents may allow video playback to affect system features that could interfere with the user's experience; for example, user agents could disable screensavers while video playback is in progress.

The **poster** IDL attribute must reflect[p105] the poster[p408] content attribute.

The **playsInline** IDL attribute must reflect[p105] the playsinline[p409] content attribute.

Example

This example shows how to detect when a video has failed to play correctly:

```
<script>
```

```
 function failed(e) {
   // video playback failed - show a message saying why
   switch (e.target.error.code) {
     case e.target.error.MEDIA_ERR_ABORTED:
       alert('You aborted the video playback.');
       break;
     case e.target.error.MEDIA_ERR_NETWORK:
       alert('A network error caused the video download to fail part-way.');
       break;
     case e.target.error.MEDIA_ERR_DECODE:
       alert('The video playback was aborted due to a corruption problem or because the video used
features your browser did not support.');
       break;
     case e.target.error.MEDIA_ERR_SRC_NOT_SUPPORTED:
       alert('The video could not be loaded, either because the server or network failed or because
the format is not supported.');
       break;
     default:
       alert('An unknown error occurred.');
       break;
   }
 }
</script>
<p><video src="tgif.vid" autoplay controls onerror="failed(event)"></video></p>
<p><a href="tgif.vid">Download the video file</a>.</p>
```

4.8.9 The audio element §[p41]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Embedded content[p151].
If the element has a controls[p465] attribute: Interactive content[p151].
If the element has a controls[p465] attribute: Palpable content[p151].

Contexts in which this element can be used[p147]:

Where embedded content[p151] is expected.

Content model[p147]:

If the element has a src[p417] attribute: zero or more track[p412] elements, then transparent[p152], but with no media element[p415] descendants.
If the element does not have a src[p417] attribute: zero or more source[p344] elements, then zero or more track[p412] elements, then transparent[p152], but with no media element[p415] descendants.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
src[p417] — Address of the resource
crossorigin[p418] — How the element handles crossorigin requests
preload[p430] — Hints how much buffering the media resource[p416] will likely need
autoplay[p436] — Hint that the media resource[p416] can be started automatically when the page is loaded
loop[p434] — Whether to loop the media resource[p416]
muted[p466] — Whether to mute the media resource[p416] by default
controls[p465] — Show user agent controls

Accessibility considerations[p148]:

For authors.

For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window,
 LegacyFactoryFunction=Audio(optional DOMString src)]
interface HTMLAudioElement : HTMLMediaElement {
  [HTMLConstructor] constructor();
};
```

An audio[p411] element represents[p142] a sound or audio stream.

Content may be provided inside the audio[p411] element. User agents should not show this content to the user; it is intended for older web browsers which do not support audio[p411], so that text can be shown to the users of these older browsers informing them of how to access the audio contents.

Note

In particular, this content is not intended to address accessibility concerns. To make audio content accessible to the deaf or to those with other physical or cognitive disabilities, a variety of features are available. If captions or a sign language video are available, the video[p407] element can be used instead of the audio[p411] element to play the audio, allowing users to enable the visual alternatives. Chapter titles can be provided to aid navigation, using the track[p412] element and a WebVTT file. And, naturally, transcripts or other textual alternatives can be provided by simply linking to them in the prose near the audio[p411] element. [WEBVTT][p1502]

The audio[p411] element is a media element[p415] whose media data[p416] is ostensibly audio data.

The src[p417], crossorigin[p418], preload[p430], autoplay[p436], loop[p434], muted[p466], and controls[p465] attributes are the attributes common to all media elements[p416].

For web developers (non-normative)

***audio* = new Audio[p412]([*url*])**

Returns a new audio[p411] element, with the src[p417] attribute set to the value passed in the argument, if applicable.

A legacy factory function is provided for creating HTMLAudioElement[p412] objects (in addition to the factory methods from DOM such as createElement()): **Audio(*src*)**. When invoked, the legacy factory function must perform the following steps:

1. Let *document* be the current global object[p1098]'s associated Document[p935].
2. Let *audio* be the result of creating an element given *document*, "audio", and the HTML namespace.
3. Set an attribute value for *audio* using "preload[p430]" and "auto[p430]".
4. If *src* is given, then set an attribute value for *audio* using "src[p417]" and *src*. (This will cause the user agent to invoke[p418] the object's resource selection algorithm[p421] before returning.)
5. Return *audio*.

4.8.10 The track element §[p412]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a media element[p415], before any flow content[p150].

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]
kind[p413] — The type of text track
src[p413] — Address of the resource
srclang[p414] — Language of the text track
label[p414] — User-visible label
default[p414] — Enable the track if no other text track[p450] is more suitable

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLTrackElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString kind;
  [CEReactions] attribute USVString src;
  [CEReactions] attribute DOMString srclang;
  [CEReactions] attribute DOMString label;
  [CEReactions] attribute boolean default;

  const unsigned short NONE = 0;
  const unsigned short LOADING = 1;
  const unsigned short LOADED = 2;
  const unsigned short ERROR = 3;
  readonly attribute unsigned short readyState;

  readonly attribute TextTrack track;
};
```

The track[p412] element allows authors to specify explicit external timed text tracks[p450] for media elements[p415]. It does not represent[p142] anything on its own.

The **kind** attribute is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
subtitles	**Subtitles**	Transcription or translation of the dialogue, suitable for when the sound is available but not understood (e.g. because the user does not understand the language of the media resource[p416]'s audio track). Overlaid on the video.
captions	**Captions**	Transcription or translation of the dialogue, sound effects, relevant musical cues, and other relevant audio information, suitable for when sound is unavailable or not clearly audible (e.g. because it is muted, drowned-out by ambient noise, or because the user is deaf). Overlaid on the video; labeled as appropriate for the hard-of-hearing.
descriptions	**Descriptions**	Textual descriptions of the video component of the media resource[p416], intended for audio synthesis when the visual component is obscured, unavailable, or not usable (e.g. because the user is interacting with the application without a screen while driving, or because the user is blind). Synthesized as audio.
chapters	**Chapters metadata**	Tracks intended for use from script. Not displayed by the user agent.
metadata	**Metadata**	

The attribute's *missing value default*[p77] is the subtitles[p413] state, and its *invalid value default*[p77] is the metadata[p413] state.

The **src** attribute gives the URL of the text track data. The value must be a valid non-empty URL potentially surrounded by spaces[p97]. This attribute must be present.

The element has an associated **track URL** (a string), initially the empty string.

When the element's src[p413] attribute is set, run these steps:

1. Let *trackURL* be failure.
2. Let *value* be the element's src[p413] attribute value.

3. If *value* is not the empty string, then set *trackURL* to the result of encoding-parsing-and-serializing a URL[p99] given *value*, relative to the element's node document.

4. Set the element's track URL[p413] to *trackURL* if it is not failure; otherwise to the empty string.

If the element's track URL[p413] identifies a WebVTT resource, and the element's `kind`[p413] attribute is not in the chapters metadata[p413] or metadata[p413] state, then the WebVTT file must be a WebVTT file using cue text. [WEBVTT][p1502]

The **`srclang`** attribute gives the language of the text track data. The value must be a valid BCP 47 language tag. This attribute must be present if the element's `kind`[p413] attribute is in the subtitles[p413] state. [BCP47][p1493]

If the element has a `srclang`[p414] attribute whose value is not the empty string, then the element's **track language** is the value of the attribute. Otherwise, the element has no track language[p414].

The **`label`** attribute gives a user-readable title for the track. This title is used by user agents when listing subtitle[p413], caption[p413], and audio description[p413] tracks in their user interface.

The value of the `label`[p414] attribute, if the attribute is present, must not be the empty string. Furthermore, there must not be two `track`[p412] element children of the same media element[p415] whose `kind`[p413] attributes are in the same state, whose `srclang`[p414] attributes are both missing or have values that represent the same language, and whose `label`[p414] attributes are again both missing or both have the same value.

If the element has a `label`[p414] attribute whose value is not the empty string, then the element's **track label** is the value of the attribute. Otherwise, the element's track label[p414] is an empty string.

The **`default`** attribute is a boolean attribute[p76], which, if specified, indicates that the track is to be enabled if the user's preferences do not indicate that another track would be more appropriate.

Each media element[p415] must have no more than one `track`[p412] element child whose `kind`[p413] attribute is in the subtitles[p413] or captions[p413] state and whose `default`[p414] attribute is specified.

Each media element[p415] must have no more than one `track`[p412] element child whose `kind`[p413] attribute is in the description[p413] state and whose `default`[p414] attribute is specified.

Each media element[p415] must have no more than one `track`[p412] element child whose `kind`[p413] attribute is in the chapters metadata[p413] state and whose `default`[p414] attribute is specified.

Note

There is no limit on the number of `track`[p412] elements whose `kind`[p413] attribute is in the metadata[p413] state and whose `default`[p414] attribute is specified.

For web developers (non-normative)

***track*.readyState**[p414]

Returns the text track readiness state[p451], represented by a number from the following list:

***track*.NONE**[p414] **(0)**
The text track not loaded[p451] state.

***track*.LOADING**[p415] **(1)**
The text track loading[p451] state.

***track*.LOADED**[p415] **(2)**
The text track loaded[p451] state.

***track*.ERROR**[p415] **(3)**
The text track failed to load[p451] state.

***track*.track**[p415]

Returns the `TextTrack`[p458] object corresponding to the text track[p450] of the `track`[p412] element.

The **`readyState`** attribute must return the numeric value corresponding to the text track readiness state[p451] of the `track`[p412] element's text track[p450], as defined by the following list:

`NONE` **(numeric value 0)**
The text track not loaded[p451] state.

LOADING (numeric value 1)

The text track loading[p451] state.

LOADED (numeric value 2)

The text track loaded[p451] state.

ERROR (numeric value 3)

The text track failed to load[p451] state.

The **track** IDL attribute must, on getting, return the track[p412] element's text track[p450]'s corresponding TextTrack[p458] object.

The **src**, **srclang**, **label**, and **default** IDL attributes must reflect[p105] the respective content attributes of the same name. The **kind** IDL attribute must reflect[p105] the content attribute of the same name, limited to only known values[p106].

Example

This video has subtitles in several languages:

```
<video src="brave.webm">
 <track kind=subtitles src=brave.en.vtt srclang=en label="English">
 <track kind=captions src=brave.en.hoh.vtt srclang=en label="English for the Hard of Hearing">
 <track kind=subtitles src=brave.fr.vtt srclang=fr lang=fr label="Français">
 <track kind=subtitles src=brave.de.vtt srclang=de lang=de label="Deutsch">
</video>
```

(The lang[p159] attributes on the last two describe the language of the label[p414] attribute, not the language of the subtitles themselves. The language of the subtitles is given by the srclang[p414] attribute.)

4.8.11 Media elements §[p415]

HTMLMediaElement[p415] objects (audio[p411] and video[p407], in this specification) are simply known as **media elements**.

IDL

```
enum CanPlayTypeResult { "" /* empty string */, "maybe", "probably" };
typedef (MediaStream or MediaSource or Blob) MediaProvider;

[Exposed=Window]
interface HTMLMediaElement : HTMLElement {

  // error state
  readonly attribute MediaError? error;

  // network state
  [CEReactions] attribute USVString src;
  attribute MediaProvider? srcObject;
  readonly attribute USVString currentSrc;
  [CEReactions] attribute DOMString? crossOrigin;
  const unsigned short NETWORK_EMPTY = 0;
  const unsigned short NETWORK_IDLE = 1;
  const unsigned short NETWORK_LOADING = 2;
  const unsigned short NETWORK_NO_SOURCE = 3;
  readonly attribute unsigned short networkState;
  [CEReactions] attribute DOMString preload;
  readonly attribute TimeRanges buffered;
  undefined load();
  CanPlayTypeResult canPlayType(DOMString type);

  // ready state
  const unsigned short HAVE_NOTHING = 0;
  const unsigned short HAVE_METADATA = 1;
  const unsigned short HAVE_CURRENT_DATA = 2;
```

```
  const unsigned short HAVE_FUTURE_DATA = 3;
  const unsigned short HAVE_ENOUGH_DATA = 4;
  readonly attribute unsigned short readyState;
  readonly attribute boolean seeking;

  // playback state
  attribute double currentTime;
  undefined fastSeek(double time);
  readonly attribute unrestricted double duration;
  object getStartDate();
  readonly attribute boolean paused;
  attribute double defaultPlaybackRate;
  attribute double playbackRate;
  attribute boolean preservesPitch;
  readonly attribute TimeRanges played;
  readonly attribute TimeRanges seekable;
  readonly attribute boolean ended;
  [CEReactions] attribute boolean autoplay;
  [CEReactions] attribute boolean loop;
  Promise<undefined> play();
  undefined pause();

  // controls
  [CEReactions] attribute boolean controls;
  attribute double volume;
  attribute boolean muted;
  [CEReactions] attribute boolean defaultMuted;

  // tracks
  [SameObject] readonly attribute AudioTrackList audioTracks;
  [SameObject] readonly attribute VideoTrackList videoTracks;
  [SameObject] readonly attribute TextTrackList textTracks;
  TextTrack addTextTrack(TextTrackKind kind, optional DOMString label = "", optional DOMString language
= "");
};
```

The **media element attributes**, src[p417], crossorigin[p418], preload[p430], autoplay[p436], loop[p434], muted[p466], and controls[p465], apply to all media elements[p415]. They are defined in this section.

Media elements[p415] are used to present audio data, or video and audio data, to the user. This is referred to as **media data** in this section, since this section applies equally to media elements[p415] for audio or for video. The term **media resource** is used to refer to the complete set of media data, e.g. the complete video file, or complete audio file.

A media resource[p416] has an associated **origin**, which is either "`none`", "`multiple`", "`rewritten`", or an origin[p909]. It is initially set to "`none`".

A media resource[p416] can have multiple audio and video tracks. For the purposes of a media element[p415], the video data of the media resource[p416] is only that of the currently selected track (if any) as given by the element's videoTracks[p446] attribute when the event loop[p1138] last reached step 1[p1141], and the audio data of the media resource[p416] is the result of mixing all the currently enabled tracks (if any) given by the element's audioTracks[p446] attribute when the event loop[p1138] last reached step 1[p1141].

Note

Both audio[p411] and video[p407] elements can be used for both audio and video. The main difference between the two is simply that the audio[p411] element has no playback area for visual content (such as video or captions), whereas the video[p407] element does.

Each media element[p415] has a unique **media element event task source**.

To **queue a media element task** with a media element[p415] *element* and a series of steps *steps*, queue an element task[p1140] on the media element[p415]'s media element event task source[p416] given *element* and *steps*.

4.8.11.1 Error codes §[p417]

For web developers (non-normative)

***media*.error**[p417]

Returns a MediaError[p417] object representing the current error state of the element.

Returns null if there is no error.

All media elements[p415] have an associated error status, which records the last error the element encountered since its resource selection algorithm[p421] was last invoked. The **error** attribute, on getting, must return the MediaError[p417] object created for this last error, or null if there has not been an error.

IDL

```
[Exposed=Window]
interface MediaError {
  const unsigned short MEDIA_ERR_ABORTED = 1;
  const unsigned short MEDIA_ERR_NETWORK = 2;
  const unsigned short MEDIA_ERR_DECODE = 3;
  const unsigned short MEDIA_ERR_SRC_NOT_SUPPORTED = 4;

  readonly attribute unsigned short code;
  readonly attribute DOMString message;
};
```

For web developers (non-normative)

***media*.error**[p417]**.code**[p417]

Returns the current error's error code, from the list below.

***media*.error**[p417]**.message**[p417]

Returns a specific informative diagnostic message about the error condition encountered. The message and message format are not generally uniform across different user agents. If no such message is available, then the empty string is returned.

Every MediaError[p417] object has a **message**, which is a string, and a **code**, which is one of the following:

MEDIA_ERR_ABORTED (numeric value 1)

The fetching process for the media resource[p416] was aborted by the user agent at the user's request.

MEDIA_ERR_NETWORK (numeric value 2)

A network error of some description caused the user agent to stop fetching the media resource[p416], after the resource was established to be usable.

MEDIA_ERR_DECODE (numeric value 3)

An error of some description occurred while decoding the media resource[p416], after the resource was established to be usable.

MEDIA_ERR_SRC_NOT_SUPPORTED (numeric value 4)

The media resource[p416] indicated by the src[p417] attribute or assigned media provider object[p418] was not suitable.

To **create a MediaError**, given an error code which is one of the above values, return a new MediaError[p417] object whose code[p417] is the given error code and whose message[p417] is a string containing any details the user agent is able to supply about the cause of the error condition, or the empty string if the user agent is unable to supply such details. This message string must not contain only the information already available via the supplied error code; for example, it must not simply be a translation of the code into a string format. If no additional information is available beyond that provided by the error code, the message[p417] must be set to the empty string.

The **code** getter steps are to return this's code[p417].

The **message** getter steps are to return this's message[p417].

4.8.11.2 Location of the media resource §[p417]

The **src** content attribute on media elements[p415] gives the URL of the media resource (video, audio) to show. The attribute, if present,

must contain a valid non-empty URL potentially surrounded by spaces[p97].

If the `itemprop`[p803] attribute is specified on the media element[p415], then the `src`[p417] attribute must also be specified.

The **`crossorigin`** content attribute on media elements[p415] is a CORS settings attribute[p101].

If a media element[p415] is created with a `src`[p417] attribute, the user agent must immediately[p44] invoke the media element[p415]'s resource selection algorithm[p421].

If a `src`[p417] attribute of a media element[p415] is set or changed, the user agent must invoke the media element[p415]'s media element load algorithm[p420]. (*Removing* the `src`[p417] attribute does not do this, even if there are `source`[p344] elements present.)

The **`src`** IDL attribute on media elements[p415] must reflect[p105] the content attribute of the same name.

The **`crossOrigin`** IDL attribute must reflect[p105] the `crossorigin`[p418] content attribute, limited to only known values[p106].

A **media provider object** is an object that can represent a media resource[p416], separate from a URL. `MediaStream` objects, `MediaSource` objects, and `Blob` objects are all media provider objects[p418].

Each media element[p415] can have an **assigned media provider object**, which is a media provider object[p418]. When a media element[p415] is created, it has no assigned media provider object[p418].

For web developers (non-normative)

***media*.srcObject**[p418] **[= *source*]**

Allows the media element[p415] to be assigned a media provider object[p418].

***media*.currentSrc**[p418]

Returns the URL of the current media resource[p416], if any.

Returns the empty string when there is no media resource[p416], or it doesn't have a URL.

The **`currentSrc`** IDL attribute must initially be set to the empty string. Its value is changed by the resource selection algorithm[p421] defined below.

The **`srcObject`** IDL attribute, on getting, must return the element's assigned media provider object[p418], if any, or null otherwise. On setting, it must set the element's assigned media provider object[p418] to the new value, and then invoke the element's media element load algorithm[p420].

Note

There are three ways to specify a media resource[p416]: the `srcObject`[p418] IDL attribute, the `src`[p417] content attribute, and `source`[p344] elements. The IDL attribute takes priority, followed by the content attribute, followed by the elements.

4.8.11.3 MIME types [§][p418]

A media resource[p416] can be described in terms of its *type*, specifically a MIME type, in some cases with a `codecs` parameter. (Whether the `codecs` parameter is allowed or not depends on the MIME type.) [RFC6381][p1499]

Types are usually somewhat incomplete descriptions; for example "`video/mpeg`" doesn't say anything except what the container type is, and even a type like "`video/mp4; codecs="avc1.42E01E, mp4a.40.2"`" doesn't include information like the actual bitrate (only the maximum bitrate). Thus, given a type, a user agent can often only know whether it *might* be able to play media of that type (with varying levels of confidence), or whether it definitely *cannot* play media of that type.

A type that the user agent knows it cannot render is one that describes a resource that the user agent definitely does not support, for example because it doesn't recognize the container type, or it doesn't support the listed codecs.

The MIME type "`application/octet-stream`" with no parameters is never a type that the user agent knows it cannot render[p418]. User agents must treat that type as equivalent to the lack of any explicit Content-Type metadata[p100] when it is used to label a potential media resource[p416].

Note

Only the MIME type "`application/octet-stream`" with no parameters is special-cased here; if any parameter appears with it, it

will be treated just like any other MIME type. This is a deviation from the rule that unknown MIME type parameters should be ignored.

For web developers (non-normative)

***media*.canPlayType(*type*)**

Returns the empty string (a negative response), "maybe", or "probably" based on how confident the user agent is that it can play media resources of the given type.

The **canPlayType(*type*)** method must return **the empty string** if *type* is a type that the user agent knows it cannot render or is the type "application/octet-stream"; it must return "**probably**" if the user agent is confident that the type represents a media resource that it can render if used in with this audio or video element; and it must return "**maybe**" otherwise. Implementers are encouraged to return "maybe" unless the type can be confidently established as being supported or not. Generally, a user agent should never return "probably" for a type that allows the `codecs` parameter if that parameter is not present.

Example

This script tests to see if the user agent supports a (fictional) new format to dynamically decide whether to use a video element:

```
<section id="video">
 <p><a href="playing-cats.nfv">Download video</a></p>
</section>
<script>
 const videoSection = document.getElementById('video');
 const videoElement = document.createElement('video');
 const support = videoElement.canPlayType('video/x-new-fictional-format;codecs="kittens,bunnies"');
 if (support === "probably") {
   videoElement.setAttribute("src", "playing-cats.nfv");
   videoSection.replaceChildren(videoElement);
 }
</script>
```

Note

The type attribute of the source element allows the user agent to avoid downloading resources that use formats it cannot render.

4.8.11.4 Network states

For web developers (non-normative)

***media*.networkState**

Returns the current state of network activity for the element, from the codes in the list below.

As media elements interact with the network, their current network activity is represented by the **networkState** attribute. On getting, it must return the current network state of the element, which must be one of the following values:

NETWORK_EMPTY (numeric value 0)

The element has not yet been initialized. All attributes are in their initial states.

NETWORK_IDLE (numeric value 1)

The element's resource selection algorithm is active and has selected a resource, but it is not actually using the network at this time.

NETWORK_LOADING (numeric value 2)

The user agent is actively trying to download data.

NETWORK_NO_SOURCE (numeric value 3)

The element's resource selection algorithm is active, but it has not yet found a resource to use.

The resource selection algorithm[p421] defined below describes exactly when the networkState[p419] attribute changes value and what events fire to indicate changes in this state.

4.8.11.5 Loading the media resource §[p420]

For web developers (non-normative)

***media*.load[p420]()**

Causes the element to reset and start selecting and loading a new media resource[p416] from scratch.

All media elements[p415] have a **can autoplay flag**, which must begin in the true state, and a **delaying-the-load-event flag**, which must begin in the false state. While the delaying-the-load-event flag[p420] is true, the element must delay the load event[p1377] of its document.

When the **load()** method on a media element[p415] is invoked, the user agent must run the media element load algorithm[p420].

A media element[p415] has an associated boolean **is currently stalled**, which is initially false.

The **media element load algorithm** consists of the following steps.

1. Set this element's is currently stalled[p420] to false.
2. Abort any already-running instance of the resource selection algorithm[p421] for this element.
3. Let *pending tasks* be a list of all tasks[p1139] from the media element[p415]'s media element event task source[p416] in one of the task queues[p1138].
4. For each task in *pending tasks* that would resolve pending play promises[p439] or reject pending play promises[p439], immediately resolve or reject those promises in the order the corresponding tasks were queued.
5. Remove each task[p1139] in *pending tasks* from its task queue[p1138].

   Note

   Basically, pending events and callbacks are discarded and promises in-flight to be resolved/rejected are resolved/rejected immediately when the media element starts loading a new resource.

6. If the media element[p415]'s networkState[p419] is set to NETWORK_LOADING[p419] or NETWORK_IDLE[p419], queue a media element task[p416] given the media element[p415] to fire an event named abort[p468] at the media element[p415].
7. If the media element[p415]'s networkState[p419] is not set to NETWORK_EMPTY[p419], then:
   1. Queue a media element task[p416] given the media element[p415] to fire an event named emptied[p468] at the media element[p415].
   2. If a fetching process is in progress for the media element[p415], the user agent should stop it.
   3. If the media element[p415]'s assigned media provider object[p418] is a MediaSource object, then detach it.
   4. Forget the media element's media-resource-specific tracks[p430].
   5. If readyState[p436] is not set to HAVE_NOTHING[p434], then set it to that state.
   6. If the paused[p437] attribute is false, then:
      1. Set the paused[p437] attribute to true.
      2. Take pending play promises[p439] and reject pending play promises[p439] with the result and an "AbortError" DOMException.
   7. If seeking[p444] is true, set it to false.
   8. Set the current playback position[p433] to 0.

      Set the official playback position[p433] to 0.

      If this changed the official playback position[p433], then queue a media element task[p416] given the media element[p415]

to fire an event named timeupdate[p469] at the media element[p415].

9. Set the timeline offset[p434] to Not-a-Number (NaN).

10. Update the duration[p433] attribute to Not-a-Number (NaN).

Note

The user agent will not[p433] fire a durationchange[p469] event for this particular change of the duration.

8. Set the playbackRate[p439] attribute to the value of the defaultPlaybackRate[p439] attribute.

9. Set the error[p417] attribute to null and the can autoplay flag[p420] to true.

10. Invoke the media element[p415]'s resource selection algorithm[p421].

Note

11. *Playback of any previously playing media resource[p416] for this element stops.*

The **resource selection algorithm** for a media element[p415] is as follows. This algorithm is always invoked as part of a task[p1139], but one of the first steps in the algorithm is to return and continue running the remaining steps in parallel[p44]. In addition, this algorithm interacts closely with the event loop[p1138] mechanism; in particular, it has synchronous sections[p1146] (which are triggered as part of the event loop[p1138] algorithm). Steps in such sections are marked with ⌛.

1. Set the element's networkState[p419] attribute to the NETWORK_NO_SOURCE[p419] value.

2. Set the element's show poster flag[p433] to true.

3. Set the media element[p415]'s delaying-the-load-event flag[p420] to true (this delays the load event[p1377]).

4. Await a stable state[p1146], allowing the task[p1139] that invoked this algorithm to continue. The synchronous section[p1146] consists of all the remaining steps of this algorithm until the algorithm says the synchronous section[p1146] has ended. (Steps in synchronous sections[p1146] are marked with ⌛.)

5. ⌛ If the media element[p415]'s blocked-on-parser[p452] flag is false, then populate the list of pending text tracks[p452].

6. ⌛ If the media element[p415] has an assigned media provider object[p418], then let *mode* be *object*.

   ⌛ Otherwise, if the media element[p415] has no assigned media provider object[p418] but has a src[p417] attribute, then let *mode* be *attribute*.

   ⌛ Otherwise, if the media element[p415] does not have an assigned media provider object[p418] and does not have a src[p417] attribute, but does have a source[p344] element child, then let *mode* be *children* and let *candidate* be the first such source[p344] element child in tree order.

   ⌛ Otherwise, the media element[p415] has no assigned media provider object[p418] and has neither a src[p417] attribute nor a source[p344] element child:

   1. ⌛ Set the networkState[p419] to NETWORK_EMPTY[p419].

   2. ⌛ Set the element's delaying-the-load-event flag[p420] to false. This stops delaying the load event[p1377].

   3. End the synchronous section[p1146] and return.

7. ⌛ Set the media element[p415]'s networkState[p419] to NETWORK_LOADING[p419].

8. ⌛ Queue a media element task[p416] given the media element[p415] to fire an event named loadstart[p468] at the media element[p415].

9. Run the appropriate steps from the following list:

   ↪ **If *mode* is *object***

   1. ⌛ Set the currentSrc[p418] attribute to the empty string.

   2. End the synchronous section[p1146], continuing the remaining steps in parallel[p44].

   3. Run the resource fetch algorithm[p424] with the assigned media provider object[p418]. If that algorithm returns without aborting *this* one, then the load failed.

4. *Failed with media provider*: Reaching this step indicates that the media resource failed to load. Take pending play promises[p439] and queue a media element task[p416] given the media element[p415] to run the dedicated media source failure steps[p423] with the result.

5. Wait for the task[p1139] queued by the previous step to have executed.

6. Return. The element won't attempt to load another resource until this algorithm is triggered again.

↪ **If *mode* is *attribute***

1. ⌛ If the `src`[p417] attribute's value is the empty string, then end the synchronous section[p1146], and jump down to the *failed with attribute* step below.

2. ⌛ Let *urlRecord* be the result of encoding-parsing a URL[p98] given the `src`[p417] attribute's value, relative to the media element[p415]'s node document when the `src`[p417] attribute was last changed.

3. ⌛ If *urlRecord* is not failure, then set the `currentSrc`[p418] attribute to the result of applying the URL serializer to *urlRecord*.

4. End the synchronous section[p1146], continuing the remaining steps in parallel[p44].

5. If *urlRecord* is not failure, then run the resource fetch algorithm[p424] with *urlRecord*. If that algorithm returns without aborting *this* one, then the load failed.

6. *Failed with attribute*: Reaching this step indicates that the media resource failed to load or that *urlRecord* is failure. Take pending play promises[p439] and queue a media element task[p416] given the media element[p415] to run the dedicated media source failure steps[p423] with the result.

7. Wait for the task[p1139] queued by the previous step to have executed.

8. Return. The element won't attempt to load another resource until this algorithm is triggered again.

↪ **Otherwise (*mode* is *children*)**

1. ⌛ Let *pointer* be a position defined by two adjacent nodes in the media element[p415]'s child list, treating the start of the list (before the first child in the list, if any) and end of the list (after the last child in the list, if any) as nodes in their own right. One node is the node before *pointer*, and the other node is the node after *pointer*. Initially, let *pointer* be the position between the *candidate* node and the next node, if there are any, or the end of the list, if it is the last node.

   As nodes are inserted, removed, and moved into the media element[p415], *pointer* must be updated as follows:

   If a new node is inserted or moved between the two nodes that define *pointer*
   Let *pointer* be the point between the node before *pointer* and the new node. In other words, insertions at *pointer* go after *pointer*.

   If the node before *pointer* is removed
   Let *pointer* be the point between the node after *pointer* and the node before the node after *pointer*. In other words, *pointer* doesn't move relative to the remaining nodes.

   If the node after *pointer* is removed
   Let *pointer* be the point between the node before *pointer* and the node after the node before *pointer*. Just as with the previous case, *pointer* doesn't move relative to the remaining nodes.

   Other changes don't affect *pointer*.

2. ⌛ *Process candidate*: If *candidate* does not have a `src`[p345] attribute, or if its `src`[p345] attribute's value is the empty string, then end the synchronous section[p1146], and jump down to the *failed with elements* step below.

3. ⌛ If *candidate* has a `media`[p344] attribute whose value does not match the environment[p97], then end the synchronous section[p1146], and jump down to the *failed with elements* step below.

4. ⌛ Let *urlRecord* be the result of encoding-parsing a URL[p98] given *candidate*'s `src`[p417] attribute's value, relative to *candidate*'s node document when the `src`[p417] attribute was last changed.

5. ⌛ If *urlRecord* is failure, then end the synchronous section[p1146], and jump down to the *failed with elements* step below.

6. ⌛ If *candidate* has a `type`[p344] attribute whose value, when parsed as a MIME type (including any codecs described by the `codecs` parameter, for types that define that parameter), represents a type that the user

agent knows it cannot render[p418], then end the synchronous section[p1146], and jump down to the *failed with elements* step below.

7. ⌛ Set the currentSrc[p418] attribute to the result of applying the URL serializer to *urlRecord*.
8. End the synchronous section[p1146], continuing the remaining steps in parallel[p44].
9. Run the resource fetch algorithm[p424] with *urlRecord*. If that algorithm returns without aborting *this* one, then the load failed.
10. *Failed with elements*: Queue a media element task[p416] given the media element[p415] to fire an event named error[p469] at *candidate*.
11. Await a stable state[p1146]. The synchronous section[p1146] consists of all the remaining steps of this algorithm until the algorithm says the synchronous section[p1146] has ended. (Steps in synchronous sections[p1146] are marked with ⌛.)
12. ⌛ Forget the media element's media-resource-specific tracks[p430].
13. ⌛ *Find next candidate*: Let *candidate* be null.
14. ⌛ *Search loop*: If the node after *pointer* is the end of the list, then jump to the *waiting* step below.
15. ⌛ If the node after *pointer* is a source[p344] element, let *candidate* be that element.
16. ⌛ Advance *pointer* so that the node before *pointer* is now the node that was after *pointer*, and the node after *pointer* is the node after the node that used to be after *pointer*, if any.
17. ⌛ If *candidate* is null, jump back to the *search loop* step. Otherwise, jump back to the *process candidate* step.
18. ⌛ *Waiting*: Set the element's networkState[p419] attribute to the NETWORK_NO_SOURCE[p419] value.
19. ⌛ Set the element's show poster flag[p433] to true.
20. ⌛ Queue a media element task[p416] given the media element[p415] to set the element's delaying-the-load-event flag[p420] to false. This stops delaying the load event[p1377].
21. End the synchronous section[p1146], continuing the remaining steps in parallel[p44].
22. Wait until the node after *pointer* is a node other than the end of the list. (This step might wait forever.)
23. Await a stable state[p1146]. The synchronous section[p1146] consists of all the remaining steps of this algorithm until the algorithm says the synchronous section[p1146] has ended. (Steps in synchronous sections[p1146] are marked with ⌛.)
24. ⌛ Set the element's delaying-the-load-event flag[p420] back to true (this delays the load event[p1377] again, in case it hasn't been fired yet).
25. ⌛ Set the networkState[p419] back to NETWORK_LOADING[p419].
26. ⌛ Jump back to the *find next candidate* step above.

The **dedicated media source failure steps** with a list of promises *promises* are the following steps:

1. Set the error[p417] attribute to the result of creating a MediaError[p417] with MEDIA_ERR_SRC_NOT_SUPPORTED[p417].
2. Forget the media element's media-resource-specific tracks[p430].
3. Set the element's networkState[p419] attribute to the NETWORK_NO_SOURCE[p419] value.
4. Set the element's show poster flag[p433] to true.
5. Fire an event named error[p468] at the media element[p415].
6. Reject pending play promises[p439] with *promises* and a "NotSupportedError" DOMException.
7. Set the element's delaying-the-load-event flag[p420] to false. This stops delaying the load event[p1377].

To **verify a media response** given a response *response*, a media resource[p416] *resource*, and "`entire resource`" or a (number, number or "`until end`") tuple *byteRange*:

1. If *response* is a network error, then return false.
2. If *byteRange* is "`entire resource`", then return true.
3. Let *internalResponse* be *response*'s unsafe response[p99].
4. If *internalResponse*'s status is 200, then return true.
5. If *internalResponse*'s status is not 206, then return false.
6. If the result of extracting content-range values from *internalResponse* is failure, then return false.

   Note

   Note that the extracted values are not used, and in particular are not compared to byteRange*. So this step serves as syntactic validation of the `Content-Range` header, but if the `Content-Range` values on the response mismatch the `Range` values on the request, that is not considered a failure.*
7. Let *origin* be "`rewritten`" if *internalResponse*'s URL is null; otherwise *internalResponse*'s URL's origin.
8. Let *previousOrigin* be *resource*'s origin[p416].
9. If any of the following are true:
   - *previousOrigin* is "`none`";
   - *origin* and *previousOrigin* are "`rewritten`"; or
   - *origin* and *previousOrigin* are origins[p909], and *origin* is same origin[p910] with *previousOrigin*,

   then set *resource*'s origin[p416] to *origin*.

   Otherwise, if *response* is CORS-cross-origin[p99], then return false.

   Otherwise, set *resource*'s origin[p416] to "`multiple`".

   Note

   This ensures that opaque responses with range headers do not leak information by being patched together with other responses from different origins.
10. Return true.

The **resource fetch algorithm** for a media element[p415] and a given URL record or media provider object[p418] is as follows:

1. Let *mode* be *remote*.
2. If the algorithm was invoked with media provider object[p418], then set *mode* to *local*.

   Otherwise:

   1. Let *object* be the result of obtaining a blob object using the URL record's blob URL entry and the media element[p415]'s node document's relevant settings object[p1098].
   2. If *object* is a media provider object[p418], then set *mode* to *local*.
3. If *mode* is *remote*, then let the *current media resource* be the resource given by the URL record passed to this algorithm; otherwise, let the *current media resource* be the resource given by the media provider object[p418]. Either way, the *current media resource* is now the element's media resource[p416].
4. Remove all media-resource-specific text tracks[p453] from the media element[p415]'s list of pending text tracks[p452], if any.
5. Run the appropriate steps from the following list:

   ↪ **If *mode* is remote**

   1. Optionally, run the following substeps. This is the expected behavior if the user agent intends to not attempt to fetch the resource until the user requests it explicitly (e.g. as a way to implement the `preload`[p430] attribute's `none`[p430] keyword).
      1. Set the `networkState`[p419] to `NETWORK_IDLE`[p419].

2. Queue a media element task[p416] given the media element[p415] to fire an event named suspend[p468] at the element.

3. Queue a media element task[p416] given the media element[p415] to set the element's delaying-the-load-event flag[p420] to false. This stops delaying the load event[p1377].

4. Wait for the task to be run.

5. Wait for an implementation-defined event (e.g., the user requesting that the media element begin playback).

6. Set the element's delaying-the-load-event flag[p420] back to true (this delays the load event[p1377] again, in case it hasn't been fired yet).

7. Set the networkState[p419] to NETWORK_LOADING[p419].

2. Let *destination* be "audio" if the media element[p415] is an audio[p411] element, or "video" otherwise.

3. Let *request* be the result of creating a potential-CORS request[p99] given *current media resource*'s URL record, *destination*, and the current state of the media element[p415]'s crossorigin[p662] content attribute.

4. Set *request*'s client to the media element[p415]'s node document's relevant settings object[p1098].

5. Set *request*'s initiator type to *destination*.

6. Let *byteRange*, which is "entire resource" or a (number, number or "until end") tuple, be the byte range required to satisfy missing data in media data[p416]. This value is implementation-defined and may rely on codec, network conditions or other heuristics. The user-agent may determine to fetch the resource in full, in which case *byteRange* would be "entire resource", to fetch from a byte offset until the end, in which case *byteRange* would be (number, "until end"), or to fetch a range between two byte offsets, in which case *byteRange* would be a (number, number) tuple representing the two offsets.

7. If *byteRange* is not "entire resource", then:

    1. If *byteRange*[1] is "until end", then add a range header to *request* given *byteRange*[0].

    2. Otherwise, add a range header to *request* given *byteRange*[0] and *byteRange*[1].

8. Fetch *request*, with *processResponse* set to the following steps given response *response*:

    1. Let *global* be the media element[p415]'s node document's relevant global object[p1098].

    2. Let *updateMedia* be to queue a media element task[p416] given the media element[p415] to run the first appropriate steps from the media data processing steps list[p427] below. (A new task is used for this so that the work described below occurs relative to the appropriate media element event task source[p416] rather than using the networking task source[p1149].)

    3. Let *processEndOfMedia* be the following step: If the fetching process has completed without errors, including decoding the media data, and if all of the data is available to the user agent without network access, then, the user agent must move on to the *final step* below. This might never happen, e.g. when streaming an infinite resource such as web radio, or if the resource is longer than the user agent's ability to cache data.

    4. If the result of verifying[p423] *response* given the *current media resource* and *byteRange* is false, then abort these steps.

    5. Otherwise, incrementally read *response*'s body given *updateMedia*, *processEndOfMedia*, an empty algorithm, and *global*.

    6. Update the media data[p416] with the contents of *response*'s unsafe response[p99] obtained in this fashion. *response* can be CORS-same-origin[p99] or CORS-cross-origin[p99]; this affects whether subtitles referenced in the media data[p416] are exposed in the API and, for video[p407] elements, whether a canvas[p684] gets tainted when the video is drawn on it.

The **media element stall timeout** is an implementation-defined length of time, which should be about three seconds. When a media element[p415] that is actively attempting to obtain media data[p416] has failed to receive any data for a duration equal to the media element stall timeout[p425], the user agent must queue a media element task[p416] given the media element[p415] to:

1. Fire an event named stalled[p468] at the element.

2. Set the element's is currently stalled[p420] to true.

User agents may allow users to selectively block or slow media data[p416] downloads. When a media element[p415]'s download has been blocked altogether, the user agent must act as if it was stalled (as opposed to acting as if the connection was closed). The rate of the download may also be throttled automatically by the user agent, e.g. to balance the download with other connections sharing the same bandwidth.

User agents may decide to not download more content at any time, e.g. after buffering five minutes of a one hour media resource, while waiting for the user to decide whether to play the resource or not, while waiting for user input in an interactive resource, or when the user navigates away from the page. When a media element[p415]'s download has been suspended, the user agent must queue a media element task[p416] given the media element[p415] to set the networkState[p419] to NETWORK_IDLE[p419] and fire an event named suspend[p468] at the element. If and when downloading of the resource resumes, the user agent must queue a media element task[p416] given the media element[p415] to set the networkState[p419] to NETWORK_LOADING[p419]. Between the queuing of these tasks, the load is suspended (so progress[p468] events don't fire, as described above).

Note

The preload[p430] attribute provides a hint regarding how much buffering the author thinks is advisable, even in the absence of the autoplay[p436] attribute.

When a user agent decides to completely suspend a download, e.g., if it is waiting until the user starts playback before downloading any further content, the user agent must queue a media element task[p416] given the media element[p415] to set the element's delaying-the-load-event flag[p420] to false. This stops delaying the load event[p1377].

Although the above steps give an algorithm for issuing requests, the user agent may use other means besides those exact ones, especially in the face of error conditions. For example, the user agent may reconnect to the server or switch to a streaming protocol. The user agent must only consider the resource erroneous, and proceed into the error branches of the above steps, if the user agent has given up trying to fetch the resource.

To determine the format of the media resource[p416], the user agent must use the rules for sniffing audio and video specifically.

While the load is not suspended (see below), every 350ms (±200ms) or for every byte received, whichever is *least* frequent, queue a media element task[p416] given the media element[p415] to:

1. Fire an event named progress[p468] at the element.

2. Set the element's is currently stalled[p420] to false.

While the user agent might still need network access to obtain parts of the media resource[p416], the user agent must remain on this step.

Example

For example, if the user agent has discarded the first half of a video, the user agent will remain at this step even once the playback has ended[p437], because there is always the chance the user will seek back to the start. In fact, in this situation, once playback has ended[p437], the user agent will end up firing a suspend[p468] event, as described earlier.

↪ **Otherwise (*mode* is *local*)**

The resource described by the *current media resource*, if any, contains the media data[p416]. It is CORS-same-origin[p99].

If the *current media resource* is a raw data stream (e.g. from a File object), then to determine the format of the media resource[p416], the user agent must use the rules for sniffing audio and video specifically. Otherwise, if the data stream is pre-decoded, then the format is the format given by the relevant specification.

Whenever new data for the *current media resource* becomes available, queue a media element task[p416] given the media element[p415] to run the first appropriate steps from the media data processing steps list[p427] below.

When the *current media resource* is permanently exhausted (e.g. all the bytes of a Blob have been processed), if

there were no decoding errors, then the user agent must move on to the *final step* below. This might never happen, e.g. if the *current media resource* is a `MediaStream`.

The **media data processing steps list** is as follows:

↪ **If the media data[p416] cannot be fetched at all, due to network errors, causing the user agent to give up trying to fetch the resource**

↪ **If the media data[p416] can be fetched but is found by inspection to be in an unsupported format, or can otherwise not be rendered at all**

DNS errors, HTTP 4xx and 5xx errors (and equivalents in other protocols), and other fatal network errors that occur before the user agent has established whether the *current media resource* is usable, as well as the file using an unsupported container format, or using unsupported codecs for all the data, must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Abort this subalgorithm, returning to the resource selection algorithm[p421].

↪ **If the media resource[p416] is found to have an audio track**

1. Create an `AudioTrack`[p446] object to represent the audio track.
2. Update the media element[p415]'s `audioTracks`[p446] attribute's `AudioTrackList`[p446] object with the new `AudioTrack`[p446] object.
3. Let *enable* be *unknown*.
4. If either the media resource[p416] or the URL of the *current media resource* indicate a particular set of audio tracks to enable, or if the user agent has information that would facilitate the selection of specific audio tracks to improve the user's experience, then: if this audio track is one of the ones to enable, then set *enable* to *true*, otherwise, set *enable* to *false*.

Example

This could be triggered by media fragment syntax, but it could also be triggered e.g. by the user agent selecting a 5.1 surround sound audio track over a stereo audio track.

5. If *enable* is still *unknown*, then, if the media element[p415] does not yet have an enabled[p449] audio track, then set *enable* to *true*, otherwise, set *enable* to *false*.
6. If *enable* is *true*, then enable this audio track, otherwise, do not enable this audio track.
7. Fire an event named `addtrack`[p469] at this `AudioTrackList`[p446] object, using `TrackEvent`[p468], with the `track`[p468] attribute initialized to the new `AudioTrack`[p446] object.

↪ **If the media resource[p416] is found to have a video track**

1. Create a `VideoTrack`[p447] object to represent the video track.
2. Update the media element[p415]'s `videoTracks`[p446] attribute's `VideoTrackList`[p446] object with the new `VideoTrack`[p447] object.
3. Let *enable* be *unknown*.
4. If either the media resource[p416] or the URL of the *current media resource* indicate a particular set of video tracks to enable, or if the user agent has information that would facilitate the selection of specific video tracks to improve the user's experience, then: if this video track is the first such video track, then set *enable* to *true*, otherwise, set *enable* to *false*.

Example

This could again be triggered by media fragment syntax.

5. If *enable* is still *unknown*, then, if the media element[p415] does not yet have a selected[p449] video track, then set *enable* to *true*, otherwise, set *enable* to *false*.
6. If *enable* is *true*, then select this track and unselect any previously selected video tracks, otherwise, do not select this video track. If other tracks are unselected, then a change event will be fired[p449].

7. Fire an event named addtrack at this VideoTrackList object, using TrackEvent, with the track attribute initialized to the new VideoTrack object.

↪ **Once enough of the media data has been fetched to determine the duration of the media resource, its dimensions, and other metadata**

This indicates that the resource is usable. The user agent must follow these substeps:

1. Establish the media timeline for the purposes of the current playback position and the earliest possible position, based on the media data.
2. Update the timeline offset to the date and time that corresponds to the zero time in the media timeline established in the previous step, if any. If no explicit time and date is given by the media resource, the timeline offset must be set to Not-a-Number (NaN).
3. Set the current playback position and the official playback position to the earliest possible position.
4. Update the duration attribute with the time of the last frame of the resource, if known, on the media timeline established above. If it is not known (e.g. a stream that is in principle infinite), update the duration attribute to the value positive Infinity.

   Note

   The user agent will queue a media element task given the media element to fire an event named durationchange at the element at this point.

5. For video elements, set the videoWidth and videoHeight attributes, and queue a media element task given the media element to fire an event named resize at the media element.

   Note

   Further resize events will be fired if the dimensions subsequently change.

6. Set the readyState attribute to HAVE_METADATA.

   Note

   A loadedmetadata DOM event will be fired as part of setting the readyState attribute to a new value.

7. Let *jumped* be false.
8. If the media element's default playback start position is greater than zero, then seek to that time, and let *jumped* be true.
9. Set the media element's default playback start position to zero.
10. Let the *initial playback position* be 0.
11. If either the media resource or the URL of the *current media resource* indicate a particular start time, then set the *initial playback position* to that time and, if *jumped* is still false, seek to that time.

    Example

    For example, with media formats that support media fragment syntax, the fragment can be used to indicate a start position.

12. If there is no enabled audio track, then enable an audio track. This will cause a change event to be fired.
13. If there is no selected video track, then select a video track. This will cause a change event to be fired.

Once the readyState attribute reaches HAVE_CURRENT_DATA, after the loadeddata event has been fired, set the element's delaying-the-load-event flag to false. This stops delaying the load event.

Note

A user agent that is attempting to reduce network usage while still fetching the metadata for each media

resource[p416] would also stop buffering at this point, following the rules described previously[p426], which involve the networkState[p419] attribute switching to the NETWORK_IDLE[p419] value and a suspend[p468] event firing.

Note

The user agent is required *to determine the duration of the media resource[p416] and go through this step before playing.*

↪ **Once the entire media resource[p416] has been fetched (but potentially before any of it has been decoded)**

Fire an event named progress[p468] at the media element[p415].

Set the networkState[p419] to NETWORK_IDLE[p419] and fire an event named suspend[p468] at the media element[p415].

If the user agent ever discards any media data[p416] and then needs to resume the network activity to obtain it again, then it must queue a media element task[p416] given the media element[p415] to set the networkState[p419] to NETWORK_LOADING[p419].

Note

If the user agent can keep the media resource[p416] loaded, then the algorithm will continue to its final step *below, which aborts the algorithm.*

↪ **If the connection is interrupted after some media data[p416] has been received, causing the user agent to give up trying to fetch the resource**

Fatal network errors that occur after the user agent has established whether the *current media resource* is usable (i.e. once the media element[p415]'s readyState[p436] attribute is no longer HAVE_NOTHING[p434]) must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Set the error[p417] attribute to the result of creating a MediaError[p417] with MEDIA_ERR_NETWORK[p417].
3. Set the element's networkState[p419] attribute to the NETWORK_IDLE[p419] value.
4. Set the element's delaying-the-load-event flag[p420] to false. This stops delaying the load event[p1377].
5. Fire an event named error[p468] at the media element[p415].
6. Abort the overall resource selection algorithm[p421].

↪ **If the media data[p416] is corrupted**

Fatal errors in decoding the media data[p416] that occur after the user agent has established whether the *current media resource* is usable (i.e. once the media element[p415]'s readyState[p436] attribute is no longer HAVE_NOTHING[p434]) must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Set the error[p417] attribute to the result of creating a MediaError[p417] with MEDIA_ERR_DECODE[p417].
3. Set the element's networkState[p419] attribute to the NETWORK_IDLE[p419] value.
4. Set the element's delaying-the-load-event flag[p420] to false. This stops delaying the load event[p1377].
5. Fire an event named error[p468] at the media element[p415].
6. Abort the overall resource selection algorithm[p421].

↪ **If the media data[p416] fetching process is aborted by the user**

The fetching process is aborted by the user, e.g. because the user pressed a "stop" button, the user agent must execute the following steps. These steps are not followed if the load()[p420] method itself is invoked while these steps are running, as the steps above handle that particular kind of abort.

1. The user agent should cancel the fetching process.
2. Set the error[p417] attribute to the result of creating a MediaError[p417] with MEDIA_ERR_ABORTED[p417].

3. Fire an event named abort at the media element.

4. If the media element's readyState attribute has a value equal to HAVE_NOTHING, set the element's networkState attribute to the NETWORK_EMPTY value, set the element's show poster flag to true, and fire an event named emptied at the element.

   Otherwise, set the element's networkState attribute to the NETWORK_IDLE value.

5. Set the element's delaying-the-load-event flag to false. This stops delaying the load event.

6. Abort the overall resource selection algorithm.

↪ **If the media data can be fetched but has non-fatal errors or uses, in part, codecs that are unsupported, preventing the user agent from rendering the content completely correctly but not preventing playback altogether**

The server returning data that is partially usable but cannot be optimally rendered must cause the user agent to render just the bits it can handle, and ignore the rest.

↪ **If the media resource is found to declare a media-resource-specific text track that the user agent supports**

If the media data is CORS-same-origin, run the steps to expose a media-resource-specific text track with the relevant data.

Note

Cross-origin videos do not expose their subtitles, since that would allow attacks such as hostile sites reading subtitles from confidential videos on a user's intranet.

6. *Final step*: If the user agent ever reaches this step (which can only happen if the entire resource gets loaded and kept available): abort the overall resource selection algorithm.

When a media element is to **forget the media element's media-resource-specific tracks**, the user agent must remove from the media element's list of text tracks all the media-resource-specific text tracks, then empty the media element's audioTracks attribute's AudioTrackList object, then empty the media element's videoTracks attribute's VideoTrackList object. No events (in particular, no removetrack events) are fired as part of this; the error and emptied events, fired by the algorithms that invoke this one, can be used instead.

The **preload** attribute is an enumerated attribute with the following keywords and states:

Keyword	State	Brief description
auto (the empty string)	**Automatic**	Hints to the user agent that the user agent can put the user's needs first without risk to the server, up to and including optimistically downloading the entire resource.
none	**None**	Hints to the user agent that either the author does not expect the user to need the media resource, or that the server wants to minimize unnecessary traffic. This state does not provide a hint regarding how aggressively to actually download the media resource if buffering starts anyway (e.g. once the user hits "play").
metadata	**Metadata**	Hints to the user agent that the author does not expect the user to need the media resource, but that fetching the resource metadata (dimensions, track list, duration, etc.), and maybe even the first few frames, is reasonable. If the user agent precisely fetches no more than the metadata, then the media element will end up with its readyState attribute set to HAVE_METADATA; typically though, some frames will be obtained as well and it will probably be HAVE_CURRENT_DATA or HAVE_FUTURE_DATA. When the media resource is playing, hints to the user agent that bandwidth is to be considered scarce, e.g. suggesting throttling the download so that the media data is obtained at the slowest possible rate that still maintains consistent playback.

The attribute's *missing value default* and *invalid value default* are both implementation-defined, though the Metadata state is suggested as a compromise between reducing server load and providing an optimal user experience.

The attribute can be changed even once the media resource is being buffered or played; the descriptions in the table above are to be interpreted with that in mind.

Note

Authors might switch the attribute from "none" or "metadata" to "auto" dynamically once the user begins playback. For example, on a page with many videos this might be used to indicate that the many videos are not to be downloaded unless

requested, but that once one is requested it is to be downloaded aggressively.

The preload[p430] attribute is intended to provide a hint to the user agent about what the author thinks will lead to the best user experience. The attribute may be ignored altogether, for example based on explicit user preferences or based on the available connectivity.

The **preload** IDL attribute must reflect[p105] the content attribute of the same name, limited to only known values[p106].

Note

The autoplay[p436] attribute can override the preload[p430] attribute (since if the media plays, it naturally has to buffer first, regardless of the hint given by the preload[p430] attribute). Including both is not an error, however.

For web developers (non-normative)

***media*.buffered[p431]**

Returns a TimeRanges[p467] object that represents the ranges of the media resource[p416] that the user agent has buffered.

The **buffered** attribute must return a new static normalized TimeRanges object[p467] that represents the ranges of the media resource[p416], if any, that the user agent has buffered, at the time the attribute is evaluated. User agents must accurately determine the ranges available, even for media streams where this can only be determined by tedious inspection.

Note

Typically this will be a single range anchored at the zero point, but if, e.g. the user agent uses HTTP range requests in response to seeking, then there could be multiple ranges.

User agents may discard previously buffered data.

Note

Thus, a time position included within a range of the objects return by the buffered[p431] attribute at one time can end up being not included in the range(s) of objects returned by the same attribute at later times.

⚠Warning!

Returning a new object each time is a bad pattern for attribute getters and is only enshrined here as it would be costly to change it. It is not to be copied to new APIs.

4.8.11.6 Offsets into the media resource §[p431]

For web developers (non-normative)

***media*.duration[p433]**

Returns the length of the media resource[p416], in seconds, assuming that the start of the media resource[p416] is at time zero.

Returns NaN if the duration isn't available.

Returns Infinity for unbounded streams.

***media*.currentTime[p433] [= *value*]**

Returns the official playback position[p433], in seconds.

Can be set, to seek to the given time.

A media resource[p416] has a **media timeline** that maps times (in seconds) to positions in the media resource[p416]. The origin of a timeline is its earliest defined position. The duration of a timeline is its last defined position.

Establishing the media timeline: if the media resource[p416] somehow specifies an explicit timeline whose origin is not negative (i.e. gives each frame a specific time offset and gives the first frame a zero or positive offset), then the media timeline[p431] should be that timeline. (Whether the media resource[p416] can specify a timeline or not depends on the media resource's[p416] format.) If the media resource[p416] specifies an explicit start time *and date*, then that time and date should be considered the zero point in the media

timeline[p431]; the timeline offset[p434] will be the time and date, exposed using the `getStartDate()`[p434] method.

If the media resource[p416] has a discontinuous timeline, the user agent must extend the timeline used at the start of the resource across the entire resource, so that the media timeline[p431] of the media resource[p416] increases linearly starting from the earliest possible position[p433] (as defined below), even if the underlying media data[p416] has out-of-order or even overlapping time codes.

Example

For example, if two clips have been concatenated into one video file, but the video format exposes the original times for the two clips, the video data might expose a timeline that goes, say, 00:15..00:29 and then 00:05..00:38. However, the user agent would not expose those times; it would instead expose the times as 00:15..00:29 and 00:29..01:02, as a single video.

In the rare case of a media resource[p416] that does not have an explicit timeline, the zero time on the media timeline[p431] should correspond to the first frame of the media resource[p416]. In the even rarer case of a media resource[p416] with no explicit timings of any kind, not even frame durations, the user agent must itself determine the time for each frame in an implementation-defined manner.

Note

An example of a file format with no explicit timeline but with explicit frame durations is the Animated GIF format. An example of a file format with no explicit timings at all is the JPEG-push format (`multipart/x-mixed-replace`[p1463] with JPEG frames, often used as the format for MJPEG streams).

If, in the case of a resource with no timing information, the user agent will nonetheless be able to seek to an earlier point than the first frame originally provided by the server, then the zero time should correspond to the earliest seekable time of the media resource[p416]; otherwise, it should correspond to the first frame received from the server (the point in the media resource[p416] at which the user agent began receiving the stream).

Note

At the time of writing, there is no known format that lacks explicit frame time offsets yet still supports seeking to a frame before the first frame sent by the server.

Example

Consider a stream from a TV broadcaster, which begins streaming on a sunny Friday afternoon in October, and always sends connecting user agents the media data on the same media timeline, with its zero time set to the start of this stream. Months later, user agents connecting to this stream will find that the first frame they receive has a time with millions of seconds. The `getStartDate()`[p434] method would always return the date that the broadcast started; this would allow controllers to display real times in their scrubber (e.g. "2:30pm") rather than a time relative to when the broadcast began ("8 months, 4 hours, 12 minutes, and 23 seconds").

Consider a stream that carries a video with several concatenated fragments, broadcast by a server that does not allow user agents to request specific times but instead just streams the video data in a predetermined order, with the first frame delivered always being identified as the frame with time zero. If a user agent connects to this stream and receives fragments defined as covering timestamps 2010-03-20 23:15:00 UTC to 2010-03-21 00:05:00 UTC and 2010-02-12 14:25:00 UTC to 2010-02-12 14:35:00 UTC, it would expose this with a media timeline[p431] starting at 0s and extending to 3,600s (one hour). Assuming the streaming server disconnected at the end of the second clip, the `duration`[p433] attribute would then return 3,600. The `getStartDate()`[p434] method would return a `Date` object with a time corresponding to 2010-03-20 23:15:00 UTC. However, if a different user agent connected five minutes later, *it* would (presumably) receive fragments covering timestamps 2010-03-20 23:20:00 UTC to 2010-03-21 00:05:00 UTC and 2010-02-12 14:25:00 UTC to 2010-02-12 14:35:00 UTC, and would expose this with a media timeline[p431] starting at 0s and extending to 3,300s (fifty five minutes). In this case, the `getStartDate()`[p434] method would return a `Date` object with a time corresponding to 2010-03-20 23:20:00 UTC.

In both of these examples, the `seekable`[p445] attribute would give the ranges that the controller would want to actually display in its UI; typically, if the servers don't support seeking to arbitrary times, this would be the range of time from the moment the user agent connected to the stream up to the latest frame that the user agent has obtained; however, if the user agent starts discarding earlier information, the actual range might be shorter.

In any case, the user agent must ensure that the earliest possible position[p433] (as defined below) using the established media timeline[p431], is greater than or equal to zero.

The media timeline[p431] also has an associated clock. Which clock is used is user-agent defined, and may be media resource[p416]-dependent, but it should approximate the user's wall clock.

Media elements[p415] have a **current playback position**, which must initially (i.e. in the absence of media data[p416]) be zero seconds. The current playback position[p433] is a time on the media timeline[p431].

Media elements[p415] also have an **official playback position**, which must initially be set to zero seconds. The official playback position[p433] is an approximation of the current playback position[p433] that is kept stable while scripts are running.

Media elements[p415] also have a **default playback start position**, which must initially be set to zero seconds. This time is used to allow the element to be seeked even before the media is loaded.

Each media element[p415] has a **show poster flag**. When a media element[p415] is created, this flag must be set to true. This flag is used to control when the user agent is to show a poster frame for a video[p407] element instead of showing the video contents.

The **currentTime** attribute must, on getting, return the media element[p415]'s default playback start position[p433], unless that is zero, in which case it must return the element's official playback position[p433]. The returned value must be expressed in seconds. On setting, if the media element[p415]'s readyState[p436] is HAVE_NOTHING[p434], then it must set the media element[p415]'s default playback start position[p433] to the new value; otherwise, it must set the official playback position[p433] to the new value and then seek[p444] to the new value. The new value must be interpreted as being in seconds.

If the media resource[p416] is a streaming resource, then the user agent might be unable to obtain certain parts of the resource after it has expired from its buffer. Similarly, some media resources[p416] might have a media timeline[p431] that doesn't start at zero. The **earliest possible position** is the earliest position in the stream or resource that the user agent can ever obtain again. It is also a time on the media timeline[p431].

Note

The earliest possible position[p433] is not explicitly exposed in the API; it corresponds to the start time of the first range in the seekable[p445] attribute's TimeRanges[p467] object, if any, or the current playback position[p433] otherwise.

When the earliest possible position[p433] changes, then: if the current playback position[p433] is before the earliest possible position[p433], the user agent must seek[p444] to the earliest possible position[p433]; otherwise, if the user agent has not fired a timeupdate[p469] event at the element in the past 15 to 250ms and is not still running event handlers for such an event, then the user agent must queue a media element task[p416] given the media element[p415] to fire an event named timeupdate[p469] at the element.

Note

Because of the above requirement and the requirement in the resource fetch algorithm[p424] that kicks in when the metadata of the clip becomes known[p428], the current playback position[p433] can never be less than the earliest possible position[p433].

If at any time the user agent learns that an audio or video track has ended and all media data[p416] relating to that track corresponds to parts of the media timeline[p431] that are *before* the earliest possible position[p433], the user agent may queue a media element task[p416] given the media element[p415] to run these steps:

1. Remove the track from the audioTracks[p446] attribute's AudioTrackList[p446] object or the videoTracks[p446] attribute's VideoTrackList[p446] object as appropriate.

2. Fire an event named removetrack[p469] at the media element[p415]'s aforementioned AudioTrackList[p446] or VideoTrackList[p446] object, using TrackEvent[p468], with the track[p468] attribute initialized to the AudioTrack[p446] or VideoTrack[p447] object representing the track.

The **duration** attribute must return the time of the end of the media resource[p416], in seconds, on the media timeline[p431]. If no media data[p416] is available, then the attributes must return the Not-a-Number (NaN) value. If the media resource[p416] is not known to be bounded (e.g. streaming radio, or a live event with no announced end time), then the attribute must return the positive Infinity value.

The user agent must determine the duration of the media resource[p416] before playing any part of the media data[p416] and before setting readyState[p436] to a value greater than or equal to HAVE_METADATA[p434], even if doing so requires fetching multiple parts of the resource.

When the length of the media resource[p416] changes to a known value (e.g. from being unknown to known, or from a previously established length to a new length), the user agent must queue a media element task[p416] given the media element[p415] to fire an event named durationchange[p469] at the media element[p415]. (The event is not fired when the duration is reset as part of loading a new media resource.) If the duration is changed such that the current playback position[p433] ends up being greater than the time of the end of the media resource[p416], then the user agent must also seek[p444] to the time of the end of the media resource[p416].

Example

If an "infinite" stream ends for some reason, then the duration would change from positive Infinity to the time of the last frame or sample in the stream, and the `durationchange`[p469] event would be fired. Similarly, if the user agent initially estimated the media resource[p416]'s duration instead of determining it precisely, and later revises the estimate based on new information, then the duration would change and the `durationchange`[p469] event would be fired.

Some video files also have an explicit date and time corresponding to the zero time in the media timeline[p431], known as the **timeline offset**. Initially, the timeline offset[p434] must be set to Not-a-Number (NaN).

The **`getStartDate()`** method must return a new `Date` object[p57] representing the current timeline offset[p434].

The **`loop`** attribute is a boolean attribute[p76] that, if specified, indicates that the media element[p415] is to seek back to the start of the media resource[p416] upon reaching the end.

The **`loop`** IDL attribute must reflect[p105] the content attribute of the same name.

4.8.11.7 Ready states [p434]

For web developers (non-normative)

***media*.readyState**[p436]

Returns a value that expresses the current state of the element with respect to rendering the current playback position[p433], from the codes in the list below.

Media elements[p415] have a *ready state*, which describes to what degree they are ready to be rendered at the current playback position[p433]. The possible values are as follows; the ready state of a media element at any particular time is the greatest value describing the state of the element:

`HAVE_NOTHING` (numeric value 0)

No information regarding the media resource[p416] is available. No data for the current playback position[p433] is available. Media elements[p415] whose `networkState`[p419] attribute are set to `NETWORK_EMPTY`[p419] are always in the `HAVE_NOTHING`[p434] state.

`HAVE_METADATA` (numeric value 1)

Enough of the resource has been obtained that the duration of the resource is available. In the case of a `video`[p407] element, the dimensions of the video are also available. No media data[p416] is available for the immediate current playback position[p433].

`HAVE_CURRENT_DATA` (numeric value 2)

Data for the immediate current playback position[p433] is available, but either not enough data is available that the user agent could successfully advance the current playback position[p433] in the direction of playback[p441] at all without immediately reverting to the `HAVE_METADATA`[p434] state, or there is no more data to obtain in the direction of playback[p441]. For example, in video this corresponds to the user agent having data from the current frame, but not the next frame, when the current playback position[p433] is at the end of the current frame; and to when playback has ended[p437].

`HAVE_FUTURE_DATA` (numeric value 3)

Data for the immediate current playback position[p433] is available, as well as enough data for the user agent to advance the current playback position[p433] in the direction of playback[p441] at least a little without immediately reverting to the `HAVE_METADATA`[p434] state, and the text tracks are ready[p452]. For example, in video this corresponds to the user agent having data for at least the current frame and the next frame when the current playback position[p433] is at the instant in time between the two frames, or to the user agent having the video data for the current frame and audio data to keep playing at least a little when the current playback position[p433] is in the middle of a frame. The user agent cannot be in this state if playback has ended[p437], as the current playback position[p433] can never advance in this case.

`HAVE_ENOUGH_DATA` (numeric value 4)

All the conditions described for the `HAVE_FUTURE_DATA`[p434] state are met, and, in addition, either of the following conditions is also true:

- The user agent estimates that data is being fetched at a rate where the current playback position[p433], if it were to advance at the element's `playbackRate`[p439], would not overtake the available data before playback reaches the end of the media resource[p416].

- The user agent has entered a state where waiting longer will not result in further data being obtained, and therefore nothing would be gained by delaying playback any further. (For example, the buffer might be full.)

Note

In practice, the difference between HAVE_METADATA and HAVE_CURRENT_DATA is negligible. Really the only time the difference is relevant is when painting a video element onto a canvas, where it distinguishes the case where something will be drawn (HAVE_CURRENT_DATA or greater) from the case where nothing is drawn (HAVE_METADATA or less). Similarly, the difference between HAVE_CURRENT_DATA (only the current frame) and HAVE_FUTURE_DATA (at least this frame and the next) can be negligible (in the extreme, only one frame). The only time that distinction really matters is when a page provides an interface for "frame-by-frame" navigation.

When the ready state of a media element whose networkState is not NETWORK_EMPTY changes, the user agent must follow the steps given below:

1. Apply the first applicable set of substeps from the following list:

↪ **If the previous ready state was HAVE_NOTHING, and the new ready state is HAVE_METADATA**

Queue a media element task given the media element to fire an event named loadedmetadata at the element.

Note

Before this task is run, as part of the event loop mechanism, the rendering will have been updated to resize the video element if appropriate.

↪ **If the previous ready state was HAVE_METADATA and the new ready state is HAVE_CURRENT_DATA or greater**

If this is the first time this occurs for this media element since the load() algorithm was last invoked, the user agent must queue a media element task given the media element to fire an event named loadeddata at the element.

If the new ready state is HAVE_FUTURE_DATA or HAVE_ENOUGH_DATA, then the relevant steps below must then be run also.

↪ **If the previous ready state was HAVE_FUTURE_DATA or more, and the new ready state is HAVE_CURRENT_DATA or less**

If the media element was potentially playing before its readyState attribute changed to a value lower than HAVE_FUTURE_DATA, and the element has not ended playback, and playback has not stopped due to errors, paused for user interaction, or paused for in-band content, the user agent must queue a media element task given the media element to fire an event named timeupdate at the element, and queue a media element task given the media element to fire an event named waiting at the element.

↪ **If the previous ready state was HAVE_CURRENT_DATA or less, and the new ready state is HAVE_FUTURE_DATA**

The user agent must queue a media element task given the media element to fire an event named canplay at the element.

If the element's paused attribute is false, the user agent must notify about playing for the element.

↪ **If the new ready state is HAVE_ENOUGH_DATA**

If the previous ready state was HAVE_CURRENT_DATA or less, the user agent must queue a media element task given the media element to fire an event named canplay at the element, and, if the element's paused attribute is false, notify about playing for the element.

The user agent must queue a media element task given the media element to fire an event named canplaythrough at the element.

If the element is not eligible for autoplay, then the user agent must abort these substeps.

The user agent may run the following substeps:

1. Set the paused attribute to false.
2. If the element's show poster flag is true, set it to false and run the *time marches on* steps.

3. Queue a media element task[p416] given the element to fire an event named play[p469] at the element.

4. Notify about playing[p439] for the element.

Alternatively, if the element is a video[p407] element, the user agent may start observing whether the element intersects the viewport[p1406]. When the element starts intersecting the viewport[p1406], if the element is still eligible for autoplay[p437], run the substeps above. Optionally, when the element stops intersecting the viewport[p1406], if the can autoplay flag[p420] is still true and the autoplay[p436] attribute is still specified, run the following substeps:

1. Run the internal pause steps[p440] and set the can autoplay flag[p420] to true.

2. Queue a media element task[p416] given the element to fire an event named pause[p469] at the element.

Note

The substeps for playing and pausing can run multiple times as the element starts or stops intersecting the viewport[p1406], as long as the can autoplay flag[p420] is true.

Note

User agents do not need to support autoplay, and it is suggested that user agents honor user preferences on the matter. Authors are urged to use the autoplay[p436] attribute rather than using script to force the video to play, so as to allow the user to override the behavior if so desired.

Note

It is possible for the ready state of a media element to jump between these states discontinuously. For example, the state of a media element can jump straight from HAVE_METADATA[p434] to HAVE_ENOUGH_DATA[p434] without passing through the HAVE_CURRENT_DATA[p434] and HAVE_FUTURE_DATA[p434] states.

The **readyState** IDL attribute must, on getting, return the value described above that describes the current ready state of the media element[p415].

The **autoplay** attribute is a boolean attribute[p76]. When present, the user agent (as described in the algorithm described herein) will automatically begin playback of the media resource[p416] as soon as it can do so without stopping.

Note

Authors are urged to use the autoplay[p436] attribute rather than using script to trigger automatic playback, as this allows the user to override the automatic playback when it is not desired, e.g. when using a screen reader. Authors are also encouraged to consider not using the automatic playback behavior at all, and instead to let the user agent wait for the user to start playback explicitly.

The **autoplay** IDL attribute must reflect[p105] the content attribute of the same name.

4.8.11.8 Playing the media resource §[p436]

For web developers (non-normative)

***media*.paused**[p437]

Returns true if playback is paused; false otherwise.

***media*.ended**[p438]

Returns true if playback has reached the end of the media resource[p416].

***media*.defaultPlaybackRate**[p439] **[= *value*]**

Returns the default rate of playback, for when the user is not fast-forwarding or reversing through the media resource[p416].

Can be set, to change the default rate of playback.

The default rate has no direct effect on playback, but if the user switches to a fast-forward mode, when they return to the normal playback mode, it is expected that the rate of playback will be returned to the default rate of playback.

***media*.playbackRate [= *value*]**

Returns the current rate playback, where 1.0 is normal speed.

Can be set, to change the rate of playback.

***media*.preservesPitch**

Returns true if pitch-preserving algorithms are used when the playbackRate is not 1.0. The default value is true.

Can be set to false to have the media resource's audio pitch change up or down depending on the playbackRate. This is useful for aesthetic and performance reasons.

***media*.played**

Returns a TimeRanges object that represents the ranges of the media resource that the user agent has played.

***media*.play()**

Sets the paused attribute to false, loading the media resource and beginning playback if necessary. If the playback had ended, will restart it from the start.

***media*.pause()**

Sets the paused attribute to true, loading the media resource if necessary.

The **paused** attribute represents whether the media element is paused or not. The attribute must initially be true.

A media element is a **blocked media element** if its readyState attribute is in the HAVE_NOTHING state, the HAVE_METADATA state, or the HAVE_CURRENT_DATA state, or if the element has paused for user interaction or paused for in-band content.

A media element is said to be **potentially playing** when its paused attribute is false, the element has not ended playback, playback has not stopped due to errors, and the element is not a blocked media element.

Note

A waiting DOM event can be fired as a result of an element that is potentially playing stopping playback due to its readyState attribute changing to a value lower than HAVE_FUTURE_DATA.

A media element is said to be **eligible for autoplay** when all of the following are true:

- its can autoplay flag is true;
- its paused attribute is true;
- it has an autoplay attribute specified;
- its node document's active sandboxing flag set does not have the sandboxed automatic features browsing context flag set; and
- its node document is allowed to use the "autoplay" feature.

A media element is said to be **allowed to play** if the user agent and the system allow media playback in the current context.

Example

For example, a user agent could allow playback only when the media element's Window object has transient activation, but an exception could be made to allow playback while muted.

A media element is said to have **ended playback** when:

- The element's readyState attribute is HAVE_METADATA or greater, and
- Either:
  - The current playback position is the end of the media resource, and
  - The direction of playback is forwards, and
  - The media element does not have a loop attribute specified.

Or:

- The current playback position[p433] is the earliest possible position[p433], and
- The direction of playback[p441] is backwards.

The **ended** attribute must return true if, the last time the event loop[p1138] reached step 1[p1141], the media element[p415] had ended playback[p437] and the direction of playback[p441] was forwards, and false otherwise.

A media element[p415] is said to have **stopped due to errors** when the element's readyState[p436] attribute is HAVE_METADATA[p434] or greater, and the user agent encounters a non-fatal error[p430] during the processing of the media data[p416], and due to that error, is not able to play the content at the current playback position[p433].

A media element[p415] is said to have **paused for user interaction** when its paused[p437] attribute is false, the readyState[p436] attribute is either HAVE_FUTURE_DATA[p434] or HAVE_ENOUGH_DATA[p434] and the user agent has reached a point in the media resource[p416] where the user has to make a selection for the resource to continue.

It is possible for a media element[p415] to have both ended playback[p437] and paused for user interaction[p438] at the same time.

When a media element[p415] that is potentially playing[p437] stops playing because it has paused for user interaction[p438], the user agent must queue a media element task[p416] given the media element[p415] to fire an event named timeupdate[p469] at the element.

A media element[p415] is said to have **paused for in-band content** when its paused[p437] attribute is false, the readyState[p436] attribute is either HAVE_FUTURE_DATA[p434] or HAVE_ENOUGH_DATA[p434] and the user agent has suspended playback of the media resource[p416] in order to play content that is temporally anchored to the media resource[p416] and has a nonzero length, or to play content that is temporally anchored to a segment of the media resource[p416] but has a length longer than that segment.

Example

One example of when a media element[p415] would be paused for in-band content[p438] is when the user agent is playing audio descriptions[p413] from an external WebVTT file, and the synthesized speech generated for a cue is longer than the time between the text track cue start time[p452] and the text track cue end time[p452].

When the current playback position[p433] reaches the end of the media resource[p416] when the direction of playback[p441] is forwards, then the user agent must follow these steps:

1. If the media element[p415] has a loop[p434] attribute specified, then seek[p444] to the earliest possible position[p433] of the media resource[p416] and return.
2. As defined above, the ended[p438] IDL attribute starts returning true once the event loop[p1138] returns to step 1[p1141].
3. Queue a media element task[p416] given the media element[p415] and the following steps:
    1. Fire an event named timeupdate[p469] at the media element[p415].
    2. If the media element[p415] has ended playback[p437], the direction of playback[p441] is forwards, and paused[p437] is false, then:
        1. Set the paused[p437] attribute to true.
        2. Fire an event named pause[p469] at the media element[p415].
        3. Take pending play promises[p439] and reject pending play promises[p439] with the result and an "AbortError" DOMException.
    3. Fire an event named ended[p469] at the media element[p415].

When the current playback position[p433] reaches the earliest possible position[p433] of the media resource[p416] when the direction of playback[p441] is backwards, then the user agent must only queue a media element task[p416] given the media element[p415] to fire an event named timeupdate[p469] at the element.

Note

The word "reaches" here does not imply that the current playback position[p433] needs to have changed during normal playback; it could be via seeking[p444], for instance.

The **defaultPlaybackRate** attribute gives the desired speed at which the media resource[p416] is to play, as a multiple of its intrinsic speed. The attribute is mutable: on getting it must return the last value it was set to, or 1.0 if it hasn't yet been set; on setting the attribute must be set to the new value.

Note

The defaultPlaybackRate[p439] is used by the user agent when it exposes a user interface to the user[p465].

The **playbackRate** attribute gives the effective playback rate, which is the speed at which the media resource[p416] plays, as a multiple of its intrinsic speed. If it is not equal to the defaultPlaybackRate[p439], then the implication is that the user is using a feature such as fast forward or slow motion playback. The attribute is mutable: on getting it must return the last value it was set to, or 1.0 if it hasn't yet been set; on setting, the user agent must follow these steps:

1. If the given value is not supported by the user agent, then throw a "NotSupportedError" DOMException.
2. Set playbackRate[p439] to the new value, and if the element is potentially playing[p437], change the playback speed.

When the defaultPlaybackRate[p439] or playbackRate[p439] attributes change value (either by being set by script or by being changed directly by the user agent, e.g. in response to user control), the user agent must queue a media element task[p416] given the media element[p415] to fire an event named ratechange[p469] at the media element[p415]. The user agent must process attribute changes smoothly and must not introduce any perceivable gaps or muting of playback in response.

The **preservesPitch** getter steps are to return true if a pitch-preserving algorithm is in effect during playback. The setter steps are to correspondingly switch the pitch-preserving algorithm on or off, without any perceivable gaps or muting of playback. By default, such a pitch-preserving algorithm must be in effect (i.e., the getter will initially return true).

The **played** attribute must return a new static normalized TimeRanges object[p467] that represents the ranges of points on the media timeline[p431] of the media resource[p416] reached through the usual monotonic increase of the current playback position[p433] during normal playback, if any, at the time the attribute is evaluated.

⚠Warning!

Returning a new object each time is a bad pattern for attribute getters and is only enshrined here as it would be costly to change it. It is not to be copied to new APIs.

Each media element[p415] has a **list of pending play promises**, which must initially be empty.

To **take pending play promises** for a media element[p415], the user agent must run the following steps:

1. Let *promises* be an empty list of promises.
2. Copy the media element[p415]'s list of pending play promises[p439] to *promises*.
3. Clear the media element[p415]'s list of pending play promises[p439].
4. Return *promises*.

To **resolve pending play promises** for a media element[p415] with a list of promises *promises*, the user agent must resolve each promise in *promises* with undefined.

To **reject pending play promises** for a media element[p415] with a list of promises *promises* and an exception name *error*, the user agent must reject each promise in *promises* with *error*.

To **notify about playing** for a media element[p415], the user agent must run the following steps:

1. Take pending play promises[p439] and let *promises* be the result.
2. Queue a media element task[p416] given the element and the following steps:
    1. Fire an event named playing[p469] at the element.
    2. Resolve pending play promises[p439] with *promises*.

When the **play()** method on a media element[p415] is invoked, the user agent must run the following steps.

1. If the media element[p415] is not allowed to play[p437], then return a promise rejected with a "NotAllowedError" DOMException.

2. If the media element[p415]'s error[p417] attribute is not null and its code[p417] is MEDIA_ERR_SRC_NOT_SUPPORTED[p417], then return a promise rejected with a "NotSupportedError" DOMException.

   Note

   This means that the dedicated media source failure steps[p423] have run. Playback is not possible until the media element load algorithm[p420] clears the error[p417] attribute.

3. Let *promise* be a new promise and append *promise* to the list of pending play promises[p439].

4. Run the internal play steps[p440] for the media element[p415].

5. Return *promise*.

The **internal play steps** for a media element[p415] are as follows:

1. If the media element[p415]'s networkState[p419] attribute has the value NETWORK_EMPTY[p419], invoke the media element[p415]'s resource selection algorithm[p421].

2. If the playback has ended[p437] and the direction of playback[p441] is forwards, seek[p444] to the earliest possible position[p433] of the media resource[p416].

   Note

   This will cause[p445] the user agent to queue a media element task[p416] given the media element[p415] to fire an event named timeupdate[p469] at the media element[p415].

3. If the media element[p415]'s paused[p437] attribute is true, then:

   1. Change the value of paused[p437] to false.

   2. If the show poster flag[p433] is true, set the element's show poster flag[p433] to false and run the *time marches on[p442]* steps.

   3. Queue a media element task[p416] given the media element[p415] to fire an event named play[p469] at the element.

   4. If the media element[p415]'s readyState[p436] attribute has the value HAVE_NOTHING[p434], HAVE_METADATA[p434], or HAVE_CURRENT_DATA[p434], queue a media element task[p416] given the media element[p415] to fire an event named waiting[p469] at the element.

      Otherwise, the media element[p415]'s readyState[p436] attribute has the value HAVE_FUTURE_DATA[p434] or HAVE_ENOUGH_DATA[p434]: notify about playing[p439] for the element.

4. Otherwise, if the media element[p415]'s readyState[p436] attribute has the value HAVE_FUTURE_DATA[p434] or HAVE_ENOUGH_DATA[p434], take pending play promises[p439] and queue a media element task[p416] given the media element[p415] to resolve pending play promises[p439] with the result.

   Note

   The media element is already playing. However, it's possible that promise *will be rejected[p439] before the queued task is run.*

5. Set the media element[p415]'s can autoplay flag[p420] to false.

When the **pause()** method is invoked, and when the user agent is required to pause the media element[p415], the user agent must run the following steps:

1. If the media element[p415]'s networkState[p419] attribute has the value NETWORK_EMPTY[p419], invoke the media element[p415]'s resource selection algorithm[p421].

2. Run the internal pause steps[p440] for the media element[p415].

The **internal pause steps** for a media element[p415] are as follows:

1. Set the media element[p415]'s can autoplay flag[p420] to false.

2. If the media element's paused attribute is false, run the following steps:

    1. Change the value of paused to true.

    2. Take pending play promises and let *promises* be the result.

    3. Queue a media element task given the media element and the following steps:

        1. Fire an event named timeupdate at the element.

        2. Fire an event named pause at the element.

        3. Reject pending play promises with *promises* and an "AbortError" DOMException.

    4. Set the official playback position to the current playback position.

If the element's playbackRate is positive or zero, then the **direction of playback** is forwards. Otherwise, it is backwards.

When a media element is potentially playing and its Document is a fully active Document, its current playback position must increase monotonically at the element's playbackRate units of media time per unit time of the media timeline's clock. (This specification always refers to this as an *increase*, but that increase could actually be a *de*crease if the element's playbackRate is negative.)

Note

The element's playbackRate can be 0.0, in which case the current playback position doesn't move, despite playback not being paused (paused doesn't become true, and the pause event doesn't fire).

Note

This specification doesn't define how the user agent achieves the appropriate playback rate — depending on the protocol and media available, it is plausible that the user agent could negotiate with the server to have the server provide the media data at the appropriate rate, so that (except for the period between when the rate is changed and when the server updates the stream's playback rate) the client doesn't actually have to drop or interpolate any frames.

Any time the user agent provides a stable state, the official playback position must be set to the current playback position.

While the direction of playback is backwards, any corresponding audio must be muted. While the element's playbackRate is so low or so high that the user agent cannot play audio usefully, the corresponding audio must also be muted. If the element's playbackRate is not 1.0 and preservesPitch is true, the user agent must apply pitch adjustment to preserve the original pitch of the audio. Otherwise, the user agent must speed up or slow down the audio without any pitch adjustment.

When a media element is potentially playing, its audio data played must be synchronized with the current playback position, at the element's effective media volume. The user agent must play the audio from audio tracks that were enabled when the event loop last reached step 1.

When a media element is not potentially playing, audio must not play for the element.

Media elements that are potentially playing while not in a document must not play any video, but should play any audio component. Media elements must not stop playing just because all references to them have been removed; only once a media element is in a state where no further audio could ever be played by that element may the element be garbage collected.

Note

It is possible for an element to which no explicit references exist to play audio, even if such an element is not still actively playing: for instance, it could be unpaused but stalled waiting for content to buffer, or it could be still buffering, but with a suspend event listener that begins playback. Even a media element whose media resource has no audio tracks could eventually play audio again if it had an event listener that changes the media resource.

Each media element has a **list of newly introduced cues**, which must be initially empty. Whenever a text track cue is added to the list of cues of a text track that is in the list of text tracks for a media element, that cue must be added to the media element's list of newly introduced cues. Whenever a text track is added to the list of text tracks for a media element, all of the cues in that text track's list of cues must be added to the media element's list of newly introduced cues. When a media element's list of newly introduced cues has new cues added while the media element's show poster

flag[p433] is not set, then the user agent must run the *time marches on*[p442] steps.

When a text track cue[p452] is removed from the list of cues[p451] of a text track[p450] that is in the list of text tracks[p450] for a media element[p415], and whenever a text track[p450] is removed from the list of text tracks[p450] of a media element[p415], if the media element[p415]'s show poster flag[p433] is not set, then the user agent must run the *time marches on*[p442] steps.

When the current playback position[p433] of a media element[p415] changes (e.g. due to playback or seeking), the user agent must run the *time marches on*[p442] steps. To support use cases that depend on the timing accuracy of cue event firing, such as synchronizing captions with shot changes in a video, user agents should fire cue events as close as possible to their position on the media timeline, and ideally within 20 milliseconds. If the current playback position[p433] changes while the steps are running, then the user agent must wait for the steps to complete, and then must immediately rerun the steps. These steps are thus run as often as possible or needed.

Note

If one iteration takes a long time, this can cause short duration cues[p452] to be skipped over as the user agent rushes ahead to "catch up", so these cues will not appear in the `activeCues`[p460] *list.*

The ***time marches on*** steps are as follows:

1. Let *current cues* be a list of cues[p452], initialized to contain all the cues[p452] of all the hidden[p451] or showing[p451] text tracks[p450] of the media element[p415] (not the disabled[p451] ones) whose start times[p452] are less than or equal to the current playback position[p433] and whose end times[p452] are greater than the current playback position[p433].

2. Let *other cues* be a list of cues[p452], initialized to contain all the cues[p452] of hidden[p451] and showing[p451] text tracks[p450] of the media element[p415] that are not present in *current cues*.

3. Let *last time* be the current playback position[p433] at the time this algorithm was last run for this media element[p415], if this is not the first time it has run.

4. If the current playback position[p433] has, since the last time this algorithm was run, only changed through its usual monotonic increase during normal playback, then let *missed cues* be the list of cues[p452] in *other cues* whose start times[p452] are greater than or equal to *last time* and whose end times[p452] are less than or equal to the current playback position[p433]. Otherwise, let *missed cues* be an empty list.

5. Remove all the cues[p452] in *missed cues* that are also in the media element[p415]'s list of newly introduced cues[p441], and then empty the element's list of newly introduced cues[p441].

6. If the time was reached through the usual monotonic increase of the current playback position[p433] during normal playback, and if the user agent has not fired a `timeupdate`[p469] event at the element in the past 15 to 250ms and is not still running event handlers for such an event, then the user agent must queue a media element task[p416] given the media element[p415] to fire an event named `timeupdate`[p469] at the element. (In the other cases, such as explicit seeks, relevant events get fired as part of the overall process of changing the current playback position[p433].)

   Note

   The event thus is not to be fired faster than about 66Hz or slower than 4Hz (assuming the event handlers don't take longer than 250ms to run). User agents are encouraged to vary the frequency of the event based on the system load and the average cost of processing the event each time, so that the UI updates are not any more frequent than the user agent can comfortably handle while decoding the video.

7. If all of the cues[p452] in *current cues* have their text track cue active flag[p453] set, none of the cues[p452] in *other cues* have their text track cue active flag[p453] set, and *missed cues* is empty, then return.

8. If the time was reached through the usual monotonic increase of the current playback position[p433] during normal playback, and there are cues[p452] in *other cues* that have their text track cue pause-on-exit flag[p452] set and that either have their text track cue active flag[p453] set or are also in *missed cues*, then immediately[p44] pause[p440] the media element[p415].

   Note

   In the other cases, such as explicit seeks, playback is not paused by going past the end time of a cue[p452], even if that cue[p452] has its text track cue pause-on-exit flag[p452] set.

9. Let *events* be a list of tasks[p1139], initially empty. Each task[p1139] in this list will be associated with a text track[p450], a text track cue[p452], and a time, which are used to sort the list before the tasks[p1139] are queued.

   Let *affected tracks* be a list of text tracks[p450], initially empty.

When the steps below say to **prepare an event** named *event* for a text track cue[p452] *target* with a time *time*, the user agent must run these steps:

1. Let *track* be the text track[p450] with which the text track cue[p452] *target* is associated.
2. Create a task[p1139] to fire an event named *event* at *target*.
3. Add the newly created task[p1139] to *events*, associated with the time *time*, the text track[p450] *track*, and the text track cue[p452] *target*.
4. Add *track* to *affected tracks*.

10. For each text track cue[p452] in *missed cues*, prepare an event[p443] named `enter`[p470] for the `TextTrackCue`[p462] object with the text track cue start time[p452].
11. For each text track cue[p452] in *other cues* that either has its text track cue active flag[p453] set or is in *missed cues*, prepare an event[p443] named `exit`[p470] for the `TextTrackCue`[p462] object with the later of the text track cue end time[p452] and the text track cue start time[p452].
12. For each text track cue[p452] in *current cues* that does not have its text track cue active flag[p453] set, prepare an event[p443] named `enter`[p470] for the `TextTrackCue`[p462] object with the text track cue start time[p452].
13. Sort the tasks[p1139] in *events* in ascending time order (tasks[p1139] with earlier times first).

    Further sort tasks[p1139] in *events* that have the same time by the relative text track cue order[p453] of the text track cues[p452] associated with these tasks[p1139].

    Finally, sort tasks[p1139] in *events* that have the same time and same text track cue order[p453] by placing tasks[p1139] that fire `enter`[p470] events before those that fire `exit`[p470] events.
14. Queue a media element task[p416] given the media element[p415] for each task[p1139] in *events*, in list order.
15. Sort *affected tracks* in the same order as the text tracks[p450] appear in the media element[p415]'s list of text tracks[p450], and remove duplicates.
16. For each text track[p450] in *affected tracks*, in the list order, queue a media element task[p416] given the media element[p415] to fire an event named `cuechange`[p469] at the `TextTrack`[p458] object, and, if the text track[p450] has a corresponding `track`[p412] element, to then fire an event named `cuechange`[p469] at the `track`[p412] element as well.
17. Set the text track cue active flag[p453] of all the cues[p452] in the *current cues*, and unset the text track cue active flag[p453] of all the cues[p452] in the *other cues*.
18. Run the rules for updating the text track rendering[p451] of each of the text tracks[p450] in *affected tracks* that are showing[p451], providing the text track[p450]'s text track language[p451] as the fallback language if it is not the empty string. For example, for text tracks[p450] based on WebVTT, the rules for updating the display of WebVTT text tracks. [WEBVTT][p1502]

For the purposes of the algorithm above, a text track cue[p452] is considered to be part of a text track[p450] only if it is listed in the text track list of cues[p451], not merely if it is associated with the text track[p450].

Note

If the media element[p415]'s node document stops being a fully active[p1017] document, then the playback will stop[p441] until the document is active again.

When a media element[p415] is removed from a `Document`[p47], the user agent must run the following steps:

1. Await a stable state[p1146], allowing the task[p1139] that removed the media element[p415] from the `Document`[p131] to continue. The synchronous section[p1146] consists of all the remaining steps of this algorithm. (Steps in the synchronous section[p1146] are marked with ⌛.)
2. ⌛ If the media element[p415] is in a document, return.
3. ⌛ Run the internal pause steps[p440] for the media element[p415].

4.8.11.9 Seeking §[p444]

For web developers (non-normative)

***media*.seeking[p444]**

Returns true if the user agent is currently seeking.

***media*.seekable[p445]**

Returns a TimeRanges[p467] object that represents the ranges of the media resource[p416] to which it is possible for the user agent to seek.

***media*.fastSeek[p444](*time*)**

Seeks to near the given *time* as fast as possible, trading precision for speed. (To seek to a precise time, use the currentTime[p433] attribute.)

This does nothing if the media resource has not been loaded.

The **seeking** attribute must initially have the value false.

The **fastSeek(*time*)** method must seek[p444] to the time given by *time*, with the *approximate-for-speed* flag set.

When the user agent is required to **seek** to a particular *new playback position* in the media resource[p416], optionally with the *approximate-for-speed* flag set, it means that the user agent must run the following steps. This algorithm interacts closely with the event loop[p1138] mechanism; in particular, it has a synchronous section[p1146] (which is triggered as part of the event loop[p1138] algorithm). Steps in that section are marked with ⌛.

1. Set the media element[p415]'s show poster flag[p433] to false.
2. If the media element[p415]'s readyState[p436] is HAVE_NOTHING[p434], return.
3. If the element's seeking[p444] IDL attribute is true, then another instance of this algorithm is already running. Abort that other instance of the algorithm without waiting for the step that it is running to complete.
4. Set the seeking[p444] IDL attribute to true.
5. If the seek was in response to a DOM method call or setting of an IDL attribute, then continue the script. The remainder of these steps must be run in parallel[p44]. With the exception of the steps marked with ⌛, they could be aborted at any time by another instance of this algorithm being invoked.
6. If the *new playback position* is later than the end of the media resource[p416], then let it be the end of the media resource[p416] instead.
7. If the *new playback position* is less than the earliest possible position[p433], let it be that position instead.
8. If the (possibly now changed) *new playback position* is not in one of the ranges given in the seekable[p445] attribute, then let it be the position in one of the ranges given in the seekable[p445] attribute that is the nearest to the *new playback position*. If two positions both satisfy that constraint (i.e. the *new playback position* is exactly in the middle between two ranges in the seekable[p445] attribute), then use the position that is closest to the current playback position[p433]. If there are no ranges given in the seekable[p445] attribute, then set the seeking[p444] IDL attribute to false and return.
9. If the *approximate-for-speed* flag is set, adjust the *new playback position* to a value that will allow for playback to resume promptly. If *new playback position* before this step is before current playback position[p433], then the adjusted *new playback position* must also be before the current playback position[p433]. Similarly, if the *new playback position* before this step is after current playback position[p433], then the adjusted *new playback position* must also be after the current playback position[p433].

   Example

   For example, the user agent could snap to a nearby key frame, so that it doesn't have to spend time decoding then discarding intermediate frames before resuming playback.

10. Queue a media element task[p416] given the media element[p415] to fire an event named seeking[p469] at the element.
11. Set the current playback position[p433] to the *new playback position*.

    Note

    If the media element[p415] was potentially playing[p437] immediately before it started seeking, but seeking caused its readyState[p436] attribute to change to a value lower than HAVE_FUTURE_DATA[p434], then a waiting[p469] event will be

fired[p435] *at the element.*

Note

This step sets the current playback position[p433]*, and thus can immediately trigger other conditions, such as the rules regarding when playback "reaches the end of the media resource*[p438]*" (part of the logic that handles looping), even before the user agent is actually able to render the media data for that position (as determined in the next step).*

Note

The `currentTime`[p433] *attribute returns the official playback position*[p433]*, not the current playback position*[p433]*, and therefore gets updated before script execution, separate from this algorithm.*

12. Wait until the user agent has established whether or not the media data[p416] for the *new playback position* is available, and, if it is, until it has decoded enough data to play back that position.

13. Await a stable state[p1146]. The synchronous section[p1146] consists of all the remaining steps of this algorithm. (Steps in the synchronous section[p1146] are marked with ⌛.)

14. ⌛ Set the `seeking`[p444] IDL attribute to false.

15. ⌛ Run the time marches on[p442] steps.

16. ⌛ Queue a media element task[p416] given the media element[p415] to fire an event named `timeupdate`[p469] at the element.

17. ⌛ Queue a media element task[p416] given the media element[p415] to fire an event named `seeked`[p469] at the element.

The **`seekable`** attribute must return a new static normalized `TimeRanges` object[p467] that represents the ranges of the media resource[p416], if any, that the user agent is able to seek to, at the time the attribute is evaluated.

Note

If the user agent can seek to anywhere in the media resource[p416]*, e.g. because it is a simple movie file and the user agent and the server support HTTP Range requests, then the attribute would return an object with one range, whose start is the time of the first frame (the earliest possible position*[p433]*, typically zero), and whose end is the same as the time of the first frame plus the* `duration`[p433] *attribute's value (which would equal the time of the last frame, and might be positive Infinity).*

Note

The range might be continuously changing, e.g. if the user agent is buffering a sliding window on an infinite stream. This is the behavior seen with DVRs viewing live TV, for instance.

⚠Warning!

Returning a new object each time is a bad pattern for attribute getters and is only enshrined here as it would be costly to change it. It is not to be copied to new APIs.

User agents should adopt a very liberal and optimistic view of what is seekable. User agents should also buffer recent content where possible to enable seeking to be fast.

Example

For instance, consider a large video file served on an HTTP server without support for HTTP Range requests. A browser *could* implement this by only buffering the current frame and data obtained for subsequent frames, never allow seeking, except for seeking to the very start by restarting the playback. However, this would be a poor implementation. A high quality implementation would buffer the last few minutes of content (or more, if sufficient storage space is available), allowing the user to jump back and rewatch something surprising without any latency, and would in addition allow arbitrary seeking by reloading the file from the start if necessary, which would be slower but still more convenient than having to literally restart the video and watch it all the way through just to get to an earlier unbuffered spot.

Media resources[p416] might be internally scripted or interactive. Thus, a media element[p415] could play in a non-linear fashion. If this happens, the user agent must act as if the algorithm for seeking[p444] was used whenever the current playback position[p433] changes in a discontinuous fashion (so that the relevant events fire).

4.8.11.10 Media resources with multiple media tracks §[p446]

A media resource[p416] can have multiple embedded audio and video tracks. For example, in addition to the primary video and audio tracks, a media resource[p416] could have foreign-language dubbed dialogues, director's commentaries, audio descriptions, alternative angles, or sign-language overlays.

For web developers (non-normative)

***media*.audioTracks**[p446]

Returns an AudioTrackList[p446] object representing the audio tracks available in the media resource[p416].

***media*.videoTracks**[p446]

Returns a VideoTrackList[p446] object representing the video tracks available in the media resource[p416].

The **audioTracks** attribute of a media element[p415] must return a live[p48] AudioTrackList[p446] object representing the audio tracks available in the media element[p415]'s media resource[p416].

The **videoTracks** attribute of a media element[p415] must return a live[p48] VideoTrackList[p446] object representing the video tracks available in the media element[p415]'s media resource[p416].

Note

There are only ever one AudioTrackList[p446] object and one VideoTrackList[p446] object per media element[p415], even if another media resource[p416] is loaded into the element: the objects are reused. (The AudioTrack[p446] and VideoTrack[p447] objects are not, though.)

4.8.11.10.1 AudioTrackList[p446] and VideoTrackList[p446] objects §[p446]

The AudioTrackList[p446] and VideoTrackList[p446] interfaces are used by attributes defined in the previous section.

IDL

```
[Exposed=Window]
interface AudioTrackList : EventTarget {
  readonly attribute unsigned long length;
  getter AudioTrack (unsigned long index);
  AudioTrack? getTrackById(DOMString id);

  attribute EventHandler onchange;
  attribute EventHandler onaddtrack;
  attribute EventHandler onremovetrack;
};

[Exposed=Window]
interface AudioTrack {
  readonly attribute DOMString id;
  readonly attribute DOMString kind;
  readonly attribute DOMString label;
  readonly attribute DOMString language;
  attribute boolean enabled;
};

[Exposed=Window]
interface VideoTrackList : EventTarget {
  readonly attribute unsigned long length;
  getter VideoTrack (unsigned long index);
  VideoTrack? getTrackById(DOMString id);
  readonly attribute long selectedIndex;

  attribute EventHandler onchange;
  attribute EventHandler onaddtrack;
  attribute EventHandler onremovetrack;
};
```

```
[Exposed=Window]
interface VideoTrack {
  readonly attribute DOMString id;
  readonly attribute DOMString kind;
  readonly attribute DOMString label;
  readonly attribute DOMString language;
  attribute boolean selected;
};
```

For web developers (non-normative)

***media*.audioTracks[p446].length[p448]**

***media*.videoTracks[p446].length[p448]**

Returns the number of tracks in the list.

***audioTrack* = *media*.audioTracks[p446][*index*]**

***videoTrack* = *media*.videoTracks[p446][*index*]**

Returns the specified AudioTrack[p446] or VideoTrack[p447] object.

***audioTrack* = *media*.audioTracks[p446].getTrackById[p448](*id*)**

***videoTrack* = *media*.videoTracks[p446].getTrackById[p448](*id*)**

Returns the AudioTrack[p446] or VideoTrack[p447] object with the given identifier, or null if no track has that identifier.

***audioTrack*.id[p448]**

***videoTrack*.id[p448]**

Returns the ID of the given track. This is the ID that can be used with a fragment if the format supports media fragment syntax, and that can be used with the `getTrackById()` method.

***audioTrack*.kind[p448]**

***videoTrack*.kind[p448]**

Returns the category the given track falls into. The possible track categories[p448] are given below.

***audioTrack*.label[p449]**

***videoTrack*.label[p449]**

Returns the label of the given track, if known, or the empty string otherwise.

***audioTrack*.language[p449]**

***videoTrack*.language[p449]**

Returns the language of the given track, if known, or the empty string otherwise.

***audioTrack*.enabled[p449] [= *value*]**

Returns true if the given track is active, and false otherwise.

Can be set, to change whether the track is enabled or not. If multiple audio tracks are enabled simultaneously, they are mixed.

***media*.videoTracks[p446].selectedIndex[p449]**

Returns the index of the currently selected track, if any, or −1 otherwise.

***videoTrack*.selected[p449] [= *value*]**

Returns true if the given track is active, and false otherwise.

Can be set, to change whether the track is selected or not. Either zero or one video track is selected; selecting a new track while a previous one is selected will unselect the previous one.

An AudioTrackList[p446] object represents a dynamic list of zero or more audio tracks, of which zero or more can be enabled at a time. Each audio track is represented by an AudioTrack[p446] object.

A VideoTrackList[p446] object represents a dynamic list of zero or more video tracks, of which zero or one can be selected at a time. Each video track is represented by a VideoTrack[p447] object.

Tracks in AudioTrackList[p446] and VideoTrackList[p446] objects must be consistently ordered. If the media resource[p416] is in a format that defines an order, then that order must be used; otherwise, the order must be the relative order in which the tracks are declared in the media resource[p416]. The order used is called the *natural order* of the list.

Note

Each track in one of these objects thus has an index; the first has the index 0, and each subsequent track is numbered one higher than the previous one. If a media resource[p416] dynamically adds or removes audio or video tracks, then the indices of the tracks will change dynamically. If the media resource[p416] changes entirely, then all the previous tracks will be removed and replaced with new tracks.

The AudioTrackList[p446] **length** and VideoTrackList[p446] **length** attribute getters must return the number of tracks represented by their objects at the time of getting.

The supported property indices of AudioTrackList[p446] and VideoTrackList[p446] objects at any instant are the numbers from zero to the number of tracks represented by the respective object minus one, if any tracks are represented. If an AudioTrackList[p446] or VideoTrackList[p446] object represents no tracks, it has no supported property indices.

To determine the value of an indexed property for a given index *index* in an AudioTrackList[p446] or VideoTrackList[p446] object *list*, the user agent must return the AudioTrack[p446] or VideoTrack[p447] object that represents the *index*th track in *list*.

The AudioTrackList[p446] **getTrackById(*id*)** and VideoTrackList[p446] **getTrackById(*id*)** methods must return the first AudioTrack[p446] or VideoTrack[p447] object (respectively) in the AudioTrackList[p446] or VideoTrackList[p446] object (respectively) whose identifier is equal to the value of the *id* argument (in the natural order of the list, as defined above). When no tracks match the given argument, the methods must return null.

The AudioTrack[p446] and VideoTrack[p447] objects represent specific tracks of a media resource[p416]. Each track can have an identifier, category, label, and language. These aspects of a track are permanent for the lifetime of the track; even if a track is removed from a media resource[p416]'s AudioTrackList[p446] or VideoTrackList[p446] objects, those aspects do not change.

In addition, AudioTrack[p446] objects can each be enabled or disabled; this is the audio track's *enabled state*. When an AudioTrack[p446] is created, its *enabled state* must be set to false (disabled). The resource fetch algorithm[p424] can override this.

Similarly, a single VideoTrack[p447] object per VideoTrackList[p446] object can be selected, this is the video track's *selection state*. When a VideoTrack[p447] is created, its *selection state* must be set to false (not selected). The resource fetch algorithm[p424] can override this.

The AudioTrack[p446] **id** and VideoTrack[p447] **id** attributes must return the identifier of the track, if it has one, or the empty string otherwise. If the media resource[p416] is in a format that supports media fragment syntax, the identifier returned for a particular track must be the same identifier that would enable the track if used as the name of a track in the track dimension of such a fragment. [INBAND][p1497]

Example

For example, in Ogg files, this would be the Name header field of the track. [OGGSKELETONHEADERS][p1498]

The AudioTrack[p446] **kind** and VideoTrack[p447] **kind** attributes must return the category of the track, if it has one, or the empty string otherwise.

The category of a track is the string given in the first column of the table below that is the most appropriate for the track based on the definitions in the table's second and third columns, as determined by the metadata included in the track in the media resource[p416]. The cell in the third column of a row says what the category given in the cell in the first column of that row applies to; a category is only appropriate for an audio track if it applies to audio tracks, and a category is only appropriate for video tracks if it applies to video tracks. Categories must only be returned for AudioTrack[p446] objects if they are appropriate for audio, and must only be returned for VideoTrack[p447] objects if they are appropriate for video.

For Ogg files, the Role header field of the track gives the relevant metadata. For DASH media resources, the `Role` element conveys the information. For WebM, only the `FlagDefault` element currently maps to a value. *Sourcing In-band Media Resource Tracks from Media Containers into HTML* has further details. [OGGSKELETONHEADERS][p1498] [DASH][p1495] [WEBMCG][p1501] [INBAND][p1497]

Return values for AudioTrack[p446]'s kind[p448] and VideoTrack[p447]'s kind[p448]

Category	Definition	Applies to...	Examples
"**alternative**"	A possible alternative to the main track, e.g. a different take of a song (audio), or a different angle (video).	Audio and video.	Ogg: "audio/alternate" or "video/alternate"; DASH: "alternate" without "main" and "commentary" roles, and, for audio, without the "dub" role (other roles ignored).
"**captions**"	A version of the main video track with captions burnt in. (For legacy content; new content would use text tracks.)	Video only.	DASH: "caption" and "main" roles together (other roles ignored).
"**descriptions**"	An audio description of a video track.	Audio	Ogg: "audio/audiodesc".

Category	Definition	Applies to...	Examples
		only.	
"**main**"	The primary audio or video track.	Audio and video.	Ogg: "audio/main" or "video/main"; WebM: the "FlagDefault" element is set; DASH: "main" role without "caption", "subtitle", and "dub" roles (other roles ignored).
"**main-desc**"	The primary audio track, mixed with audio descriptions.	Audio only.	AC3 audio in MPEG-2 TS: bsmod=2 and full_svc=1.
"**sign**"	A sign-language interpretation of an audio track.	Video only.	Ogg: "video/sign".
"**subtitles**"	A version of the main video track with subtitles burnt in. (For legacy content; new content would use text tracks.)	Video only.	DASH: "subtitle" and "main" roles together (other roles ignored).
"**translation**"	A translated version of the main audio track.	Audio only.	Ogg: "audio/dub". DASH: "dub" and "main" roles together (other roles ignored).
"**commentary**"	Commentary on the primary audio or video track, e.g. a director's commentary.	Audio and video.	DASH: "commentary" role without "main" role (other roles ignored).
"" (empty string)	No explicit kind, or the kind given by the track's metadata is not recognized by the user agent.	Audio and video.	

The AudioTrack[p446] **label** and VideoTrack[p447] **label** attributes must return the label of the track, if it has one, or the empty string otherwise. [INBAND][p1497]

The AudioTrack[p446] **language** and VideoTrack[p447] **language** attributes must return the BCP 47 language tag of the language of the track, if it has one, or the empty string otherwise. If the user agent is not able to express that language as a BCP 47 language tag (for example because the language information in the media resource[p416]'s format is a free-form string without a defined interpretation), then the method must return the empty string, as if the track had no language. [INBAND][p1497]

The AudioTrack[p446] **enabled** attribute, on getting, must return true if the track is currently enabled, and false otherwise. On setting, it must enable the track if the new value is true, and disable it otherwise. (If the track is no longer in an AudioTrackList[p446] object, then the track being enabled or disabled has no effect beyond changing the value of the attribute on the AudioTrack[p446] object.)

Whenever an audio track in an AudioTrackList[p446] that was disabled is enabled, and whenever one that was enabled is disabled, the user agent must queue a media element task[p416] given the media element[p415] to fire an event named change[p469] at the AudioTrackList[p446] object.

An audio track that has no data for a particular position on the media timeline[p431], or that does not exist at that position, must be interpreted as being silent at that point on the timeline.

The VideoTrackList[p446] **selectedIndex** attribute must return the index of the currently selected track, if any. If the VideoTrackList[p446] object does not currently represent any tracks, or if none of the tracks are selected, it must instead return −1.

The VideoTrack[p447] **selected** attribute, on getting, must return true if the track is currently selected, and false otherwise. On setting, it must select the track if the new value is true, and unselect it otherwise. If the track is in a VideoTrackList[p446], then all the other VideoTrack[p447] objects in that list must be unselected. (If the track is no longer in a VideoTrackList[p446] object, then the track being selected or unselected has no effect beyond changing the value of the attribute on the VideoTrack[p447] object.)

Whenever a track in a VideoTrackList[p446] that was previously not selected is selected, and whenever the selected track in a VideoTrackList[p446] is unselected without a new track being selected in its stead, the user agent must queue a media element task[p416] given the media element[p415] to fire an event named change[p469] at the VideoTrackList[p446] object. This task[p1139] must be queued[p1140] before the task[p1139] that fires the resize[p469] event, if any.

A video track that has no data for a particular position on the media timeline[p431] must be interpreted as being transparent black at that point on the timeline, with the same dimensions as the last frame before that position, or, if the position is before all the data for that track, the same dimensions as the first frame for that track. A track that does not exist at all at the current position must be treated as if it existed but had no data.

Example

For instance, if a video has a track that is only introduced after one hour of playback, and the user selects that track then goes back to the start, then the user agent will act as if that track started at the start of the media resource[p416] but was simply transparent until one hour in.

The following are the event handlers[p1151] (and their corresponding event handler event types[p1154]) that must be supported, as event handler IDL attributes[p1152], by all objects implementing the AudioTrackList[p446] and VideoTrackList[p446] interfaces:

Event handler[p1151]	Event handler event type[p1154]
onchange	change[p469]
onaddtrack	addtrack[p469]
onremovetrack	removetrack[p469]

4.8.11.10.2 Selecting specific audio and video tracks declaratively §[p45]

The audioTracks[p446] and videoTracks[p446] attributes allow scripts to select which track should play, but it is also possible to select specific tracks declaratively, by specifying particular tracks in the fragment of the URL of the media resource[p416]. The format of the fragment depends on the MIME type of the media resource[p416]. [RFC2046][p1499] [URL][p1501]

Example

In this example, a video that uses a format that supports media fragment syntax is embedded in such a way that the alternative angles labeled "Alternative" are enabled instead of the default video track.

```
<video src="myvideo#track=Alternative"></video>
```

4.8.11.11 Timed text tracks §[p45]

4.8.11.11.1 Text track model §[p45]

A media element[p415] can have a group of associated **text tracks**, known as the media element[p415]'s **list of text tracks**. The text tracks[p450] are sorted as follows:

1. The text tracks[p450] corresponding to track[p412] element children of the media element[p415], in tree order.
2. Any text tracks[p450] added using the addTextTrack()[p459] method, in the order they were added, oldest first.
3. Any media-resource-specific text tracks[p453] (text tracks[p450] corresponding to data in the media resource[p416]), in the order defined by the media resource[p416]'s format specification.

A text track[p450] consists of:

The kind of text track

This decides how the track is handled by the user agent. The kind is represented by a string. The possible strings are:

- **subtitles**
- **captions**
- **descriptions**
- **chapters**
- **metadata**

The kind of track[p450] can change dynamically, in the case of a text track[p450] corresponding to a track[p412] element.

A label

This is a human-readable string intended to identify the track for the user.

The label of a track[p450] can change dynamically, in the case of a text track[p450] corresponding to a track[p412] element.

When a text track label[p450] is the empty string, the user agent should automatically generate an appropriate label from the text track's other properties (e.g. the kind of text track and the text track's language) for use in its user interface. This automatically-generated label is not exposed in the API.

An in-band metadata track dispatch type

This is a string extracted from the media resource[p416] specifically for in-band metadata tracks to enable such tracks to be dispatched to different scripts in the document.

Example

For example, a traditional TV station broadcast streamed on the web and augmented with web-specific interactive features could include text tracks with metadata for ad targeting, trivia game data during game shows, player states during sports games, recipe information during food programs, and so forth. As each program starts and ends, new tracks might be added or removed from the stream, and as each one is added, the user agent could bind them to dedicated script modules using the value of this attribute.

Other than for in-band metadata text tracks, the in-band metadata track dispatch type[p450] is the empty string. How this value is populated for different media formats is described in steps to expose a media-resource-specific text track[p453].

A language

This is a string (a BCP 47 language tag) representing the language of the text track's cues. [BCP47][p1493]

The language of a text track[p451] can change dynamically, in the case of a text track[p450] corresponding to a `track`[p412] element.

A readiness state

One of the following:

Not loaded

Indicates that the text track's cues have not been obtained.

Loading

Indicates that the text track is loading and there have been no fatal errors encountered so far. Further cues might still be added to the track by the parser.

Loaded

Indicates that the text track has been loaded with no fatal errors.

Failed to load

Indicates that the text track was enabled, but when the user agent attempted to obtain it, this failed in some way (e.g., URL could not be parsed[p98], network error, unknown text track format). Some or all of the cues are likely missing and will not be obtained.

The readiness state[p451] of a text track[p450] changes dynamically as the track is obtained.

A mode

One of the following:

Disabled

Indicates that the text track is not active. Other than for the purposes of exposing the track in the DOM, the user agent is ignoring the text track. No cues are active, no events are fired, and the user agent will not attempt to obtain the track's cues.

Hidden

Indicates that the text track is active, but that the user agent is not actively displaying the cues. If no attempt has yet been made to obtain the track's cues, the user agent will perform such an attempt momentarily. The user agent is maintaining a list of which cues are active, and events are being fired accordingly.

Showing

Indicates that the text track is active. If no attempt has yet been made to obtain the track's cues, the user agent will perform such an attempt momentarily. The user agent is maintaining a list of which cues are active, and events are being fired accordingly. In addition, for text tracks whose kind[p450] is `subtitles`[p450] or `captions`[p450], the cues are being overlaid on the video as appropriate; for text tracks whose kind[p450] is `descriptions`[p450], the user agent is making the cues available to the user in a non-visual fashion; and for text tracks whose kind[p450] is `chapters`[p450], the user agent is making available to the user a mechanism by which the user can navigate to any point in the media resource[p416] by selecting a cue.

A list of zero or more cues

A list of text track cues[p452], along with **rules for updating the text track rendering**. For example, for WebVTT, the rules for updating the display of WebVTT text tracks. [WEBVTT][p1502]

The list of cues of a text track[p451] can change dynamically, either because the text track[p450] has not yet been loaded[p451] or is still loading[p451], or due to DOM manipulation.

Each text track[p450] has a corresponding `TextTrack`[p458] object.

Each media element[p415] has a **list of pending text tracks**, which must initially be empty, a **blocked-on-parser** flag, which must initially be false, and a **did-perform-automatic-track-selection** flag, which must also initially be false.

When the user agent is required to **populate the list of pending text tracks** of a media element[p415], the user agent must add to the element's list of pending text tracks[p452] each text track[p450] in the element's list of text tracks[p450] whose text track mode[p451] is not disabled[p451] and whose text track readiness state[p451] is loading[p451].

Whenever a `track`[p412] element's parent node changes, the user agent must remove the corresponding text track[p450] from any list of pending text tracks[p452] that it is in.

Whenever a text track[p450]'s text track readiness state[p451] changes to either loaded[p451] or failed to load[p451], the user agent must remove it from any list of pending text tracks[p452] that it is in.

When a media element[p415] is created by an HTML parser[p1289] or XML parser[p1402], the user agent must set the element's blocked-on-parser[p452] flag to true. When a media element[p415] is popped off the stack of open elements[p1304] of an HTML parser[p1289] or XML parser[p1402], the user agent must honor user preferences for automatic text track selection[p455], populate the list of pending text tracks[p452], and set the element's blocked-on-parser[p452] flag to false.

The text tracks[p450] of a media element[p415] are **ready** when both the element's list of pending text tracks[p452] is empty and the element's blocked-on-parser[p452] flag is false.

Each media element[p415] has a **pending text track change notification flag**, which must initially be unset.

Whenever a text track[p450] that is in a media element[p415]'s list of text tracks[p450] has its text track mode[p451] change value, the user agent must run the following steps for the media element[p415]:

1. If the media element[p415]'s pending text track change notification flag[p452] is set, return.
2. Set the media element[p415]'s pending text track change notification flag[p452].
3. Queue a media element task[p416] given the media element[p415] to run these steps:
    1. Unset the media element[p415]'s pending text track change notification flag[p452].
    2. Fire an event named `change`[p469] at the media element[p415]'s `textTracks`[p458] attribute's `TextTrackList`[p457] object.
4. If the media element[p415]'s show poster flag[p433] is not set, run the *time marches on*[p442] steps.

The task source[p1139] for the tasks[p1139] listed in this section is the DOM manipulation task source[p1149].

A **text track cue** is the unit of time-sensitive data in a text track[p450], corresponding for instance for subtitles and captions to the text that appears at a particular time and disappears at another time.

Each text track cue[p452] consists of:

An identifier

An arbitrary string.

A start time

The time, in seconds and fractions of a second, that describes the beginning of the range of the media data[p416] to which the cue applies.

An end time

The time, in seconds and fractions of a second, that describes the end of the range of the media data[p416] to which the cue applies, or positive Infinity for an unbounded text track cue[p453].

A pause-on-exit flag

A boolean indicating whether playback of the media resource[p416] is to pause when the end of the range to which the cue applies is reached.

Some additional format-specific data

Additional fields, as needed for the format, including the actual data of the cue. For example, WebVTT has a text track cue writing direction and so forth. [WEBVTT][p1502]

An **unbounded text track cue** is a text track cue with a text track cue end time[p452] set to positive Infinity. An active unbounded text track cue[p453] cannot become inactive through the usual monotonic increase of the current playback position[p433] during normal playback (e.g. a metadata cue for a chapter in a live event with no announced end time.)

Note

The text track cue start time[p452] and text track cue end time[p452] can be negative. (The current playback position[p433] can never be negative, though, so cues entirely before time zero cannot be active.)

Each text track cue[p452] has a corresponding TextTrackCue[p462] object (or more specifically, an object that inherits from TextTrackCue[p462] — for example, WebVTT cues use the VTTCue interface). A text track cue[p452]'s in-memory representation can be dynamically changed through this TextTrackCue[p462] API. [WEBVTT][p1502]

A text track cue[p452] is associated with rules for updating the text track rendering[p451], as defined by the specification for the specific kind of text track cue[p452]. These rules are used specifically when the object representing the cue is added to a TextTrack[p458] object using the addCue()[p460] method.

In addition, each text track cue[p452] has two pieces of dynamic information:

The *active flag*

This flag must be initially unset. The flag is used to ensure events are fired appropriately when the cue becomes active or inactive, and to make sure the right cues are rendered.

The user agent must synchronously unset this flag whenever the text track cue[p452] is removed from its text track[p450]'s text track list of cues[p451]; whenever the text track[p450] itself is removed from its media element[p415]'s list of text tracks[p450] or has its text track mode[p451] changed to disabled[p451]; and whenever the media element[p415]'s readyState[p436] is changed back to HAVE_NOTHING[p434]. When the flag is unset in this way for one or more cues in text tracks[p450] that were showing[p451] prior to the relevant incident, the user agent must, after having unset the flag for all the affected cues, apply the rules for updating the text track rendering[p451] of those text tracks[p450]. For example, for text tracks[p450] based on WebVTT, the rules for updating the display of WebVTT text tracks. [WEBVTT][p1502]

The *display state*

This is used as part of the rendering model, to keep cues in a consistent position. It must initially be empty. Whenever the text track cue active flag[p453] is unset, the user agent must empty the text track cue display state[p453].

The text track cues[p452] of a media element[p415]'s text tracks[p450] are ordered relative to each other in the **text track cue order**, which is determined as follows: first group the cues[p452] by their text track[p450], with the groups being sorted in the same order as their text tracks[p450] appear in the media element[p415]'s list of text tracks[p450]; then, within each group, cues[p452] must be sorted by their start time[p452], earliest first; then, any cues[p452] with the same start time[p452] must be sorted by their end time[p452], latest first; and finally, any cues[p452] with identical end times[p452] must be sorted in the order they were last added to their respective text track list of cues[p451], oldest first (so e.g. for cues from a WebVTT file, that would initially be the order in which the cues were listed in the file). [WEBVTT][p1502]

4.8.11.11.2 Sourcing in-band text tracks §[p453]

A **media-resource-specific text track** is a text track[p450] that corresponds to data found in the media resource[p416].

Rules for processing and rendering such data are defined by the relevant specifications, e.g. the specification of the video format if the media resource[p416] is a video. Details for some legacy formats can be found in *Sourcing In-band Media Resource Tracks from Media Containers into HTML*. [INBAND][p1497]

When a media resource[p416] contains data that the user agent recognizes and supports as being equivalent to a text track[p450], the user agent runs[p430] the **steps to expose a media-resource-specific text track** with the relevant data, as follows.

1. Associate the relevant data with a new text track[p450] and its corresponding new TextTrack[p458] object. The text track[p450] is a media-resource-specific text track[p453].
2. Set the new text track[p450]'s kind[p450], label[p450], and language[p451] based on the semantics of the relevant data, as defined by the relevant specification. If there is no label in that data, then the label[p450] must be set to the empty string.
3. Associate the text track list of cues[p451] with the rules for updating the text track rendering[p451] appropriate for the format in question.

4. If the new text track's kind is chapters or metadata, then set the text track in-band metadata track dispatch type as follows, based on the type of the media resource:

   ↪ **If the media resource is an Ogg file**

   The text track in-band metadata track dispatch type must be set to the value of the Name header field. [OGGSKELETONHEADERS]

   ↪ **If the media resource is a WebM file**

   The text track in-band metadata track dispatch type must be set to the value of the `CodecID` element. [WEBMCG]

   ↪ **If the media resource is an MPEG-2 file**

   Let *stream type* be the value of the "stream_type" field describing the text track's type in the file's program map section, interpreted as an 8-bit unsigned integer. Let *length* be the value of the "ES_info_length" field for the track in the same part of the program map section, interpreted as an integer as defined by *Generic coding of moving pictures and associated audio information*. Let *descriptor bytes* be the *length* bytes following the "ES_info_length" field. The text track in-band metadata track dispatch type must be set to the concatenation of the *stream type* byte and the zero or more *descriptor bytes* bytes, expressed in hexadecimal using ASCII upper hex digits. [MPEG2]

   ↪ **If the media resource is an MPEG-4 file**

   Let *stsd box* be the first `stsd` box of the first `stbl` box of the first `minf` box of the first `mdia` box of the text track's `trak` box in the first `moov` box of the file, or null if no such `stsd` box exists. If *stsd box* is null, or if *stsd box* has neither a `mett` box nor a `metx` box, then the text track in-band metadata track dispatch type must be set to the empty string. Otherwise, if *stsd box* has a `mett` box, then the text track in-band metadata track dispatch type must be set to the concatenation of the string "`mett`", a U+0020 SPACE character, and the value of the first `mime_format` field of the first `mett` box of *stsd box*, or the empty string if that field is absent in that box. Otherwise, if *stsd box* has no `mett` box but has a `metx` box, then the text track in-band metadata track dispatch type must be set to the concatenation of the string "`metx`", a U+0020 SPACE character, and the value of the first `namespace` field of the first `metx` box of *stsd box*, or the empty string if that field is absent in that box. [MPEG4]

5. Populate the new text track's list of cues with the cues parsed so far, following the guidelines for exposing cues, and begin updating it dynamically as necessary.

6. Set the new text track's readiness state to loaded.

7. Set the new text track's mode to the mode consistent with the user's preferences and the requirements of the relevant specification for the data.

   Note

   For instance, if there are no other active subtitles, and this is a forced subtitle track (a subtitle track giving subtitles in the audio track's primary language, but only for audio that is actually in another language), then those subtitles might be activated here.

8. Add the new text track to the media element's list of text tracks.

9. Fire an event named `addtrack` at the media element's `textTracks` attribute's `TextTrackList` object, using `TrackEvent`, with the `track` attribute initialized to the text track's `TextTrack` object.

4.8.11.11.3 Sourcing out-of-band text tracks §

When a `track` element is created, it must be associated with a new text track (with its value set as defined below) and its corresponding new `TextTrack` object.

The text track kind is determined from the state of the element's `kind` attribute according to the following table; for a state given in a cell of the first column, the kind is the string given in the second column:

State	String
Subtitles	`subtitles`
Captions	`captions`
Descriptions	`descriptions`
Chapters metadata	`chapters`
Metadata	`metadata`

The text track label[p450] is the element's track label[p414].

The text track language[p451] is the element's track language[p414], if any, or the empty string otherwise.

As the kind[p413], label[p414], and srclang[p414] attributes are set, changed, or removed, the text track[p450] must update accordingly, as per the definitions above.

Note

Changes to the track URL[p413] are handled in the algorithm below.

The text track readiness state[p451] is initially not loaded[p451], and the text track mode[p451] is initially disabled[p451].

The text track list of cues[p451] is initially empty. It is dynamically modified when the referenced file is parsed. Associated with the list are the rules for updating the text track rendering[p451] appropriate for the format in question; for WebVTT, this is the rules for updating the display of WebVTT text tracks. [WEBVTT][p1502]

When a track[p412] element's parent element changes and the new parent is a media element[p415], then the user agent must add the track[p412] element's corresponding text track[p450] to the media element[p415]'s list of text tracks[p450], and then queue a media element task[p416] given the media element[p415] to fire an event named addtrack[p469] at the media element[p415]'s textTracks[p458] attribute's TextTrackList[p457] object, using TrackEvent[p468], with the track[p468] attribute initialized to the text track[p450]'s TextTrack[p458] object.

When a track[p412] element's parent element changes and the old parent was a media element[p415], then the user agent must remove the track[p412] element's corresponding text track[p450] from the media element[p415]'s list of text tracks[p450], and then queue a media element task[p416] given the media element[p415] to fire an event named removetrack[p469] at the media element[p415]'s textTracks[p458] attribute's TextTrackList[p457] object, using TrackEvent[p468], with the track[p468] attribute initialized to the text track[p450]'s TextTrack[p458] object.

When a text track[p450] corresponding to a track[p412] element is added to a media element[p415]'s list of text tracks[p450], the user agent must queue a media element task[p416] given the media element[p415] to run the following steps for the media element[p415]:

1. If the element's blocked-on-parser[p452] flag is true, then return.
2. If the element's did-perform-automatic-track-selection[p452] flag is true, then return.
3. Honor user preferences for automatic text track selection[p455] for this element.

When the user agent is required to **honor user preferences for automatic text track selection** for a media element[p415], the user agent must run the following steps:

1. Perform automatic text track selection[p455] for subtitles[p450] and captions[p450].
2. Perform automatic text track selection[p455] for descriptions[p450].
3. If there are any text tracks[p450] in the media element[p415]'s list of text tracks[p450] whose text track kind[p450] is chapters[p450] or metadata[p450] that correspond to track[p412] elements with a default[p414] attribute set whose text track mode[p451] is set to disabled[p451], then set the text track mode[p451] of all such tracks to hidden[p451].
4. Set the element's did-perform-automatic-track-selection[p452] flag to true.

When the steps above say to **perform automatic text track selection** for one or more text track kinds[p450], it means to run the following steps:

1. Let *candidates* be a list consisting of the text tracks[p450] in the media element[p415]'s list of text tracks[p450] whose text track kind[p450] is one of the kinds that were passed to the algorithm, if any, in the order given in the list of text tracks[p450].
2. If *candidates* is empty, then return.
3. If any of the text tracks[p450] in *candidates* have a text track mode[p451] set to showing[p451], return.
4. If the user has expressed an interest in having a track from *candidates* enabled based on its text track kind[p450], text track language[p451], and text track label[p450], then set its text track mode[p451] to showing[p451].

Note

For example, the user could have set a browser preference to the effect of "I want French captions whenever possible",

or "If there is a subtitle track with 'Commentary' in the title, enable it", or "If there are audio description tracks available, enable one, ideally in Swiss German, but failing that in Standard Swiss German or Standard German".

Otherwise, if there are any text tracks[p450] in *candidates* that correspond to `track`[p412] elements with a `default`[p414] attribute set whose text track mode[p451] is set to disabled[p451], then set the text track mode[p451] of the first such track to showing[p451].

When a text track[p450] corresponding to a `track`[p412] element experiences any of the following circumstances, the user agent must start the `track` processing model[p456] for that text track[p450] and its `track`[p412] element:

- The `track`[p412] element is created.
- The text track[p450] has its text track mode[p451] changed.
- The `track`[p412] element's parent element changes and the new parent is a media element[p415].

When a user agent is to **start the `track` processing model** for a text track[p450] and its `track`[p412] element, it must run the following algorithm. This algorithm interacts closely with the event loop[p1138] mechanism; in particular, it has a synchronous section[p1146] (which is triggered as part of the event loop[p1138] algorithm). The steps in that section are marked with ⌛.

1. If another occurrence of this algorithm is already running for this text track[p450] and its `track`[p412] element, return, letting that other algorithm take care of this element.
2. If the text track[p450]'s text track mode[p451] is not set to one of hidden[p451] or showing[p451], then return.
3. If the text track[p450]'s `track`[p412] element does not have a media element[p415] as a parent, return.
4. Run the remainder of these steps in parallel[p44], allowing whatever caused these steps to run to continue.
5. *Top*: Await a stable state[p1146]. The synchronous section[p1146] consists of the following steps. (The steps in the synchronous section[p1146] are marked with ⌛.)
6. ⌛ Set the text track readiness state[p451] to loading[p451].
7. ⌛ Let *URL* be the track URL[p413] of the `track`[p412] element.
8. ⌛ If the `track`[p412] element's parent is a media element[p415], then let *corsAttributeState* be the state of the parent media element[p415]'s `crossorigin`[p418] content attribute. Otherwise, let *corsAttributeState* be No CORS[p101].
9. End the synchronous section[p1146], continuing the remaining steps in parallel[p44].
10. If *URL* is not the empty string, then:
    1. Let *request* be the result of creating a potential-CORS request[p99] given *URL*, "`track`", and *corsAttributeState*, and with the *same-origin fallback flag* set.
    2. Set *request*'s client to the `track`[p412] element's node document's relevant settings object[p1098].
    3. Set *request*'s initiator type to "`track`".
    4. Fetch *request*.

The tasks[p1139] queued[p1139] by the fetching algorithm on the networking task source[p1149] to process the data as it is being fetched must determine the type of the resource. If the type of the resource is not a supported text track format, the load will fail, as described below. Otherwise, the resource's data must be passed to the appropriate parser (e.g., the WebVTT parser) as it is received, with the text track list of cues[p451] being used for that parser's output. [WEBVTT][p1502]

Note

The appropriate parser will incrementally update the text track list of cues[p451] during these networking task source[p1149] tasks[p1139], as each such task is run with whatever data has been received from the network).

This specification does not currently say whether or how to check the MIME types of text tracks, or whether or how to perform file type sniffing using the actual file data. Implementers differ in their intentions on this matter and it is therefore unclear what the right solution is. In the absence of any requirement here, the HTTP specifications' strict requirement to follow the Content-Type header prevails ("Content-Type specifies the media type of the underlying data." ... "If and only if the media type is not given by a Content-Type field, the recipient MAY attempt to guess the media type

via inspection of its content and/or the name extension(s) of the URI used to identify the resource.").

If fetching fails for any reason (network error, the server returns an error code, CORS fails, etc.), or if *URL* is the empty string, then queue an element task[p1140] on the DOM manipulation task source[p1149] given the media element[p415] to first change the text track readiness state[p451] to failed to load[p451] and then fire an event named `error`[p470] at the `track`[p412] element.

If fetching does not fail, but the type of the resource is not a supported text track format, or the file was not successfully processed (e.g., the format in question is an XML format and the file contained a well-formedness error that *XML* requires be detected and reported to the application), then the task[p1139] that is queued[p1140] on the networking task source[p1149] in which the aforementioned problem is found must change the text track readiness state[p451] to failed to load[p451] and fire an event named `error`[p470] at the `track`[p412] element.

If fetching does not fail, and the file was successfully processed, then the final task[p1139] that is queued[p1140] by the networking task source[p1149], after it has finished parsing the data, must change the text track readiness state[p451] to loaded[p451], and fire an event named `load`[p470] at the `track`[p412] element.

If, while fetching is ongoing, either:

- the track URL[p413] changes so that it is no longer equal to *URL*, while the text track mode[p451] is set to hidden[p451] or showing[p451]; or
- the text track mode[p451] changes to hidden[p451] or showing[p451], while the track URL[p413] is not equal to *URL*,

...then the user agent must abort fetching, discarding any pending tasks[p1139] generated by that algorithm (and in particular, not adding any cues to the text track list of cues[p451] after the moment the URL changed), and then queue an element task[p1140] on the DOM manipulation task source[p1149] given the `track`[p412] element that first changes the text track readiness state[p451] to failed to load[p451] and then fires an event named `error`[p470] at the `track`[p412] element.

11. Wait until the text track readiness state[p451] is no longer set to loading[p451].
12. Wait until the track URL[p413] is no longer equal to *URL*, at the same time as the text track mode[p451] is set to hidden[p451] or showing[p451].
13. Jump to the step labeled *top*.

Whenever a `track`[p412] element has its `src`[p413] attribute set, changed, or removed, the user agent must immediately[p44] empty the element's text track[p450]'s text track list of cues[p451]. (This also causes the algorithm above to stop adding cues from the resource being obtained using the previously given URL, if any.)

4.8.11.11.4 Guidelines for exposing cues in various formats as text track cues[p452] §[p457]

How a specific format's text track cues are to be interpreted for the purposes of processing by an HTML user agent is defined by that format. In the absence of such a specification, this section provides some constraints within which implementations can attempt to consistently expose such formats.

To support the text track[p450] model of HTML, each unit of timed data is converted to a text track cue[p452]. Where the mapping of the format's features to the aspects of a text track cue[p452] as defined in this specification are not defined, implementations must ensure that the mapping is consistent with the definitions of the aspects of a text track cue[p452] as defined above, as well as with the following constraints:

The text track cue identifier[p452]

Should be set to the empty string if the format has no obvious analogue to a per-cue identifier.

The text track cue pause-on-exit flag[p452]

Should be set to false.

4.8.11.11.5 Text track API §[p457]

MDN

IDL

```
[Exposed=Window]
interface TextTrackList : EventTarget {
```

```
  readonly attribute unsigned long length;
  getter TextTrack (unsigned long index);
  TextTrack? getTrackById(DOMString id);

  attribute EventHandler onchange;
  attribute EventHandler onaddtrack;
  attribute EventHandler onremovetrack;
};
```

For web developers (non-normative)

***media*.textTracks[p458].length**

Returns the number of text tracks[p450] associated with the media element[p415] (e.g. from track[p412] elements). This is the number of text tracks[p450] in the media element[p415]'s list of text tracks[p450].

***media*.textTracks[p458][*n*]**

Returns the TextTrack[p458] object representing the *n*th text track[p450] in the media element[p415]'s list of text tracks[p450].

***textTrack* = *media*.textTracks[p458].getTrackById[p458](*id*)**

Returns the TextTrack[p458] object with the given identifier, or null if no track has that identifier.

A TextTrackList[p457] object represents a dynamically updating list of text tracks[p450] in a given order.

The **textTracks** attribute of media elements[p415] must return a TextTrackList[p457] object representing the TextTrack[p458] objects of the text tracks[p450] in the media element[p415]'s list of text tracks[p450], in the same order as in the list of text tracks[p450].

The **length** attribute of a TextTrackList[p457] object must return the number of text tracks[p450] in the list represented by the TextTrackList[p457] object.

The supported property indices of a TextTrackList[p457] object at any instant are the numbers from zero to the number of text tracks[p450] in the list represented by the TextTrackList[p457] object minus one, if any. If there are no text tracks[p450] in the list, there are no supported property indices.

To determine the value of an indexed property of a TextTrackList[p457] object for a given index *index*, the user agent must return the *index*th text track[p450] in the list represented by the TextTrackList[p457] object.

The **getTrackById(*id*)** method must return the first TextTrack[p458] in the TextTrackList[p457] object whose id[p460] IDL attribute would return a value equal to the value of the *id* argument. When no tracks match the given argument, the method must return null.

IDL

```
enum TextTrackMode { "disabled", "hidden", "showing" };
enum TextTrackKind { "subtitles", "captions", "descriptions", "chapters", "metadata" };

[Exposed=Window]
interface TextTrack : EventTarget {
  readonly attribute TextTrackKind kind;
  readonly attribute DOMString label;
  readonly attribute DOMString language;

  readonly attribute DOMString id;
  readonly attribute DOMString inBandMetadataTrackDispatchType;

  attribute TextTrackMode mode;

  readonly attribute TextTrackCueList? cues;
  readonly attribute TextTrackCueList? activeCues;

  undefined addCue(TextTrackCue cue);
  undefined removeCue(TextTrackCue cue);

  attribute EventHandler oncuechange;
};
```

For web developers (non-normative)

***textTrack* = *media*.addTextTrack(*kind* [, *label* [, *language*]])**

Creates and returns a new TextTrack object, which is also added to the media element's list of text tracks.

textTrack.kind

Returns the text track kind string.

textTrack.label

Returns the text track label, if there is one, or the empty string otherwise (indicating that a custom label probably needs to be generated from the other attributes of the object if the object is exposed to the user).

textTrack.language

Returns the text track language string.

textTrack.id

Returns the ID of the given track.

For in-band tracks, this is the ID that can be used with a fragment if the format supports media fragment syntax, and that can be used with the getTrackById() method.

For TextTrack objects corresponding to track elements, this is the ID of the track element.

textTrack.inBandMetadataTrackDispatchType

Returns the text track in-band metadata track dispatch type string.

textTrack.mode [= *value*]

Returns the text track mode, represented by a string from the following list:

"disabled"
The text track disabled mode.

"hidden"
The text track hidden mode.

"showing"
The text track showing mode.

Can be set, to change the mode.

textTrack.cues

Returns the text track list of cues, as a TextTrackCueList object.

textTrack.activeCues

Returns the text track cues from the text track list of cues that are currently active (i.e. that start before the current playback position and end after it), as a TextTrackCueList object.

textTrack.addCue(*cue*)

Adds the given cue to *textTrack*'s text track list of cues.

textTrack.removeCue(*cue*)

Removes the given cue from *textTrack*'s text track list of cues.

The **addTextTrack(*kind*, *label*, *language*)** method of media elements, when invoked, must run the following steps:

1. Create a new TextTrack object.
2. Create a new text track corresponding to the new object, and set its text track kind to *kind*, its text track label to *label*, its text track language to *language*, its text track readiness state to the text track loaded state, its text track mode to the text track hidden mode, and its text track list of cues to an empty list.

   Initially, the text track list of cues is not associated with any rules for updating the text track rendering. When a text track cue is added to it, the text track list of cues has its rules permanently set accordingly.
3. Add the new text track to the media element's list of text tracks.
4. Queue a media element task given the media element to fire an event named addtrack at the media element's textTracks attribute's TextTrackList object, using TrackEvent, with the track attribute initialized to the new text track's TextTrack object.
5. Return the new TextTrack object.

The **kind** attribute must return the text track kind[p450] of the text track[p450] that the TextTrack[p458] object represents.

The **label** attribute must return the text track label[p450] of the text track[p450] that the TextTrack[p458] object represents.

The **language** attribute must return the text track language[p451] of the text track[p450] that the TextTrack[p458] object represents.

The **id** attribute returns the track's identifier, if it has one, or the empty string otherwise. For tracks that correspond to track[p412] elements, the track's identifier is the value of the element's id[p156] attribute, if any. For in-band tracks, the track's identifier is specified by the media resource[p416]. If the media resource[p416] is in a format that supports media fragment syntax, the identifier returned for a particular track must be the same identifier that would enable the track if used as the name of a track in the track dimension of such a fragment.

The **inBandMetadataTrackDispatchType** attribute must return the text track in-band metadata track dispatch type[p450] of the text track[p450] that the TextTrack[p458] object represents.

The **mode** attribute, on getting, must return the string corresponding to the text track mode[p451] of the text track[p450] that the TextTrack[p458] object represents, as defined by the following list:

"disabled"
: The text track disabled[p451] mode.

"hidden"
: The text track hidden[p451] mode.

"showing"
: The text track showing[p451] mode.

On setting, if the new value isn't equal to what the attribute would currently return, the new value must be processed as follows:

↪ **If the new value is "disabled[p460]"**
: Set the text track mode[p451] of the text track[p450] that the TextTrack[p458] object represents to the text track disabled[p451] mode.

↪ **If the new value is "hidden[p460]"**
: Set the text track mode[p451] of the text track[p450] that the TextTrack[p458] object represents to the text track hidden[p451] mode.

↪ **If the new value is "showing[p460]"**
: Set the text track mode[p451] of the text track[p450] that the TextTrack[p458] object represents to the text track showing[p451] mode.

If the text track mode[p451] of the text track[p450] that the TextTrack[p458] object represents is not the text track disabled[p451] mode, then the **cues** attribute must return a live[p48] TextTrackCueList[p461] object that represents the subset of the text track list of cues[p451] of the text track[p450] that the TextTrack[p458] object represents whose end times[p452] occur at or after the earliest possible position when the script started[p460], in text track cue order[p453]. Otherwise, it must return null. For each TextTrack[p458] object, when an object is returned, the same TextTrackCueList[p461] object must be returned each time.

The **earliest possible position when the script started** is whatever the earliest possible position[p433] was the last time the event loop[p1138] reached step 1.

If the text track mode[p451] of the text track[p450] that the TextTrack[p458] object represents is not the text track disabled[p451] mode, then the **activeCues** attribute must return a live[p48] TextTrackCueList[p461] object that represents the subset of the text track list of cues[p451] of the text track[p450] that the TextTrack[p458] object represents whose active flag was set when the script started[p460], in text track cue order[p453]. Otherwise, it must return null. For each TextTrack[p458] object, when an object is returned, the same TextTrackCueList[p461] object must be returned each time.

A text track cue[p452]'s **active flag was set when the script started** if its text track cue active flag[p453] was set the last time the event loop[p1138] reached step 1[p1141].

The **addCue(*cue*)** method of TextTrack[p458] objects, when invoked, must run the following steps:

1. If the text track list of cues[p451] does not yet have any associated rules for updating the text track rendering[p451], then associate the text track list of cues[p451] with the rules for updating the text track rendering[p451] appropriate to *cue*.
2. If text track list of cues[p451]' associated rules for updating the text track rendering[p451] are not the same rules for updating the text track rendering[p451] as appropriate for *cue*, then throw an "InvalidStateError" DOMException.

3. If the given *cue* is in a text track list of cues[p451], then remove *cue* from that text track list of cues[p451].

4. Add *cue* to the TextTrack[p458] object's text track[p450]'s text track list of cues[p451].

The **removeCue(*cue*)** method of TextTrack[p458] objects, when invoked, must run the following steps:

1. If the given *cue* is not in the TextTrack[p458] object's text track[p450]'s text track list of cues[p451], then throw a "NotFoundError" DOMException.

2. Remove *cue* from the TextTrack[p458] object's text track[p450]'s text track list of cues[p451].

Example

In this example, an audio[p411] element is used to play a specific sound-effect from a sound file containing many sound effects. A cue is used to pause the audio, so that it ends exactly at the end of the clip, even if the browser is busy running some script. If the page had relied on script to pause the audio, then the start of the next clip might be heard if the browser was not able to run the script at the exact time specified.

```
var sfx = new Audio('sfx.wav');
var sounds = sfx.addTextTrack('metadata');

// add sounds we care about
function addFX(start, end, name) {
  var cue = new VTTCue(start, end, '');
  cue.id = name;
  cue.pauseOnExit = true;
  sounds.addCue(cue);
}
addFX(12.783, 13.612, 'dog bark');
addFX(13.612, 15.091, 'kitten mew');

function playSound(id) {
  sfx.currentTime = sounds.getCueById(id).startTime;
  sfx.play();
}

// play a bark as soon as we can
sfx.oncanplaythrough = function () {
  playSound('dog bark');
}
// meow when the user tries to leave,
// and have the browser ask them to stay
window.onbeforeunload = function (e) {
  playSound('kitten mew');
  e.preventDefault();
}
```

IDL

```
[Exposed=Window]
interface TextTrackCueList {
  readonly attribute unsigned long length;
  getter TextTrackCue (unsigned long index);
  TextTrackCue? getCueById(DOMString id);
};
```

For web developers (non-normative)

***cuelist*.length**[p462]

Returns the number of cues[p452] in the list.

***cuelist*[*index*]**

Returns the text track cue[p452] with index *index* in the list. The cues are sorted in text track cue order[p453].

***cuelist*.getCueById(*id*)**

Returns the first text track cue (in text track cue order) with text track cue identifier *id*.

Returns null if none of the cues have the given identifier or if the argument is the empty string.

A TextTrackCueList object represents a dynamically updating list of text track cues in a given order.

The **length** attribute must return the number of cues in the list represented by the TextTrackCueList object.

The supported property indices of a TextTrackCueList object at any instant are the numbers from zero to the number of cues in the list represented by the TextTrackCueList object minus one, if any. If there are no cues in the list, there are no supported property indices.

To determine the value of an indexed property for a given index *index*, the user agent must return the *index*th text track cue in the list represented by the TextTrackCueList object.

The **getCueById(*id*)** method, when called with an argument other than the empty string, must return the first text track cue in the list represented by the TextTrackCueList object whose text track cue identifier is *id*, if any, or null otherwise. If the argument is the empty string, then the method must return null.

IDL

```
[Exposed=Window]
interface TextTrackCue : EventTarget {
  readonly attribute TextTrack? track;

  attribute DOMString id;
  attribute double startTime;
  attribute unrestricted double endTime;
  attribute boolean pauseOnExit;

  attribute EventHandler onenter;
  attribute EventHandler onexit;
};
```

For web developers (non-normative)

***cue*.track**

Returns the TextTrack object to which this text track cue belongs, if any, or null otherwise.

***cue*.id [= *value*]**

Returns the text track cue identifier.

Can be set.

***cue*.startTime [= *value*]**

Returns the text track cue start time, in seconds.

Can be set.

***cue*.endTime [= *value*]**

Returns the text track cue end time, in seconds.

Returns positive Infinity for an unbounded text track cue.

Can be set.

***cue*.pauseOnExit [= *value*]**

Returns true if the text track cue pause-on-exit flag is set, false otherwise.

Can be set.

The **track** attribute, on getting, must return the TextTrack object of the text track in whose list of cues the text track cue that the TextTrackCue object represents finds itself, if any; or null otherwise.

The **id** attribute, on getting, must return the text track cue identifier of the text track cue that the TextTrackCue object

represents. On setting, the text track cue identifier[p452] must be set to the new value.

The **startTime** attribute, on getting, must return the text track cue start time[p452] of the text track cue[p452] that the TextTrackCue[p462] object represents, in seconds. On setting, the text track cue start time[p452] must be set to the new value, interpreted in seconds; then, if the TextTrackCue[p462] object's text track cue[p452] is in a text track[p450]'s list of cues[p451], and that text track[p450] is in a media element[p415]'s list of text tracks[p450], and the media element[p415]'s show poster flag[p433] is not set, then run the *time marches on*[p442] steps for that media element[p415].

The **endTime** attribute, on getting, must return the text track cue end time[p452] of the text track cue[p452] that the TextTrackCue[p462] object represents, in seconds or positive Infinity. On setting, if the new value is negative Infinity or a Not-a-Number (NaN) value, then throw a TypeError exception. Otherwise, the text track cue end time[p452] must be set to the new value. Then, if the TextTrackCue[p462] object's text track cue[p452] is in a text track[p450]'s list of cues[p451], and that text track[p450] is in a media element[p415]'s list of text tracks[p450], and the media element[p415]'s show poster flag[p433] is not set, then run the *time marches on*[p442] steps for that media element[p415].

The **pauseOnExit** attribute, on getting, must return true if the text track cue pause-on-exit flag[p452] of the text track cue[p452] that the TextTrackCue[p462] object represents is set; or false otherwise. On setting, the text track cue pause-on-exit flag[p452] must be set if the new value is true, and must be unset otherwise.

4.8.11.11.6 Event handlers for objects of the text track APIs §[p463]

The following are the event handlers[p1151] that (and their corresponding event handler event types[p1154]) that must be supported, as event handler IDL attributes[p1152], by all objects implementing the TextTrackList[p457] interface:

Event handler[p1151]	Event handler event type[p1154]
onchange	change[p469]
onaddtrack	addtrack[p469]
onremovetrack	removetrack[p469]

The following are the event handlers[p1151] that (and their corresponding event handler event types[p1154]) that must be supported, as event handler IDL attributes[p1152], by all objects implementing the TextTrack[p458] interface:

Event handler[p1151]	Event handler event type[p1154]
oncuechange	cuechange[p469]

The following are the event handlers[p1151] (and their corresponding event handler event types[p1154]) that must be supported, as event handler IDL attributes[p1152], by all objects implementing the TextTrackCue[p462] interface:

Event handler[p1151]	Event handler event type[p1154]
onenter	enter[p470]
onexit	exit[p470]

4.8.11.11.7 Best practices for metadata text tracks §[p463]

This section is non-normative.

Text tracks can be used for storing data relating to the media data, for interactive or augmented views.

For example, a page showing a sports broadcast could include information about the current score. Suppose a robotics competition was being streamed live. The image could be overlaid with the scores, as follows:

In order to make the score display render correctly whenever the user seeks to an arbitrary point in the video, the metadata text track cues need to be as long as is appropriate for the score. For example, in the frame above, there would be maybe one cue that lasts the length of the match that gives the match number, one cue that lasts until the blue alliance's score changes, and one cue that lasts until the red alliance's score changes. If the video is just a stream of the live event, the time in the bottom right would presumably be automatically derived from the current video time, rather than based on a cue. However, if the video was just the highlights, then that might be given in cues also.

The following shows what fragments of this could look like in a WebVTT file:

```
WEBVTT

...

05:10:00.000 --> 05:12:15.000
matchtype:qual
matchnumber:37

...

05:11:02.251 --> 05:11:17.198
red:78

05:11:03.672 --> 05:11:54.198
blue:66

05:11:17.198 --> 05:11:25.912
red:80

05:11:25.912 --> 05:11:26.522
red:83

05:11:26.522 --> 05:11:26.982
red:86

05:11:26.982 --> 05:11:27.499
red:89
```

. . .

The key here is to notice that the information is given in cues that span the length of time to which the relevant event applies. If, instead, the scores were given as zero-length (or very brief, nearly zero-length) cues when the score changes, for example saying "red+2" at 05:11:17.198, "red+3" at 05:11:25.912, etc, problems arise: primarily, seeking is much harder to implement, as the script has to walk the entire list of cues to make sure that no notifications have been missed; but also, if the cues are short it's possible the script will never see that they are active unless it listens to to them specifically.

When using cues in this manner, authors are encouraged to use the `cuechange` event to update the current annotations. (In particular, using the `timeupdate` event would be less appropriate as it would require doing work even when the cues haven't changed, and, more importantly, would introduce a higher latency between when the metadata cues become active and when the display is updated, since `timeupdate` events are rate-limited.)

4.8.11.12 Identifying a track kind through a URL

Other specifications or formats that need a URL to identify the return values of the `AudioTrack` `kind` or `VideoTrack` `kind` IDL attributes, or identify the kind of text track, must use the `about:html-kind` URL.

4.8.11.13 User interface

The **`controls`** attribute is a boolean attribute. If present, it indicates that the author has not provided a scripted controller and would like the user agent to provide its own set of controls.

If the attribute is present, or if scripting is disabled for the media element, then the user agent should **expose a user interface to the user**. This user interface should include features to begin playback, pause playback, seek to an arbitrary position in the content (if the content supports arbitrary seeking), change the volume, change the display of closed captions or embedded sign-language tracks, select different audio tracks or turn on audio descriptions, and show the media content in manners more suitable to the user (e.g. fullscreen video or in an independent resizable window). Other controls may also be made available.

Even when the attribute is absent, however, user agents may provide controls to affect playback of the media resource (e.g. play, pause, seeking, track selection, and volume controls), but such features should not interfere with the page's normal rendering. For example, such features could be exposed in the media element's context menu, platform media keys, or a remote control. The user agent may implement this simply by exposing a user interface to the user as described above (as if the `controls` attribute was present).

If the user agent exposes a user interface to the user by displaying controls over the media element, then the user agent should suppress any user interaction events while the user agent is interacting with this interface. (For example, if the user clicks on a video's playback control, `mousedown` events and so forth would not simultaneously be fired at elements on the page.)

Where possible (specifically, for starting, stopping, pausing, and unpausing playback, for seeking, for changing the rate of playback, for fast-forwarding or rewinding, for listing, enabling, and disabling text tracks, and for muting or changing the volume of the audio), user interface features exposed by the user agent must be implemented in terms of the DOM API described above, so that, e.g., all the same events fire.

Features such as fast-forward or rewind must be implemented by only changing the `playbackRate` attribute (and not the `defaultPlaybackRate` attribute).

Seeking must be implemented in terms of seeking to the requested position in the media element's media timeline. For media resources where seeking to an arbitrary position would be slow, user agents are encouraged to use the *approximate-for-speed* flag when seeking in response to the user manipulating an approximate position interface such as a seek bar.

The **`controls`** IDL attribute must reflect the content attribute of the same name.

For web developers (non-normative)

***media*.volume [= *value*]**

Returns the current playback volume, as a number in the range 0.0 to 1.0, where 0.0 is the quietest and 1.0 the loudest.

Can be set, to change the volume.

Throws an "IndexSizeError" DOMException if the new value is not in the range 0.0 .. 1.0.

***media*.muted[p466] [= *value*]**

Returns true if audio is muted, overriding the volume[p466] attribute, and false if the volume[p466] attribute is being honored.

Can be set, to change whether the audio is muted or not.

A media element[p415] has a **playback volume**, which is a fraction in the range 0.0 (silent) to 1.0 (loudest). Initially, the volume should be 1.0, but user agents may remember the last set value across sessions, on a per-site basis or otherwise, so the volume may start at other values.

The **volume** IDL attribute must return the playback volume[p466] of any audio portions of the media element[p415]. On setting, if the new value is in the range 0.0 to 1.0 inclusive, the media element[p415]'s playback volume[p466] must be set to the new value. If the new value is outside the range 0.0 to 1.0 inclusive, then, on setting, an "IndexSizeError" DOMException must be thrown instead.

A media element[p415] can also be **muted**. If anything is muting the element, then it is muted. (For example, when the direction of playback[p441] is backwards, the element is muted.)

The **muted** IDL attribute must return the value to which it was last set. When a media element[p415] is created, if the element has a muted[p466] content attribute specified, then the muted[p466] IDL attribute should be set to true; otherwise, the user agents may set the value to the user's preferred value (e.g. remembering the last set value across sessions, on a per-site basis or otherwise). While the muted[p466] IDL attribute is set to true, the media element[p415] must be muted[p466].

Whenever either of the values that would be returned by the volume[p466] and muted[p466] IDL attributes change, the user agent must queue a media element task[p416] given the media element[p415] to fire an event named volumechange[p469] at the media element[p415]. Then, if the media element[p415] is not allowed to play[p437], the user agent must run the internal pause steps[p440] for the media element[p415].

A user agent has an associated **volume locked** (a boolean). Its value is implementation-defined and determines whether the playback volume[p466] takes effect.

An element's **effective media volume** is determined as follows:

1. If the user has indicated that the user agent is to override the volume of the element, then return the volume desired by the user.
2. If the user agent's volume locked[p466] is true, then return the system volume.
3. If the element's audio output is muted[p466], then return zero.
4. Let *volume* be the playback volume[p466] of the audio portions of the media element[p415], in range 0.0 (silent) to 1.0 (loudest).
5. Return *volume*, interpreted relative to the range 0.0 to 1.0, with 0.0 being silent, and 1.0 being the loudest setting, values in between increasing in loudness. The range need not be linear. The loudest setting may be lower than the system's loudest possible setting; for example the user could have set a maximum volume.

The **muted** content attribute on media elements[p415] is a boolean attribute[p76] that controls the default state of the audio output of the media resource[p416], potentially overriding user preferences.

The **defaultMuted** IDL attribute must reflect[p105] the muted[p466] content attribute.

Note

This attribute has no dynamic effect (it only controls the default state of the element).

Example

This video (an advertisement) autoplays, but to avoid annoying users, it does so without sound, and allows the user to turn the sound on. The user agent can pause the video if it's unmuted without a user interaction.

```
<video src="adverts.cgi?kind=video" controls autoplay loop muted></video>
```

4.8.11.14 Time ranges §[p467]

Objects implementing the TimeRanges[p467] interface represent a list of ranges (periods) of time.

IDL

```
[Exposed=Window]
interface TimeRanges {
  readonly attribute unsigned long length;
  double start(unsigned long index);
  double end(unsigned long index);
};
```

For web developers (non-normative)

***media*.length**[p467]

Returns the number of ranges in the object.

***time* = *media*.start**[p467]**(*index*)**

Returns the time for the start of the range with the given index.

Throws an "IndexSizeError" DOMException if the index is out of range.

***time* = *media*.end**[p467]**(*index*)**

Returns the time for the end of the range with the given index.

Throws an "IndexSizeError" DOMException if the index is out of range.

The **length** IDL attribute must return the number of ranges represented by the object.

The **start(*index*)** method must return the position of the start of the *index*th range represented by the object, in seconds measured from the start of the timeline that the object covers.

The **end(*index*)** method must return the position of the end of the *index*th range represented by the object, in seconds measured from the start of the timeline that the object covers.

These methods must throw "IndexSizeError" DOMExceptions if called with an *index* argument greater than or equal to the number of ranges represented by the object.

When a TimeRanges[p467] object is said to be a **normalized TimeRanges object**, the ranges it represents must obey the following criteria:

- The start of a range must be greater than the end of all earlier ranges.
- The start of a range must be less than or equal to the end of that same range.

In other words, the ranges in such an object are ordered, don't overlap, and don't touch (adjacent ranges are folded into one bigger range). A range can be empty (referencing just a single moment in time), e.g. to indicate that only one frame is currently buffered in the case that the user agent has discarded the entire media resource[p416] except for the current frame, when a media element[p415] is paused.

Ranges in a TimeRanges[p467] object must be inclusive.

Example

Thus, the end of a range would be equal to the start of a following adjacent (touching but not overlapping) range. Similarly, a range covering a whole timeline anchored at zero would have a start equal to zero and an end equal to the duration of the timeline.

The timelines used by the objects returned by the buffered[p431], seekable[p445], and played[p439] IDL attributes of media elements[p415] must be that element's media timeline[p431].

4.8.11.15 The TrackEvent[p468] interface §[p467]

IDL

```
[Exposed=Window]
```

```
interface TrackEvent : Event {
  constructor(DOMString type, optional TrackEventInit eventInitDict = {});

  readonly attribute (VideoTrack or AudioTrack or TextTrack)? track;
};

dictionary TrackEventInit : EventInit {
  (VideoTrack or AudioTrack or TextTrack)? track = null;
};
```

For web developers (non-normative)

***event*.track**[p468]

Returns the track object (TextTrack[p458], AudioTrack[p446], or VideoTrack[p447]) to which the event relates.

The **track** attribute must return the value it was initialized to. It represents the context information for the event.

4.8.11.16 Events summary §[p468]

This section is non-normative.

The following events fire on media elements[p415] as part of the processing model described above:

Event name	Interface	Fired when...	Preconditions
loadstart	Event	The user agent begins looking for media data[p416], as part of the resource selection algorithm[p421].	networkState[p419] equals NETWORK_LOADING[p419]
progress	Event	The user agent is fetching media data[p416].	networkState[p419] equals NETWORK_LOADING[p419]
suspend	Event	The user agent is intentionally not currently fetching media data[p416].	networkState[p419] equals NETWORK_IDLE[p419]
abort	Event	The user agent stops fetching the media data[p416] before it is completely downloaded, but not due to an error.	error[p417] is an object with the code MEDIA_ERR_ABORTED[p417]. networkState[p419] equals either NETWORK_EMPTY[p419] or NETWORK_IDLE[p419], depending on when the download was aborted.
error	Event	An error occurs while fetching the media data[p416] or the type of the resource is not a supported media format.	error[p417] is an object with the code MEDIA_ERR_NETWORK[p417] or higher. networkState[p419] equals either NETWORK_EMPTY[p419] or NETWORK_IDLE[p419], depending on when the download was aborted.
emptied	Event	A media element[p415] whose networkState[p419] was previously not in the NETWORK_EMPTY[p419] state has just switched to that state (either because of a fatal error during load that's about to be reported, or because the load()[p420] method was invoked while the resource selection algorithm[p421] was already running).	networkState[p419] is NETWORK_EMPTY[p419]; all the IDL attributes are in their initial states.
stalled	Event	The user agent is trying to fetch media data[p416], but data is unexpectedly not forthcoming.	networkState[p419] is NETWORK_LOADING[p419].
loadedmetadata	Event	The user agent has just determined the duration and dimensions of the media resource[p416] and the text tracks are ready[p452].	readyState[p436] is newly equal to HAVE_METADATA[p434] or greater for the first time.
loadeddata	Event	The user agent can render the media data[p416] at the current playback position[p433] for the first time.	readyState[p436] newly increased to HAVE_CURRENT_DATA[p434] or greater for the first time.
canplay	Event	The user agent can resume playback of the media data[p416], but estimates that if playback were to be started now, the media resource[p416] could not be rendered at the current playback rate up to its end without having to stop for further buffering of content.	readyState[p436] newly increased to HAVE_FUTURE_DATA[p434] or greater.
canplaythrough	Event	The user agent estimates that if playback were to be started now, the media resource[p416] could be rendered at the current	readyState[p436] is newly equal to HAVE_ENOUGH_DATA[p434].

Event name	Interface	Fired when...	Preconditions
		playback rate all the way to its end without having to stop for further buffering.	
playing	Event	Playback is ready to start after having been paused or delayed due to lack of media data[p416].	readyState[p436] is newly greater than or equal to HAVE_FUTURE_DATA[p434] and paused[p437] is false, or paused[p437] is newly false and readyState[p436] is greater than or equal to HAVE_FUTURE_DATA[p434]. Even if this event fires, the element might still not be potentially playing[p437], e.g. if the element is paused for user interaction[p438] or paused for in-band content[p438].
waiting	Event	Playback has stopped because the next frame is not available, but the user agent expects that frame to become available in due course.	readyState[p436] is less than or equal to HAVE_CURRENT_DATA[p434], and paused[p437] is false. Either seeking[p444] is true, or the current playback position[p433] is not contained in any of the ranges in buffered[p431]. It is possible for playback to stop for other reasons without paused[p437] being false, but those reasons do not fire this event (and when those situations resolve, a separate playing[p469] event is not fired either): e.g., playback has ended[p437], or playback stopped due to errors[p438], or the element has paused for user interaction[p438] or paused for in-band content[p438].
seeking	Event	The seeking[p444] IDL attribute changed to true, and the user agent has started seeking to a new position.	
seeked	Event	The seeking[p444] IDL attribute changed to false after the current playback position[p433] was changed.	
ended	Event	Playback has stopped because the end of the media resource[p416] was reached.	currentTime[p433] equals the end of the media resource[p416]; ended[p438] is true.
durationchange	Event	The duration[p433] attribute has just been updated.	
timeupdate	Event	The current playback position[p433] changed as part of normal playback or in an especially interesting way, for example discontinuously.	
play	Event	The element is no longer paused. Fired after the play()[p439] method has returned, or when the autoplay[p436] attribute has caused playback to begin.	paused[p437] is newly false.
pause	Event	The element has been paused. Fired after the pause()[p440] method has returned.	paused[p437] is newly true.
ratechange	Event	Either the defaultPlaybackRate[p439] or the playbackRate[p439] attribute has just been updated.	
resize	Event	One or both of the videoWidth[p410] and videoHeight[p410] attributes have just been updated.	Media element[p415] is a video[p407] element; readyState[p436] is not HAVE_NOTHING[p434]
volumechange	Event	Either the volume[p466] attribute or the muted[p466] attribute has changed. Fired after the relevant attribute's setter has returned.	

The following event fires on source[p344] elements:

Event name	Interface	Fired when...
error	Event	An error occurs while fetching the media data[p416] or the type of the resource is not a supported media format.

The following events fire on AudioTrackList[p446], VideoTrackList[p446], and TextTrackList[p457] objects:

Event name	Interface	Fired when...
change	Event	One or more tracks in the track list have been enabled or disabled.
addtrack	TrackEvent[p468]	A track has been added to the track list.
removetrack	TrackEvent[p468]	A track has been removed from the track list.

The following event fires on TextTrack[p458] objects and track[p412] elements:

Event name	Interface	Fired when...
cuechange	Event	One or more cues in the track have become active or stopped being active.

The following events fire on track[p412] elements:

Event name	Interface	Fired when...
error	Event	An error occurs while fetching the track data or the type of the resource is not supported text track format.
load	Event	A track data has been fetched and successfully processed.

The following events fire on TextTrackCue[p462] objects:

Event name	Interface	Fired when...
enter	Event	The cue has become active.
exit	Event	The cue has stopped being active.

4.8.11.17 Security and privacy considerations §[p47]

The main security and privacy implications of the video[p407] and audio[p411] elements come from the ability to embed media cross-origin. There are two directions that threats can flow: from hostile content to a victim page, and from a hostile page to victim content.

If a victim page embeds hostile content, the threat is that the content might contain scripted code that attempts to interact with the Document[p131] that embeds the content. To avoid this, user agents must ensure that there is no access from the content to the embedding page. In the case of media content that uses DOM concepts, the embedded content must be treated as if it was in its own unrelated top-level traversable[p1003].

Example

For instance, if an SVG animation was embedded in a video[p407] element, the user agent would not give it access to the DOM of the outer page. From the perspective of scripts in the SVG resource, the SVG file would appear to be in a lone top-level traversable with no parent.

If a hostile page embeds victim content, the threat is that the embedding page could obtain information from the content that it would not otherwise have access to. The API does expose some information: the existence of the media, its type, its duration, its size, and the performance characteristics of its host. Such information is already potentially problematic, but in practice the same information can more or less be obtained using the img[p347] element, and so it has been deemed acceptable.

However, significantly more sensitive information could be obtained if the user agent further exposes metadata within the content, such as subtitles. That information is therefore only exposed if the video resource uses CORS. The crossorigin[p418] attribute allows authors to enable CORS. [FETCH][p1496]

Example

Without this restriction, an attacker could trick a user running within a corporate network into visiting a site that attempts to load a video from a previously leaked location on the corporation's intranet. If such a video included confidential plans for a new product, then being able to read the subtitles would present a serious confidentiality breach.

4.8.11.18 Best practices for authors using media elements §[p47]

This section is non-normative.

Playing audio and video resources on small devices such as set-top boxes or mobile phones is often constrained by limited hardware resources in the device. For example, a device might only support three simultaneous videos. For this reason, it is a good practice to release resources held by media elements[p415] when they are done playing, either by being very careful about removing all references to the element and allowing it to be garbage collected, or, even better, by setting the element's src[p417] attribute to an empty string. In cases where srcObject[p418] was set, instead set the srcObject[p418] to null.

Similarly, when the playback rate is not exactly 1.0, hardware, software, or format limitations can cause video frames to be dropped and audio to be choppy or muted.

4.8.11.19 Best practices for implementers of media elements §[p47]

This section is non-normative.

How accurately various aspects of the media element[p415] API are implemented is considered a quality-of-implementation issue.

For example, when implementing the `buffered`[p431] attribute, how precise an implementation reports the ranges that have been buffered depends on how carefully the user agent inspects the data. Since the API reports ranges as times, but the data is obtained in byte streams, a user agent receiving a variable-bitrate stream might only be able to determine precise times by actually decoding all of the data. User agents aren't required to do this, however; they can instead return estimates (e.g. based on the average bitrate seen so far) which get revised as more information becomes available.

As a general rule, user agents are urged to be conservative rather than optimistic. For example, it would be bad to report that everything had been buffered when it had not.

Another quality-of-implementation issue would be playing a video backwards when the codec is designed only for forward playback (e.g. there aren't many key frames, and they are far apart, and the intervening frames only have deltas from the previous frame). User agents could do a poor job, e.g. only showing key frames; however, better implementations would do more work and thus do a better job, e.g. actually decoding parts of the video forwards, storing the complete frames, and then playing the frames backwards.

Similarly, while implementations are allowed to drop buffered data at any time (there is no requirement that a user agent keep all the media data obtained for the lifetime of the media element), it is again a quality of implementation issue: user agents with sufficient resources to keep all the data around are encouraged to do so, as this allows for a better user experience. For example, if the user is watching a live stream, a user agent could allow the user only to view the live video; however, a better user agent would buffer everything and allow the user to seek through the earlier material, pause it, play it forwards and backwards, etc.

When a media element[p415] that is paused is removed from a document[p47] and not reinserted before the next time the event loop[p1138] reaches step 1[p1141], implementations that are resource constrained are encouraged to take that opportunity to release all hardware resources (like video planes, networking resources, and data buffers) used by the media element[p415]. (User agents still have to keep track of the playback position and so forth, though, in case playback is later restarted.)

4.8.12 The `map` element §[p47]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Transparent[p152].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
`name`[p472] — Name of image map[p474] to reference[p142] from the `usemap`[p474] attribute

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLMapElement : HTMLElement {
  [HTMLConstructor] constructor();
```

```
  [CEReactions] attribute DOMString name;
  [SameObject] readonly attribute HTMLCollection areas;
};
```

The map element, in conjunction with an img element and any area element descendants, defines an image map. The element represents its children.

The **name** attribute gives the map a name so that it can be referenced. The attribute must be present and must have a non-empty value with no ASCII whitespace. The value of the name attribute must not be equal to the value of the name attribute of another map element in the same tree. If the id attribute is also specified, both attributes must have the same value.

For web developers (non-normative)

***map*.areas**

Returns an HTMLCollection of the area elements in the map.

The **areas** attribute must return an HTMLCollection rooted at the map element, whose filter matches only area elements.

The IDL attribute **name** must reflect the content attribute of the same name.

Example

Image maps can be defined in conjunction with other content on the page, to ease maintenance. This example is of a page with an image map at the top of the page and a corresponding set of text links at the bottom.

```
<!DOCTYPE HTML>
<HTML LANG="EN">
<TITLE>Babies™: Toys</TITLE>
<HEADER>
 <H1>Toys</H1>
 <IMG SRC="/images/menu.gif"
      ALT="Babies™ navigation menu. Select a department to go to its page."
      USEMAP="#NAV">
</HEADER>
 ...
<FOOTER>
 <MAP NAME="NAV">
  <P>
   <A HREF="/clothes/">Clothes</A>
   <AREA ALT="Clothes" COORDS="0,0,100,50" HREF="/clothes/"> |
   <A HREF="/toys/">Toys</A>
   <AREA ALT="Toys" COORDS="100,0,200,50" HREF="/toys/"> |
   <A HREF="/food/">Food</A>
   <AREA ALT="Food" COORDS="200,0,300,50" HREF="/food/"> |
   <A HREF="/books/">Books</A>
   <AREA ALT="Books" COORDS="300,0,400,50" HREF="/books/">
  </P>
 </MAP>
</FOOTER>
```

4.8.13 The area element

Categories:

Flow content.
Phrasing content.

Contexts in which this element can be used:

Where phrasing content is expected, but only if there is a map element ancestor.

Content model[p147]**:**

Nothing[p149].

Tag omission in text/html[p148]**:**

No end tag[p1280].

Content attributes[p148]**:**

Global attributes[p155]
alt[p473] — Replacement text for use when images are not available
coords[p474] — Coordinates for the shape to be created in an image map[p474]
shape[p473] — The kind of shape to be created in an image map[p474]
href[p304] — Address of the hyperlink[p303]
target[p304] — Navigable[p1001] for hyperlink[p303] navigation[p1028]
download[p304] — Whether to download the resource instead of navigating to it, and its filename if so
ping[p304] — URLs to ping
rel[p304] — Relationship between the location in the document containing the hyperlink[p303] and the destination resource
referrerpolicy[p304] — Referrer policy for fetches initiated by the element

Accessibility considerations[p148]**:**

If the element has an href[p304] attribute: for authors; for implementers.
Otherwise: for authors; for implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLAreaElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString alt;
  [CEReactions] attribute DOMString coords;
  [CEReactions] attribute DOMString shape;
  [CEReactions] attribute DOMString target;
  [CEReactions] attribute DOMString download;
  [CEReactions] attribute USVString ping;
  [CEReactions] attribute DOMString rel;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList relList;
  [CEReactions] attribute DOMString referrerPolicy;

  // also has obsolete members
};
HTMLAreaElement includes HTMLHyperlinkElementUtils;
```

The area[p472] element represents[p142] either a hyperlink with some text and a corresponding area on an image map[p474], or a dead area on an image map.

An area[p472] element with a parent node must have a map[p471] element ancestor.

If the area[p472] element has an href[p304] attribute, then the area[p472] element represents a hyperlink[p303]. In this case, the **alt** attribute must be present. It specifies the text of the hyperlink. Its value must be text that, when presented with the texts specified for the other hyperlinks of the image map[p474], and with the alternative text of the image, but without the image itself, provides the user with the same kind of choice as the hyperlink would when used without its text but with its shape applied to the image. The alt[p473] attribute may be left blank if there is another area[p472] element in the same image map[p474] that points to the same resource and has a non-blank alt[p473] attribute.

If the area[p472] element has no href[p304] attribute, then the area represented by the element cannot be selected, and the alt[p473] attribute must be omitted.

In both cases, the shape[p473] and coords[p474] attributes specify the area.

The **shape** attribute is an enumerated attribute[p77] with the following keywords and states:

Keyword	Conforming	State	Brief description
circle		Circle state[p474]	Designates a circle, using exactly three integers in the coords[p474] attribute.

Keyword	Conforming	State	Brief description
circ	No		
default		Default state[p474]	This area is the whole image. (The coords[p474] attribute is not used.)
poly		Polygon state[p474]	Designates a polygon, using at-least six integers in the coords[p474] attribute.
polygon	No		
rect		Rectangle state[p474]	Designates a rectangle, using exactly four integers in the coords[p474] attribute.
rectangle	No		

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the rectangle[p474] state.

The **coords** attribute must, if specified, contain a valid list of floating-point numbers[p82]. This attribute gives the coordinates for the shape described by the shape[p473] attribute. The processing for this attribute is described as part of the image map[p474] processing model.

In the **circle state**, area[p472] elements must have a coords[p474] attribute present, with three integers, the last of which must be non-negative. The first integer must be the distance in CSS pixels from the left edge of the image to the center of the circle, the second integer must be the distance in CSS pixels from the top edge of the image to the center of the circle, and the third integer must be the radius of the circle, again in CSS pixels.

In the **default state**, area[p472] elements must not have a coords[p474] attribute. (The area is the whole image.)

In the **polygon state**, area[p472] elements must have a coords[p474] attribute with at least six integers, and the number of integers must be even. Each pair of integers must represent a coordinate given as the distances from the left and the top of the image in CSS pixels respectively, and all the coordinates together must represent the points of the polygon, in order.

In the **rectangle state**, area[p472] elements must have a coords[p474] attribute with exactly four integers, the first of which must be less than the third, and the second of which must be less than the fourth. The four points must represent, respectively, the distance from the left edge of the image to the left side of the rectangle, the distance from the top edge to the top side, the distance from the left edge to the right side, and the distance from the top edge to the bottom side, all in CSS pixels.

When user agents allow users to follow hyperlinks[p310] or download hyperlinks[p311] created using the area[p472] element, the href[p304], target[p304], download[p304], and ping[p304] attributes decide how the link is followed. The rel[p304] attribute may be used to indicate to the user the likely nature of the target resource before the user follows the link.

The target[p304], download[p304], ping[p304], rel[p304], and referrerpolicy[p304] attributes must be omitted if the href[p304] attribute is not present.

If the itemprop[p803] attribute is specified on an area[p472] element, then the href[p304] attribute must also be specified.

The IDL attributes **alt**, **coords**, **shape**, **target**, **download**, **ping**, and **rel**, each must reflect[p105] the respective content attributes of the same name.

The IDL attribute **relList** must reflect[p105] the rel[p304] content attribute.

The IDL attribute **referrerPolicy** must reflect[p105] the referrerpolicy[p304] content attribute, limited to only known values[p106].

4.8.14 Image maps §[p474]

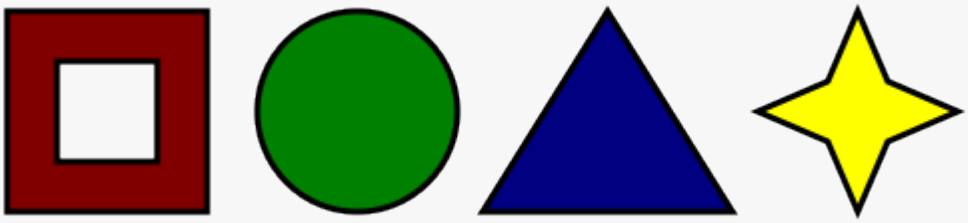
4.8.14.1 Authoring §[p474]

An **image map** allows geometric areas on an image to be associated with hyperlinks[p303].

An image, in the form of an img[p347] element, may be associated with an image map (in the form of a map[p471] element) by specifying a **usemap** attribute on the img[p347] element. The usemap[p474] attribute, if specified, must be a valid hash-name reference[p97] to a map[p471] element.

Example

Consider an image that looks as follows:



If we wanted just the colored areas to be clickable, we could do it as follows:

```
<p>
 Please select a shape:
 <img src="shapes.png" usemap="#shapes"
      alt="Four shapes are available: a red hollow box, a green circle, a blue triangle, and a
yellow four-pointed star.">
 <map name="shapes">
  <area shape=rect coords="50,50,100,100"> <!-- the hole in the red box -->
  <area shape=rect coords="25,25,125,125" href="red.html" alt="Red box.">
  <area shape=circle coords="200,75,50" href="green.html" alt="Green circle.">
  <area shape=poly coords="325,25,262,125,388,125" href="blue.html" alt="Blue triangle.">
  <area shape=poly coords="450,25,435,60,400,75,435,90,450,125,465,90,500,75,465,60"
        href="yellow.html" alt="Yellow star.">
 </map>
</p>
```

4.8.14.2 Processing model §[p47]

If an `img`[p347] element has a `usemap`[p474] attribute specified, user agents must process it as follows:

1. Parse the attribute's value using the rules for parsing a hash-name reference[p97] to a `map`[p471] element, with the element as the context node. This will return either an element (the *map*) or null.
2. If that returned null, then return. The image is not associated with an image map after all.
3. Otherwise, the user agent must collect all the `area`[p472] elements that are descendants of the *map*. Let *areas* be that list.

Having obtained the list of `area`[p472] elements that form the image map (the *areas*), interactive user agents must process the list in one of two ways.

If the user agent intends to show the text that the `img`[p347] element represents, then it must use the following steps:

1. Remove all the `area`[p472] elements in *areas* that have no `href`[p304] attribute.
2. Remove all the `area`[p472] elements in *areas* that have no `alt`[p473] attribute, or whose `alt`[p473] attribute's value is the empty string, *if* there is another `area`[p472] element in *areas* with the same value in the `href`[p304] attribute and with a non-empty `alt`[p473] attribute.
3. Each remaining `area`[p472] element in *areas* represents a hyperlink[p303]. Those hyperlinks should all be made available to the user in a manner associated with the text of the `img`[p347].

   In this context, user agents may represent `area`[p472] and `img`[p347] elements with no specified `alt` attributes, or whose `alt` attributes are the empty string or some other non-visible text, in an implementation-defined fashion intended to indicate the lack of suitable author-provided text.

If the user agent intends to show the image and allow interaction with the image to select hyperlinks, then the image must be associated with a set of layered shapes, taken from the `area`[p472] elements in *areas*, in reverse tree order (so the last specified `area`[p472] element in the *map* is the bottom-most shape, and the first element in the *map*, in tree order, is the top-most shape).

Each area[p472] element in *areas* must be processed as follows to obtain a shape to layer onto the image:

1. Find the state that the element's shape[p473] attribute represents.
2. Use the rules for parsing a list of floating-point numbers[p82] to parse the element's coords[p474] attribute, if it is present, and let the *coords* list be the result. If the attribute is absent, let the *coords* list be the empty list.
3. If the number of items in the *coords* list is less than the minimum number given for the area[p472] element's current state, as per the following table, then the shape is empty; return.

State	Minimum number of items
Circle state[p474]	3
Default state[p474]	0
Polygon state[p474]	6
Rectangle state[p474]	4

4. Check for excess items in the *coords* list as per the entry in the following list corresponding to the shape[p473] attribute's state:

   ↪ **Circle state[p474]**

   Drop any items in the list beyond the third.

   ↪ **Default state[p474]**

   Drop all items in the list.

   ↪ **Polygon state[p474]**

   Drop the last item if there's an odd number of items.

   ↪ **Rectangle state[p474]**

   Drop any items in the list beyond the fourth.

5. If the shape[p473] attribute represents the rectangle state[p474], and the first number in the list is numerically greater than the third number in the list, then swap those two numbers around.
6. If the shape[p473] attribute represents the rectangle state[p474], and the second number in the list is numerically greater than the fourth number in the list, then swap those two numbers around.
7. If the shape[p473] attribute represents the circle state[p474], and the third number in the list is less than or equal to zero, then the shape is empty; return.
8. Now, the shape represented by the element is the one described for the entry in the list below corresponding to the state of the shape[p473] attribute:

   ↪ **Circle state[p474]**

   Let x be the first number in *coords*, y be the second number, and r be the third number.

   The shape is a circle whose center is x CSS pixels from the left edge of the image and y CSS pixels from the top edge of the image, and whose radius is r CSS pixels.

   ↪ **Default state[p474]**

   The shape is a rectangle that exactly covers the entire image.

   ↪ **Polygon state[p474]**

   Let x_i be the $(2i)$th entry in *coords*, and y_i be the $(2i+1)$th entry in *coords* (the first entry in *coords* being the one with index 0).

   Let *the coordinates* be (x_i, y_i), interpreted in CSS pixels measured from the top left of the image, for all integer values of i from 0 to $(N/2)-1$, where N is the number of items in *coords*.

   The shape is a polygon whose vertices are given by *the coordinates*, and whose interior is established using the even-odd rule. [GRAPHICS][p1496]

   ↪ **Rectangle state[p474]**

   Let x_1 be the first number in *coords*, y_1 be the second number, x_2 be the third number, and y_2 be the fourth number.

   The shape is a rectangle whose top-left corner is given by the coordinate (x_1, y_1) and whose bottom right corner is given by the coordinate (x_2, y_2), those coordinates being interpreted as CSS pixels from the top left corner of the

image.

For historical reasons, the coordinates must be interpreted relative to the *displayed* image after any stretching caused by the CSS 'width' and 'height' properties (or, for non-CSS browsers, the image element's `width` and `height` attributes — CSS browsers map those attributes to the aforementioned CSS properties).

Note

Browser zoom features and transforms applied using CSS or SVG do not affect the coordinates.

Pointing device interaction with an image associated with a set of layered shapes per the above algorithm must result in the relevant user interaction events being first fired to the top-most shape covering the point that the pointing device indicated, if any, or to the image element itself, if there is no shape covering that point. User agents may also allow individual `area` elements representing hyperlinks to be selected and activated (e.g. using a keyboard).

Note

Because a `map` element (and its `area` elements) can be associated with multiple `img` elements, it is possible for an `area` element to correspond to multiple focusable areas of the document.

Image maps are live; if the DOM is mutated, then the user agent must act as if it had rerun the algorithms for image maps.

4.8.15 MathML

The MathML `math` element falls into the embedded content, phrasing content, flow content, and palpable content categories for the purposes of the content models in this specification.

When the MathML `annotation-xml` element contains elements from the HTML namespace, such elements must all be flow content.

When the MathML token elements (`mi`, `mo`, `mn`, `ms`, and `mtext`) are descendants of HTML elements, they may contain phrasing content elements from the HTML namespace.

User agents must handle text other than inter-element whitespace found in MathML elements whose content models do not allow straight text by pretending for the purposes of MathML content models, layout, and rendering that the text is actually wrapped in a MathML `mtext` element. (Such text is not, however, conforming.)

User agents must act as if any MathML element whose contents does not match the element's content model was replaced, for the purposes of MathML layout and rendering, by a MathML `merror` element containing some appropriate error message.

The semantics of MathML elements are defined by *MathML* and other applicable specifications. [MATHML]

Example

Here is an example of the use of MathML in an HTML document:

```
<!DOCTYPE html>
<html lang="en">
 <head>
  <title>The quadratic formula</title>
 </head>
 <body>
  <h1>The quadratic formula</h1>
  <p>
   <math>
    <mi>x</mi>
    <mo>=</mo>
    <mfrac>
     <mrow>
      <mo form="prefix">−</mo> <mi>b</mi>
      <mo>±</mo>
      <msqrt>
       <msup> <mi>b</mi> <mn>2</mn> </msup>
```

```
        <mo>−</mo>
        <mn>4</mn> <mo></mo> <mi>a</mi> <mo></mo> <mi>c</mi>
       </msqrt>
      </mrow>
      <mrow>
       <mn>2</mn> <mo></mo> <mi>a</mi>
      </mrow>
     </mfrac>
    </math>
   </p>
  </body>
 </html>
```

4.8.16 SVG §[p47]

The SVG `svg` element falls into the embedded content[p151], phrasing content[p151], flow content[p150], and palpable content[p151] categories for the purposes of the content models in this specification.

When the SVG `foreignObject` element contains elements from the HTML namespace, such elements must all be flow content[p150].

The content model for the SVG `title` element inside HTML documents is phrasing content[p151]. (This further constrains the requirements given in *SVG 2*.)

The semantics of SVG elements are defined by *SVG 2* and other applicable specifications[p74]. [SVG][p1500]

For web developers (non-normative)

***doc* = *iframe*.getSVGDocument[p478]()**
***doc* = *embed*.getSVGDocument[p478]()**
***doc* = *object*.getSVGDocument[p478]()**

Returns the Document[p131] object, in the case of `iframe`[p391], `embed`[p400], or `object`[p403] elements being used to embed SVG.

The **`getSVGDocument()`** method steps are:

1. Let *document* be this's content document[p1004].
2. If *document* is non-null and was created by the page load processing model for XML files[p1075] section because the computed type of the resource in the navigate[p1028] algorithm was `image/svg+xml`[p1492], then return *document*.
3. Return null.

4.8.17 Dimension attributes §[p47]

Author requirements: The **`width`** and **`height`** attributes on `img`[p347], `iframe`[p391], `embed`[p400], `object`[p403], `video`[p407], `source`[p344] when the parent is a `picture`[p343] element and, when their `type`[p524] attribute is in the Image Button[p548] state, `input`[p521] elements may be specified to give the dimensions of the visual content of the element (the width and height respectively, relative to the nominal direction of the output medium), in CSS pixels. The attributes, if specified, must have values that are valid non-negative integers[p78].

The specified dimensions given may differ from the dimensions specified in the resource itself, since the resource may have a resolution that differs from the CSS pixel resolution. (On screens, CSS pixels have a resolution of 96ppi, but in general the CSS pixel resolution depends on the reading distance.) If both attributes are specified, then one of the following statements must be true:

- *specified width* - 0.5 ≤ *specified height* * *target ratio* ≤ *specified width* + 0.5
- *specified height* - 0.5 ≤ *specified width* / *target ratio* ≤ *specified height* + 0.5
- *specified height* = *specified width* = 0

The *target ratio* is the ratio of the natural width to the natural height in the resource. The *specified width* and *specified height* are the values of the `width`[p478] and `height`[p478] attributes respectively.

The two attributes must be omitted if the resource in question does not have both a natural width and a natural height.

If the two attributes are both 0, it indicates that the element is not intended for the user (e.g. it might be a part of a service to count page views).

Note

The dimension attributes are not intended to be used to stretch the image.

User agent requirements: User agents are expected to use these attributes as hints for the rendering[p1428].

The **`width`** and **`height`** IDL attributes on the `iframe`[p391], `embed`[p400], `object`[p403], `source`[p344], and `video`[p407] elements must reflect[p105] the respective content attributes of the same name.

Note

For `iframe`[p391], `embed`[p400] and `object`[p403] the IDL attributes are `DOMString`; for `video`[p407] and `source`[p344] the IDL attributes are `unsigned long`.

Note

The corresponding IDL attributes for `img`[p352] and `input`[p528] elements are defined in those respective elements' sections, as they are slightly more specific to those elements' other behaviors.

4.9 Tabular data §[p479]

4.9.1 The `table` element §[p479]

Categories[p147]:

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

In this order: optionally a `caption`[p487] element, followed by zero or more `colgroup`[p488] elements, followed optionally by a `thead`[p491] element, followed by either zero or more `tbody`[p490] elements or one or more `tr`[p493] elements, followed optionally by a `tfoot`[p492] element, optionally intermixed with one or more script-supporting elements[p152].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLTableElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute HTMLTableCaptionElement? caption;
  HTMLTableCaptionElement createCaption();
  [CEReactions] undefined deleteCaption();
```

```
  [CEReactions] attribute HTMLTableSectionElement? tHead;
  HTMLTableSectionElement createTHead();
  [CEReactions] undefined deleteTHead();

  [CEReactions] attribute HTMLTableSectionElement? tFoot;
  HTMLTableSectionElement createTFoot();
  [CEReactions] undefined deleteTFoot();

  [SameObject] readonly attribute HTMLCollection tBodies;
  HTMLTableSectionElement createTBody();

  [SameObject] readonly attribute HTMLCollection rows;
  HTMLTableRowElement insertRow(optional long index = -1);
  [CEReactions] undefined deleteRow(long index);

  // also has obsolete members
};
```

The table[p479] element represents[p142] data with more than one dimension, in the form of a table[p498].

The table[p479] element takes part in the table model[p498]. Tables have rows, columns, and cells given by their descendants. The rows and columns form a grid; a table's cells must completely cover that grid without overlap.

Note

Precise rules for determining whether this conformance requirement is met are described in the description of the table model[p498].

Authors are encouraged to provide information describing how to interpret complex tables. Guidance on how to provide such information[p483] is given below.

Tables must not be used as layout aids. Historically, some web authors have misused tables in HTML as a way to control their page layout. This usage is non-conforming, because tools attempting to extract tabular data from such documents would obtain very confusing results. In particular, users of accessibility tools like screen readers are likely to find it very difficult to navigate pages with tables used for layout.

Note

There are a variety of alternatives to using HTML tables for layout, such as CSS grid layout, CSS flexible box layout ("flexbox"), CSS multi-column layout, CSS positioning, and the CSS table model. [CSS][p1494]

Tables can be complicated to understand and navigate. To help users with this, user agents should clearly delineate cells in a table from each other, unless the user agent has classified the table as a (non-conforming) layout table.

Note

Authors and implementers are encouraged to consider using some of the table design techniques[p487] described below to make tables easier to navigate for users.

User agents, especially those that do table analysis on arbitrary content, are encouraged to find heuristics to determine which tables actually contain data and which are merely being used for layout. This specification does not define a precise heuristic, but the following are suggested as possible indicators:

Feature	Indication
The use of the role[p69] attribute with the value presentation	Probably a layout table
The use of the non-conforming border[p1449] attribute with the non-conforming value 0	Probably a layout table
The use of the non-conforming cellspacing[p1449] and cellpadding[p1449] attributes with the value 0	Probably a layout table
The use of caption[p487], thead[p491], or th[p496] elements	Probably a non-layout table
The use of the headers[p498] and scope[p496] attributes	Probably a non-layout table

Feature	Indication
The use of the non-conforming border[p1449] attribute with a value other than 0	Probably a non-layout table
Explicit visible borders set using CSS	Probably a non-layout table
The use of the summary[p1447] attribute	Not a good indicator (both layout and non-layout tables have historically been given this attribute)

Note

It is quite possible that the above suggestions are wrong. Implementers are urged to provide feedback elaborating on their experiences with trying to create a layout table detection heuristic.

If a table[p479] element has a (non-conforming) summary[p1447] attribute, and the user agent has not classified the table as a layout table, the user agent may report the contents of that attribute to the user.

For web developers (non-normative)

***table*.caption[p482] [= *value*]**

Returns the table's caption[p487] element.

Can be set, to replace the caption[p487] element.

***caption* = *table*.createCaption[p482]()**

Ensures the table has a caption[p487] element, and returns it.

***table*.deleteCaption[p482]()**

Ensures the table does not have a caption[p487] element.

***table*.tHead[p482] [= *value*]**

Returns the table's thead[p491] element.

Can be set, to replace the thead[p491] element. If the new value is not a thead[p491] element, throws a "HierarchyRequestError" DOMException.

***thead* = *table*.createTHead[p482]()**

Ensures the table has a thead[p491] element, and returns it.

***table*.deleteTHead[p482]()**

Ensures the table does not have a thead[p491] element.

***table*.tFoot[p482] [= *value*]**

Returns the table's tfoot[p492] element.

Can be set, to replace the tfoot[p492] element. If the new value is not a tfoot[p492] element, throws a "HierarchyRequestError" DOMException.

***tfoot* = *table*.createTFoot[p482]()**

Ensures the table has a tfoot[p492] element, and returns it.

***table*.deleteTFoot[p482]()**

Ensures the table does not have a tfoot[p492] element.

***table*.tBodies[p482]**

Returns an HTMLCollection of the tbody[p490] elements of the table.

***tbody* = *table*.createTBody[p482]()**

Creates a tbody[p490] element, inserts it into the table, and returns it.

***table*.rows[p482]**

Returns an HTMLCollection of the tr[p493] elements of the table.

***tr* = *table*.insertRow[p482]([*index*])**

Creates a tr[p493] element, along with a tbody[p490] if required, inserts them into the table at the position given by the argument, and returns the tr[p493].

The position is relative to the rows in the table. The index −1, which is the default if the argument is omitted, is equivalent to inserting at the end of the table.

If the given position is less than −1 or greater than the number of rows, throws an "IndexSizeError" DOMException.

***table*.deleteRow(*index*)**

Removes the tr element with the given position in the table.

The position is relative to the rows in the table. The index −1 is equivalent to deleting the last row of the table.

If the given position is less than −1 or greater than the index of the last row, or if there are no rows, throws an "IndexSizeError" DOMException.

In all of the following attribute and method definitions, when an element is to be **table-created**, that means to create an element given the table element's node document, the given local name, and the HTML namespace.

The **caption** IDL attribute must return, on getting, the first caption element child of the table element, if any, or null otherwise. On setting, the first caption element child of the table element, if any, must be removed, and the new value, if not null, must be inserted as the first node of the table element.

The **createCaption()** method must return the first caption element child of the table element, if any; otherwise a new caption element must be table-created, inserted as the first node of the table element, and then returned.

The **deleteCaption()** method must remove the first caption element child of the table element, if any.

The **tHead** IDL attribute must return, on getting, the first thead element child of the table element, if any, or null otherwise. On setting, if the new value is null or a thead element, the first thead element child of the table element, if any, must be removed, and the new value, if not null, must be inserted immediately before the first element in the table element that is neither a caption element nor a colgroup element, if any, or at the end of the table if there are no such elements. If the new value is neither null nor a thead element, then a "HierarchyRequestError" DOMException must be thrown instead.

The **createTHead()** method must return the first thead element child of the table element, if any; otherwise a new thead element must be table-created and inserted immediately before the first element in the table element that is neither a caption element nor a colgroup element, if any, or at the end of the table if there are no such elements, and then that new element must be returned.

The **deleteTHead()** method must remove the first thead element child of the table element, if any.

The **tFoot** IDL attribute must return, on getting, the first tfoot element child of the table element, if any, or null otherwise. On setting, if the new value is null or a tfoot element, the first tfoot element child of the table element, if any, must be removed, and the new value, if not null, must be inserted at the end of the table. If the new value is neither null nor a tfoot element, then a "HierarchyRequestError" DOMException must be thrown instead.

The **createTFoot()** method must return the first tfoot element child of the table element, if any; otherwise a new tfoot element must be table-created and inserted at the end of the table, and then that new element must be returned.

The **deleteTFoot()** method must remove the first tfoot element child of the table element, if any.

The **tBodies** attribute must return an HTMLCollection rooted at the table node, whose filter matches only tbody elements that are children of the table element.

The **createTBody()** method must table-create a new tbody element, insert it immediately after the last tbody element child in the table element, if any, or at the end of the table element if the table element has no tbody element children, and then must return the new tbody element.

The **rows** attribute must return an HTMLCollection rooted at the table node, whose filter matches only tr elements that are either children of the table element, or children of thead, tbody, or tfoot elements that are themselves children of the table element. The elements in the collection must be ordered such that those elements whose parent is a thead are included first, in tree order, followed by those elements whose parent is either a table or tbody element, again in tree order, followed finally by those elements whose parent is a tfoot element, still in tree order.

The behavior of the **insertRow(*index*)** method depends on the state of the table. When it is called, the method must act as required by the first item in the following list of conditions that describes the state of the table and the *index* argument:

↪ **If *index* is less than −1 or greater than the number of elements in rows collection:**

The method must throw an "IndexSizeError" DOMException.

↪ **If the rows[p482] collection has zero elements in it, and the table[p479] has no tbody[p490] elements in it:**

The method must table-create[p482] a tbody[p490] element, then table-create[p482] a tr[p493] element, then append the tr[p493] element to the tbody[p490] element, then append the tbody[p490] element to the table[p479] element, and finally return the tr[p493] element.

↪ **If the rows[p482] collection has zero elements in it:**

The method must table-create[p482] a tr[p493] element, append it to the last tbody[p490] element in the table, and return the tr[p493] element.

↪ **If *index* is −1 or equal to the number of items in rows[p482] collection:**

The method must table-create[p482] a tr[p493] element, and append it to the parent of the last tr[p493] element in the rows[p482] collection. Then, the newly created tr[p493] element must be returned.

↪ **Otherwise:**

The method must table-create[p482] a tr[p493] element, insert it immediately before the *index*th tr[p493] element in the rows[p482] collection, in the same parent, and finally must return the newly created tr[p493] element.

When the **deleteRow(*index*)** method is called, the user agent must run the following steps:

1. If *index* is less than −1 or greater than or equal to the number of elements in the rows[p482] collection, then throw an "IndexSizeError" DOMException.
2. If *index* is −1, then remove the last element in the rows[p482] collection from its parent, or do nothing if the rows[p482] collection is empty.
3. Otherwise, remove the *index*th element in the rows[p482] collection from its parent.

Example

Here is an example of a table being used to mark up a Sudoku puzzle. Observe the lack of headers, which are not necessary in such a table.

```
<style>
 #sudoku { border-collapse: collapse; border: solid thick; }
 #sudoku colgroup, table#sudoku tbody { border: solid medium; }
 #sudoku td { border: solid thin; height: 1.4em; width: 1.4em; text-align: center; padding: 0; }
</style>
<h1>Today's Sudoku</h1>
<table id="sudoku">
 <colgroup><col><col><col>
 <colgroup><col><col><col>
 <colgroup><col><col><col>
 <tbody>
  <tr> <td> 1 <td>   <td> 3 <td> 6 <td>   <td> 4 <td> 7 <td>   <td> 9
  <tr> <td>   <td> 2 <td>   <td>   <td> 9 <td>   <td>   <td> 1 <td>
  <tr> <td> 7 <td>   <td>   <td>   <td>   <td>   <td>   <td>   <td> 6
 <tbody>
  <tr> <td> 2 <td>   <td> 4 <td>   <td> 3 <td>   <td> 9 <td>   <td> 8
  <tr> <td>   <td>   <td>   <td>   <td>   <td>   <td>   <td>   <td>
  <tr> <td> 5 <td>   <td>   <td> 9 <td>   <td> 7 <td>   <td>   <td> 1
 <tbody>
  <tr> <td> 6 <td>   <td>   <td>   <td> 5 <td>   <td>   <td>   <td> 2
  <tr> <td>   <td>   <td>   <td>   <td> 7 <td>   <td>   <td>   <td>
  <tr> <td> 9 <td>   <td>   <td> 8 <td>   <td> 2 <td>   <td>   <td> 5
</table>
```

4.9.1.1 Techniques for describing tables §[p483]

For tables that consist of more than just a grid of cells with headers in the first row and headers in the first column, and for any table in general where the reader might have difficulty understanding the content, authors should include explanatory information introducing the table. This information is useful for all users, but is especially useful for users who cannot see the table, e.g. users of screen readers.

Such explanatory information should introduce the purpose of the table, outline its basic cell structure, highlight any trends or patterns, and generally teach the user how to use the table.

For instance, the following table:

Characteristics with positive and negative sides

Negative	Characteristic	Positive
Sad	**Mood**	Happy
Failing	**Grade**	Passing

...might benefit from a description explaining the way the table is laid out, something like "Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column".

There are a variety of ways to include this information, such as:

In prose, surrounding the table

Example

```
<p>In the following table, characteristics are given in the second
column, with the negative side in the left column and the positive
side in the right column.</p>
<table>
 <caption>Characteristics with positive and negative sides</caption>
 <thead>
  <tr>
   <th id="n"> Negative
   <th> Characteristic
   <th> Positive
 <tbody>
  <tr>
   <td headers="n r1"> Sad
   <th id="r1"> Mood
   <td> Happy
  <tr>
   <td headers="n r2"> Failing
   <th id="r2"> Grade
   <td> Passing
</table>
```

In the table's caption[p487]

Example

```
<table>
 <caption>
  <strong>Characteristics with positive and negative sides.</strong>
  <p>Characteristics are given in the second column, with the
  negative side in the left column and the positive side in the right
  column.</p>
 </caption>
 <thead>
  <tr>
   <th id="n"> Negative
   <th> Characteristic
   <th> Positive
 <tbody>
  <tr>
   <td headers="n r1"> Sad
   <th id="r1"> Mood
   <td> Happy
```

```
  <tr>
   <td headers="n r2"> Failing
   <th id="r2"> Grade
   <td> Passing
</table>
```

In the table's caption[p487], in a details[p641] element

Example

```
<table>
 <caption>
  <strong>Characteristics with positive and negative sides.</strong>
  <details>
   <summary>Help</summary>
   <p>Characteristics are given in the second column, with the
   negative side in the left column and the positive side in the right
   column.</p>
  </details>
 </caption>
 <thead>
  <tr>
   <th id="n"> Negative
   <th> Characteristic
   <th> Positive
 <tbody>
  <tr>
   <td headers="n r1"> Sad
   <th id="r1"> Mood
   <td> Happy
  <tr>
   <td headers="n r2"> Failing
   <th id="r2"> Grade
   <td> Passing
</table>
```

Next to the table, in the same figure[p250]

Example

```
<figure>
 <figcaption>Characteristics with positive and negative sides</figcaption>
 <p>Characteristics are given in the second column, with the
 negative side in the left column and the positive side in the right
 column.</p>
 <table>
  <thead>
   <tr>
    <th id="n"> Negative
    <th> Characteristic
    <th> Positive
  <tbody>
   <tr>
    <td headers="n r1"> Sad
    <th id="r1"> Mood
    <td> Happy
   <tr>
    <td headers="n r2"> Failing
    <th id="r2"> Grade
    <td> Passing
```

```
  </table>
 </figure>
```

Next to the table, in a figure[p250]'s figcaption[p253]

Example

```
<figure>
 <figcaption>
  <strong>Characteristics with positive and negative sides</strong>
  <p>Characteristics are given in the second column, with the
  negative side in the left column and the positive side in the right
  column.</p>
 </figcaption>
 <table>
  <thead>
   <tr>
    <th id="n"> Negative
    <th> Characteristic
    <th> Positive
  <tbody>
   <tr>
    <td headers="n r1"> Sad
    <th id="r1"> Mood
    <td> Happy
   <tr>
    <td headers="n r2"> Failing
    <th id="r2"> Grade
    <td> Passing
 </table>
</figure>
```

Authors may also use other techniques, or combinations of the above techniques, as appropriate.

The best option, of course, rather than writing a description explaining the way the table is laid out, is to adjust the table such that no explanation is needed.

Example

In the case of the table used in the examples above, a simple rearrangement of the table so that the headers are on the top and left sides removes the need for an explanation as well as removing the need for the use of headers[p498] attributes:

```
<table>
 <caption>Characteristics with positive and negative sides</caption>
 <thead>
  <tr>
   <th> Characteristic
   <th> Negative
   <th> Positive
 <tbody>
  <tr>
   <th> Mood
   <td> Sad
   <td> Happy
  <tr>
   <th> Grade
   <td> Failing
   <td> Passing
</table>
```

4.9.1.2 Techniques for table design §[p48]

Good table design is key to making tables more readable and usable.

In visual media, providing column and row borders and alternating row backgrounds can be very effective to make complicated tables more readable.

For tables with large volumes of numeric content, using monospaced fonts can help users see patterns, especially in situations where a user agent does not render the borders. (Unfortunately, for historical reasons, not rendering borders on tables is a common default.)

In speech media, table cells can be distinguished by reporting the corresponding headers before reading the cell's contents, and by allowing users to navigate the table in a grid fashion, rather than serializing the entire contents of the table in source order.

Authors are encouraged to use CSS to achieve these effects.

User agents are encouraged to render tables using these techniques whenever the page does not use CSS and the table is not classified as a layout table.

4.9.2 The `caption` element §[p48]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As the first element child of a `table`[p479] element.

Content model[p147]:

Flow content[p150], but with no descendant `table`[p479] elements.

Tag omission in text/html[p148]:

A `caption`[p487] element's end tag[p1280] can be omitted if the `caption`[p487] element is not immediately followed by ASCII whitespace or a comment[p1288].

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLTableCaptionElement : HTMLElement {
  [HTMLConstructor] constructor();

  // also has obsolete members
};
```

The `caption`[p487] element represents[p142] the title of the `table`[p479] that is its parent, if it has a parent and that is a `table`[p479] element.

The `caption`[p487] element takes part in the table model[p498].

When a `table`[p479] element is the only content in a `figure`[p250] element other than the `figcaption`[p253], the `caption`[p487] element should be omitted in favor of the `figcaption`[p253].

A caption can introduce context for a table, making it significantly easier to understand.

Example

Consider, for instance, the following table:

	1	2	3	4	5	6

1	2	3	4	5	6	7
2	3	4	5	6	7	8
3	4	5	6	7	8	9
4	5	6	7	8	9	10
5	6	7	8	9	10	11
6	7	8	9	10	11	12

In the abstract, this table is not clear. However, with a caption giving the table's number (for reference[p142] in the main prose) and explaining its use, it makes more sense:

```
<caption>
<p>Table 1.
<p>This table shows the total score obtained from rolling two
six-sided dice. The first row represents the value of the first die,
the first column the value of the second die. The total is given in
the cell that corresponds to the values of the two dice.
</caption>
```

This provides the user with more context:

Table 1.

This table shows the total score obtained from rolling two six-sided dice. The first row represents the value of the first die, the first column the value of the second die. The total is given in the cell that corresponds to the values of the two dice.

	1	**2**	**3**	**4**	**5**	**6**
1	2	3	4	5	6	7
2	3	4	5	6	7	8
3	4	5	6	7	8	9
4	5	6	7	8	9	10
5	6	7	8	9	10	11
6	7	8	9	10	11	12

4.9.3 The `colgroup` element §[p488]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a `table`[p479] element, after any `caption`[p487] elements and before any `thead`[p491], `tbody`[p490], `tfoot`[p492], and `tr`[p493] elements.

Content model[p147]:

If the `span`[p489] attribute is present: Nothing[p149].
If the `span`[p489] attribute is absent: Zero or more `col`[p489] and `template`[p679] elements.

Tag omission in text/html[p148]:

A `colgroup`[p488] element's start tag[p1279] can be omitted if the first thing inside the `colgroup`[p488] element is a `col`[p489] element, and if the element is not immediately preceded by another `colgroup`[p488] element whose end tag[p1280] has been omitted. (It can't be omitted if the element is empty.)
A `colgroup`[p488] element's end tag[p1280] can be omitted if the `colgroup`[p488] element is not immediately followed by ASCII whitespace or a comment[p1288].

Content attributes[p148]:

Global attributes[p155]
`span`[p489] — Number of columns spanned by the element

Accessibility considerations[p148]:

For authors.

For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLTableColElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute unsigned long span;

  // also has obsolete members
};
```

The colgroup[p488] element represents[p142] a group[p499] of one or more columns[p499] in the table[p479] that is its parent, if it has a parent and that is a table[p479] element.

If the colgroup[p488] element contains no col[p489] elements, then the element may have a **span** content attribute specified, whose value must be a valid non-negative integer[p78] greater than zero and less than or equal to 1000.

The colgroup[p488] element and its span[p489] attribute take part in the table model[p498].

The **span** IDL attribute must reflect[p105] the content attribute of the same name. It is clamped to the range[p108] [1, 1000], and its default value[p108] is 1.

4.9.4 The col element §[p489]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a colgroup[p488] element that doesn't have a span[p489] attribute.

Content model[p147]:

Nothing[p149].

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]
span[p489] — Number of columns spanned by the element

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLTableColElement[p489], as defined for colgroup[p488] elements.

If a col[p489] element has a parent and that is a colgroup[p488] element that itself has a parent that is a table[p479] element, then the col[p489] element represents[p142] one or more columns[p499] in the column group[p499] represented by that colgroup[p488].

The element may have a **span** content attribute specified, whose value must be a valid non-negative integer[p78] greater than zero and less than or equal to 1000.

The col[p489] element and its span[p489] attribute take part in the table model[p498].

4.9.5 The tbody element §

Categories:

None.

Contexts in which this element can be used:

As a child of a table element, after any caption, colgroup, and thead elements, but only if there are no tr elements that are children of the table element.

Content model:

Zero or more tr and script-supporting elements.

Tag omission in text/html:

A tbody element's start tag can be omitted if the first thing inside the tbody element is a tr element, and if the element is not immediately preceded by a tbody, thead, or tfoot element whose end tag has been omitted. (It can't be omitted if the element is empty.)

A tbody element's end tag can be omitted if the tbody element is immediately followed by a tbody or tfoot element, or if there is no more content in the parent element.

Content attributes:

Global attributes

Accessibility considerations:

For authors.

For implementers.

DOM interface:

IDL

```
[Exposed=Window]
interface HTMLTableSectionElement : HTMLElement {
  [HTMLConstructor] constructor();

  [SameObject] readonly attribute HTMLCollection rows;
  HTMLTableRowElement insertRow(optional long index = -1);
  [CEReactions] undefined deleteRow(long index);

  // also has obsolete members
};
```

The HTMLTableSectionElement interface is also used for thead and tfoot elements.

The tbody element represents a block of rows that consist of a body of data for the parent table element, if the tbody element has a parent and it is a table.

The tbody element takes part in the table model.

For web developers (non-normative)

***tbody*.rows**

Returns an HTMLCollection of the tr elements of the table section.

***tr* = *tbody*.insertRow([*index*])**

Creates a tr element, inserts it into the table section at the position given by the argument, and returns the tr.

The position is relative to the rows in the table section. The index −1, which is the default if the argument is omitted, is equivalent to inserting at the end of the table section.

If the given position is less than −1 or greater than the number of rows, throws an "IndexSizeError" DOMException.

***tbody*.deleteRow(*index*)**

Removes the tr element with the given position in the table section.

The position is relative to the rows in the table section. The index −1 is equivalent to deleting the last row of the table section.

If the given position is less than −1 or greater than the index of the last row, or if there are no rows, throws an "IndexSizeError" DOMException.

The **rows** attribute must return an HTMLCollection rooted at this element, whose filter matches only tr[p493] elements that are children of this element.

The **insertRow(*index*)** method must act as follows:

1. If *index* is less than −1 or greater than the number of elements in the rows[p491] collection, throw an "IndexSizeError" DOMException.
2. Let *table row* be the result of creating an element given this element's node document, "tr", and the HTML namespace.
3. If *index* is −1 or equal to the number of items in the rows[p491] collection, then append *table row* to this element.
4. Otherwise, insert *table row* as a child of this element, immediately before the *index*th tr[p493] element in the rows[p491] collection.
5. Return *table row*.

The **deleteRow(*index*)** method must, when invoked, act as follows:

1. If *index* is less than −1 or greater than or equal to the number of elements in the rows[p491] collection, then throw an "IndexSizeError" DOMException.
2. If *index* is −1, then remove the last element in the rows[p491] collection from this element, or do nothing if the rows[p491] collection is empty.
3. Otherwise, remove the *index*th element in the rows[p491] collection from this element.

4.9.6 The thead element §[p491]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a table[p479] element, after any caption[p487], and colgroup[p488] elements and before any tbody[p490], tfoot[p492], and tr[p493] elements, but only if there are no other thead[p491] elements that are children of the table[p479] element.

Content model[p147]:

Zero or more tr[p493] and script-supporting[p152] elements.

Tag omission in text/html[p148]:

A thead[p491] element's end tag[p1280] can be omitted if the thead[p491] element is immediately followed by a tbody[p490] or tfoot[p492] element.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLTableSectionElement[p490], as defined for tbody[p490] elements.

The thead[p491] element represents[p142] the block[p499] of rows[p498] that consist of the column labels (headers) and any ancillary non-header cells for the parent table[p479] element, if the thead[p491] element has a parent and it is a table[p479].

The thead[p491] element takes part in the table model[p498].

Example

This example shows a thead[p491] element being used. Notice the use of both th[p496] and td[p494] elements in the thead[p491] element: the first row is the headers, and the second row is an explanation of how to fill in the table.

```
<table>
```

```
 <caption> School auction sign-up sheet </caption>
 <thead>
  <tr>
   <th><label for=e1>Name</label>
   <th><label for=e2>Product</label>
   <th><label for=e3>Picture</label>
   <th><label for=e4>Price</label>
  <tr>
   <td>Your name here
   <td>What are you selling?
   <td>Link to a picture
   <td>Your reserve price
 <tbody>
  <tr>
   <td>Ms Danus
   <td>Doughnuts
   <td><img src="https://example.com/mydoughnuts.png" title="Doughnuts from Ms Danus">
   <td>$45
  <tr>
   <td><input id=e1 type=text name=who required form=f>
   <td><input id=e2 type=text name=what required form=f>
   <td><input id=e3 type=url name=pic form=f>
   <td><input id=e4 type=number step=0.01 min=0 value=0 required form=f>
</table>
<form id=f action="/auction.cgi">
 <input type=button name=add value="Submit">
</form>
```

4.9.7 The `tfoot` element §[p492]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a `table`[p479] element, after any `caption`[p487], `colgroup`[p488], `thead`[p491], `tbody`[p490], and `tr`[p493] elements, but only if there are no other `tfoot`[p492] elements that are children of the `table`[p479] element.

Content model[p147]:

Zero or more `tr`[p493] and script-supporting[p152] elements.

Tag omission in text/html[p148]:

A `tfoot`[p492] element's end tag[p1280] can be omitted if there is no more content in the parent element.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses `HTMLTableSectionElement`[p490], as defined for `tbody`[p490] elements.

The `tfoot`[p492] element represents[p142] the block[p499] of rows[p498] that consist of the column summaries (footers) for the parent `table`[p479] element, if the `tfoot`[p492] element has a parent and it is a `table`[p479].

The `tfoot`[p492] element takes part in the table model[p498].

4.9.8 The tr element §[p493]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a thead[p491] element.
As a child of a tbody[p490] element.
As a child of a tfoot[p492] element.
As a child of a table[p479] element, after any caption[p487], colgroup[p488], and thead[p491] elements, but only if there are no tbody[p490] elements that are children of the table[p479] element.

Content model[p147]:

Zero or more td[p494], th[p496], and script-supporting[p152] elements.

Tag omission in text/html[p148]:

A tr[p493] element's end tag[p1280] can be omitted if the tr[p493] element is immediately followed by another tr[p493] element, or if there is no more content in the parent element.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLTableRowElement : HTMLElement {
  [HTMLConstructor] constructor();

  readonly attribute long rowIndex;
  readonly attribute long sectionRowIndex;
  [SameObject] readonly attribute HTMLCollection cells;
  HTMLTableCellElement insertCell(optional long index = -1);
  [CEReactions] undefined deleteCell(long index);

  // also has obsolete members
};
```

The tr[p493] element represents[p142] a row[p498] of cells[p498] in a table[p498].

The tr[p493] element takes part in the table model[p498].

For web developers (non-normative)

***tr*.rowIndex[p494]**

Returns the position of the row in the table's rows[p482] list.

Returns −1 if the element isn't in a table.

***tr*.sectionRowIndex[p494]**

Returns the position of the row in the table section's rows[p491] list.

Returns −1 if the element isn't in a table section.

***tr*.cells[p494]**

Returns an HTMLCollection of the td[p494] and th[p496] elements of the row.

***cell* = *tr*.insertCell[p494]([*index*])**

Creates a td[p494] element, inserts it into the table row at the position given by the argument, and returns the td[p494].

The position is relative to the cells in the row. The index −1, which is the default if the argument is omitted, is equivalent to inserting at the end of the row.

If the given position is less than −1 or greater than the number of cells, throws an "IndexSizeError" DOMException.

***tr*.deleteCell(*index*)**

Removes the td or th element with the given position in the row.

The position is relative to the cells in the row. The index −1 is equivalent to deleting the last cell of the row.

If the given position is less than −1 or greater than the index of the last cell, or if there are no cells, throws an "IndexSizeError" DOMException.

The **rowIndex** attribute must, if this element has a parent table element, or a parent tbody, thead, or tfoot element and a *grandparent* table element, return the index of this tr element in that table element's rows collection. If there is no such table element, then the attribute must return −1.

The **sectionRowIndex** attribute must, if this element has a parent table, tbody, thead, or tfoot element, return the index of the tr element in the parent element's `rows` collection (for tables, that's HTMLTableElement's rows collection; for table sections, that's HTMLTableSectionElement's rows collection). If there is no such parent element, then the attribute must return −1.

The **cells** attribute must return an HTMLCollection rooted at this tr element, whose filter matches only td and th elements that are children of the tr element.

The **insertCell(*index*)** method must act as follows:

1. If *index* is less than −1 or greater than the number of elements in the cells collection, then throw an "IndexSizeError" DOMException.
2. Let *table cell* be the result of creating an element given this tr element's node document, "`td`", and the HTML namespace.
3. If *index* is equal to −1 or equal to the number of items in cells collection, then append *table cell* to this tr element.
4. Otherwise, insert *table cell* as a child of this tr element, immediately before the *index*th td or th element in the cells collection.
5. Return *table cell*.

The **deleteCell(*index*)** method must act as follows:

1. If *index* is less than −1 or greater than or equal to the number of elements in the cells collection, then throw an "IndexSizeError" DOMException.
2. If *index* is −1, then remove the last element in the cells collection from its parent, or do nothing if the cells collection is empty.
3. Otherwise, remove the *index*th element in the cells collection from its parent.

4.9.9 The td element §4

Categories:

None.

Contexts in which this element can be used:

As a child of a tr element.

Content model:

Flow content.

Tag omission in text/html:

A td element's end tag can be omitted if the td element is immediately followed by a td or th element, or if there is no more content in the parent element.

Content attributes:

Global attributes

colspan — Number of columns that the cell is to span

rowspan[p498] — Number of rows that the cell is to span
headers[p498] — The header cells for this cell

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLTableCellElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute unsigned long colSpan;
  [CEReactions] attribute unsigned long rowSpan;
  [CEReactions] attribute DOMString headers;
  readonly attribute long cellIndex;

  [CEReactions] attribute DOMString scope; // only conforming for th elements
  [CEReactions] attribute DOMString abbr;  // only conforming for th elements

  // also has obsolete members
};
```

The HTMLTableCellElement[p495] interface is also used for th[p496] elements.

The td[p494] element represents[p142] a data cell[p498] in a table.

The td[p494] element and its colspan[p497], rowspan[p498], and headers[p498] attributes take part in the table model[p498].

User agents, especially in non-visual environments or where displaying the table as a 2D grid is impractical, may give the user context for the cell when rendering the contents of a cell; for instance, giving its position in the table model[p498], or listing the cell's header cells (as determined by the algorithm for assigning header cells[p502]). When a cell's header cells are being listed, user agents may use the value of abbr[p496] attributes on those header cells, if any, instead of the contents of the header cells themselves.

Example

In this example, we see a snippet of a web application consisting of a grid of editable cells (essentially a simple spreadsheet). One of the cells has been configured to show the sum of the cells above it. Three have been marked as headings, which use th[p496] elements instead of td[p494] elements. A script would attach event handlers to these elements to maintain the total.

```
<table>
 <tr>
  <th><input value="Name">
  <th><input value="Paid ($)">
 <tr>
  <td><input value="Jeff">
  <td><input value="14">
 <tr>
  <td><input value="Britta">
  <td><input value="9">
 <tr>
  <td><input value="Abed">
  <td><input value="25">
 <tr>
  <td><input value="Shirley">
  <td><input value="2">
 <tr>
  <td><input value="Annie">
  <td><input value="5">
 <tr>
  <td><input value="Troy">
  <td><input value="5">
```

```
  <tr>
   <td><input value="Pierce">
   <td><input value="1000">
  <tr>
   <th><input value="Total">
   <td><output value="1060">
</table>
```

4.9.10 The th element §[p496]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As a child of a tr[p493] element.

Content model[p147]:

Flow content[p150], but with no header[p219], footer[p221], sectioning content[p150], or heading content[p151] descendants.

Tag omission in text/html[p148]:

A th[p496] element's end tag[p1280] can be omitted if the th[p496] element is immediately followed by a td[p494] or th[p496] element, or if there is no more content in the parent element.

Content attributes[p148]:

Global attributes[p155]
colspan[p497] — Number of columns that the cell is to span
rowspan[p498] — Number of rows that the cell is to span
headers[p498] — The header cells for this cell
scope[p496] — Specifies which cells the header cell applies to
abbr[p496] — Alternative label to use for the header cell when referencing the cell in other contexts

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLTableCellElement[p495], as defined for td[p494] elements.

The th[p496] element represents[p142] a header cell[p498] in a table.

The th[p496] element may have a **scope** content attribute specified.

The scope[p496] attribute is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
row	**Row**	The header cell applies to some of the subsequent cells in the same row(s).
col	**Column**	The header cell applies to some of the subsequent cells in the same column(s).
rowgroup	**Row Group**	The header cell applies to all the remaining cells in the row group.
colgroup	**Column Group**	The header cell applies to all the remaining cells in the column group.

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the **Auto** state. (In this state the header cell applies to a set of cells selected based on context.)

A th[p496] element's scope[p496] attribute must not be in the Row Group[p496] state if the element is not anchored in a row group[p499], nor in the Column Group[p496] state if the element is not anchored in a column group[p499].

The th[p496] element may have an **abbr** content attribute specified. Its value must be an alternative label for the header cell, to be used when referencing the cell in other contexts (e.g. when describing the header cells that apply to a data cell). It is typically an abbreviated form of the full header cell, but can also be an expansion, or merely a different phrasing.

The th[p496] element and its colspan[p497], rowspan[p498], headers[p498], and scope[p496] attributes take part in the table model[p498].

Example

The following example shows how the scope[p496] attribute's rowgroup[p496] value affects which data cells a header cell applies to.

Here is a markup fragment showing a table:

```
<table>
 <thead>
  <tr> <th> ID <th> Measurement <th> Average <th> Maximum
 <tbody>
  <tr> <td> <th scope=rowgroup> Cats <td> <td>
  <tr> <td> 93 <th> Legs <td> 3.5 <td> 4
  <tr> <td> 10 <th> Tails <td> 1 <td> 1
 <tbody>
  <tr> <td> <th scope=rowgroup> English speakers <td> <td>
  <tr> <td> 32 <th> Legs <td> 2.67 <td> 4
  <tr> <td> 35 <th> Tails <td> 0.33 <td> 1
</table>
```

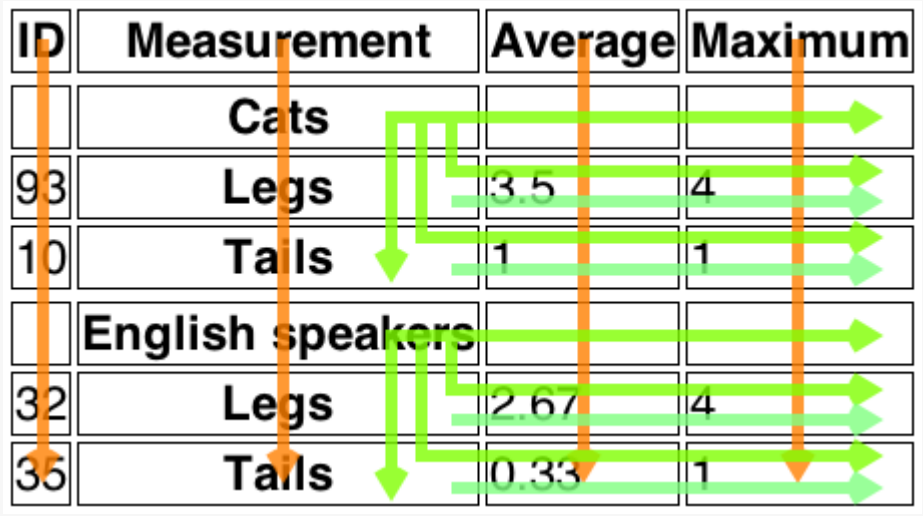
This would result in the following table:

ID	Measurement	Average	Maximum
	Cats		
93	**Legs**	3.5	4
10	**Tails**	1	1
	English speakers		
32	**Legs**	2.67	4
35	**Tails**	0.33	1

The headers in the first row all apply directly down to the rows in their column.

The headers with a scope[p496] attribute in the Row Group[p496] state apply to all the cells in their row group other than the cells in the first column.

The remaining headers apply just to the cells to the right of them.



4.9.11 Attributes common to td[p494] and th[p496] elements §[p497]

The td[p494] and th[p496] elements may have a **colspan** content attribute specified, whose value must be a valid non-negative integer[p78] greater than zero and less than or equal to 1000.

The td[p494] and th[p496] elements may also have a **rowspan** content attribute specified, whose value must be a valid non-negative integer[p78] less than or equal to 65534. For this attribute, the value zero means that the cell is to span all the remaining rows in the row group.

These attributes give the number of columns and rows respectively that the cell is to span. These attributes must not be used to overlap cells, as described in the description of the table model[p498].

The td[p494] and th[p496] element may have a **headers** content attribute specified. The headers[p498] attribute, if specified, must contain a string consisting of an unordered set of unique space-separated tokens[p96], none of which are identical to another token and each of which must have the value of an ID of a th[p496] element taking part in the same table[p498] as the td[p494] or th[p496] element (as defined by the table model[p498]).

A th[p496] element with ID *id* is said to be *directly targeted* by all td[p494] and th[p496] elements in the same table[p498] that have headers[p498] attributes whose values include as one of their tokens the ID *id*. A th[p496] element *A* is said to be *targeted* by a th[p496] or td[p494] element *B* if either *A* is *directly targeted* by *B* or if there exists an element *C* that is itself *targeted* by the element *B* and *A* is *directly targeted* by *C*.

A th[p496] element must not be *targeted* by itself.

The colspan[p497], rowspan[p498], and headers[p498] attributes take part in the table model[p498].

For web developers (non-normative)

***cell*.cellIndex**[p498]

Returns the position of the cell in the row's cells[p494] list. This does not necessarily correspond to the *x*-position of the cell in the table, since earlier cells might cover multiple rows or columns.

Returns −1 if the element isn't in a row.

The **colSpan** IDL attribute must reflect[p105] the colspan[p497] content attribute. It is clamped to the range[p108] [1, 1000], and its default value[p108] is 1.

The **rowSpan** IDL attribute must reflect[p105] the rowspan[p498] content attribute. It is clamped to the range[p108] [0, 65534], and its default value[p108] is 1.

The **headers** IDL attribute must reflect[p105] the content attribute of the same name.

The **cellIndex** IDL attribute must, if the element has a parent tr[p493] element, return the index of the cell's element in the parent element's cells[p494] collection. If there is no such parent element, then the attribute must return −1.

The **scope** IDL attribute must reflect[p105] the content attribute of the same name, limited to only known values[p106].

The **abbr** IDL attribute must reflect[p105] the content attribute of the same name.

4.9.12 Processing model §[p498]

The various table elements and their content attributes together define the **table model**.

A **table** consists of cells aligned on a two-dimensional grid of **slots** with coordinates (x, y). The grid is finite, and is either empty or has one or more slots. If the grid has one or more slots, then the x coordinates are always in the range $0 \le x < x_{width}$, and the y coordinates are always in the range $0 \le y < y_{height}$. If one or both of x_{width} and y_{height} are zero, then the table is empty (has no slots). Tables correspond to table[p479] elements.

A **cell** is a set of slots anchored at a slot ($cell_x$, $cell_y$), and with a particular *width* and *height* such that the cell covers all the slots with coordinates (x, y) where $cell_x \le x < cell_x + width$ and $cell_y \le y < cell_y + height$. Cells can either be *data cells* or *header cells*. Data cells correspond to td[p494] elements, and header cells correspond to th[p496] elements. Cells of both types can have zero or more associated header cells.

It is possible, in certain error cases, for two cells to occupy the same slot.

A **row** is a complete set of slots from x=0 to $x=x_{width}-1$, for a particular value of y. Rows usually correspond to tr[p493] elements, though

a row group[p499] can have some implied rows[p498] at the end in some cases involving cells[p498] spanning multiple rows.

A **column** is a complete set of slots from y=0 to y=y_{height}-1, for a particular value of x. Columns can correspond to `col`[p489] elements. In the absence of `col`[p489] elements, columns are implied.

A **row group** is a set of rows[p498] anchored at a slot (0, $group_y$) with a particular *height* such that the row group covers all the slots with coordinates (x, y) where $0 \le x < x_{width}$ and $group_y \le y < group_y+height$. Row groups correspond to `tbody`[p490], `thead`[p491], and `tfoot`[p492] elements. Not every row is necessarily in a row group.

A **column group** is a set of columns[p499] anchored at a slot ($group_x$, 0) with a particular *width* such that the column group covers all the slots with coordinates (x, y) where $group_x \le x < group_x+width$ and $0 \le y < y_{height}$. Column groups correspond to `colgroup`[p488] elements. Not every column is necessarily in a column group.

Row groups[p499] cannot overlap each other. Similarly, column groups[p499] cannot overlap each other.

A cell[p498] cannot cover slots that are from two or more row groups[p499]. It is, however, possible for a cell to be in multiple column groups[p499]. All the slots that form part of one cell are part of zero or one row groups[p499] and zero or more column groups[p499].

In addition to cells[p498], columns[p499], rows[p498], row groups[p499], and column groups[p499], tables[p498] can have a `caption`[p487] element associated with them. This gives the table a heading, or legend.

A **table model error** is an error with the data represented by `table`[p479] elements and their descendants. Documents must not have table model errors.

4.9.12.1 Forming a table §[p499]

To determine which elements correspond to which slots in a table[p498] associated with a `table`[p479] element, to determine the dimensions of the table (x_{width} and y_{height}), and to determine if there are any table model errors[p499], user agents must use the following algorithm:

1. Let x_{width} be 0.
2. Let y_{height} be 0.
3. Let *pending* `tfoot`[p492] *elements* be a list of `tfoot`[p492] elements, initially empty.
4. Let *the table* be the table[p498] represented by the `table`[p479] element. The x_{width} and y_{height} variables give *the table*'s dimensions. *The table* is initially empty.
5. If the `table`[p479] element has no children elements, then return *the table* (which will be empty).
6. Associate the first `caption`[p487] element child of the `table`[p479] element with *the table*. If there are no such children, then it has no associated `caption`[p487] element.
7. Let the *current element* be the first element child of the `table`[p479] element.

   If a step in this algorithm ever requires the *current element* to be **advanced to the next child of the `table`** when there is no such next child, then the user agent must jump to the step labeled *end*, near the end of this algorithm.
8. While the *current element* is not one of the following elements, advance[p499] the *current element* to the next child of the `table`[p479]:

   - `colgroup`[p488]
   - `thead`[p491]
   - `tbody`[p490]
   - `tfoot`[p492]
   - `tr`[p493]
9. If the *current element* is a `colgroup`[p488], follow these substeps:

   1. *Column groups*: Process the *current element* according to the appropriate case below:

      ↪ **If the *current element* has any `col`[p489] element children**

      Follow these steps:

      1. Let x_{start} have the value of x_{width}.

2. Let the *current column* be the first col[p489] element child of the colgroup[p488] element.

3. *Columns*: If the *current column* col[p489] element has a span[p489] attribute, then parse its value using the rules for parsing non-negative integers[p78].

   If the result of parsing the value is not an error or zero, then let *span* be that value.

   Otherwise, if the col[p489] element has no span[p489] attribute, or if trying to parse the attribute's value resulted in an error or zero, then let *span* be 1.

   If *span* is greater than 1000, let it be 1000 instead.

4. Increase x_{width} by *span*.

5. Let the last *span* columns[p499] in *the table* correspond to the *current column* col[p489] element.

6. If *current column* is not the last col[p489] element child of the colgroup[p488] element, then let the *current column* be the next col[p489] element child of the colgroup[p488] element, and return to the step labeled *columns*.

7. Let all the last columns[p499] in *the table* from x=x_{start} to x=x_{width}-1 form a new column group[p499], anchored at the slot (x_{start}, 0), with width x_{width}-x_{start}, corresponding to the colgroup[p488] element.

↪ **If the *current element* has no col[p489] element children**

1. If the colgroup[p488] element has a span[p489] attribute, then parse its value using the rules for parsing non-negative integers[p78].

   If the result of parsing the value is not an error or zero, then let *span* be that value.

   Otherwise, if the colgroup[p488] element has no span[p489] attribute, or if trying to parse the attribute's value resulted in an error or zero, then let *span* be 1.

   If *span* is greater than 1000, let it be 1000 instead.

2. Increase x_{width} by *span*.

3. Let the last *span* columns[p499] in *the table* form a new column group[p499], anchored at the slot (x_{width}-*span*, 0), with width *span*, corresponding to the colgroup[p488] element.

2. Advance[p499] the *current element* to the next child of the table[p479].

3. While the *current element* is not one of the following elements, advance[p499] the *current element* to the next child of the table[p479]:

   - colgroup[p488]
   - thead[p491]
   - tbody[p490]
   - tfoot[p492]
   - tr[p493]

4. If the *current element* is a colgroup[p488] element, jump to the step labeled *column groups* above.

10. Let $y_{current}$ be 0.

11. Let the *list of downward-growing cells* be an empty list.

12. *Rows*: While the *current element* is not one of the following elements, advance[p499] the *current element* to the next child of the table[p479]:

    - thead[p491]
    - tbody[p490]
    - tfoot[p492]
    - tr[p493]

13. If the *current element* is a tr[p493], then run the algorithm for processing rows[p501], advance[p499] the *current element* to the next child of the table[p479], and return to the step labeled *rows*.

14. Run the algorithm for ending a row group[p501].

15. If the *current element* is a tfoot[p492], then add that element to the list of *pending* tfoot[p492] *elements*, advance[p499] the *current element* to the next child of the table[p479], and return to the step labeled *rows*.

16. The *current element* is either a `thead`[p491] or a `tbody`[p490].

    Run the algorithm for processing row groups[p501].

17. Advance[p499] the *current element* to the next child of the `table`[p479].

18. Return to the step labeled *rows*.

19. *End*: For each `tfoot`[p492] element in the list of *pending* `tfoot`[p492] *elements*, in tree order, run the algorithm for processing row groups[p501].

20. If there exists a row[p498] or column[p499] in *the table* containing only slots[p498] that do not have a cell[p498] anchored to them, then this is a table model error[p499].

21. Return *the table*.

The **algorithm for processing row groups**, which is invoked by the set of steps above for processing `thead`[p491], `tbody`[p490], and `tfoot`[p492] elements, is:

1. Let y_{start} have the value of y_{height}.

2. For each `tr`[p493] element that is a child of the element being processed, in tree order, run the algorithm for processing rows[p501].

3. If $y_{height} > y_{start}$, then let all the last rows[p498] in *the table* from y=y_{start} to y=y_{height}-1 form a new row group[p499], anchored at the slot with coordinate (0, y_{start}), with height y_{height}-y_{start}, corresponding to the element being processed.

4. Run the algorithm for ending a row group[p501].

The **algorithm for ending a row group**, which is invoked by the set of steps above when starting and ending a block of rows, is:

1. While $y_{current}$ is less than y_{height}, follow these steps:

    1. Run the algorithm for growing downward-growing cells[p502].

    2. Increase $y_{current}$ by 1.

2. Empty the *list of downward-growing cells*.

The **algorithm for processing rows**, which is invoked by the set of steps above for processing `tr`[p493] elements, is:

1. If y_{height} is equal to $y_{current}$, then increase y_{height} by 1. ($y_{current}$ is never *greater* than y_{height}.)

2. Let $x_{current}$ be 0.

3. Run the algorithm for growing downward-growing cells[p502].

4. If the `tr`[p493] element being processed has no `td`[p494] or `th`[p496] element children, then increase $y_{current}$ by 1, abort this set of steps, and return to the algorithm above.

5. Let *current cell* be the first `td`[p494] or `th`[p496] element child in the `tr`[p493] element being processed.

6. *Cells*: While $x_{current}$ is less than x_{width} and the slot with coordinate ($x_{current}$, $y_{current}$) already has a cell assigned to it, increase $x_{current}$ by 1.

7. If $x_{current}$ is equal to x_{width}, increase x_{width} by 1. ($x_{current}$ is never *greater* than x_{width}.)

8. If the *current cell* has a `colspan`[p497] attribute, then parse that attribute's value[p78], and let *colspan* be the result.

    If parsing that value failed, or returned zero, or if the attribute is absent, then let *colspan* be 1, instead.

    If *colspan* is greater than 1000, let it be 1000 instead.

9. If the *current cell* has a `rowspan`[p498] attribute, then parse that attribute's value[p78], and let *rowspan* be the result.

    If parsing that value failed or if the attribute is absent, then let *rowspan* be 1, instead.

    If *rowspan* is greater than 65534, let it be 65534 instead.

10. If *rowspan* is zero and the `table`[p479] element's node document is not set to quirks mode, then let *cell grows downward* be true, and set *rowspan* to 1. Otherwise, let *cell grows downward* be false.

11. If $x_{width} < x_{current}+colspan$, then let x_{width} be $x_{current}+colspan$.

12. If $y_{height} < y_{current}+rowspan$, then let y_{height} be $y_{current}+rowspan$.

13. Let the slots with coordinates (x, y) such that $x_{current} \leq x < x_{current}+colspan$ and $y_{current} \leq y < y_{current}+rowspan$ be covered by a new cell[p498] c, anchored at ($x_{current}$, $y_{current}$), which has width *colspan* and height *rowspan*, corresponding to the *current cell* element.

    If the *current cell* element is a `th`[p496] element, let this new cell c be a header cell; otherwise, let it be a data cell.

    To establish which header cells apply to the *current cell* element, use the algorithm for assigning header cells[p502] described in the next section.

    If any of the slots involved already had a cell[p498] covering them, then this is a table model error[p499]. Those slots now have two cells overlapping.

14. If *cell grows downward* is true, then add the tuple {c, $x_{current}$, *colspan*} to the *list of downward-growing cells*.

15. Increase $x_{current}$ by *colspan*.

16. If *current cell* is the last `td`[p494] or `th`[p496] element child in the `tr`[p493] element being processed, then increase $y_{current}$ by 1, abort this set of steps, and return to the algorithm above.

17. Let *current cell* be the next `td`[p494] or `th`[p496] element child in the `tr`[p493] element being processed.

18. Return to the step labeled *cells*.

When the algorithms above require the user agent to run the **algorithm for growing downward-growing cells**, the user agent must, for each {*cell*, $cell_x$, *width*} tuple in the *list of downward-growing cells*, if any, extend the cell[p498] *cell* so that it also covers the slots with coordinates (x, $y_{current}$), where $cell_x \leq x < cell_x+width$.

4.9.12.2 Forming relationships between data cells and header cells §[p502]

Each cell can be assigned zero or more header cells. The **algorithm for assigning header cells** to a cell *principal cell* is as follows.

1. Let *header list* be an empty list of cells.

2. Let ($principal_x$, $principal_y$) be the coordinate of the slot to which the *principal cell* is anchored.

3↦ **If the *principal cell* has a `headers`[p498] attribute specified**

    1. Take the value of the *principal cell*'s `headers`[p498] attribute and split it on ASCII whitespace, letting *id list* be the list of tokens obtained.

    2. For each token in the *id list*, if the first element in the `Document`[p131] with an ID equal to the token is a cell in the same table[p498], and that cell is not the *principal cell*, then add that cell to *header list*.

↪ **If *principal cell* does not have a `headers`[p498] attribute specified**

    1. Let $principal_{width}$ be the width of the *principal cell*.

    2. Let $principal_{height}$ be the height of the *principal cell*.

    3. For each value of y from $principal_y$ to $principal_y+principal_{height}-1$, run the internal algorithm for scanning and assigning header cells[p503], with the *principal cell*, the *header list*, the initial coordinate ($principal_x$, y), and the increments $\Delta x=-1$ and $\Delta y=0$.

    4. For each value of x from $principal_x$ to $principal_x+principal_{width}-1$, run the internal algorithm for scanning and assigning header cells[p503], with the *principal cell*, the *header list*, the initial coordinate (x, $principal_y$), and the increments $\Delta x=0$ and $\Delta y=-1$.

    5. If the *principal cell* is anchored in a row group[p499], then add all header cells that are row group headers[p504] and are anchored in the same row group with an x-coordinate less than or equal to $principal_x+principal_{width}-1$ and a y-coordinate less than or equal to $principal_y+principal_{height}-1$ to *header list*.

    6. If the *principal cell* is anchored in a column group[p499], then add all header cells that are column group

headers[p504] and are anchored in the same column group with an *x*-coordinate less than or equal to $principal_x+principal_{width}-1$ and a *y*-coordinate less than or equal to $principal_y+principal_{height}-1$ to *header list*.

4. Remove all the empty cells[p504] from the *header list*.
5. Remove any duplicates from the *header list*.
6. Remove *principal cell* from the *header list* if it is there.
7. Assign the headers in the *header list* to the *principal cell*.

The **internal algorithm for scanning and assigning header cells**, given a *principal cell*, a *header list*, an initial coordinate ($initial_x$, $initial_y$), and Δx and Δy increments, is as follows:

1. Let *x* equal $initial_x$.
2. Let *y* equal $initial_y$.
3. Let *opaque headers* be an empty list of cells.

4↦ **If *principal cell* is a header cell**

Let *in header block* be true, and let *headers from current header block* be a list of cells containing just the *principal cell*.

↪ **Otherwise**

Let *in header block* be false and let *headers from current header block* be an empty list of cells.

5. *Loop*: Increment *x* by Δx; increment *y* by Δy.

Note

For each invocation of this algorithm, one of Δx and Δy will be −1, and the other will be 0.

6. If either *x* or *y* are less than 0, then abort this internal algorithm.
7. If there is no cell covering slot (*x*, *y*), or if there is more than one cell covering slot (*x*, *y*), return to the substep labeled *loop*.
8. Let *current cell* be the cell covering slot (*x*, *y*).

9↦ **If *current cell* is a header cell**

1. Set *in header block* to true.
2. Add *current cell* to *headers from current header block*.
3. Let *blocked* be false.

4↦ **If Δ*x* is 0**

If there are any cells in the *opaque headers* list anchored with the same *x*-coordinate as the *current cell*, and with the same width as *current cell*, then let *blocked* be true.

If the *current cell* is not a column header[p503], then let *blocked* be true.

↪ **If Δ*y* is 0**

If there are any cells in the *opaque headers* list anchored with the same *y*-coordinate as the *current cell*, and with the same height as *current cell*, then let *blocked* be true.

If the *current cell* is not a row header[p504], then let *blocked* be true.

5. If *blocked* is false, then add the *current cell* to the *header list*.

↪ **If *current cell* is a data cell and *in header block* is true**

Set *in header block* to false. Add all the cells in *headers from current header block* to the *opaque headers* list, and empty the *headers from current header block* list.

10. Return to the step labeled *loop*.

A header cell anchored at the slot with coordinate (*x*, *y*) with width *width* and height *height* is said to be a **column header** if any of the

following are true:

- the cell's scope[p496] attribute is in the Column[p496] state; or
- the cell's scope[p496] attribute is in the Auto[p496] state, and there are no data cells in any of the cells covering slots with *y*-coordinates *y* .. *y*+*height*-1.

A header cell anchored at the slot with coordinate (*x*, *y*) with width *width* and height *height* is said to be a **row header** if any of the following are true:

- the cell's scope[p496] attribute is in the Row[p496] state; or
- the cell's scope[p496] attribute is in the Auto[p496] state, the cell is not a column header[p503], and there are no data cells in any of the cells covering slots with *x*-coordinates *x* .. *x*+*width*-1.

A header cell is said to be a **column group header** if its scope[p496] attribute is in the Column Group[p496] state.

A header cell is said to be a **row group header** if its scope[p496] attribute is in the Row Group[p496] state.

A cell is said to be an **empty cell** if it contains no elements and its child text content, if any, consists only of ASCII whitespace.

4.9.13 Examples §[p504]

This section is non-normative.

The following shows how one might mark up the bottom part of table 45 of the *Smithsonian physical tables, Volume 71*:

```
<table>
 <caption>Specification values: <b>Steel</b>, <b>Castings</b>,
 Ann. A.S.T.M. A27-16, Class B;* P max. 0.06; S max. 0.05.</caption>
 <thead>
  <tr>
   <th rowspan=2>Grade.</th>
   <th rowspan=2>Yield Point.</th>
   <th colspan=2>Ultimate tensile strength</th>
   <th rowspan=2>Per cent elong. 50.8 mm or 2 in.</th>
   <th rowspan=2>Per cent reduct. area.</th>
  </tr>
  <tr>
   <th>kg/mm<sup>2</sup></th>
   <th>lb/in<sup>2</sup></th>
  </tr>
 </thead>
 <tbody>
  <tr>
   <td>Hard</td>
   <td>0.45 ultimate</td>
   <td>56.2</td>
   <td>80,000</td>
   <td>15</td>
   <td>20</td>
  </tr>
  <tr>
   <td>Medium</td>
   <td>0.45 ultimate</td>
   <td>49.2</td>
   <td>70,000</td>
   <td>18</td>
   <td>25</td>
  </tr>
  <tr>
   <td>Soft</td>
```

```
   <td>0.45 ultimate</td>
   <td>42.2</td>
   <td>60,000</td>
   <td>22</td>
   <td>30</td>
  </tr>
 </tbody>
</table>
```

This table could look like this:

Specification values: **Steel, Castings,** Ann. A.S.T.M. A27-16, Class B;* P max. 0.06; S max. 0.05.

Grade.	Yield Point.	Ultimate tensile strength		Per cent elong. 50.8 mm or 2 in.	Per cent reduct. area.
		kg/mm^2	lb/in^2		
Hard.	0.45 ultimate	56.2	80,000	15	20
Medium . . .	0.45 ultimate	49.2	70,000	18	25
Soft	0.45 ultimate	42.2	60,000	22	30

The following shows how one might mark up the gross margin table on page 46 of Apple, Inc's 10-K filing for fiscal year 2008:

```
<table>
 <thead>
  <tr>
   <th>
   <th>2008
   <th>2007
   <th>2006
 <tbody>
  <tr>
   <th>Net sales
   <td>$ 32,479
   <td>$ 24,006
   <td>$ 19,315
  <tr>
   <th>Cost of sales
   <td>  21,334
   <td>  15,852
   <td>  13,717
 <tbody>
  <tr>
   <th>Gross margin
   <td>$ 11,145
   <td>$  8,154
   <td>$  5,598
 <tfoot>
  <tr>
   <th>Gross margin percentage
   <td>34.3%
   <td>34.0%
   <td>29.0%
</table>
```

This table could look like this:

	2008	2007	2006
Net sales	$ 32,479	$ 24,006	$ 19,315
Cost of sales	21,334	15,852	13,717
Gross margin	$ 11,145	$ 8,154	$ 5,598
Gross margin percentage	34.3%	34.0%	29.0%

The following shows how one might mark up the operating expenses table from lower on the same page of that document:

```
<table>
 <colgroup> <col>
 <colgroup> <col> <col> <col>
 <thead>
  <tr> <th> <th>2008 <th>2007 <th>2006
 <tbody>
  <tr> <th scope=rowgroup> Research and development
       <td> $ 1,109 <td> $ 782 <td> $ 712
  <tr> <th scope=row> Percentage of net sales
       <td> 3.4% <td> 3.3% <td> 3.7%
 <tbody>
  <tr> <th scope=rowgroup> Selling, general, and administrative
       <td> $ 3,761 <td> $ 2,963 <td> $ 2,433
  <tr> <th scope=row> Percentage of net sales
       <td> 11.6% <td> 12.3% <td> 12.6%
</table>
```

This table could look like this:

	2008	2007	2006
Research and development	$ 1,109	$ 782	$ 712
Percentage of net sales	3.4%	3.3%	3.7%
Selling, general, and administrative	$ 3,761	$ 2,963	$ 2,433
Percentage of net sales	11.6%	12.3%	12.6%

4.10 Forms §p506

4.10.1 Introduction §p506

This section is non-normative.

A form is a component of a web page that has form controls, such as text, buttons, checkboxes, range, or color picker controls. A user can interact with such a form, providing data that can then be sent to the server for further processing (e.g. returning the results of a search or calculation). No client-side scripting is needed in many cases, though an API is available so that scripts can augment the user experience or use forms for purposes other than submitting data to a server.

Writing a form consists of several steps, which can be performed in any order: writing the user interface, implementing the server-side processing, and configuring the user interface to communicate with the server.

4.10.1.1 Writing a form's user interface §p506

This section is non-normative.

For the purposes of this brief introduction, we will create a pizza ordering form.

Any form starts with a form p515 element, inside which are placed the controls. Most controls are represented by the input p521 element, which by default provides a text control. To label a control, the label p519 element is used; the label text and the control itself go inside the label p519 element. Each part of a form is considered a paragraph p153, and is typically separated from other parts using p p230 elements. Putting this together, here is how one might ask for the customer's name:

```
<form>
 <p><label>Customer name: <input></label></p>
</form>
```

To let the user select the size of the pizza, we can use a set of radio buttons. Radio buttons also use the input p521 element, this time

with a type[p524] attribute with the value radio[p544]. To make the radio buttons work as a group, they are given a common name using the name[p603] attribute. To group a batch of controls together, such as, in this case, the radio buttons, one can use the fieldset[p597] element. The title of such a group of controls is given by the first element in the fieldset[p597], which has to be a legend[p600] element.

```
<form>
 <p><label>Customer name: <input></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size> Small </label></p>
  <p><label> <input type=radio name=size> Medium </label></p>
  <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
</form>
```

Note

Changes from the previous step are highlighted.

To pick toppings, we can use checkboxes. These use the input[p521] element with a type[p524] attribute with the value checkbox[p544]:

```
<form>
 <p><label>Customer name: <input></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size> Small </label></p>
  <p><label> <input type=radio name=size> Medium </label></p>
  <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox> Bacon </label></p>
  <p><label> <input type=checkbox> Extra Cheese </label></p>
  <p><label> <input type=checkbox> Onion </label></p>
  <p><label> <input type=checkbox> Mushroom </label></p>
 </fieldset>
</form>
```

The pizzeria for which this form is being written is always making mistakes, so it needs a way to contact the customer. For this purpose, we can use form controls specifically for telephone numbers (input[p521] elements with their type[p524] attribute set to tel[p529]) and email addresses (input[p521] elements with their type[p524] attribute set to email[p531]):

```
<form>
 <p><label>Customer name: <input></label></p>
 <p><label>Telephone: <input type=tel></label></p>
 <p><label>Email address: <input type=email></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size> Small </label></p>
  <p><label> <input type=radio name=size> Medium </label></p>
  <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox> Bacon </label></p>
  <p><label> <input type=checkbox> Extra Cheese </label></p>
  <p><label> <input type=checkbox> Onion </label></p>
  <p><label> <input type=checkbox> Mushroom </label></p>
 </fieldset>
</form>
```

We can use an input[p521] element with its type[p524] attribute set to time[p536] to ask for a delivery time. Many of these form controls have attributes to control exactly what values can be specified; in this case, three attributes of particular interest are min[p557], max[p557], and

step[p558]. These set the minimum time, the maximum time, and the interval between allowed values (in seconds). This pizzeria only delivers between 11am and 9pm, and doesn't promise anything better than 15 minute increments, which we can mark up as follows:

```
<form>
 <p><label>Customer name: <input></label></p>
 <p><label>Telephone: <input type=tel></label></p>
 <p><label>Email address: <input type=email></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size> Small </label></p>
  <p><label> <input type=radio name=size> Medium </label></p>
  <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox> Bacon </label></p>
  <p><label> <input type=checkbox> Extra Cheese </label></p>
  <p><label> <input type=checkbox> Onion </label></p>
  <p><label> <input type=checkbox> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"></label></p>
</form>
```

The textarea[p583] element can be used to provide a multiline text control. In this instance, we are going to use it to provide a space for the customer to give delivery instructions:

```
<form>
 <p><label>Customer name: <input></label></p>
 <p><label>Telephone: <input type=tel></label></p>
 <p><label>Email address: <input type=email></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size> Small </label></p>
  <p><label> <input type=radio name=size> Medium </label></p>
  <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox> Bacon </label></p>
  <p><label> <input type=checkbox> Extra Cheese </label></p>
  <p><label> <input type=checkbox> Onion </label></p>
  <p><label> <input type=checkbox> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"></label></p>
 <p><label>Delivery instructions: <textarea></textarea></label></p>
</form>
```

Finally, to make the form submittable we use the button[p567] element:

```
<form>
 <p><label>Customer name: <input></label></p>
 <p><label>Telephone: <input type=tel></label></p>
 <p><label>Email address: <input type=email></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size> Small </label></p>
  <p><label> <input type=radio name=size> Medium </label></p>
  <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
```

```
  <p><label> <input type=checkbox> Bacon </label></p>
  <p><label> <input type=checkbox> Extra Cheese </label></p>
  <p><label> <input type=checkbox> Onion </label></p>
  <p><label> <input type=checkbox> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"></label></p>
 <p><label>Delivery instructions: <textarea></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

4.10.1.2 Implementing the server-side processing for a form §[p509]

This section is non-normative.

The exact details for writing a server-side processor are out of scope for this specification. For the purposes of this introduction, we will assume that the script at `https://pizza.example.com/order.cgi` is configured to accept submissions using the application/x-www-form-urlencoded[p607] format, expecting the following parameters sent in an HTTP POST body:

`custname`
: Customer's name

`custtel`
: Customer's telephone number

`custemail`
: Customer's email address

`size`
: The pizza size, either `small`, `medium`, or `large`

`topping`
: A topping, specified once for each selected topping, with the allowed values being `bacon`, `cheese`, `onion`, and `mushroom`

`delivery`
: The requested delivery time

`comments`
: The delivery instructions

4.10.1.3 Configuring a form to communicate with a server §[p509]

This section is non-normative.

Form submissions are exposed to servers in a variety of ways, most commonly as HTTP GET or POST requests. To specify the exact method used, the method[p606] attribute is specified on the form[p515] element. This doesn't specify how the form data is encoded, though; to specify that, you use the enctype[p607] attribute. You also have to specify the URL of the service that will handle the submitted data, using the action[p606] attribute.

For each form control you want submitted, you then have to give a name that will be used to refer to the data in the submission. We already specified the name for the group of radio buttons; the same attribute (name[p603]) also specifies the submission name. Radio buttons can be distinguished from each other in the submission by giving them different values, using the value[p526] attribute.

Multiple controls can have the same name; for example, here we give all the checkboxes the same name, and the server distinguishes which checkbox was checked by seeing which values are submitted with that name — like the radio buttons, they are also given unique values with the value[p526] attribute.

Given the settings in the previous section, this all becomes:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
```

```
      action="https://pizza.example.com/order.cgi">
 <p><label>Customer name: <input name="custname"></label></p>
 <p><label>Telephone: <input type=tel name="custtel"></label></p>
 <p><label>Email address: <input type=email name="custemail"></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size value="small"> Small </label></p>
  <p><label> <input type=radio name=size value="medium"> Medium </label></p>
  <p><label> <input type=radio name=size value="large"> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
  <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
  <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
  <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"
name="delivery"></label></p>
 <p><label>Delivery instructions: <textarea name="comments"></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

Note

There is no particular significance to the way some of the attributes have their values quoted and others don't. The HTML syntax allows a variety of equally valid ways to specify attributes, as discussed in the syntax section[p1280].

For example, if the customer entered "Denise Lawrence" as their name, "555-321-8642" as their telephone number, did not specify an email address, asked for a medium-sized pizza, selected the Extra Cheese and Mushroom toppings, entered a delivery time of 7pm, and left the delivery instructions text control blank, the user agent would submit the following to the online web service:

```
custname=Denise+Lawrence&custtel=555-321-8642&custemail=&size=medium&topping=cheese&topping=mushroom&de
livery=19%3A00&comments=
```

4.10.1.4 Client-side form validation §[p510]

This section is non-normative.

Forms can be annotated in such a way that the user agent will check the user's input before the form is submitted. The server still has to verify the input is valid (since hostile users can easily bypass the form validation), but it allows the user to avoid the wait incurred by having the server be the sole checker of the user's input.

The simplest annotation is the `required`[p554] attribute, which can be specified on `input`[p521] elements to indicate that the form is not to be submitted until a value is given. By adding this attribute to the customer name, pizza size, and delivery time fields, we allow the user agent to notify the user when the user submits the form without filling in those fields:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
 <p><label>Customer name: <input name="custname" required></label></p>
 <p><label>Telephone: <input type=tel name="custtel"></label></p>
 <p><label>Email address: <input type=email name="custemail"></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size required value="small"> Small </label></p>
  <p><label> <input type=radio name=size required value="medium"> Medium </label></p>
  <p><label> <input type=radio name=size required value="large"> Large </label></p>
 </fieldset>
 <fieldset>
```

```
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
  <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
  <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
  <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"
name="delivery" required></label></p>
 <p><label>Delivery instructions: <textarea name="comments"></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

It is also possible to limit the length of the input, using the maxlength[p604] attribute. By adding this to the textarea[p583] element, we can limit users to 1000 characters, preventing them from writing huge essays to the busy delivery drivers instead of staying focused and to the point:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
 <p><label>Customer name: <input name="custname" required></label></p>
 <p><label>Telephone: <input type=tel name="custtel"></label></p>
 <p><label>Email address: <input type=email name="custemail"></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size required value="small"> Small </label></p>
  <p><label> <input type=radio name=size required value="medium"> Medium </label></p>
  <p><label> <input type=radio name=size required value="large"> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
  <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
  <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
  <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"
name="delivery" required></label></p>
 <p><label>Delivery instructions: <textarea name="comments" maxlength=1000></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

Note

When a form is submitted, invalid[p1490] events are fired at each form control that is invalid. This can be useful for displaying a summary of the problems with the form, since typically the browser itself will only report one problem at a time.

4.10.1.5 Enabling client-side automatic filling of form controls §[p51]

This section is non-normative.

Some browsers attempt to aid the user by automatically filling form controls rather than having the user reenter their information each time. For example, a field asking for the user's telephone number can be automatically filled with the user's phone number.

To help the user agent with this, the autocomplete[p608] attribute can be used to describe the field's purpose. In the case of this form, we have three fields that can be usefully annotated in this way: the information about who the pizza is to be delivered to. Adding this information looks like this:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
```

```
 <p><label>Customer name: <input name="custname" required autocomplete="shipping name"></label></p>
 <p><label>Telephone: <input type=tel name="custtel" autocomplete="shipping tel"></label></p>
 <p><label>Email address: <input type=email name="custemail" autocomplete="shipping email"></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size required value="small"> Small </label></p>
  <p><label> <input type=radio name=size required value="medium"> Medium </label></p>
  <p><label> <input type=radio name=size required value="large"> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
  <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
  <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
  <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"
name="delivery" required></label></p>
 <p><label>Delivery instructions: <textarea name="comments" maxlength=1000></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

4.10.1.6 Improving the user experience on mobile devices §[p51]

This section is non-normative.

Some devices, in particular those with virtual keyboards can provide the user with multiple input modalities. For example, when typing in a credit card number the user may wish to only see keys for digits 0-9, while when typing in their name they may wish to see a form field that by default capitalizes each word.

Using the `inputmode`[p870] attribute we can select appropriate input modalities:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
 <p><label>Customer name: <input name="custname" required autocomplete="shipping name"></label></p>
 <p><label>Telephone: <input type=tel name="custtel" autocomplete="shipping tel"></label></p>
 <p><label>Buzzer code: <input name="custbuzz" inputmode="numeric"></label></p>
 <p><label>Email address: <input type=email name="custemail" autocomplete="shipping email"></label></p>
 <fieldset>
  <legend> Pizza Size </legend>
  <p><label> <input type=radio name=size required value="small"> Small </label></p>
  <p><label> <input type=radio name=size required value="medium"> Medium </label></p>
  <p><label> <input type=radio name=size required value="large"> Large </label></p>
 </fieldset>
 <fieldset>
  <legend> Pizza Toppings </legend>
  <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
  <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
  <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
  <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"
name="delivery" required></label></p>
 <p><label>Delivery instructions: <textarea name="comments" maxlength=1000></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

4.10.1.7 The difference between the field type, the autofill field name, and the input modality §[p513]

This section is non-normative.

The type[p524], autocomplete[p608], and inputmode[p870] attributes can seem confusingly similar. For instance, in all three cases, the string "email" is a valid value. This section attempts to illustrate the difference between the three attributes and provides advice suggesting how to use them.

The type[p524] attribute on input[p521] elements decides what kind of control the user agent will use to expose the field. Choosing between different values of this attribute is the same choice as choosing whether to use an input[p521] element, a textarea[p583] element, a select[p572] element, etc.

The autocomplete[p608] attribute, in contrast, describes what the value that the user will enter actually represents. Choosing between different values of this attribute is the same choice as choosing what the label for the element will be.

First, consider telephone numbers. If a page is asking for a telephone number from the user, the right form control to use is <input type=tel>[p529]. However, which autocomplete[p608] value to use depends on which phone number the page is asking for, whether they expect a telephone number in the international format or just the local format, and so forth.

For example, a page that forms part of a checkout process on an e-commerce site for a customer buying a gift to be shipped to a friend might need both the buyer's telephone number (in case of payment issues) and the friend's telephone number (in case of delivery issues). If the site expects international phone numbers (with the country code prefix), this could thus look like this:

```
<p><label>Your phone number: <input type=tel name=custtel autocomplete="billing tel"></label>
<p><label>Recipient's phone number: <input type=tel name=shiptel autocomplete="shipping tel"></label>
<p>Please enter complete phone numbers including the country code prefix, as in "+1 555 123 4567".
```

But if the site only supports British customers and recipients, it might instead look like this (notice the use of tel-national[p612] rather than tel[p612]):

```
<p><label>Your phone number: <input type=tel name=custtel autocomplete="billing tel-national"></label>
<p><label>Recipient's phone number: <input type=tel name=shiptel autocomplete="shipping tel-
national"></label>
<p>Please enter complete UK phone numbers, as in "(01632) 960 123".
```

Now, consider a person's preferred languages. The right autocomplete[p608] value is language[p612]. However, there could be a number of different form controls used for the purpose: a text control (<input type=text>[p529]), a drop-down list (<select>[p572]), radio buttons (<input type=radio>[p544]), etc. It only depends on what kind of interface is desired.

Finally, consider names. If a page just wants one name from the user, then the relevant control is <input type=text>[p529]. If the page is asking for the user's full name, then the relevant autocomplete[p608] value is name[p611].

```
<p><label>Japanese name: <input name="j" type="text" autocomplete="section-jp name"></label>
<label>Romanized name: <input name="e" type="text" autocomplete="section-en name"></label>
```

In this example, the "section-*[p608]" keywords in the autocomplete[p608] attributes' values tell the user agent that the two fields expect *different* names. Without them, the user agent could automatically fill the second field with the value given in the first field when the user gave a value to the first field.

Note

The "-jp" and "-en" parts of the keywords are opaque to the user agent; the user agent cannot guess, from those, that the two names are expected to be in Japanese and English respectively.

Separate from the choices regarding type[p524] and autocomplete[p608], the inputmode[p870] attribute decides what kind of input modality (e.g., virtual keyboard) to use, when the control is a text control.

Consider credit card numbers. The appropriate input type is *not* <input type=number>[p538], as explained below[p539]; it is instead <input type=text>[p529]. To encourage the user agent to use a numeric input modality anyway (e.g., a virtual keyboard displaying only digits), the page would use

```
<p><label>Credit card number:
```

```
                <input name="cc" type="text" inputmode="numeric" pattern="[0-9]{8,19}"
autocomplete="cc-number">
</label></p>
```

4.10.1.8 Date, time, and number formats §[p51]

This section is non-normative.

In this pizza delivery example, the times are specified in the format "HH:MM": two digits for the hour, in 24-hour format, and two digits for the time. (Seconds could also be specified, though they are not necessary in this example.)

In some locales, however, times are often expressed differently when presented to users. For example, in the United States, it is still common to use the 12-hour clock with an am/pm indicator, as in "2pm". In France, it is common to separate the hours from the minutes using an "h" character, as in "14h00".

Similar issues exist with dates, with the added complication that even the order of the components is not always consistent — for example, in Cyprus the first of February 2003 would typically be written "1/2/03", while that same date in Japan would typically be written as "2003年02月01日" — and even with numbers, where locales differ, for example, in what punctuation is used as the decimal separator and the thousands separator.

It is therefore important to distinguish the time, date, and number formats used in HTML and in form submissions, which are always the formats defined in this specification (and based on the well-established ISO 8601 standard for computer-readable date and time formats), from the time, date, and number formats presented to the user by the browser and accepted as input from the user by the browser.

The format used "on the wire", i.e., in HTML markup and in form submissions, is intended to be computer-readable and consistent irrespective of the user's locale. Dates, for instance, are always written in the format "YYYY-MM-DD", as in "2003-02-01". While some users might see this format, others might see it as "01.02.2003" or "February 1, 2003".

The time, date, or number given by the page in the wire format is then translated to the user's preferred presentation (based on user preferences or on the locale of the page itself), before being displayed to the user. Similarly, after the user inputs a time, date, or number using their preferred format, the user agent converts it back to the wire format before putting it in the DOM or submitting it.

This allows scripts in pages and on servers to process times, dates, and numbers in a consistent manner without needing to support dozens of different formats, while still supporting the users' needs.

Note

See also the implementation notes[p552] regarding localization of form controls.

4.10.2 Categories §[p51]

Mostly for historical reasons, elements in this section fall into several overlapping (but subtly different) categories in addition to the usual ones like flow content[p150], phrasing content[p151], and interactive content[p151].

A number of the elements are **form-associated elements**, which means they can have a form owner[p601].

> ⇒ button[p567], fieldset[p597], input[p521], object[p403], output[p588], select[p572], textarea[p583], img[p347], form-associated custom elements[p767]

The form-associated elements[p514] fall into several subcategories:

Listed elements

Denotes elements that are listed in the *form*.elements[p517] and *fieldset*.elements[p598] APIs. These elements also have a form[p601] content attribute, and a matching form[p603] IDL attribute, that allow authors to specify an explicit form owner[p601].

> ⇒ button[p567], fieldset[p597], input[p521], object[p403], output[p588], select[p572], textarea[p583], form-associated custom elements[p767]

Submittable elements

Denotes elements that can be used for constructing the entry list[p636] when a `form`[p515] element is submitted[p633].

⇒ `button`[p567], `input`[p521], `select`[p572], `textarea`[p583], form-associated custom elements[p767]

Some submittable elements[p515] can be, depending on their attributes, **buttons**. The prose below defines when an element is a button. Some buttons are specifically **submit buttons**.

Resettable elements

Denotes elements that can be affected when a `form`[p515] element is reset[p641].

⇒ `input`[p521], `output`[p588], `select`[p572], `textarea`[p583], form-associated custom elements[p767]

Autocapitalize-and-autocorrect-inheriting elements

Denotes elements that inherit the `autocapitalize`[p868] and `autocorrect`[p869] attributes from their form owner[p601].

⇒ `button`[p567], `fieldset`[p597], `input`[p521], `output`[p588], `select`[p572], `textarea`[p583]

Some elements, not all of them form-associated[p514], are categorized as **labelable elements**. These are elements that can be associated with a `label`[p519] element.

⇒ `button`[p567], `input`[p521] (if the `type`[p524] attribute is *not* in the Hidden[p528] state), `meter`[p592], `output`[p588], `progress`[p590], `select`[p572], `textarea`[p583], form-associated custom elements[p767]

4.10.3 The `form` element §[p515]

Categories[p147]**:**

Flow content[p150].
Palpable content[p151].

Contexts in which this element can be used[p147]**:**

Where flow content[p150] is expected.

Content model[p147]**:**

Flow content[p150], but with no `form`[p515] element descendants.

Tag omission in text/html[p148]**:**

Neither tag is omissible.

Content attributes[p148]**:**

Global attributes[p155]
`accept-charset`[p516] — Character encodings to use for form submission[p632]
`action`[p606] — URL to use for form submission[p632]
`autocomplete`[p516] — Default setting for autofill feature for controls in the form
`enctype`[p607] — Entry list[p636] encoding type to use for form submission[p632]
`method`[p606] — Variant to use for form submission[p632]
`name`[p516] — Name of form to use in the `document.forms`[p138] API
`novalidate`[p607] — Bypass form control validation for form submission[p632]
`target`[p607] — Navigable[p1001] for form submission[p632]
`rel`[p516]

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window,
 LegacyOverrideBuiltIns,
 LegacyUnenumerableNamedProperties]
interface HTMLFormElement : HTMLElement {
  [HTMLConstructor] constructor();
```

```
  [CEReactions] attribute DOMString acceptCharset;
  [CEReactions] attribute USVString action;
  [CEReactions] attribute DOMString autocomplete;
  [CEReactions] attribute DOMString enctype;
  [CEReactions] attribute DOMString encoding;
  [CEReactions] attribute DOMString method;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute boolean noValidate;
  [CEReactions] attribute DOMString target;
  [CEReactions] attribute DOMString rel;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList relList;

  [SameObject] readonly attribute HTMLFormControlsCollection elements;
  readonly attribute unsigned long length;
  getter Element (unsigned long index);
  getter (RadioNodeList or Element) (DOMString name);

  undefined submit();
  undefined requestSubmit(optional HTMLElement? submitter = null);
  [CEReactions] undefined reset();
  boolean checkValidity();
  boolean reportValidity();
};
```

The form element represents a hyperlink that can be manipulated through a collection of form-associated elements, some of which can represent editable values that can be submitted to a server for processing.

The **accept-charset** attribute gives the character encodings that are to be used for the submission. If specified, the value must be an ASCII case-insensitive match for "UTF-8". [ENCODING]

The **name** attribute represents the form's name within the forms collection. The value must not be the empty string, and the value must be unique amongst the form elements in the forms collection that it is in, if any.

The **autocomplete** attribute is an enumerated attribute with the following keywords and states:

Keyword	State	Brief description
on	On	Form controls will have their autofill field name set to "on" by default.
off	Off	Form controls will have their autofill field name set to "off" by default.

The attribute's *missing value default* and *invalid value default* are both the On state.

The action, enctype, method, novalidate, and target attributes are attributes for form submission.

The **rel** attribute on form elements controls what kinds of links the elements create. The attribute's value must be a unordered set of unique space-separated tokens. The allowed keywords and their meanings are defined in an earlier section.

rel's supported tokens are the keywords defined in HTML link types which are allowed on form elements, impact the processing model, and are supported by the user agent. The possible supported tokens are noreferrer, noopener, and opener. rel's supported tokens must only include the tokens from this list that the user agent implements the processing model for.

For web developers (non-normative)

***form*.elements**

Returns an HTMLFormControlsCollection of the form controls in the form (excluding image buttons for historical reasons).

***form*.length**

Returns the number of form controls in the form (excluding image buttons for historical reasons).

***form*[*index*]**

Returns the *index*th element in the form (excluding image buttons for historical reasons).

***form*[*name*]**

Returns the form control (or, if there are several, a RadioNodeList[p114] of the form controls) in the form with the given ID or name[p603] (excluding image buttons for historical reasons); or, if there are none, returns the img[p347] element with the given ID.

Once an element has been referenced using a particular name, that name will continue being available as a way to reference that element in this method, even if the element's actual ID or name[p603] changes, for as long as the element remains in the tree.

If there are multiple matching items, then a RadioNodeList[p114] object containing all those elements is returned.

***form*.submit[p518]()**

Submits the form, bypassing interactive constraint validation[p628] and without firing a submit[p1490] event.

***form*.requestSubmit[p518]([*submitter*])**

Requests to submit the form. Unlike submit()[p518], this method includes interactive constraint validation[p628] and firing a submit[p1490] event, either of which can cancel submission.

The *submitter* argument can be used to point to a specific submit button[p515], whose formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], and formtarget[p607] attributes can impact submission. Additionally, the submitter will be included when constructing the entry list[p636] for submission; normally, buttons are excluded.

***form*.reset[p518]()**

Resets the form.

***form*.checkValidity[p519]()**

Returns true if the form's controls are all valid; otherwise, returns false.

***form*.reportValidity[p519]()**

Returns true if the form's controls are all valid; otherwise, returns false and informs the user.

The **autocomplete** IDL attribute must reflect[p105] the content attribute of the same name, limited to only known values[p106].

The **name** and **rel** IDL attributes must reflect[p105] the content attribute of the same name.

The **acceptCharset** IDL attribute must reflect[p105] the accept-charset[p516] content attribute.

The **relList** IDL attribute must reflect[p105] the rel[p516] content attribute.

The **elements** IDL attribute must return an HTMLFormControlsCollection[p114] rooted at the form[p515] element's root, whose filter matches listed elements[p514] whose form owner[p601] is the form[p515] element, with the exception of input[p521] elements whose type[p524] attribute is in the Image Button[p548] state, which must, for historical reasons, be excluded from this particular collection.

The **length** IDL attribute must return the number of nodes represented by the elements[p517] collection.

The supported property indices at any instant are the indices supported by the object returned by the elements[p517] attribute at that instant.

To determine the value of an indexed property for a form[p515] element, the user agent must return the value returned by the item method on the elements[p517] collection, when invoked with the given index as its argument.

Each form[p515] element has a mapping of names to elements called the **past names map**. It is used to persist names of controls even when they change names.

The supported property names consist of the names obtained from the following algorithm, in the order obtained from this algorithm:

1. Let *sourced names* be an initially empty ordered list of tuples consisting of a string, an element, a source, where the source is either *id*, *name*, or *past*, and, if the source is *past*, an age.
2. For each listed element[p514] *candidate* whose form owner[p601] is the form[p515] element, with the exception of any input[p521] elements whose type[p524] attribute is in the Image Button[p548] state:
    1. If *candidate* has an id[p156] attribute, add an entry to *sourced names* with that id[p156] attribute's value as the string, *candidate* as the element, and *id* as the source.

2. If *candidate* has a `name`[p603] attribute, add an entry to *sourced names* with that `name`[p603] attribute's value as the string, *candidate* as the element, and *name* as the source.

3. For each `img`[p347] element *candidate* whose form owner[p601] is the `form`[p515] element:

    1. If *candidate* has an `id`[p156] attribute, add an entry to *sourced names* with that `id`[p156] attribute's value as the string, *candidate* as the element, and *id* as the source.

    2. If *candidate* has a `name`[p1445] attribute, add an entry to *sourced names* with that `name`[p1445] attribute's value as the string, *candidate* as the element, and *name* as the source.

4. For each entry *past entry* in the past names map[p517], add an entry to *sourced names* with the *past entry*'s name as the string, *past entry*'s element as the element, *past* as the source, and the length of time *past entry* has been in the past names map[p517] as the age.

5. Sort *sourced names* by tree order of the element entry of each tuple, sorting entries with the same element by putting entries whose source is *id* first, then entries whose source is *name*, and finally entries whose source is *past*, and sorting entries with the same element and source by their age, oldest first.

6. Remove any entries in *sourced names* that have the empty string as their name.

7. Remove any entries in *sourced names* that have the same name as an earlier entry in the map.

8. Return the list of names from *sourced names*, maintaining their relative order.

To determine the value of a named property *name* for a `form`[p515] element, the user agent must run the following steps:

1. Let *candidates* be a live[p48] `RadioNodeList`[p114] object containing all the listed elements[p514], whose form owner[p601] is the `form`[p515] element, that have either an `id`[p156] attribute or a `name`[p603] attribute equal to *name*, with the exception of `input`[p521] elements whose `type`[p524] attribute is in the Image Button[p548] state, in tree order.

2. If *candidates* is empty, let *candidates* be a live[p48] `RadioNodeList`[p114] object containing all the `img`[p347] elements, whose form owner[p601] is the `form`[p515] element, that have either an `id`[p156] attribute or a `name`[p1445] attribute equal to *name*, in tree order.

3. If *candidates* is empty, *name* is the name of one of the entries in the `form`[p515] element's past names map[p517]: return the object associated with *name* in that map.

4. If *candidates* contains more than one node, return *candidates*.

5. Otherwise, *candidates* contains exactly one node. Add a mapping from *name* to the node in *candidates* in the `form`[p515] element's past names map[p517], replacing the previous entry with the same name, if any.

6. Return the node in *candidates*.

If an element listed in a `form`[p515] element's past names map[p517] changes form owner[p601], then its entries must be removed from that map.

The **`submit()`** method steps are to submit[p633] this from this, with *submitted from `submit()` method*[p633] set to true.

The **`requestSubmit(submitter)`** method, when invoked, must run the following steps:

1. If *submitter* is not null, then:

    1. If *submitter* is not a submit button[p515], then throw a `TypeError`.

    2. If *submitter*'s form owner[p601] is not this `form`[p515] element, then throw a `"NotFoundError"` `DOMException`.

2. Otherwise, set *submitter* to this `form`[p515] element.

3. Submit[p633] this `form`[p515] element, from *submitter*.

The **`reset()`** method, when invoked, must run the following steps:

1. If the `form`[p515] element is marked as *locked for reset*[p518], then return.

2. Mark the `form`[p515] element as **locked for reset**.

3. Reset[p641] the `form`[p515] element.

4. Unmark the form element as *locked for reset*.

If the **checkValidity()** method is invoked, the user agent must statically validate the constraints of the form element, and return true if the constraint validation returned a *positive* result, and false if it returned a *negative* result.

If the **reportValidity()** method is invoked, the user agent must interactively validate the constraints of the form element, and return true if the constraint validation returned a *positive* result, and false if it returned a *negative* result.

Example

This example shows two search forms:

```
<form action="https://www.google.com/search" method="get">
 <label>Google: <input type="search" name="q"></label> <input type="submit" value="Search...">
</form>
<form action="https://www.bing.com/search" method="get">
 <label>Bing: <input type="search" name="q"></label> <input type="submit" value="Search...">
</form>
```

4.10.4 The label element §

Categories:

Flow content.
Phrasing content.
Interactive content.
Palpable content.

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:

Phrasing content, but with no descendant labelable elements unless it is the element's labeled control, and no descendant label elements.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes
for — Associate the label with form control

Accessibility considerations:

For authors.
For implementers.

DOM interface:

IDL

```
[Exposed=Window]
interface HTMLLabelElement : HTMLElement {
  [HTMLConstructor] constructor();

  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute DOMString htmlFor;
  readonly attribute HTMLElement? control;
};
```

The label element represents a caption in a user interface. The caption can be associated with a specific form control, known as the label element's **labeled control**, either using the for attribute, or by putting the form control inside the label element itself.

Except where otherwise specified by the following rules, a label element has no labeled control.

The **for** attribute may be specified to indicate a form control with which the caption is to be associated. If the attribute is specified, the attribute's value must be the ID of a labelable element[p515] in the same tree as the label[p519] element. If the attribute is specified and there is an element in the tree whose ID is equal to the value of the for[p520] attribute, and the first such element in tree order is a labelable element[p515], then that element is the label[p519] element's labeled control[p519].

If the for[p520] attribute is not specified, but the label[p519] element has a labelable element[p515] descendant, then the first such descendant in tree order is the label[p519] element's labeled control[p519].

The label[p519] element's exact default presentation and behavior, in particular what its activation behavior might be, if anything, should match the platform's label behavior. The activation behavior of a label[p519] element for events targeted at interactive content[p151] descendants of a label[p519] element, and any descendants of those interactive content[p151] descendants, must be to do nothing.

Note

Form-associated custom elements[p767] are labelable elements[p515], so for user agents where the label[p519] element's activation behavior impacts the labeled control[p519], both built-in and custom elements will be impacted.

Example

For example, on platforms where clicking a label activates the form control, clicking the label[p519] in the following snippet could trigger the user agent to fire a click event[p1162] at the input[p521] element, as if the element itself had been triggered by the user:

```
<label><input type=checkbox name=lost> Lost</label>
```

Similarly, assuming `my-checkbox` was declared as a form-associated custom element[p767] (like in this example[p757]), then the code

```
<label><my-checkbox name=lost></my-checkbox> Lost</label>
```

would have the same behavior, firing a click event[p1162] at the `my-checkbox` element.

On other platforms, the behavior in both cases might be just to focus the control, or to do nothing.

Example

The following example shows three form controls each with a label, two of which have small text showing the right format for users to use.

```
<p><label>Full name: <input name=fn> <small>Format: First Last</small></label></p>
<p><label>Age: <input name=age type=number min=0></label></p>
<p><label>Post code: <input name=pc> <small>Format: AB12 3CD</small></label></p>
```

For web developers (non-normative)

***label*.control**[p520]

Returns the form control that is associated with this element.

***label*.form**[p520]

Returns the form owner[p601] of the form control that is associated with this element.

Returns null if there isn't one.

The **htmlFor** IDL attribute must reflect[p105] the for[p520] content attribute.

The **control** IDL attribute must return the label[p519] element's labeled control[p519], if any, or null if there isn't one.

The **form** IDL attribute must run the following steps:

1. If the label[p519] element has no labeled control[p519], then return null.
2. If the label[p519] element's labeled control[p519] is not a form-associated element[p514], then return null.
3. Return the label[p519] element's labeled control[p519]'s form owner[p601] (which can still be null).

Note

The `form` IDL attribute on the `label` element is different from the `form` IDL attribute on listed form-associated elements, and the `label` element does not have a `form` content attribute.

For web developers (non-normative)

***control*.labels**

Returns a `NodeList` of all the `label` elements that the form control is associated with.

Labelable elements and all `input` elements have a live `NodeList` object associated with them that represents the list of `label` elements, in tree order, whose labeled control is the element in question. The **`labels`** IDL attribute of labelable elements that are not form-associated custom elements, and the `labels` IDL attribute of `input` elements, on getting, must return that `NodeList` object, and that same value must always be returned, unless this element is an `input` element whose `type` attribute is in the Hidden state, in which case it must instead return null.

Form-associated custom elements don't have a `labels` IDL attribute. Instead, their `ElementInternals` object has a **`labels`** IDL attribute. On getting, it must throw a `"NotSupportedError"` `DOMException` if the target element is not a form-associated custom element. Otherwise, it must return that `NodeList` object, and that same value must always be returned.

Example

This (non-conforming) example shows what happens to the `NodeList` and what `labels` returns when an `input` element has its `type` attribute changed.

```
<!doctype html>
<p><label><input></label></p>
<script>
 const input = document.querySelector('input');
 const labels = input.labels;
 console.assert(labels.length === 1);

 input.type = 'hidden';
 console.assert(labels.length === 0); // the input is no longer the label's labeled control
 console.assert(input.labels === null);

 input.type = 'checkbox';
 console.assert(labels.length === 1); // the input is once again the label's labeled control
 console.assert(input.labels === labels); // same value as returned originally
</script>
```

4.10.5 The `input` element

Categories:

Flow content.
Phrasing content.
If the `type` attribute is *not* in the Hidden state: Interactive content.
If the `type` attribute is *not* in the Hidden state: Listed, labelable, submittable, resettable, and autocapitalize-and-autocorrect inheriting form-associated element.
If the `type` attribute is in the Hidden state: Listed, submittable, resettable, and autocapitalize-and-autocorrect inheriting form-associated element.
If the `type` attribute is *not* in the Hidden state: Palpable content.

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:

Nothing.

Tag omission in text/html[p148]:

No end tag[p1280].

Content attributes[p148]:

Global attributes[p155]
accept[p546] — Hint for expected file type in file upload controls[p546]
alpha[p542] — Allow the color's alpha component to be set
alt[p549] — Replacement text for use when images are not available
autocomplete[p608] — Hint for form autofill feature
checked[p526] — Whether the control is checked
colorspace[p542] — The color space of the serialized color
dirname[p604] — Name of form control to use for sending the element's directionality[p161] in form submission[p632]
disabled[p605] — Whether the form control is disabled
form[p601] — Associates the element with a form[p515] element
formaction[p606] — URL to use for form submission[p632]
formenctype[p607] — Entry list[p636] encoding type to use for form submission[p632]
formmethod[p606] — Variant to use for form submission[p632]
formnovalidate[p607] — Bypass form control validation for form submission[p632]
formtarget[p607] — Navigable[p1001] for form submission[p632]
height[p478] — Vertical dimension
list[p558] — List of autocomplete options
max[p557] — Maximum value
maxlength[p552] — Maximum length of value
min[p557] — Minimum value
minlength[p552] — Minimum length of value
multiple[p554] — Whether to allow multiple values
name[p603] — Name of the element to use for form submission[p632] and in the form.elements[p517] API
pattern[p555] — Pattern to be matched by the form control's value
placeholder[p561] — User-visible label to be placed within the form control
popovertarget[p905] — Targets a popover element to toggle, show, or hide
popovertargetaction[p905] — Indicates whether a targeted popover element is to be toggled, shown, or hidden
readonly[p553] — Whether to allow the value to be edited by the user
required[p554] — Whether the control is required for form submission[p632]
size[p553] — Size of the control
src[p549] — Address of the resource
step[p558] — Granularity to be matched by the form control's value
type[p524] — Type of form control
value[p526] — Value of the form control
width[p478] — Horizontal dimension
Also, the title[p556] attribute has special semantics[p556] on this element: Description of pattern (when used with pattern[p555] attribute)

Accessibility considerations[p148]:

type[p524] attribute in the Hidden[p528] state: for authors; for implementers.
type[p524] attribute in the Text[p529] state: for authors; for implementers.

  // also has obsolete members
};
HTMLInputElement includes PopoverInvokerElement;
```

The input element represents a typed data field, usually with a form control to allow the user to edit the data.

The **type** attribute controls the data type (and associated control) of the element. It is an enumerated attribute with the following keywords and states:

Keyword	State	Data type	Control type
hidden	Hidden	An arbitrary string	n/a
text	Text	Text with no line breaks	A text control
search	Search	Text with no line breaks	Search control
tel	Telephone	Text with no line breaks	A text control
url	URL	An absolute URL	A text control
email	Email	An email address or list of email addresses	A text control
password	Password	Text with no line breaks (sensitive information)	A text control that obscures data entry
date	Date	A date (year, month, day) with no time zone	A date control
month	Month	A date consisting of a year and a month with no time zone	A month control
week	Week	A date consisting of a week-year number and a week number with no time zone	A week control
time	Time	A time (hour, minute, seconds, fractional seconds) with no time zone	A time control
datetime-local	Local Date and Time	A date and time (year, month, day, hour, minute, second, fraction of a second) with no time zone	A date and time control
number	Number	A numerical value	A text control or spinner control
range	Range	A numerical value, with the extra semantic that the exact value is not important	A slider control or similar
color	Color	An sRGB color with 8-bit red, green, and blue components	A color picker
checkbox	Checkbox	A set of zero or more values from a predefined list	A checkbox
radio	Radio Button	An enumerated value	A radio button
file	File Upload	Zero or more files each with a MIME type and optionally a filename	A label and a button
submit	Submit Button	An enumerated value, with the extra semantic that it must be the last value selected and initiates form submission	A button
image	Image Button	A coordinate, relative to a particular image's size, with the extra semantic that it must be the last value selected and initiates form submission	Either a clickable image, or a button
reset	Reset Button	n/a	A button
button	Button	n/a	A button

The attribute's *missing value default* and *invalid value default* are both the Text state.

Which of the accept, alpha, alt, autocomplete, checked, colorspace, dirname, formaction, formenctype, formmethod, formnovalidate, formtarget, height, list, max, maxlength, min, minlength, multiple, pattern, placeholder, readonly, required, size, src, step, and width content attributes, the checked, files, valueAsDate, valueAsNumber, and list IDL attributes, the select() method, the selectionStart, selectionEnd, and selectionDirection, IDL attributes, the setRangeText() and setSelectionRange() methods, the stepUp() and stepDown() methods, and the input and change events **apply** to an input element depends on the state of its type attribute. The subsections that define each type also clearly define in normative

"bookkeeping" sections which of these feature apply, and which **do not apply**, to each type. The behavior of these features depends on whether they apply or not, as defined in their various sections (q.v. for content attributes[p552], for APIs[p562], for events[p566]).

The following table is non-normative and summarizes which of those content attributes, IDL attributes, methods, and events apply[p524] to each state:

	Hidden[p528]	Text[p529], Search[p529]	Telephone[p529], URL[p530]	Email[p531]	Password[p533]	Date[p533], Month[p534], Week[p535], Time[p536]	Local Date and Time[p537]	Number[p538]	Range[p540]	Color[p542]	Checkbox[p544], Radio Button[p544]
Content attributes											
accept[p546]	·	·	·	·	·	·	·	·	·	·	·
alpha[p542]	·	·	·	·	·	·	·	·	·	Yes	·

change event	·	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

† If the control has no selectable text, the `select()` method results in a no-op, with no `"InvalidStateError"` `DOMException`.

Some states of the `type` attribute define a **value sanitization algorithm**.

Each `input` element has a value, which is exposed by the `value` IDL attribute. Some states define an **algorithm to convert a string to a number**, an **algorithm to convert a number to a string**, an **algorithm to convert a string to a `Date` object**, and an **algorithm to convert a `Date` object to a string**, which are used by `max`, `min`, `step`, `valueAsDate`, `valueAsNumber`, and `stepUp()`.

An `input` element's dirty value flag must be set to true whenever the user interacts with the control in a way that changes the value. (It is also set to true when the value is programmatically changed, as described in the definition of the `value` IDL attribute.)

The **`value`** content attribute gives the default value of the `input` element. When the `value` content attribute is added, set, or removed, if the control's dirty value flag is false, the user agent must set the value of the element to the value of the `value` content attribute, if there is one, or the empty string otherwise, and then run the current value sanitization algorithm, if one is defined.

Each `input` element has a checkedness, which is exposed by the `checked` IDL attribute.

Each `input` element has a boolean **dirty checkedness flag**. When it is true, the element is said to have a ***dirty checkedness***. The dirty checkedness flag must be initially set to false when the element is created, and must be set to true whenever the user interacts with the control in a way that changes the checkedness.

The **`checked`** content attribute is a boolean attribute that gives the default checkedness of the `input` element. When the `checked` content attribute is added, if the control does not have *dirty checkedness*, the user agent must set the checkedness of the element to true; when the `checked` content attribute is removed, if the control does not have *dirty checkedness*, the user agent must set the checkedness of the element to false.

The reset algorithm for `input` elements is to set its user validity, dirty value flag, and dirty checkedness flag back to false, set the value of the element to the value of the `value` content attribute, if there is one, or the empty string otherwise, set the checkedness of the element to true if the element has a `checked` content attribute and false if it does not, empty the list of selected files, and then invoke the value sanitization algorithm, if the `type` attribute's current state defines one.

Each `input` element can be *mutable*. Except where otherwise specified, an `input` element is always *mutable*. Similarly, except where otherwise specified, the user agent should not allow the user to modify the element's value or checkedness.

When an `input` element is disabled, it is not *mutable*.

Note

The `readonly` attribute can also in some cases (e.g. for the Date state, but not the Checkbox state) stop an `input` element from being mutable.

The `input` element can **support a picker**. A picker is a user interface element that allows the end user to choose a value. Whether an `input` element supports a picker depends on the `type` attribute state and implementation-defined behavior. An `input` element must support a picker when its `type` attribute is in the File Upload state.

Note

As of the time of this writing, typical browser implementations show such picker UI for:

- *`input` elements whose `type` attributes are in the Date, Month, Week, Time, Local Date and Time, and Color states;*
- *`input` elements in various states that have a suggestions source element;*
- *`input` elements whose `type` attribute is in the File Upload state; and*

- `select`[p572] *elements.*

The cloning steps for `input`[p521] elements given *node*, *copy*, and *subtree* are to propagate the value[p601], dirty value flag[p601], checkedness[p601], and dirty checkedness flag[p526] from *node* to *copy*.

The activation behavior for `input`[p521] elements *element*, given *event*, are these steps:

1. If *element* is not *mutable*[p601], and *element*'s `type`[p524] attribute is neither in the Checkbox[p544] nor in the Radio[p544] state, then return.
2. Run *element*'s **input activation behavior**, if any, and do nothing otherwise.
3. If *element* has a form owner[p601] and *element*'s `type`[p524] attribute is not in the Button[p551] state, then return.
4. Run the popover target attribute activation behavior[p906] given *element* and *event*'s target.

Note

Recall that an element's activation behavior runs for both user-initiated activations and for synthetic activations (e.g., via `el.click()`*). User agents might also have behaviors for a given control — not specified here — that are triggered only by true user-initiated activations. A common choice is to show the picker, if applicable[p565], for the control. In contrast, the input activation behavior[p527] only shows pickers for the special historical cases of the File Upload[p546] and Color[p542] states.*

The legacy-pre-activation behavior for `input`[p521] elements are these steps:

1. If this element's `type`[p524] attribute is in the Checkbox state[p544], then set this element's checkedness[p601] to its opposite value (i.e. true if it is false, false if it is true) and set this element's `indeterminate`[p528] IDL attribute to false.
2. If this element's `type`[p524] attribute is in the Radio Button state[p544], then get a reference to the element in this element's radio button group[p544] that has its checkedness[p601] set to true, if any, and then set this element's checkedness[p601] to true.

The legacy-canceled-activation behavior for `input`[p521] elements are these steps:

1. If the element's `type`[p524] attribute is in the Checkbox state[p544], then set the element's checkedness[p601] and the element's `indeterminate`[p528] IDL attribute back to the values they had before the legacy-pre-activation behavior was run.
2. If this element's `type`[p524] attribute is in the Radio Button state[p544], then if the element to which a reference was obtained in the legacy-pre-activation behavior, if any, is still in what is now this element's radio button group[p544], if it still has one, and if so, set that element's checkedness[p601] to true; or else, if there was no such element, or that element is no longer in this element's radio button group[p544], or if this element no longer has a radio button group[p544], set this element's checkedness[p601] to false.

When an `input`[p521] element is first created, the element's rendering and behavior must be set to the rendering and behavior defined for the `type`[p524] attribute's state, and the value sanitization algorithm[p526], if one is defined for the `type`[p524] attribute's state, must be invoked.

When an `input`[p521] element's `type`[p524] attribute changes state, the user agent must run the following steps:

1. If the previous state of the element's `type`[p524] attribute put the `value`[p562] IDL attribute in the *value*[p562] mode, and the element's value[p601] is not the empty string, and the new state of the element's `type`[p524] attribute puts the `value`[p562] IDL attribute in either the *default*[p563] mode or the *default/on*[p563] mode, then set the element's `value`[p526] content attribute to the element's value[p601].
2. Otherwise, if the previous state of the element's `type`[p524] attribute put the `value`[p562] IDL attribute in any mode other than the *value*[p562] mode, and the new state of the element's `type`[p524] attribute puts the `value`[p562] IDL attribute in the *value*[p562] mode, then set the value[p601] of the element to the value of the `value`[p526] content attribute, if there is one, or the empty string otherwise, and then set the control's dirty value flag[p601] to false.
3. Otherwise, if the previous state of the element's `type`[p524] attribute put the `value`[p562] IDL attribute in any mode other than the *filename*[p563] mode, and the new state of the element's `type`[p524] attribute puts the `value`[p562] IDL attribute in the *filename*[p563] mode, then set the value[p601] of the element to the empty string.

4. Update the element's rendering and behavior to the new state's.
5. **Signal a type change** for the element. (The Radio Button[p544] state uses this, in particular.)
6. Invoke the value sanitization algorithm[p526], if one is defined for the type[p524] attribute's new state.
7. Let *previouslySelectable* be true if setRangeText()[p625] previously applied[p524] to the element, and false otherwise.
8. Let *nowSelectable* be true if setRangeText()[p625] now applies[p524] to the element, and false otherwise.
9. If *previouslySelectable* is false and *nowSelectable* is true, set the element's text entry cursor position[p622] to the beginning of the text control, and set its selection direction[p623] to "none".

The name[p603] attribute represents the element's name. The dirname[p604] attribute controls how the element's directionality[p161] is submitted. The disabled[p605] attribute is used to make the control non-interactive and to prevent its value from being submitted. The form[p601] attribute is used to explicitly associate the input[p521] element with its form owner[p601]. The autocomplete[p608] attribute controls how the user agent provides autofill behavior.

The **indeterminate** IDL attribute must initially be set to false. On getting, it must return the last value it was set to. On setting, it must be set to the new value. It has no effect except for changing the appearance of checkbox[p544] controls.

The **accept**, **alpha**, **alt**, **max**, **min**, **multiple**, **pattern**, **placeholder**, **required**, **size**, **src**, and **step** IDL attributes must reflect[p105] the respective content attributes of the same name. The **dirName** IDL attribute must reflect[p105] the dirname[p604] content attribute. The **readOnly** IDL attribute must reflect[p105] the readonly[p553] content attribute. The **defaultChecked** IDL attribute must reflect[p105] the checked[p526] content attribute. The **defaultValue** IDL attribute must reflect[p105] the value[p526] content attribute.

The **colorSpace** IDL attribute must reflect[p105] the colorspace[p542] content attribute, limited to only known values[p106]. The **type** IDL attribute must reflect[p105] the respective content attribute of the same name, limited to only known values[p106]. The **maxLength** IDL attribute must reflect[p105] the maxlength[p552] content attribute, limited to only non-negative numbers[p108]. The **minLength** IDL attribute must reflect[p105] the minlength[p552] content attribute, limited to only non-negative numbers[p108].

The IDL attributes **width** and **height** must return the rendered width and height of the image, in CSS pixels, if an image is being rendered[p1406]; or else the natural width and height of the image, in CSS pixels, if an image is *available*[p549] but not being rendered[p1406]; or else 0, if no image is *available*[p549]. When the input[p521] element's type[p524] attribute is not in the Image Button[p548] state, then no image is *available*[p549]. [CSS][p1494]

On setting, they must act as if they reflected[p105] the respective content attributes of the same name.

The willValidate[p629], validity[p629], and validationMessage[p631] IDL attributes, and the checkValidity()[p631], reportValidity()[p631], and setCustomValidity()[p629] methods, are part of the constraint validation API[p628]. The labels[p521] IDL attribute provides a list of the element's label[p519]s. The select()[p623], selectionStart[p623], selectionEnd[p624], selectionDirection[p624], setRangeText()[p625], and setSelectionRange()[p624] methods and IDL attributes expose the element's text selection. The disabled[p606], form[p603], and name[p603] IDL attributes are part of the element's forms API.

4.10.5.1 States of the type[p524] attribute §[p52]8

4.10.5.1.1 Hidden state (type=hidden) §[p52]8

When an input[p521] element's type[p524] attribute is in the Hidden[p528] state, the rules in this section apply.

The input[p521] element represents[p142] a value that is not intended to be examined or manipulated by the user.

Constraint validation: If an input[p521] element's type[p524] attribute is in the Hidden[p528] state, it is barred from constraint validation[p626].

If the name[p603] attribute is present and has a value that is an ASCII case-insensitive match for "_charset_[p603]", then the element's value[p526] attribute must be omitted.

Bookkeeping details

- The autocomplete[p608] and dirname[p604] content attributes apply[p524] to this element.
- The value[p562] IDL attribute applies[p524] to this element and is in mode default[p563].
- The following content attributes must not be specified and do not apply[p525] to the element: accept[p546], alpha[p542], alt[p549], checked[p526], colorspace[p542], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], height[p478], list[p558], max[p557], maxlength[p552], min[p557], minlength[p552], multiple[p554], pattern[p555], placeholder[p561], popovertarget[p905], popovertargetaction[p905], readonly[p553], required[p554], size[p553], src[p549], step[p558], and width[p478].

- The following IDL attributes and methods do not apply to the element: checked, files, list, selectionStart, selectionEnd, selectionDirection, valueAsDate, and valueAsNumber IDL attributes; select(), setRangeText(), setSelectionRange(), stepDown(), and stepUp() methods.
- The input and change events do not apply.

4.10.5.1.2 Text (type=text) state and Search state (type=search)

When an input element's type attribute is in the Text state or the Search state, the rules in this section apply.

The input element represents a one line plain text edit control for the element's value.

Note

The difference between the Text state and the Search state is primarily stylistic: on platforms where search controls are distinguished from regular text controls, the Search state might result in an appearance consistent with the platform's search controls rather than appearing like a regular text control.

If the element is *mutable*, its value should be editable by the user. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the element's value.

If the element is *mutable*, the user agent should allow the user to change the writing direction of the element, setting it either to a left-to-right writing direction or a right-to-left writing direction. If the user does so, the user agent must then run the following steps:

1. Set the element's dir attribute to "ltr" if the user selected a left-to-right writing direction, and "rtl" if the user selected a right-to-left writing direction.
2. Queue an element task on the user interaction task source given the element to fire an event named input at the element, with the bubbles and composed attributes initialized to true.

The value attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The value sanitization algorithm is as follows: Strip newlines from the value.

Bookkeeping details

- The following common input element content attributes, IDL attributes, and methods apply to the element: autocomplete, dirname, list, maxlength, minlength, pattern, placeholder, readonly, required, and size content attributes; list, selectionStart, selectionEnd, selectionDirection, and value IDL attributes; select(), setRangeText(), and setSelectionRange() methods.
- The value IDL attribute is in mode value.
- The input and change events apply.
- The following content attributes must not be specified and do not apply to the element: accept, alpha, alt, checked, colorspace, formaction, formenctype, formmethod, formnovalidate, formtarget, height, max, min, multiple, popovertarget, popovertargetaction, src, step, and width.
- The following IDL attributes and methods do not apply to the element: checked, files, valueAsDate, and valueAsNumber IDL attributes; stepDown() and stepUp() methods.

4.10.5.1.3 Telephone state (type=tel)

When an input element's type attribute is in the Telephone state, the rules in this section apply.

The input element represents a control for editing a telephone number given in the element's value.

If the element is *mutable*, its value should be editable by the user. User agents may change the spacing and, with care, the punctuation of values that the user enters. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the element's value.

The value attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The value sanitization algorithm is as follows: Strip newlines from the value.

Note

Unlike the URL[p530] and Email[p531] types, the Telephone[p529] type does not enforce a particular syntax. This is intentional; in practice, telephone number fields tend to be free-form fields, because there are a wide variety of valid phone numbers. Systems that need to enforce a particular format are encouraged to use the pattern[p555] attribute or the setCustomValidity()[p629] method to hook into the client-side validation mechanism.

Bookkeeping details

- The following common input[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: autocomplete[p608], dirname[p604], list[p558], maxlength[p552], minlength[p552], pattern[p555], placeholder[p561], readonly[p553], required[p554], and size[p553] content attributes; list[p565], selectionStart[p623], selectionEnd[p624], selectionDirection[p624], and value[p562] IDL attributes; select()[p623], setRangeText()[p625], and setSelectionRange()[p624] methods.
- The value[p562] IDL attribute is in mode value[p562].
- The input and change[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: accept[p546], alpha[p542], alt[p549], checked[p526], colorspace[p542], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], height[p478], max[p557], min[p557], multiple[p554], popovertarget[p905], popovertargetaction[p905], src[p549], step[p558], and width[p478].
- The following IDL attributes and methods do not apply[p525] to the element: checked[p563], files[p563], valueAsDate[p563], and valueAsNumber[p564] IDL attributes; stepDown()[p564] and stepUp()[p564] methods.

4.10.5.1.4 URL state (`type=url`) §[p530]

When an input[p521] element's type[p524] attribute is in the URL[p530] state, the rules in this section apply.

The input[p521] element represents[p142] a control for editing a single absolute URL given in the element's value[p601].

If the element is *mutable*[p601], the user agent should allow the user to change the URL represented by its value[p601]. User agents may allow the user to set the value[p601] to a string that is not a valid absolute URL, but may also or instead automatically escape characters entered by the user so that the value[p601] is always a valid absolute URL (even if that isn't the actual value seen and edited by the user in the interface). User agents should allow the user to set the value[p601] to the empty string. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the value[p601].

The value[p526] attribute, if specified and not empty, must have a value that is a valid URL potentially surrounded by spaces[p97] that is also an absolute URL.

The value sanitization algorithm[p526] is as follows: Strip newlines from the value[p601], then strip leading and trailing ASCII whitespace from the value[p601].

Constraint validation: While the value[p601] of the element is neither the empty string nor a valid absolute URL, the element is suffering from a type mismatch[p626].

Bookkeeping details

- The following common input[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: autocomplete[p608], dirname[p604], list[p558], maxlength[p552], minlength[p552], pattern[p555], placeholder[p561], readonly[p553], required[p554], and size[p553] content attributes; list[p565], selectionStart[p623], selectionEnd[p624], selectionDirection[p624], and value[p562] IDL attributes; select()[p623], setRangeText()[p625], and setSelectionRange()[p624] methods.
- The value[p562] IDL attribute is in mode value[p562].
- The input and change[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: accept[p546], alpha[p542], alt[p549], checked[p526], colorspace[p542], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], height[p478], max[p557], min[p557], multiple[p554], popovertarget[p905], popovertargetaction[p905], src[p549], step[p558], and width[p478].
- The following IDL attributes and methods do not apply[p525] to the element: checked[p563], files[p563], valueAsDate[p563], and valueAsNumber[p564] IDL attributes; stepDown()[p564] and stepUp()[p564] methods.

Example

If a document contained the following markup:

```
<input type="url" name="location" list="urls">
<datalist id="urls">
 <option label="MIME: Format of Internet Message Bodies" value="https://www.rfc-editor.org/rfc/
rfc2045">
 <option label="HTML" value="https://html.spec.whatwg.org/">
 <option label="DOM" value="https://dom.spec.whatwg.org/">
```

```
  <option label="Fullscreen" value="https://fullscreen.spec.whatwg.org/">
  <option label="Media Session" value="https://mediasession.spec.whatwg.org/">
  <option label="The Single UNIX Specification, Version 3" value="http://www.unix.org/version3/">
</datalist>
```

...and the user had typed "spec.w", and the user agent had also found that the user had visited `https://url.spec.whatwg.org/#url-parsing` and `https://streams.spec.whatwg.org/` in the recent past, then the rendering might look like this:

The first four URLs in this sample consist of the four URLs in the author-specified list that match the text the user has entered, sorted in some implementation-defined manner (maybe by how frequently the user refers to those URLs). Note how the UA is using the knowledge that the values are URLs to allow the user to omit the scheme part and perform intelligent matching on the domain name.

The last two URLs (and probably many more, given the scrollbar's indications of more values being available) are the matches from the user agent's session history data. This data is not made available to the page DOM. In this particular case, the UA has no titles to provide for those values.

4.10.5.1.5 Email state (`type=email`) §[p53]

When an `input`[p521] element's `type`[p524] attribute is in the Email[p531] state, the rules in this section apply.

How the Email[p531] state operates depends on whether the `multiple`[p554] attribute is specified or not.

↪ **When the `multiple`[p554] attribute is not specified on the element**

The `input`[p521] element represents[p142] a control for editing an email address given in the element's value[p601].

If the element is *mutable*[p601], the user agent should allow the user to change the email address represented by its value[p601]. User agents may allow the user to set the value[p601] to a string that is not a valid email address[p532]. The user agent should act in a manner consistent with expecting the user to provide a single email address. User agents should allow the user to set the value[p601] to the empty string. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the value[p601]. User agents may transform the value[p601] for display and editing; in particular, user agents should convert punycode in the domain labels of the value[p601] to IDN in the display and vice versa.

Constraint validation: While the user interface is representing input that the user agent cannot convert to punycode, the control is suffering from bad input[p627].

The `value`[p526] attribute, if specified and not empty, must have a value that is a single valid email address[p532].

The value sanitization algorithm[p526] is as follows: Strip newlines from the value[p601], then strip leading and trailing ASCII whitespace from the value[p601].

Constraint validation: While the value[p601] of the element is neither the empty string nor a single valid email address[p532], the element is suffering from a type mismatch[p626].

↪ **When the `multiple`[p554] attribute *is* specified on the element**

The `input`[p521] element represents[p142] a control for adding, removing, and editing the email addresses given in the element's values[p601].

If the element is *mutable*[p601], the user agent should allow the user to add, remove, and edit the email addresses represented by its values[p601]. User agents may allow the user to set any individual value in the list of values[p601] to a string that is not a valid email address[p532], but must not allow users to set any individual value to a string containing U+002C COMMA (,), U+000A LINE FEED (LF), or U+000D CARRIAGE RETURN (CR) characters. User agents should allow the user to remove all the addresses in the element's values[p601]. User agents may transform the values[p601] for display and editing; in particular, user agents should convert punycode in the domain labels of the value[p601] to IDN in the display and vice versa.

Constraint validation: While the user interface describes a situation where an individual value contains a U+002C COMMA (,) or is representing input that the user agent cannot convert to punycode, the control is suffering from bad input[p627].

Whenever the user changes the element's values[p601], the user agent must run the following steps:

1. Let *latest values* be a copy of the element's values[p601].
2. Strip leading and trailing ASCII whitespace from each value in *latest values*.
3. Set the element's value[p601] to the result of concatenating all the values in *latest values*, separating each value from the next by a single U+002C COMMA character (,), maintaining the list's order.

The `value`[p526] attribute, if specified, must have a value that is a valid email address list[p532].

The value sanitization algorithm[p526] is as follows:

1. Split on commas the element's value[p601], strip leading and trailing ASCII whitespace from each resulting token, if any, and let the element's values[p601] be the (possibly empty) resulting list of (possibly empty) tokens, maintaining the original order.
2. Set the element's value[p601] to the result of concatenating the element's values[p601], separating each value from the next by a single U+002C COMMA character (,), maintaining the list's order.

Constraint validation: While the value[p601] of the element is not a valid email address list[p532], the element is suffering from a type mismatch[p626].

When the `multiple`[p554] attribute is set or removed, the user agent must run the value sanitization algorithm[p526].

A **valid email address** is a string that matches the `email` production of the following ABNF, the character set for which is Unicode. This ABNF implements the extensions described in RFC 1123. [ABNF][p1493] [RFC5322][p1499] [RFC1034][p1499] [RFC1123][p1499]

```
email         = 1*( atext / "." ) "@" label *( "." label )
label         = let-dig [ [ ldh-str ] let-dig ]  ; limited to a length of 63 characters by RFC 1034 section 3.5
atext         = < as defined in RFC 5322 section 3.2.3 >
let-dig       = < as defined in RFC 1034 section 3.5 >
ldh-str       = < as defined in RFC 1034 section 3.5 >
```

Note

This requirement is a willful violation of RFC 5322, which defines a syntax for email addresses that is simultaneously too strict (before the "@" character), too vague (after the "@" character), and too lax (allowing comments, whitespace characters, and quoted strings in manners unfamiliar to most users) to be of practical use here.

Note

The following JavaScript- and Perl-compatible regular expression is an implementation of the above definition.

```
/^[a-zA-Z0-9.!#$%&'*+\/=?^_`{|}~-]+@[a-zA-Z0-9](?:[a-zA-Z0-9-]{0,61}[a-zA-Z0-9])?(?:\.[a-zA-Z0-9](?:[a-zA-Z0-9-]{0,61}[a-zA-Z0-9])?)*$/
```

A **valid email address list** is a set of comma-separated tokens[p96], where each token is itself a valid email address[p532]. To obtain the list of tokens from a valid email address list[p532], an implementation must split the string on commas.

Bookkeeping details

■The following common `input`[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: `autocomplete`[p608], `dirname`[p604], `list`[p558], `maxlength`[p552], `minlength`[p552], `multiple`[p554], `pattern`[p555], `placeholder`[p561], `readonly`[p553], `required`[p554], and `size`[p553] content attributes; `list`[p565] and `value`[p562] IDL attributes; `select()`[p623] method.

- The value[p562] IDL attribute is in mode value[p562].
- The input and change[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: accept[p546], alpha[p542], alt[p549], checked[p526], colorspace[p542], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], height[p478], max[p557], min[p557], popovertarget[p905], popovertargetaction[p905], src[p549], step[p558], and width[p478].
- The following IDL attributes and methods do not apply[p525] to the element: checked[p563], files[p563], selectionStart[p623], selectionEnd[p624], selectionDirection[p624], valueAsDate[p563], and valueAsNumber[p564] IDL attributes; setRangeText()[p625], setSelectionRange()[p624], stepDown()[p564] and stepUp()[p564] methods.

4.10.5.1.6 Password state (type=password) §[p53]

When an input[p521] element's type[p524] attribute is in the Password[p533] state, the rules in this section apply.

The input[p521] element represents[p142] a one line plain text edit control for the element's value[p601]. The user agent should obscure the value so that people other than the user cannot see it.

If the element is *mutable*[p601], its value[p601] should be editable by the user. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the value[p601].

The value[p526] attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The value sanitization algorithm[p526] is as follows: Strip newlines from the value[p601].

Bookkeeping details

- The following common input[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: autocomplete[p608], dirname[p604], maxlength[p552], minlength[p552], pattern[p555], placeholder[p561], readonly[p553], required[p554], and size[p553] content attributes; selectionStart[p623], selectionEnd[p624], selectionDirection[p624], and value[p562] IDL attributes; select()[p623], setRangeText()[p625], and setSelectionRange()[p624] methods.
- The value[p562] IDL attribute is in mode value[p562].
- The input and change[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: accept[p546], alpha[p542], alt[p549], checked[p526], colorspace[p542], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], height[p478], list[p558], max[p557], min[p557], multiple[p554], popovertarget[p905], popovertargetaction[p905], src[p549], step[p558], and width[p478].
- The following IDL attributes and methods do not apply[p525] to the element: checked[p563], files[p563], list[p565], valueAsDate[p563], and valueAsNumber[p564] IDL attributes; stepDown()[p564] and stepUp()[p564] methods.

4.10.5.1.7 Date state (type=date) §[p53]

When an input[p521] element's type[p524] attribute is in the Date[p533] state, the rules in this section apply.

The input[p521] element represents[p142] a control for setting the element's value[p601] to a string representing a specific date[p84].

If the element is *mutable*[p601], the user agent should allow the user to change the date[p84] represented by its value[p601], as obtained by parsing a date[p84] from it. User agents must not allow the user to set the value[p601] to a non-empty string that is not a valid date string[p84]. If the user agent provides a user interface for selecting a date[p84], then the value[p601] must be set to a valid date string[p84] representing the user's selection. User agents should allow the user to set the value[p601] to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid date string[p84], the control is suffering from bad input[p627].

Note

See the introduction section[p514] for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes[p552] regarding localization of form controls.

The value[p526] attribute, if specified and not empty, must have a value that is a valid date string[p84].

The value sanitization algorithm[p526] is as follows: If the value[p601] of the element is not a valid date string[p84], then set it to the empty string instead.

The min[p557] attribute, if specified, must have a value that is a valid date string[p84]. The max[p557] attribute, if specified, must have a value

that is a valid date string[p84].

The step[p558] attribute is expressed in days. The step scale factor[p558] is 86,400,000 (which converts the days to milliseconds, as used in the other algorithms). The default step[p558] is 1 day.

When the element is suffering from a step mismatch[p627], the user agent may round the element's value[p601] to the nearest date[p84] for which the element would not suffer from a step mismatch[p627].

The algorithm to convert a string to a number[p526], given a string *input*, is as follows: If parsing a date[p84] from *input* results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z") to midnight UTC on the morning of the parsed date[p84], ignoring leap seconds.

The algorithm to convert a number to a string[p526], given a number *input*, is as follows: Return a valid date string[p84] that represents the date[p84] that, in UTC, is current *input* milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z").

The algorithm to convert a string to a Date object[p526], given a string *input*, is as follows: If parsing a date[p84] from *input* results in an error, then return an error; otherwise, return a new Date object[p57] representing midnight UTC on the morning of the parsed date[p84].

The algorithm to convert a Date object to a string[p526], given a Date object *input*, is as follows: Return a valid date string[p84] that represents the date[p84] current at the time represented by *input* in the UTC time zone.

¶[p53] 4 Note

The Date[p533] state (and other date- and time-related states described in subsequent sections) is not intended for the entry of values for which a precise date and time relative to the contemporary calendar cannot be established. For example, it would be inappropriate for the entry of times like "one millisecond after the big bang", "the early part of the Jurassic period", or "a winter around 250 BCE".

For the input of dates before the introduction of the Gregorian calendar, authors are encouraged to not use the Date[p533] state (and the other date- and time-related states described in subsequent sections), as user agents are not required to support converting dates and times from earlier periods to the Gregorian calendar, and asking users to do so manually puts an undue burden on users. (This is complicated by the manner in which the Gregorian calendar was phased in, which occurred at different times in different countries, ranging from partway through the 16th century all the way to early in the 20th.) Instead, authors are encouraged to provide fine-grained input controls using the select[p572] element and input[p521] elements with the Number[p538] state.

Bookkeeping details

- The following common input[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: autocomplete[p608], list[p558], max[p557], min[p557], readonly[p553], required[p554], and step[p558] content attributes; list[p565], value[p562], valueAsDate[p563], and valueAsNumber[p564] IDL attributes; select()[p623], stepDown()[p564], and stepUp()[p564] methods.
- The value[p562] IDL attribute is in mode value[p562].
- The input and change[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: accept[p546], alpha[p542], alt[p549], checked[p526], colorspace[p542], dirname[p604], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], height[p478], maxlength[p552], minlength[p552], multiple[p554], pattern[p555], placeholder[p561], popovertarget[p905], popovertargetaction[p905], size[p553], src[p549], and width[p478].
- The following IDL attributes and methods do not apply[p525] to the element: checked[p563], selectionStart[p623], selectionEnd[p624], and selectionDirection[p624] IDL attributes; setRangeText()[p625], and setSelectionRange()[p624] methods.

4.10.5.1.8 Month state (type=month) §[p53] 4

When an input[p521] element's type[p524] attribute is in the Month[p534] state, the rules in this section apply.

The input[p521] element represents[p142] a control for setting the element's value[p601] to a string representing a specific month[p83].

If the element is *mutable*[p601], the user agent should allow the user to change the month[p83] represented by its value[p601], as obtained by parsing a month[p83] from it. User agents must not allow the user to set the value[p601] to a non-empty string that is not a valid month string[p83]. If the user agent provides a user interface for selecting a month[p83], then the value[p601] must be set to a valid month string[p83] representing the user's selection. User agents should allow the user to set the value[p601] to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid month string[p83], the control is suffering from bad input[p627].

Note

See the introduction section[p514] for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes[p552] regarding localization of form controls.

The `value`[p526] attribute, if specified and not empty, must have a value that is a valid month string[p83].

The value sanitization algorithm[p526] is as follows: If the value[p601] of the element is not a valid month string[p83], then set it to the empty string instead.

The `min`[p557] attribute, if specified, must have a value that is a valid month string[p83]. The `max`[p557] attribute, if specified, must have a value that is a valid month string[p83].

The `step`[p558] attribute is expressed in months. The step scale factor[p558] is 1 (there is no conversion needed as the algorithms use months). The default step[p558] is 1 month.

When the element is suffering from a step mismatch[p627], the user agent may round the element's value[p601] to the nearest month[p83] for which the element would not suffer from a step mismatch[p627].

The algorithm to convert a string to a number[p526], given a string *input*, is as follows: If parsing a month[p83] from *input* results in an error, then return an error; otherwise, return the number of months between January 1970 and the parsed month[p83].

The algorithm to convert a number to a string[p526], given a number *input*, is as follows: Return a valid month string[p83] that represents the month[p83] that has *input* months between it and January 1970.

The algorithm to convert a string to a `Date` object[p526], given a string *input*, is as follows: If parsing a month[p83] from *input* results in an error, then return an error; otherwise, return a new `Date` object[p57] representing midnight UTC on the morning of the first day of the parsed month[p83].

The algorithm to convert a `Date` object to a string[p526], given a `Date` object *input*, is as follows: Return a valid month string[p83] that represents the month[p83] current at the time represented by *input* in the UTC time zone.

Bookkeeping details

- The following common `input`[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: `autocomplete`[p608], `list`[p558], `max`[p557], `min`[p557], `readonly`[p553], `required`[p554], and `step`[p558] content attributes; `list`[p565], `value`[p562], `valueAsDate`[p563], and `valueAsNumber`[p564] IDL attributes; `select()`[p623], `stepDown()`[p564], and `stepUp()`[p564] methods.
- The `value`[p562] IDL attribute is in mode value[p562].
- The `input` and `change`[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: `accept`[p546], `alpha`[p542], `alt`[p549], `checked`[p526], `colorspace`[p542], `dirname`[p604], `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], `formtarget`[p607], `height`[p478], `maxlength`[p552], `minlength`[p552], `multiple`[p554], `pattern`[p555], `placeholder`[p561], `popovertarget`[p905], `popovertargetaction`[p905], `size`[p553], `src`[p549], and `width`[p478].
- The following IDL attributes and methods do not apply[p525] to the element: `checked`[p563], `files`[p563], `selectionStart`[p623], `selectionEnd`[p624], and `selectionDirection`[p624] IDL attributes; `setRangeText()`[p625], and `setSelectionRange()`[p624] methods.

MDN

4.10.5.1.9 Week state (`type=week`) §[p53 5]

When an `input`[p521] element's `type`[p524] attribute is in the Week[p535] state, the rules in this section apply.

The `input`[p521] element represents[p142] a control for setting the element's value[p601] to a string representing a specific week[p90].

If the element is *mutable*[p601], the user agent should allow the user to change the week[p90] represented by its value[p601], as obtained by parsing a week[p91] from it. User agents must not allow the user to set the value[p601] to a non-empty string that is not a valid week string[p90]. If the user agent provides a user interface for selecting a week[p90], then the value[p601] must be set to a valid week string[p90] representing the user's selection. User agents should allow the user to set the value[p601] to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid week string[p90], the control is suffering from bad input[p627].

Note

See the introduction section[p514] for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes[p552] regarding localization of form controls.

The value[p526] attribute, if specified and not empty, must have a value that is a valid week string[p90].

The value sanitization algorithm[p526] is as follows: If the value[p601] of the element is not a valid week string[p90], then set it to the empty string instead.

The min[p557] attribute, if specified, must have a value that is a valid week string[p90]. The max[p557] attribute, if specified, must have a value that is a valid week string[p90].

The step[p558] attribute is expressed in weeks. The step scale factor[p558] is 604,800,000 (which converts the weeks to milliseconds, as used in the other algorithms). The default step[p558] is 1 week. The default step base[p558] is −259,200,000 (the start of week 1970-W01).

When the element is suffering from a step mismatch[p627], the user agent may round the element's value[p601] to the nearest week[p90] for which the element would not suffer from a step mismatch[p627].

The algorithm to convert a string to a number[p526], given a string *input*, is as follows: If parsing a week string[p91] from *input* results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "`1970-01-01T00:00:00.0Z`") to midnight UTC on the morning of the Monday of the parsed week[p90], ignoring leap seconds.

The algorithm to convert a number to a string[p526], given a number *input*, is as follows: Return a valid week string[p90] that represents the week[p90] that, in UTC, is current *input* milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "`1970-01-01T00:00:00.0Z`").

The algorithm to convert a string to a `Date` object[p526], given a string *input*, is as follows: If parsing a week[p91] from *input* results in an error, then return an error; otherwise, return a new `Date` object[p57] representing midnight UTC on the morning of the Monday of the parsed week[p90].

The algorithm to convert a `Date` object to a string[p526], given a `Date` object *input*, is as follows: Return a valid week string[p90] that represents the week[p90] current at the time represented by *input* in the UTC time zone.

Bookkeeping details

- The following common `input`[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: `autocomplete`[p608], `list`[p558], `max`[p557], `min`[p557], `readonly`[p553], `required`[p554], and `step`[p558] content attributes; `list`[p565], `value`[p562], `valueAsDate`[p563], and `valueAsNumber`[p564] IDL attributes; `select()`[p623], `stepDown()`[p564], and `stepUp()`[p564] methods.
- The `value`[p562] IDL attribute is in mode value[p562].
- The `input` and `change`[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: `accept`[p546], `alpha`[p542], `alt`[p549], `checked`[p526], `colorspace`[p542], `dirname`[p604], `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], `formtarget`[p607], `height`[p478], `maxlength`[p552], `minlength`[p552], `multiple`[p554], `pattern`[p555], `placeholder`[p561], `popovertarget`[p905], `popovertargetaction`[p905], `size`[p553], `src`[p549], and `width`[p478].
- The following IDL attributes and methods do not apply[p525] to the element: `checked`[p563], `files`[p563], `selectionStart`[p623], `selectionEnd`[p624], and `selectionDirection`[p624] IDL attributes; `setRangeText()`[p625], and `setSelectionRange()`[p624] methods.

4.10.5.1.10 Time state (`type=time`) §[p53 6]

When an `input`[p521] element's `type`[p524] attribute is in the Time[p536] state, the rules in this section apply.

The `input`[p521] element represents[p142] a control for setting the element's value[p601] to a string representing a specific time[p86].

If the element is *mutable*[p601], the user agent should allow the user to change the time[p86] represented by its value[p601], as obtained by parsing a time[p86] from it. User agents must not allow the user to set the value[p601] to a non-empty string that is not a valid time string[p86]. If the user agent provides a user interface for selecting a time[p86], then the value[p601] must be set to a valid time string[p86] representing the user's selection. User agents should allow the user to set the value[p601] to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid time string[p86], the control is suffering from bad input[p627].

Note

See the introduction section[p514] for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes[p552] regarding localization of form controls.

The value[p526] attribute, if specified and not empty, must have a value that is a valid time string[p86].

The value sanitization algorithm[p526] is as follows: If the value[p601] of the element is not a valid time string[p86], then set it to the empty string instead.

The form control has a periodic domain[p556].

The min[p557] attribute, if specified, must have a value that is a valid time string[p86]. The max[p557] attribute, if specified, must have a value that is a valid time string[p86].

The step[p558] attribute is expressed in seconds. The step scale factor[p558] is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The default step[p558] is 60 seconds.

When the element is suffering from a step mismatch[p627], the user agent may round the element's value[p601] to the nearest time[p86] for which the element would not suffer from a step mismatch[p627].

The algorithm to convert a string to a number[p526], given a string *input*, is as follows: If parsing a time[p86] from *input* results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight to the parsed time[p86] on a day with no time changes.

The algorithm to convert a number to a string[p526], given a number *input*, is as follows: Return a valid time string[p86] that represents the time[p86] that is *input* milliseconds after midnight on a day with no time changes.

The algorithm to convert a string to a `Date` object[p526], given a string *input*, is as follows: If parsing a time[p86] from *input* results in an error, then return an error; otherwise, return a new `Date` object[p57] representing the parsed time[p86] in UTC on 1970-01-01.

The algorithm to convert a `Date` object to a string[p526], given a `Date` object *input*, is as follows: Return a valid time string[p86] that represents the UTC time[p86] component that is represented by *input*.

Bookkeeping details

- The following common input[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: autocomplete[p608], list[p558], max[p557], min[p557], readonly[p553], required[p554], and step[p558] content attributes; list[p565], value[p562], valueAsDate[p563], and valueAsNumber[p564] IDL attributes; select()[p623], stepDown()[p564], and stepUp()[p564] methods.
- The value[p562] IDL attribute is in mode value[p562].
- The input and change[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: accept[p546], alpha[p542], alt[p549], checked[p526], colorspace[p542], dirname[p604], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], height[p478], maxlength[p552], minlength[p552], multiple[p554], pattern[p555], placeholder[p561], popovertarget[p905], popovertargetaction[p905], size[p553], src[p549], and width[p478].
- The following IDL attributes and methods do not apply[p525] to the element: checked[p563], files[p563], selectionStart[p623], selectionEnd[p624], and selectionDirection[p624] IDL attributes; setRangeText()[p625], and setSelectionRange()[p624] methods.

4.10.5.1.11 Local Date and Time state (`type=datetime-local`) §[p537]

When an input[p521] element's type[p524] attribute is in the Local Date and Time[p537] state, the rules in this section apply.

The input[p521] element represents[p142] a control for setting the element's value[p601] to a string representing a local date and time[p87], with no time-zone offset information.

If the element is *mutable*[p601], the user agent should allow the user to change the date and time[p87] represented by its value[p601], as obtained by parsing a date and time[p87] from it. User agents must not allow the user to set the value[p601] to a non-empty string that is not a valid normalized local date and time string[p87]. If the user agent provides a user interface for selecting a local date and time[p87], then the value[p601] must be set to a valid normalized local date and time string[p87] representing the user's selection. User agents should allow the user to set the value[p601] to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid normalized local date and time string[p87], the control is suffering from bad input[p627].

Note

See the introduction section[p514] for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the implementation notes[p552] regarding localization of form controls.

The value[p526] attribute, if specified and not empty, must have a value that is a valid local date and time string[p87].

The value sanitization algorithm[p526] is as follows: If the value[p601] of the element is a valid local date and time string[p87], then set it

to a valid normalized local date and time string[p87] representing the same date and time; otherwise, set it to the empty string instead.

The `min`[p557] attribute, if specified, must have a value that is a valid local date and time string[p87]. The `max`[p557] attribute, if specified, must have a value that is a valid local date and time string[p87].

The `step`[p558] attribute is expressed in seconds. The step scale factor[p558] is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The default step[p558] is 60 seconds.

When the element is suffering from a step mismatch[p627], the user agent may round the element's value[p601] to the nearest local date and time[p87] for which the element would not suffer from a step mismatch[p627].

The algorithm to convert a string to a number[p526], given a string *input*, is as follows: If parsing a date and time[p87] from *input* results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight on the morning of 1970-01-01 (the time represented by the value "`1970-01-01T00:00:00.0`") to the parsed local date and time[p87], ignoring leap seconds.

The algorithm to convert a number to a string[p526], given a number *input*, is as follows: Return a valid normalized local date and time string[p87] that represents the date and time that is *input* milliseconds after midnight on the morning of 1970-01-01 (the time represented by the value "`1970-01-01T00:00:00.0`").

Note

See the note on historical dates[p534] in the Date[p533] state section.

Bookkeeping details

- The following common `input`[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: `autocomplete`[p608], `list`[p558], `max`[p557], `min`[p557], `readonly`[p553], `required`[p554], and `step`[p558] content attributes; `list`[p565], `value`[p562], and `valueAsNumber`[p564] IDL attributes; `select()`[p623], `stepDown()`[p564], and `stepUp()`[p564] methods.
- The `value`[p562] IDL attribute is in mode value[p562].
- The `input` and `change`[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: `accept`[p546], `alpha`[p542], `alt`[p549], `checked`[p526], `colorspace`[p542], `dirname`[p604], `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], `formtarget`[p607], `height`[p478], `maxlength`[p552], `minlength`[p552], `multiple`[p554], `pattern`[p555], `placeholder`[p561], `popovertarget`[p905], `popovertargetaction`[p905], `size`[p553], `src`[p549], and `width`[p478].
- The following IDL attributes and methods do not apply[p525] to the element: `checked`[p563], `files`[p563], `selectionStart`[p623], `selectionEnd`[p624], `selectionDirection`[p624], and `valueAsDate`[p563] IDL attributes; `setRangeText()`[p625], and `setSelectionRange()`[p624] methods.

Example

The following example shows part of a flight booking application. The application uses an `input`[p521] element with its `type`[p524] attribute set to `datetime-local`[p537], and it then interprets the given date and time in the time zone of the selected airport.

```
<fieldset>
 <legend>Destination</legend>
 <p><label>Airport: <input type=text name=to list=airports></label></p>
 <p><label>Departure time: <input type=datetime-local name=totime step=3600></label></p>
</fieldset>
<datalist id=airports>
 <option value=ATL label="Atlanta">
 <option value=MEM label="Memphis">
 <option value=LHR label="London Heathrow">
 <option value=LAX label="Los Angeles">
 <option value=FRA label="Frankfurt">
</datalist>
```

4.10.5.1.12 Number state (`type=number`) §[p538]

When an `input`[p521] element's `type`[p524] attribute is in the Number[p538] state, the rules in this section apply.

The `input`[p521] element represents[p142] a control for setting the element's value[p601] to a string representing a number.

If the element is *mutable*[p601], the user agent should allow the user to change the number represented by its value[p601], as obtained from applying the rules for parsing floating-point number values[p79] to it. User agents must not allow the user to set the value[p601] to a non-

empty string that is not a valid floating-point number[p78]. If the user agent provides a user interface for selecting a number, then the value[p601] must be set to the best representation of the number representing the user's selection as a floating-point number[p79]. User agents should allow the user to set the value[p601] to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid floating-point number[p78], the control is suffering from bad input[p627].

Note

This specification does not define what user interface user agents are to use; user agent vendors are encouraged to consider what would best serve their users' needs. For example, a user agent in Persian or Arabic markets might support Persian and Arabic numeric input (converting it to the format required for submission as described above). Similarly, a user agent designed for Romans might display the value in Roman numerals rather than in decimal; or (more realistically) a user agent designed for the French market might display the value with apostrophes between thousands and commas before the decimals, and allow the user to enter a value in that manner, internally converting it to the submission format described above.

The `value`[p526] attribute, if specified and not empty, must have a value that is a valid floating-point number[p78].

The value sanitization algorithm[p526] is as follows: If the value[p601] of the element is not a valid floating-point number[p78], then set it to the empty string instead.

The `min`[p557] attribute, if specified, must have a value that is a valid floating-point number[p78]. The `max`[p557] attribute, if specified, must have a value that is a valid floating-point number[p78].

The step scale factor[p558] is 1. The default step[p558] is 1 (allowing only integers to be selected by the user, unless the step base[p558] has a non-integer value).

When the element is suffering from a step mismatch[p627], the user agent may round the element's value[p601] to the nearest number for which the element would not suffer from a step mismatch[p627]. If there are two such numbers, user agents are encouraged to pick the one nearest positive infinity.

The algorithm to convert a string to a number[p526], given a string *input*, is as follows: If applying the rules for parsing floating-point number values[p79] to *input* results in an error, then return an error; otherwise, return the resulting number.

The algorithm to convert a number to a string[p526], given a number *input*, is as follows: Return a valid floating-point number[p78] that represents *input*.

Bookkeeping details

- The following common `input`[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: `autocomplete`[p608], `list`[p558], `max`[p557], `min`[p557], `placeholder`[p561], `readonly`[p553], `required`[p554], and `step`[p558] content attributes; `list`[p565], `value`[p562], and `valueAsNumber`[p564] IDL attributes; `select()`[p623], `stepDown()`[p564], and `stepUp()`[p564] methods.
- The `value`[p562] IDL attribute is in mode value[p562].
- The `input` and `change`[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: `accept`[p546], `alpha`[p542], `alt`[p549], `checked`[p526], `colorspace`[p542], `dirname`[p604], `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], `formtarget`[p607], `height`[p478], `maxlength`[p552], `minlength`[p552], `multiple`[p554], `pattern`[p555], `popovertarget`[p905], `popovertargetaction`[p905], `size`[p553], `src`[p549], and `width`[p478].
- The following IDL attributes and methods do not apply[p525] to the element: `checked`[p563], `files`[p563], `selectionStart`[p623], `selectionEnd`[p624], `selectionDirection`[p624], and `valueAsDate`[p563] IDL attributes; `setRangeText()`[p625], and `setSelectionRange()`[p624] methods.

Example

Here is an example of using a numeric input control:

```
<label>How much do you want to charge? $<input type=number min=0 step=0.01 name=price></label>
```

As described above, a user agent might support numeric input in the user's local format, converting it to the format required for submission as described above. This might include handling grouping separators (as in "872,000,000,000") and various decimal separators (such as "3,99" vs "3.99") or using local digits (such as those in Arabic, Devanagari, Persian, and Thai).

¶ p539

Note

The `type=number` state is not appropriate for input that happens to only consist of numbers but isn't strictly speaking a number. For example, it would be inappropriate for credit card numbers or US postal codes. A simple way of determining whether to use `type=number` is to consider whether it would make sense for the input control to have a spinbox interface (e.g. with "up" and

"down" arrows). Getting a credit card number wrong by 1 in the last digit isn't a minor mistake, it's as wrong as getting every digit incorrect. So it would not make sense for the user to select a credit card number using "up" and "down" buttons. When a spinbox interface is not appropriate, `type=text` is probably the right choice (possibly with an `inputmode`[p870] or `pattern`[p555] attribute).

4.10.5.1.13 Range state (`type=range`) §[p54] 0

When an `input`[p521] element's `type`[p524] attribute is in the Range[p540] state, the rules in this section apply.

The `input`[p521] element represents[p142] a control for setting the element's value[p601] to a string representing a number, but with the caveat that the exact value is not important, letting UAs provide a simpler interface than they do for the Number[p538] state.

If the element is *mutable*[p601], the user agent should allow the user to change the number represented by its value[p601], as obtained from applying the rules for parsing floating-point number values[p79] to it. User agents must not allow the user to set the value[p601] to a string that is not a valid floating-point number[p78]. If the user agent provides a user interface for selecting a number, then the value[p601] must be set to a best representation of the number representing the user's selection as a floating-point number[p79]. User agents must not allow the user to set the value[p601] to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a valid floating-point number[p78], the control is suffering from bad input[p627].

The `value`[p526] attribute, if specified, must have a value that is a valid floating-point number[p78].

The value sanitization algorithm[p526] is as follows: If the value[p601] of the element is not a valid floating-point number[p78], then set it to the best representation, as a floating-point number[p79], of the default value[p540].

The **default value** is the minimum[p557] plus half the difference between the minimum[p557] and the maximum[p557], unless the maximum[p557] is less than the minimum[p557], in which case the default value[p540] is the minimum[p557].

When the element is suffering from an underflow[p627], the user agent must set the element's value[p601] to the best representation, as a floating-point number[p79], of the minimum[p557].

When the element is suffering from an overflow[p627], if the maximum[p557] is not less than the minimum[p557], the user agent must set the element's value[p601] to a valid floating-point number[p78] that represents the maximum[p557].

When the element is suffering from a step mismatch[p627], the user agent must round the element's value[p601] to the nearest number for which the element would not suffer from a step mismatch[p627], and which is greater than or equal to the minimum[p557], and, if the maximum[p557] is not less than the minimum[p557], which is less than or equal to the maximum[p557], if there is a number that matches these constraints. If two numbers match these constraints, then user agents must use the one nearest to positive infinity.

Example

For example, the markup `<input type="range" min=0 max=100 step=20 value=50>` results in a range control whose initial value is 60.

Example

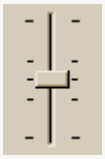
Here is an example of a range control using an autocomplete list with the `list`[p558] attribute. This could be useful if there are values along the full range of the control that are especially important, such as preconfigured light levels or typical speed limits in a range control used as a speed control. The following markup fragment:

```
<input type="range" min="-100" max="100" value="0" step="10" name="power" list="powers">
<datalist id="powers">
<option value="0">
<option value="-30">
<option value="30">
 <option value="++50">
</datalist>
```

...with the following style sheet applied:

```css
input { writing-mode: vertical-lr; height: 75px; width: 49px; background: #D5CCBB; color: black; }
```

...might render as:



Note how the UA determined the orientation of the control from the ratio of the style-sheet-specified height and width properties. The colors were similarly derived from the style sheet. The tick marks, however, were derived from the markup. In particular, the step[p558] attribute has not affected the placement of tick marks, the UA deciding to only use the author-specified completion values and then adding longer tick marks at the extremes.

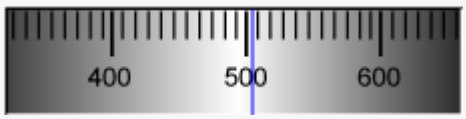
Note also how the invalid value `++50` was ignored.

Example

For another example, consider the following markup fragment:

```
<input name=x type=range min=100 max=700 step=9.09090909 value=509.090909>
```

A user agent could display in a variety of ways, for instance:



Or, alternatively, for instance:

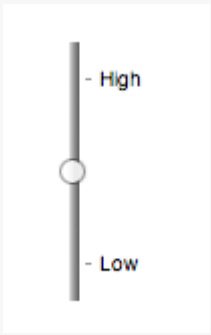
The user agent could pick which one to display based on the dimensions given in the style sheet. This would allow it to maintain the same resolution for the tick marks, despite the differences in width.

Example

Finally, here is an example of a range control with two labeled values:

```
<input type="range" name="a" list="a-values">
<datalist id="a-values">
<option value="10" label="Low">
<option value="90" label="High">
</datalist>
```

With styles that make the control draw vertically, it might look as follows:



Note

In this state, the range and step constraints are enforced even during user input, and there is no way to set the value to the empty string.

The `min`[p557] attribute, if specified, must have a value that is a valid floating-point number[p78]. The default minimum[p557] is 0. The `max`[p557] attribute, if specified, must have a value that is a valid floating-point number[p78]. The default maximum[p557] is 100.

The step scale factor[p558] is 1. The default step[p558] is 1 (allowing only integers, unless the `min`[p557] attribute has a non-integer value).

The algorithm to convert a string to a number[p526], given a string *input*, is as follows: If applying the rules for parsing floating-point number values[p79] to *input* results in an error, then return an error; otherwise, return the resulting number.

The algorithm to convert a number to a string[p526], given a number *input*, is as follows: Return the best representation, as a floating-point number[p79], of *input*.

Bookkeeping details

- The following common `input`[p521] element content attributes, IDL attributes, and methods apply[p524] to the element: `autocomplete`[p608], `list`[p558], `max`[p557], `min`[p557], and `step`[p558] content attributes; `list`[p565], `value`[p562], and `valueAsNumber`[p564] IDL attributes; `stepDown()`[p564] and `stepUp()`[p564] methods.
- The `value`[p562] IDL attribute is in mode value[p562].
- The `input` and `change`[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: `accept`[p546], `alpha`[p542], `alt`[p549], `checked`[p526], `colorspace`[p542], `dirname`[p604], `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], `formtarget`[p607], `height`[p478], `maxlength`[p552], `minlength`[p552], `multiple`[p554], `pattern`[p555], `placeholder`[p561], `popovertarget`[p905], `popovertargetaction`[p905], `readonly`[p553], `required`[p554], `size`[p553], `src`[p549], and `width`[p478].
- The following IDL attributes and methods do not apply[p525] to the element: `checked`[p563], `files`[p563], `selectionStart`[p623], `selectionEnd`[p624], `selectionDirection`[p624], and `valueAsDate`[p563] IDL attributes; `select()`[p623], `setRangeText()`[p625], and `setSelectionRange()`[p624] methods.

4.10.5.1.14 Color state (`type=color`) §[p54]

When an `input`[p521] element's `type`[p524] attribute is in the Color[p542] state, the rules in this section apply.

The `input`[p521] element represents[p142] a color well control, for setting the element's value[p601] to a string representing the serialization of a CSS color.

Note

In this state, there is always a CSS color picked, and there is no way for the end user to set the value to the empty string.

The **`alpha`** attribute is a boolean attribute[p76]. If present, it indicates the CSS color's alpha component can be manipulated by the end user and does not have to be fully opaque.

The **`colorspace`** attribute indicates the color space of the serialized CSS color. It also hints at the desired user interface for selecting a CSS color. It is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
`limited-srgb`	**Limited sRGB**	The CSS color is converted to the 'srgb' color space and limited to 8-bits per component, e.g., "`#123456`" or "`color(srgb 0 1 0 / 0.5)`".
`display-p3`	**Display P3**	The CSS color is converted to the 'display-p3' color space, e.g., "`color(display-p3 1.84 -0.19 0.72 / 0.6)`".

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the Limited sRGB[p542] state.

Whenever the element's `alpha`[p542] or `colorspace`[p542] attributes are changed, the user agent must run update a color well control color[p543] given the element.

If the element is *mutable*[p601], the user agent should allow the user to change the color represented by its value[p601], as obtained from parsing it. User agents must not allow the user to set the value[p601] to a string that running update a color well control color[p543] for the element would not set it to. If the user agent provides a user interface for selecting a CSS color, then the value[p601] must be set to the result of serializing a color well control color[p543] given the element and the end user's selection.

The input activation behavior[p527] for such an element *element* is to show the picker, if applicable[p565], for *element*.

Constraint validation: While the element's value[p601] is not the empty string and parsing it returns failure, the control is suffering from bad input[p627].

The `value`[p526] attribute, if specified and not the empty string, must have a value that is a CSS color.

The value sanitization algorithm[p526] is as follows: Run update a color well control color[p543] for the element.

To **update a color well control color**, given an element *element*:

1. Assert: *element* is an `input`[p521] element whose `type`[p524] attribute is in the Color[p542] state.
2. Let *color* be the result of parsing *element*'s value[p601].
3. If *color* is failure, then set *color* to opaque black.
4. Set *element*'s value[p601] to the result of serializing a color well control color[p543] given *element* and *color*.

To **serialize a color well control color**, given an element *element* and a CSS color *color*:

1. Assert: *element* is an `input`[p521] element whose `type`[p524] attribute is in the Color[p542] state.
2. Let *htmlCompatible* be false.
3. If *element*'s `alpha`[p542] attribute is not specified, then set *color*'s alpha component to be fully opaque.
4. If *element*'s `colorspace`[p542] attribute is in the Limited sRGB[p542] state:
    1. Set *color* to *color* converted to the 'srgb' color space.
    2. Round each of *color*'s components so they are in the range 0 to 255, inclusive. Components are to be rounded towards +∞.
    3. If *element*'s `alpha`[p542] attribute is not specified, then set *htmlCompatible* to true.

    > **Note**
    > *This intentionally uses a different serialization path for compatibility with an earlier version of the color well control.*

    4. Otherwise, set *color* to *color* converted using the 'color()' function.
5. Otherwise:
    1. Assert: *element*'s `colorspace`[p542] attribute is in the Display P3[p542] state.
    2. Set *color* to *color* converted to the 'display-p3' color space.
6. Return the result of serializing *color*. If *htmlCompatible* is true, then do so with HTML-compatible serialization requested.

Bookkeeping details

- The following common `input`[p521] element content attributes and IDL attributes apply[p524] to the element: `alpha`[p542], `autocomplete`[p608], `colorspace`[p542], and `list`[p558] content attributes; `list`[p565] and `value`[p562] IDL attributes; `select()`[p623] method.
- The `value`[p562] IDL attribute is in mode value[p562].
- The `input` and `change`[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: `accept`[p546], `alt`[p549], `checked`[p526], `dirname`[p604], `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], `formtarget`[p607], `height`[p478], `max`[p557], `maxlength`[p552], `min`[p557], `minlength`[p552], `multiple`[p554], `pattern`[p555], `placeholder`[p561], `popovertarget`[p905], `popovertargetaction`[p905], `readonly`[p553], `required`[p554], `size`[p553], `src`[p549], `step`[p558], and `width`[p478].

- The following IDL attributes and methods do not apply to the element: checked, files, selectionStart, selectionEnd, selectionDirection, valueAsDate and, valueAsNumber IDL attributes; setRangeText(), setSelectionRange(), stepDown(), and stepUp() methods.

4.10.5.1.15 Checkbox state (type=checkbox)

When an input element's type attribute is in the Checkbox state, the rules in this section apply.

The input element represents a two-state control that represents the element's checkedness state. If the element's checkedness state is true, the control represents a positive selection, and if it is false, a negative selection. If the element's indeterminate IDL attribute is set to true, then the control's selection should be obscured as if the control was in a third, indeterminate, state.

Note

The control is never a true tri-state control, even if the element's indeterminate IDL attribute is set to true. The indeterminate IDL attribute only gives the appearance of a third state.

The input activation behavior is to run the following steps:

1. If the element is not connected, then return.
2. Fire an event named input at the element with the bubbles and composed attributes initialized to true.
3. Fire an event named change at the element with the bubbles attribute initialized to true.

Constraint validation: If the element is *required* and its checkedness is false, then the element is suffering from being missing.

For web developers (non-normative)

***input*.indeterminate [= *value*]**

When set, overrides the rendering of checkbox controls so that the current value is not visible.

Bookkeeping details

- The following common input element content attributes and IDL attributes apply to the element: checked, and required content attributes; checked and value IDL attributes.
- The value IDL attribute is in mode default/on.
- The input and change events apply.
- The following content attributes must not be specified and do not apply to the element: accept, alpha, alt, autocomplete, colorspace, dirname, formaction, formenctype, formmethod, formnovalidate, formtarget, height, list, max, maxlength, min, minlength, multiple, pattern, placeholder, popovertarget, popovertargetaction, readonly, size, src, step, and width.
- The following IDL attributes and methods do not apply to the element: files, list, selectionStart, selectionEnd, selectionDirection, valueAsDate, and valueAsNumber IDL attributes; select(), setRangeText(), setSelectionRange(), stepDown(), and stepUp() methods.

4.10.5.1.16 Radio Button state (type=radio)

When an input element's type attribute is in the Radio Button state, the rules in this section apply.

The input element represents a control that, when used in conjunction with other input elements, forms a *radio button group* in which only one control can have its checkedness state set to true. If the element's checkedness state is true, the control represents the selected control in the group, and if it is false, it indicates a control in the group that is not selected.

The ***radio button group*** that contains an input element *a* also contains all the other input elements *b* that fulfill all of the following conditions:

- The input element *b*'s type attribute is in the Radio Button state.
- Either *a* and *b* have the same form owner, or they both have no form owner.
- Both *a* and *b* are in the same tree.

- They both have a `name` attribute, their `name` attributes are not empty, and the value of *a*'s `name` attribute equals the value of *b*'s `name` attribute.

A tree must not contain an `input` element whose *radio button group* contains only that element.

When any of the following phenomena occur, if the element's checkedness state is true after the occurrence, the checkedness state of all the other elements in the same *radio button group* must be set to false:

- The element's checkedness state is set to true (for whatever reason).
- The element's `name` attribute is set, changed, or removed.
- The element's form owner changes.
- A type change is signalled for the element.
- The element becomes connected.

The input activation behavior is to run the following steps:

1. If the element is not connected, then return.
2. Fire an event named `input` at the element with the `bubbles` and `composed` attributes initialized to true.
3. Fire an event named `change` at the element with the `bubbles` attribute initialized to true.

Constraint validation: If an element in the *radio button group* is *required*, and all of the `input` elements in the *radio button group* have a checkedness that is false, then the element is suffering from being missing.

Example

The following example, for some reason, has specified that puppers are both required and disabled:

```
<form>
 <p><label><input type="radio" name="dog-type" value="pupper" required disabled> Pupper</label>
 <p><label><input type="radio" name="dog-type" value="doggo"> Doggo</label>
 <p><button>Make your choice</button>
</form>
```

If the user tries to submit this form without first selecting "Doggo", then *both* `input` elements will be suffering from being missing, since an element in the radio button group is required (viz. the first element), and both of the elements in the radio button group have a false checkedness.

On the other hand, if the user selects "Doggo" and then submits the form, then neither `input` element will be suffering from being missing, since while one of them is required, not all of them have a false checkedness.

Note

If none of the radio buttons in a radio button group are checked, then they will all be initially unchecked in the interface, until such time as one of them is checked (either by the user or by script).

Bookkeeping details

- The following common `input` element content attributes and IDL attributes apply to the element: `checked` and `required` content attributes; `checked` and `value` IDL attributes.
- The `value` IDL attribute is in mode default/on.
- The `input` and `change` events apply.
- The following content attributes must not be specified and do not apply to the element: `accept`, `alpha`, `alt`, `autocomplete`, `colorspace`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `popovertarget`, `popovertargetaction`, `readonly`, `size`, `src`, `step`, and `width`.
- The following IDL attributes and methods do not apply to the element: `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsNumber` IDL attributes; `select()`, `setRangeText()`, `setSelectionRange()`, `stepDown()`, and `stepUp()` methods.

4.10.5.1.17 File Upload state (type=file) §[p546]

When an input[p521] element's type[p524] attribute is in the File Upload[p546] state, the rules in this section apply.

The input[p521] element represents[p142] a list of **selected files**, each file consisting of a filename, a file type, and a file body (the contents of the file).

Filenames must not contain path components[p546], even in the case that a user has selected an entire directory hierarchy or multiple files with the same name from different directories. **Path components**, for the purposes of the File Upload[p546] state, are those parts of filenames that are separated by U+005C REVERSE SOLIDUS character (\) characters.

Unless the multiple[p554] attribute is set, there must be no more than one file in the list of selected files[p546].

The input activation behavior[p527] for such an element *element* is to show the picker, if applicable[p565], for *element*.

If the element is *mutable*[p601], the user agent should allow the user to change the files on the list in other ways also, e.g., adding or removing files by drag-and-drop. When the user does so, the user agent must update the file selection[p546] for the element.

If the element is not *mutable*[p601], the user agent must not allow the user to change the element's selection.

To **update the file selection** for an element *element*:

1. Queue an element task[p1140] on the user interaction task source[p1149] given *element* and the following steps:
    1. Update *element*'s selected files[p546] so that it represents the user's selection.
    2. Fire an event named input at the input[p521] element, with the bubbles and composed attributes initialized to true.
    3. Fire an event named change[p1489] at the input[p521] element, with the bubbles attribute initialized to true.

Constraint validation: If the element is *required*[p554] and the list of selected files[p546] is empty, then the element is suffering from being missing[p626].

The **accept** attribute may be specified to provide user agents with a hint of what file types will be accepted.

If specified, the attribute must consist of a set of comma-separated tokens[p96], each of which must be an ASCII case-insensitive match for one of the following:

The string "audio/*"
: Indicates that sound files are accepted.

The string "video/*"
: Indicates that video files are accepted.

The string "image/*"
: Indicates that image files are accepted.

A valid MIME type string with no parameters
: Indicates that files of the specified type are accepted.

A string whose first character is a U+002E FULL STOP character (.)
: Indicates that files with the specified file extension are accepted.

The tokens must not be ASCII case-insensitive matches for any of the other tokens (i.e. duplicates are not allowed). To obtain the list of tokens from the attribute, the user agent must split the attribute value on commas.

User agents may use the value of this attribute to display a more appropriate user interface than a generic file picker. For instance, given the value image/*, a user agent could offer the user the option of using a local camera or selecting a photograph from their photo collection; given the value audio/*, a user agent could offer the user the option of recording a clip using a headset microphone.

User agents should prevent the user from selecting files that are not accepted by one (or more) of these tokens.

Note

Authors are encouraged to specify both any MIME types and any corresponding extensions when looking for data in a specific format.

Example

For example, consider an application that converts Microsoft Word documents to Open Document Format files. Since Microsoft Word documents are described with a wide variety of MIME types and extensions, the site can list several, as follows:

```
<input type="file" accept=".doc,.docx,.xml,application/msword,application/vnd.openxmlformats-officedocument.wordprocessingml.document">
```

On platforms that only use file extensions to describe file types, the extensions listed here can be used to filter the allowed documents, while the MIME types can be used with the system's type registration table (mapping MIME types to extensions used by the system), if any, to determine any other extensions to allow. Similarly, on a system that does not have filenames or extensions but labels documents with MIME types internally, the MIME types can be used to pick the allowed files, while the extensions can be used if the system has an extension registration table that maps known extensions to MIME types used by the system.

⚠Warning!

Extensions tend to be ambiguous (e.g. there are an untold number of formats that use the ".dat" extension, and users can typically quite easily rename their files to have a ".doc" extension even if they are not Microsoft Word documents), and MIME types tend to be unreliable (e.g. many formats have no formally registered types, and many formats are in practice labeled using a number of different MIME types). Authors are reminded that, as usual, data received from a client should be treated with caution, as it may not be in an expected format even if the user is not hostile and the user agent fully obeyed the accept[p546] attribute's requirements.

¶[p547] **Example**

For historical reasons, the value[p562] IDL attribute prefixes the filename with the string "C:\fakepath\". Some legacy user agents actually included the full path (which was a security vulnerability). As a result of this, obtaining the filename from the value[p562] IDL attribute in a backwards-compatible way is non-trivial. The following function extracts the filename in a suitably compatible manner:

```
function extractFilename(path) {
  if (path.substr(0, 12) == "C:\\fakepath\\")
    return path.substr(12); // modern browser
  var x;
  x = path.lastIndexOf('/');
  if (x >= 0) // Unix-based path
    return path.substr(x+1);
  x = path.lastIndexOf('\\');
  if (x >= 0) // Windows-based path
    return path.substr(x+1);
  return path; // just the filename
}
```

This can be used as follows:

```
<p><input type=file name=image onchange="updateFilename(this.value)"></p>
<p>The name of the file you picked is: <span id="filename">(none)</span></p>
<script>
 function updateFilename(path) {
   var name = extractFilename(path);
   document.getElementById('filename').textContent = name;
 }
</script>
```

Bookkeeping details

- The following common input[p521] element content attributes and IDL attributes apply[p524] to the element: accept[p546], multiple[p554], and required[p554] content attributes; files[p563] and value[p562] IDL attributes; select()[p623] method.
- The value[p562] IDL attribute is in mode filename[p563].
- The input and change[p1489] events apply[p524].
- The following content attributes must not be specified and do not apply[p525] to the element: alpha[p542], alt[p549], autocomplete[p608], checked[p526], colorspace[p542], dirname[p604], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], height[p478], list[p558], max[p557], maxlength[p552], min[p557],

minlength[p552], pattern[p555], popovertarget[p905], popovertargetaction[p905], placeholder[p561], readonly[p553], size[p553], src[p549], step[p558], and width[p478].

- The element's value[p526] attribute must be omitted.
- The following IDL attributes and methods do not apply[p525] to the element: checked[p563], list[p565], selectionStart[p623], selectionEnd[p624], selectionDirection[p624], valueAsDate[p563], and valueAsNumber[p564] IDL attributes; setRangeText()[p625], setSelectionRange()[p624], stepDown()[p564], and stepUp()[p564] methods.

4.10.5.1.18 Submit Button state (type=submit) §[p54]

When an input[p521] element's type[p524] attribute is in the Submit Button[p548] state, the rules in this section apply.

The input[p521] element represents[p142] a button that, when activated, submits the form. If the element has a value[p526] attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Submit" or some such. The element is a button[p515], specifically a submit button[p515].

Note

Since the default label is implementation-defined, and the width of the button typically depends on the button's label, the button's width can leak a few bits of fingerprintable information. These bits are likely to be strongly correlated to the identity of the user agent and the user's locale.

The element's optional value[p601] is the value of the element's value[p570] attribute, if there is one; otherwise null.

The element's input activation behavior[p527] given *event* is as follows:

1. If the element does not have a form owner[p601], then return.
2. If the element's node document is not fully active[p1017], then return.
3. Submit[p633] the element's form owner[p601] from the element with *userInvolvement*[p633] set to *event*'s user navigation involvement[p1028].

The formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], and formtarget[p607] attributes are attributes for form submission[p606].

Note

The formnovalidate[p607] attribute can be used to make submit buttons that do not trigger the constraint validation.

Bookkeeping details

- The following common input[p521] element content attributes and IDL attributes apply[p524] to the element: dirname[p604], formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], formtarget[p607], popovertarget[p905], and popovertargetaction[p905] content attributes; value[p562] IDL attribute.
- The value[p562] IDL attribute is in mode default[p563].
- The following content attributes must not be specified and do not apply[p525] to the element: accept[p546], alpha[p542], alt[p549], autocomplete[p608], checked[p526], colorspace[p542], height[p478], list[p558], max[p557], maxlength[p552], min[p557], minlength[p552], multiple[p554], pattern[p555], placeholder[p561], readonly[p553], required[p554], size[p553], src[p549], step[p558], and width[p478].
- The following IDL attributes and methods do not apply[p525] to the element: checked[p563], files[p563], list[p565], selectionStart[p623], selectionEnd[p624], selectionDirection[p624], valueAsDate[p563], and valueAsNumber[p564] IDL attributes; select()[p623], setRangeText()[p625], setSelectionRange()[p624], stepDown()[p564], and stepUp()[p564] methods.
- The input and change[p1489] events do not apply[p525].

4.10.5.1.19 Image Button state (type=image) §[p54]

When an input[p521] element's type[p524] attribute is in the Image Button[p548] state, the rules in this section apply.

The input[p521] element represents[p142] either an image from which a user can select a coordinate and submit the form, or alternatively a button from which the user can submit the form. The element is a button[p515], specifically a submit button[p515].

Note

The coordinate is sent to the server during form submission[p636] by sending two entries for the element, derived from the name of the control but with ".x" and ".y" appended to the name with the x and y components of the coordinate respectively.

The image is given by the **src** attribute. The src[p549] attribute must be present, and must contain a valid non-empty URL potentially surrounded by spaces[p97] referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.

When any of these events occur:

- the input[p521] element's type[p524] attribute is first set to the Image Button[p548] state (possibly when the element is first created), and the src[p549] attribute is present
- the input[p521] element's type[p524] attribute is changed back to the Image Button[p548] state, and the src[p549] attribute is present, and its value has changed since the last time the type[p524] attribute was in the Image Button[p548] state
- the input[p521] element's type[p524] attribute is in the Image Button[p548] state, and the src[p549] attribute is set or changed

then unless the user agent cannot support images, or its support for images has been disabled, or the user agent only fetches images on demand, or the src[p549] attribute's value is the empty string, run these steps:

1. Let *url* be the result of encoding-parsing a URL[p98] given the src[p549] attribute's value, relative to the element's node document.
2. If *url* is failure, then return.
3. Let *request* be a new request whose URL is *url*, client is the element's node document's relevant settings object[p1098], destination is "`image`", initiator type is "`input`", credentials mode is "`include`", and whose use-URL-credentials flag is set.
4. Fetch *request*, with *processResponseEndOfBody* set to the following steps given response *response*:
    1. If the download was successful and the image is *available*[p549], queue an element task[p1140] on the user interaction task source[p1149] given the input[p521] element to fire an event named load[p1490] at the input[p521] element.
    2. Otherwise, if the fetching process fails without a response from the remote server, or completes but the image is not a valid or supported image, then queue an element task[p1140] on the user interaction task source[p1149] given the input[p521] element to fire an event named error[p1489] on the input[p521] element.

Fetching the image must delay the load event[p1377] of the element's node document until the task[p1139] that is queued[p1139] by the networking task source[p1149] once the resource has been fetched (defined below) has been run.

If the image was successfully obtained, with no network errors, and the image's type is a supported image type, and the image is a valid image of that type, then the image is said to be ***available***. If this is true before the image is completely downloaded, each task[p1139] that is queued[p1139] by the networking task source[p1149] while the image is being fetched must update the presentation of the image appropriately.

The user agent should apply the image sniffing rules to determine the type of the image, with the image's associated Content-Type headers[p100] giving the *official type*. If these rules are not applied, then the type of the image must be the type given by the image's associated Content-Type headers[p100].

User agents must not support non-image resources with the input[p521] element. User agents must not run executable code embedded in the image resource. User agents must only display the first page of a multipage resource. User agents must not allow the resource to act in an interactive fashion, but should honor any animation in the resource.

The **alt** attribute provides the textual label for the button for users and user agents who cannot use the image. The alt[p549] attribute must be present, and must contain a non-empty string giving the label that would be appropriate for an equivalent button if the image was unavailable.

The input[p521] element supports dimension attributes[p478].

If the src[p549] attribute is set, and the image is *available*[p549] and the user agent is configured to display that image, then the element represents[p142] a control for selecting a coordinate[p550] from the image specified by the src[p549] attribute. In that case, if the element is *mutable*[p601], the user agent should allow the user to select this coordinate[p550].

Otherwise, the element represents[p142] a submit button whose label is given by the value of the alt[p549] attribute.

The element's input activation behavior[p527] given *event* is as follows:

1. If the element does not have a form owner[p601], then return.

2. If the element's node document is not fully active[p1017], then return.

3. If the user activated the control while explicitly selecting a coordinate, then set the element's selected coordinate[p550] to that coordinate.

   Note

   This is only possible under the conditions outlined above, when the element represents[p142] a control for selecting such a coordinate. Even then, the user might activate the control without explicitly selecting a coordinate.

4. Submit[p633] the element's form owner[p601] from the element with *userInvolvement*[p633] set to *event*'s user navigation involvement[p1028].

The element's **selected coordinate** consists of an *x*-component and a *y*-component. It is initially (0, 0). The coordinates represent the position relative to the edge of the element's image, with the coordinate space having the positive *x* direction to the right, and the positive *y* direction downwards.

The *x*-component must be a valid integer[p78] representing a number x in the range $-(border_{left}+padding_{left}) \le x \le width+border_{right}+padding_{right}$, where *width* is the rendered width of the image, $border_{left}$ is the width of the border on the left of the image, $padding_{left}$ is the width of the padding on the left of the image, $border_{right}$ is the width of the border on the right of the image, and $padding_{right}$ is the width of the padding on the right of the image, with all dimensions given in CSS pixels.

The *y*-component must be a valid integer[p78] representing a number y in the range $-(border_{top}+padding_{top}) \le y \le height+border_{bottom}+padding_{bottom}$, where *height* is the rendered height of the image, $border_{top}$ is the width of the border above the image, $padding_{top}$ is the width of the padding above the image, $border_{bottom}$ is the width of the border below the image, and $padding_{bottom}$ is the width of the padding below the image, with all dimensions given in CSS pixels.

Where a border or padding is missing, its width is zero CSS pixels.

The `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], and `formtarget`[p607] attributes are attributes for form submission[p606].

For web developers (non-normative)

***image*.width[p528] [= *value*]**

***image*.height[p528] [= *value*]**

These attributes return the actual rendered dimensions of the image, or 0 if the dimensions are not known.

They can be set, to change the corresponding content attributes.

Bookkeeping details

- The following common `input`[p521] element content attributes and IDL attributes apply[p524] to the element: `alt`[p549], `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], `formtarget`[p607], `height`[p478], `popovertarget`[p905], `popovertargetaction`[p905], `src`[p549], and `width`[p478] content attributes; `value`[p562] IDL attribute.
- The `value`[p562] IDL attribute is in mode default[p563].
- The following content attributes must not be specified and do not apply[p525] to the element: `accept`[p546], `alpha`[p542], `autocomplete`[p608], `checked`[p526], `colorspace`[p542], `dirname`[p604], `list`[p558], `max`[p557], `maxlength`[p552], `min`[p557], `minlength`[p552], `multiple`[p554], `pattern`[p555], `placeholder`[p561], `readonly`[p553], `required`[p554], `size`[p553], and `step`[p558].
- The element's `value`[p526] attribute must be omitted.
- The following IDL attributes and methods do not apply[p525] to the element: `checked`[p563], `files`[p563], `list`[p565], `selectionStart`[p623], `selectionEnd`[p624], `selectionDirection`[p624], `valueAsDate`[p563], and `valueAsNumber`[p564] IDL attributes; `select()`[p623], `setRangeText()`[p625], `setSelectionRange()`[p624], `stepDown()`[p564], and `stepUp()`[p564] methods.
- The `input` and `change`[p1489] events do not apply[p525].

Note

Many aspects of this state's behavior are similar to the behavior of the `img`[p347] element. Readers are encouraged to read that section, where many of the same requirements are described in more detail.

Example

Take the following form:

```
<form action="process.cgi">
```

```
 <input type=image src=map.png name=where alt="Show location list">
</form>
```

If the user clicked on the image at coordinate (127,40) then the URL used to submit the form would be "`process.cgi?where.x=127&where.y=40`".

(In this example, it's assumed that for users who don't see the map, and who instead just see a button labeled "Show location list", clicking the button will cause the server to show a list of locations to pick from instead of the map.)

4.10.5.1.20 Reset Button state (`type=reset`) §[p55 1]

When an `input`[p521] element's `type`[p524] attribute is in the Reset Button[p551] state, the rules in this section apply.

The `input`[p521] element represents[p142] a button that, when activated, resets the form. If the element has a `value`[p526] attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Reset" or some such. The element is a button[p515].

Note

Since the default label is implementation-defined, and the width of the button typically depends on the button's label, the button's width can leak a few bits of fingerprintable information. These bits are likely to be strongly correlated to the identity of the user agent and the user's locale.

The element's input activation behavior[p527] is as follows:

1. If the element does not have a form owner[p601], then return.
2. If the element's node document is not fully active[p1017], then return.
3. Reset[p641] the form owner[p601] from the element.

Constraint validation: The element is barred from constraint validation[p626].

Bookkeeping details

- The `value`[p562] IDL attribute applies[p524] to this element and is in mode default[p563].
- The following common `input`[p521] element content attributes apply[p524] to the element: `popovertarget`[p905] and `popovertargetaction`[p905].
- The following content attributes must not be specified and do not apply[p525] to the element: `accept`[p546], `alpha`[p542], `alt`[p549], `autocomplete`[p608], `checked`[p526], `colorspace`[p542], `dirname`[p604], `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], `formtarget`[p607], `height`[p478], `list`[p558], `max`[p557], `maxlength`[p552], `min`[p557], `minlength`[p552], `multiple`[p554], `pattern`[p555], `placeholder`[p561], `readonly`[p553], `required`[p554], `size`[p553], `src`[p549], `step`[p558], and `width`[p478].
- The following IDL attributes and methods do not apply[p525] to the element: `checked`[p563], `files`[p563], `list`[p565], `selectionStart`[p623], `selectionEnd`[p624], `selectionDirection`[p624], `valueAsDate`[p563], and `valueAsNumber`[p564] IDL attributes; `select()`[p623], `setRangeText()`[p625], `setSelectionRange()`[p624], `stepDown()`[p564], and `stepUp()`[p564] methods.
- The `input` and `change`[p1489] events do not apply[p525].

4.10.5.1.21 Button state (`type=button`) §[p55 1]

When an `input`[p521] element's `type`[p524] attribute is in the Button[p551] state, the rules in this section apply.

The `input`[p521] element represents[p142] a button with no default behavior. A label for the button must be provided in the `value`[p526] attribute, though it may be the empty string. If the element has a `value`[p526] attribute, the button's label must be the value of that attribute; otherwise, it must be the empty string. The element is a button[p515].

The element has no input activation behavior[p527].

Constraint validation: The element is barred from constraint validation[p626].

Bookkeeping details

- The `value`[p562] IDL attribute applies[p524] to this element and is in mode default[p563].
- The following common `input`[p521] element content attributes apply[p524] to the element: `popovertarget`[p905] and `popovertargetaction`[p905].

- The following content attributes must not be specified and do not apply to the element: accept, alpha, alt, autocomplete, checked, colorspace, dirname, formaction, formenctype, formmethod, formnovalidate, formtarget, height, list, max, maxlength, min, minlength, multiple, pattern, placeholder, readonly, required, size, src, step, and width.
- The following IDL attributes and methods do not apply to the element: checked, files, list, selectionStart, selectionEnd, selectionDirection, valueAsDate, and valueAsNumber IDL attributes; select(), setRangeText(), setSelectionRange(), stepDown(), and stepUp() methods.
- The input and change events do not apply.

4.10.5.2 Implementation notes regarding localization of form controls

This section is non-normative.

The formats shown to the user in date, time, and number controls is independent of the format used for form submission.

Browsers are encouraged to use user interfaces that present dates, times, and numbers according to the conventions of either the locale implied by the input element's language or the user's preferred locale. Using the page's locale will ensure consistency with page-provided data.

Example

For example, it would be confusing to users if an American English page claimed that a Cirque De Soleil show was going to be showing on 02/03, but their browser, configured to use the British English locale, only showed the date 03/02 in the ticket purchase date picker. Using the page's locale would at least ensure that the date was presented in the same format everywhere. (There's still a risk that the user would end up arriving a month late, of course, but there's only so much that can be done about such cultural differences...)

4.10.5.3 Common input element attributes

These attributes only apply to an input element if its type attribute is in a state whose definition declares that the attribute applies. When an attribute doesn't apply to an input element, user agents must ignore the attribute, regardless of the requirements and definitions below.

4.10.5.3.1 The maxlength and minlength attributes

The **maxlength** attribute, when it applies, is a form control maxlength attribute.

The **minlength** attribute, when it applies, is a form control minlength attribute.

If the input element has a maximum allowed value length, then the length of the value of the element's value attribute must be less than or equal to the element's maximum allowed value length.

Example

The following extract shows how a messaging client's text entry could be arbitrarily restricted to a fixed number of characters, thus forcing any conversation through this medium to be terse and discouraging intelligent discourse.

```
<label>What are you doing? <input name=status maxlength=140></label>
```

Example

Here, a password is given a minimum length:

```
<p><label>Username: <input name=u required></label>
<p><label>Password: <input name=p required minlength=12></label>
```

4.10.5.3.2 The `size` attribute

The **`size`** attribute gives the number of characters that, in a visual rendering, the user agent is to allow the user to see while editing the element's value.

The `size` attribute, if specified, must have a value that is a valid non-negative integer greater than zero.

If the attribute is present, then its value must be parsed using the rules for parsing non-negative integers, and if the result is a number greater than zero, then the user agent should ensure that at least that many characters are visible.

The `size` IDL attribute is limited to only positive numbers and has a default value of 20.

4.10.5.3.3 The `readonly` attribute

The **`readonly`** attribute is a boolean attribute that controls whether or not the user can edit the form control. When specified, the element is not *mutable*.

Constraint validation: If the `readonly` attribute is specified on an `input` element, the element is barred from constraint validation.

Note

The difference between `disabled` and `readonly` is that read-only controls can still function, whereas disabled controls generally do not function as controls until they are enabled. This is spelled out in more detail elsewhere in this specification with normative requirements that refer to the disabled concept (for example, the element's activation behavior, whether or not it is a focusable area, or when constructing the entry list). Any other behavior related to user interaction with disabled controls, such as whether text can be selected or copied, is not defined in this standard.

Only text controls can be made read-only, since for other controls (such as checkboxes and buttons) there is no useful distinction between being read-only and being disabled, so the `readonly` attribute does not apply.

Example

In the following example, the existing product identifiers cannot be modified, but they are still displayed as part of the form, for consistency with the row representing a new product (where the identifier is not yet filled in).

```
<form action="products.cgi" method="post" enctype="multipart/form-data">
 <table>
  <tr> <th> Product ID <th> Product name <th> Price <th> Action
  <tr>
   <td> <input readonly="readonly" name="1.pid" value="H412">
   <td> <input required="required" name="1.pname" value="Floor lamp Ulke">
   <td> $<input required="required" type="number" min="0" step="0.01" name="1.pprice"
value="49.99">
   <td> <button formnovalidate="formnovalidate" name="action" value="delete:1">Delete</button>
  <tr>
   <td> <input readonly="readonly" name="2.pid" value="FG28">
   <td> <input required="required" name="2.pname" value="Table lamp Ulke">
   <td> $<input required="required" type="number" min="0" step="0.01" name="2.pprice"
value="24.99">
   <td> <button formnovalidate="formnovalidate" name="action" value="delete:2">Delete</button>
  <tr>
   <td> <input required="required" name="3.pid" value="" pattern="[A-Z0-9]+">
   <td> <input required="required" name="3.pname" value="">
   <td> $<input required="required" type="number" min="0" step="0.01" name="3.pprice" value="">
   <td> <button formnovalidate="formnovalidate" name="action" value="delete:3">Delete</button>
 </table>
 <p> <button formnovalidate="formnovalidate" name="action" value="add">Add</button> </p>
 <p> <button name="action" value="update">Save</button> </p>
</form>
```

4.10.5.3.4 The required attribute

The **required** attribute is a boolean attribute. When specified, the element is ***required***.

Constraint validation: If the element is *required*, and its value IDL attribute applies and is in the mode value, and the element is *mutable*, and the element's value is the empty string, then the element is suffering from being missing.

Example

The following form has two required fields, one for an email address and one for a password. It also has a third field that is only considered valid if the user types the same password in the password field and this third field.

```
<h1>Create new account</h1>
<form action="/newaccount" method=post
      oninput="up2.setCustomValidity(up2.value != up.value ? 'Passwords do not match.' : '')">
 <p>
  <label for="username">Email address:</label>
  <input id="username" type=email required name=un>
 <p>
  <label for="password1">Password:</label>
  <input id="password1" type=password required name=up>
 <p>
  <label for="password2">Confirm password:</label>
  <input id="password2" type=password name=up2>
 <p>
  <input type=submit value="Create account">
</form>
```

Example

For radio buttons, the required attribute is satisfied if any of the radio buttons in the group is selected. Thus, in the following example, any of the radio buttons can be checked, not just the one marked as required:

```
<fieldset>
 <legend>Did the movie pass the Bechdel test?</legend>
 <p><label><input type="radio" name="bechdel" value="no-characters"> No, there are not even two
female characters in the movie. </label>
 <p><label><input type="radio" name="bechdel" value="no-names"> No, the female characters never
talk to each other. </label>
 <p><label><input type="radio" name="bechdel" value="no-topic"> No, when female characters talk to
each other it's always about a male character. </label>
 <p><label><input type="radio" name="bechdel" value="yes" required> Yes. </label>
 <p><label><input type="radio" name="bechdel" value="unknown"> I don't know. </label>
</fieldset>
```

To avoid confusion as to whether a radio button group is required or not, authors are encouraged to specify the attribute on all the radio buttons in a group. Indeed, in general, authors are encouraged to avoid having radio button groups that do not have any initially checked controls in the first place, as this is a state that the user cannot return to, and is therefore generally considered a poor user interface.

4.10.5.3.5 The multiple attribute

The **multiple** attribute is a boolean attribute that indicates whether the user is to be allowed to specify more than one value.

Example

The following extract shows how an email client's "To" field could accept multiple email addresses.

```
<label>To: <input type=email multiple name=to></label>
```

If the user had, amongst many friends in their user contacts database, two friends "Spider-Man" (with address "spider@parker.example.net") and "Scarlet Witch" (with address "scarlet@avengers.example.net"), then, after the user has typed "s", the user agent might suggest these two email addresses to the user.

The page could also link in the user's contacts database from the site:

```
<label>To: <input type=email multiple name=to list=contacts></label>
...
<datalist id="contacts">
 <option value="hedral@damowmow.com">
 <option value="pillar@example.com">
 <option value="astrophy@cute.example">
 <option value="astronomy@science.example.org">
</datalist>
```

Suppose the user had entered "bob@example.net" into this text control, and then started typing a second email address starting with "s". The user agent might show both the two friends mentioned earlier, as well as the "astrophy" and "astronomy" values given in the `datalist`[p578] element.

Example

The following extract shows how an email client's "Attachments" field could accept multiple files for upload.

```
<label>Attachments: <input type=file multiple name=att></label>
```

4.10.5.3.6 The `pattern`[p555] attribute §[p55 5]

The **`pattern`** attribute specifies a regular expression against which the control's value[p601], or, when the `multiple`[p554] attribute applies[p524] and is set, the control's values[p601], are to be checked.

If specified, the attribute's value must match the JavaScript *Pattern*`[+UnicodeSetsMode, +N]` production.

The **compiled pattern regular expression** of an `input`[p521] element, if it exists, is a JavaScript RegExp object. It is determined as follows:

1. If the element does not have a `pattern`[p555] attribute specified, then return nothing. The element has no compiled pattern regular expression[p555].
2. Let *pattern* be the value of the `pattern`[p555] attribute of the element.
3. Let *regexpCompletion* be RegExpCreate(*pattern*, "`v`").

4. If *regexpCompletion* is an abrupt completion, then return nothing. The element has no compiled pattern regular expression[p555].

   Note

   User agents are encouraged to log this error in a developer console, to aid debugging.

5. Let *anchoredPattern* be the string "`^(?:`", followed by *pattern*, followed by "`)$`".

6. Return ! RegExpCreate(*anchoredPattern*, "`v`").

Note

The reasoning behind these steps, instead of just using the value of the `pattern`[p555] attribute directly, is twofold. First, we want to ensure that when matched against a string, the regular expression's start is anchored to the start of the string and its end to the end of the string. Second, we want to ensure that the regular expression is valid in standalone form, instead of only becoming valid after being surrounded by the "`^(?:`" and "`)$`" anchors.

A RegExp object *regexp* **matches** a string *input*, if ! RegExpBuiltinExec(*regexp*, *input*) is not null.

Constraint validation: If the element's value[p601] is not the empty string, and either the element's `multiple`[p554] attribute is not specified or it does not apply[p525] to the `input`[p521] element given its `type`[p524] attribute's current state, and the element has a compiled pattern regular expression[p555] but that regular expression does not match[p556] the element's value[p601], then the element is suffering from a pattern mismatch[p626].

Constraint validation: If the element's value[p601] is not the empty string, and the element's `multiple`[p554] attribute is specified and applies[p524] to the `input`[p521] element, and the element has a compiled pattern regular expression[p555] but that regular expression does not match[p556] each of the element's values[p601], then the element is suffering from a pattern mismatch[p626].

When an `input`[p521] element has a `pattern`[p555] attribute specified, authors should include a **`title`** attribute to give a description of the pattern. User agents may use the contents of this attribute, if it is present, when informing the user that the pattern is not matched, or at any other suitable time, such as in a tooltip or read out by assistive technology when the control gains focus[p845].

Example

For example, the following snippet:

```
<label> Part number:
 <input pattern="[0-9][A-Z]{3}" name="part"
        title="A part number is a digit followed by three uppercase letters."/>
</label>
```

...could cause the UA to display an alert such as:

```
A part number is a digit followed by three uppercase letters.
You cannot submit this form when the field is incorrect.
```

When a control has a `pattern`[p555] attribute, the `title`[p556] attribute, if used, must describe the pattern. Additional information could also be included, so long as it assists the user in filling in the control. Otherwise, assistive technology would be impaired.

Example

For instance, if the title attribute contained the caption of the control, assistive technology could end up saying something like `The text you have entered does not match the required pattern. Birthday`, which is not useful.

UAs may still show the `title`[p158] in non-error situations (for example, as a tooltip when hovering over the control), so authors should be careful not to word `title`[p556]s as if an error has necessarily occurred.

4.10.5.3.7 The `min`[p557] and `max`[p557] attributes §[p556]

Some form controls can have explicit constraints applied limiting the allowed range of values that the user can provide. Normally, such a range would be linear and continuous. A form control can **have a periodic domain**, however, in which case the form control's broadest possible range is finite, and authors can specify explicit ranges within it that span the boundaries.

Example

Specifically, the broadest range of a `type=time` control is midnight to midnight (24 hours), and authors can set both continuous linear ranges (such as 9pm to 11pm) and discontinuous ranges spanning midnight (such as 11pm to 1am).

The **`min`** and **`max`** attributes indicate the allowed range of values for the element.

Their syntax is defined by the section that defines the `type` attribute's current state.

If the element has a `min` attribute, and the result of applying the algorithm to convert a string to a number to the value of the `min` attribute is a number, then that number is the element's **minimum**; otherwise, if the `type` attribute's current state defines a **default minimum**, then that is the minimum; otherwise, the element has no minimum.

The `min` attribute also defines the step base.

If the element has a `max` attribute, and the result of applying the algorithm to convert a string to a number to the value of the `max` attribute is a number, then that number is the element's **maximum**; otherwise, if the `type` attribute's current state defines a **default maximum**, then that is the maximum; otherwise, the element has no maximum.

If the element does not have a periodic domain, the `max` attribute's value (the maximum) must not be less than the `min` attribute's value (its minimum).

Note

If an element that does not have a periodic domain has a maximum that is less than its minimum, then so long as the element has a value, it will either be suffering from an underflow or suffering from an overflow.

An element **has a reversed range** if it has a periodic domain and its maximum is less than its minimum.

An element **has range limitations** if it has a defined minimum or a defined maximum.

Constraint validation: When the element has a minimum and does not have a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is less than the minimum, the element is suffering from an underflow.

Constraint validation: When the element has a maximum and does not have a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is more than the maximum, the element is suffering from an overflow.

Constraint validation: When an element has a reversed range, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and the number obtained from that algorithm is more than the maximum *and* less than the minimum, the element is simultaneously suffering from an underflow and suffering from an overflow.

Example

The following date control limits input to dates that are before the 1980s:

```
<input name=bday type=date max="1979-12-31">
```

Example

The following number control limits input to whole numbers greater than zero:

```
<input name=quantity required="" type="number" min="1" value="1">
```

Example

The following time control limits input to those minutes that occur between 9pm and 6am, defaulting to midnight:

```
<input name="sleepStart" type=time min="21:00" max="06:00" step="60" value="00:00">
```

4.10.5.3.8 The step attribute

The **step** attribute indicates the granularity that is expected (and required) of the value or values, by limiting the allowed values. The section that defines the type attribute's current state also defines the **default step**, the **step scale factor**, and in some cases the **default step base**, which are used in processing the attribute as described below.

The step attribute, if specified, must either have a value that is a valid floating-point number that parses to a number that is greater than zero, or must have a value that is an ASCII case-insensitive match for the string "any".

The attribute provides the **allowed value step** for the element, as follows:

1. If the attribute does not apply, then there is no allowed value step.
2. Otherwise, if the attribute is absent, then the allowed value step is the default step multiplied by the step scale factor.
3. Otherwise, if the attribute's value is an ASCII case-insensitive match for the string "any", then there is no allowed value step.
4. Otherwise, if the rules for parsing floating-point number values, when they are applied to the attribute's value, return an error, zero, or a number less than zero, then the allowed value step is the default step multiplied by the step scale factor.
5. Otherwise, the allowed value step is the number returned by the rules for parsing floating-point number values when they are applied to the attribute's value, multiplied by the step scale factor.

The **step base** is the value returned by the following algorithm:

1. If the element has a min content attribute, and the result of applying the algorithm to convert a string to a number to the value of the min content attribute is not an error, then return that result.
2. If the element has a value content attribute, and the result of applying the algorithm to convert a string to a number to the value of the value content attribute is not an error, then return that result.
3. If a default step base is defined for this element given its type attribute's state, then return it.
4. Return zero.

Constraint validation: When the element has an allowed value step, and the result of applying the algorithm to convert a string to a number to the string given by the element's value is a number, and that number subtracted from the step base is not an integral multiple of the allowed value step, the element is suffering from a step mismatch.

Example

The following range control only accepts values in the range 0..1, and allows 256 steps in that range:

```
<input name=opacity type=range min=0 max=1 step=0.00392156863>
```

Example

The following control allows any time in the day to be selected, with any accuracy (e.g. thousandth-of-a-second accuracy or more):

```
<input name=favtime type=time step=any>
```

Normally, time controls are limited to an accuracy of one minute.

4.10.5.3.9 The list attribute

The **list** attribute is used to identify an element that lists predefined options suggested to the user.

If present, its value must be the ID of a datalist element in the same tree.

The **suggestions source element** is the first element in the tree in tree order to have an ID equal to the value of the list attribute, if that element is a datalist element. If there is no list attribute, or if there is no element with that ID, or if the first

element with that ID is not a datalist element, then there is no suggestions source element.

If there is a suggestions source element, then, when the user agent is allowing the user to edit the input element's value, the user agent should offer the suggestions represented by the suggestions source element to the user in a manner suitable for the type of control used. If appropriate, the user agent should use the suggestion's label and value to identify the suggestion to the user.

User agents are encouraged to filter the suggestions represented by the suggestions source element when the number of suggestions is large, including only the most relevant ones (e.g. based on the user's input so far). No precise threshold is defined, but capping the list at four to seven values is reasonable. If filtering based on the user's input, user agents should search within both the label and value of the suggestions for matches. User agents should consider how input variations affect the matching process. Unicode normalization should be applied so that different underlying Unicode code point sequences, caused by different keyboard- or input-specific mechanisms, do not interfere with the matching process. Case variations should be ignored, which may require language-specific case mapping. For examples of these, see *Character Model for the World Wide Web: String Matching*. User agents may also provide other matching features: for illustration, a few examples include matching different forms of kana to each other (or to kanji), ignoring accents, or applying spelling correction. [CHARMODNORM]

Example

This text field allows you to choose a type of JavaScript function.

```
<input type="text" list="function-types">
<datalist id="function-types">
  <option value="function">function</option>
  <option value="async function">async function</option>
  <option value="function*">generator function</option>
  <option value="=>">arrow function</option>
  <option value="async =>">async arrow function</option>
  <option value="async function*">async generator function</option>
</datalist>
```

For user agents that follow the above suggestions, both the label and value would be shown:

Then, typing "`arrow`" or "`=>`" would filter the list to the entries with labels "arrow function" and "async arrow function". Typing "`generator`" or "`*`" would filter the list to the entries with labels "generator function" and "async generator function".

Note

As always, user agents are free to make user interface decisions which are appropriate for their particular requirements and for the user's particular circumstances. However, this has historically been an area of confusion for implementers, web developers, and users alike, so we've given some "should" suggestions above.

How user selections of suggestions are handled depends on whether the element is a control accepting a single value only, or whether it accepts multiple values:

↪ **If the element does not have a `multiple` attribute specified or if the `multiple` attribute does not apply**

When the user selects a suggestion, the input element's value must be set to the selected suggestion's value, as if the user had written that value themself.

↪ **If the element's type attribute is in the Email state and the element has a `multiple` attribute specified**

When the user selects a suggestion, the user agent must either add a new entry to the input element's values, whose value is the selected suggestion's value, or change an existing entry in the input element's values to have the value

given by the selected suggestion's value[p582], as if the user had themself added an entry with that value, or edited an existing entry to be that value. Which behavior is to be applied depends on the user interface in an implementation-defined manner.

If the list[p558] attribute does not apply[p525], there is no suggestions source element[p558].

Example

This URL field offers some suggestions.

```
<label>Homepage: <input name=hp type=url list=hpurls></label>
<datalist id=hpurls>
 <option value="https://www.google.com/" label="Google">
 <option value="https://www.reddit.com/" label="Reddit">
</datalist>
```

Other URLs from the user's history might show also; this is up to the user agent.

Example

This example demonstrates how to design a form that uses the autocompletion list feature while still degrading usefully in legacy user agents.

If the autocompletion list is merely an aid, and is not important to the content, then simply using a datalist[p578] element with children option[p580] elements is enough. To prevent the values from being rendered in legacy user agents, they need to be placed inside the value[p582] attribute instead of inline.

```
<p>
 <label>
  Enter a breed:
  <input type="text" name="breed" list="breeds">
  <datalist id="breeds">
   <option value="Abyssinian">
   <option value="Alpaca">
   <!-- ... -->
  </datalist>
 </label>
</p>
```

However, if the values need to be shown in legacy UAs, then fallback content can be placed inside the datalist[p578] element, as follows:

```
<p>
 <label>
  Enter a breed:
  <input type="text" name="breed" list="breeds">
 </label>
 <datalist id="breeds">
  <label>
   or select one from the list:
   <select name="breed">
    <option value=""> (none selected)
    <option>Abyssinian
    <option>Alpaca
    <!-- ... -->
   </select>
  </label>
 </datalist>
</p>
```

The fallback content will only be shown in UAs that don't support datalist[p578]. The options, on the other hand, will be detected by

all UAs, even though they are not children of the datalist[p578] element.

Note that if an option[p580] element used in a datalist[p578] is selected[p582], it will be selected by default by legacy UAs (because it affects the select[p572] element), but it will not have any effect on the input[p521] element in UAs that support datalist[p578].

4.10.5.3.10 The placeholder[p561] attribute §[p561]

The **placeholder** attribute represents a *short* hint (a word or short phrase) intended to aid the user with data entry when the control has no value. A hint could be a sample value or a brief description of the expected format. The attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The placeholder[p561] attribute should not be used as an alternative to a label[p519]. For a longer hint or other advisory text, the title[p158] attribute is more appropriate.

Note

These mechanisms are very similar but subtly different: the hint given by the control's label[p519] is shown at all times; the short hint given in the placeholder[p561] attribute is shown before the user enters a value; and the hint in the title[p158] attribute is shown when the user requests further help.

User agents should present this hint to the user, after having stripped newlines from it, when the element's value[p601] is the empty string, especially if the control is not focused[p845].

If a user agent normally doesn't show this hint to the user when the control is focused[p845], then the user agent should nonetheless show the hint for the control if it was focused as a result of the autofocus[p857] attribute, since in that case the user will not have had an opportunity to examine the control before focusing it.

Example

Here is an example of a mail configuration user interface that uses the placeholder[p561] attribute:

```
<fieldset>
 <legend>Mail Account</legend>
 <p><label>Name: <input type="text" name="fullname" placeholder="John Ratzenberger"></label></p>
 <p><label>Address: <input type="email" name="address" placeholder="john@example.net"></label></p>
 <p><label>Password: <input type="password" name="password"></label></p>
 <p><label>Description: <input type="text" name="desc" placeholder="My Email Account"></label></p>
</fieldset>
```

Example

In situations where the control's content has one directionality but the placeholder needs to have a different directionality, Unicode's bidirectional-algorithm formatting characters can be used in the attribute value:

```
<input name=t1 type=tel placeholder="&#x202B;رقم الهاتف 1&#x202E;">
<input name=t2 type=tel placeholder="&#x202B;رقم الهاتف 2&#x202E;">
```

For slightly more clarity, here's the same example using numeric character references instead of inline Arabic:

```
<input name=t1 type=tel
placeholder="&#x202B;&#1585;&#1602;&#1605; &#1575;&#1604;&#1607;&#1575;&#1578;&#1601; 1&#x202E;">
<input name=t2 type=tel
placeholder="&#x202B;&#1585;&#1602;&#1605; &#1575;&#1604;&#1607;&#1575;&#1578;&#1601; 2&#x202E;">
```

4.10.5.4 Common `input` element APIs

For web developers (non-normative)

***input*.value [= *value*]**

Returns the current value of the form control.

Can be set, to change the value.

Throws an "InvalidStateError" DOMException if it is set to any value other than the empty string when the control is a file upload control.

***input*.checked [= *value*]**

Returns the current checkedness of the form control.

Can be set, to change the checkedness.

***input*.files [= *files*]**

Returns a FileList object listing the selected files of the form control.

Returns null if the control isn't a file control.

Can be set to a FileList object to change the selected files of the form control. For instance, as the result of a drag-and-drop operation.

***input*.valueAsDate [= *value*]**

Returns a Date object representing the form control's value, if applicable; otherwise, returns null.

Can be set, to change the value.

Throws an "InvalidStateError" DOMException if the control isn't date- or time-based.

***input*.valueAsNumber [= *value*]**

Returns a number representing the form control's value, if applicable; otherwise, returns NaN.

Can be set, to change the value. Setting this to NaN will set the underlying value to the empty string.

Throws an "InvalidStateError" DOMException if the control is neither date- or time-based nor numeric.

***input*.stepUp([*n*])**

***input*.stepDown([*n*])**

Changes the form control's value by the value given in the step attribute, multiplied by *n*. The default value for *n* is 1.

Throws "InvalidStateError" DOMException if the control is neither date- or time-based nor numeric, or if the step attribute's value is "any".

***input*.list**

Returns the datalist element indicated by the list attribute.

***input*.showPicker()**

Shows any applicable picker UI for *input*, so that the user can select a value.

If *input* does not support a picker, this method does nothing.

Throws an "InvalidStateError" DOMException if *input* is not mutable.

Throws a "NotAllowedError" DOMException if called without transient user activation.

Throws a "SecurityError" DOMException if *input* is inside a cross-origin iframe, unless *input* is in the File Upload or Color states.

The **value** IDL attribute allows scripts to manipulate the value of an input element. The attribute is in one of the following modes, which define its behavior:

value

On getting, return the current value of the element.

On setting:

1. Let *oldValue* be the element's value.
2. Set the element's value to the new value.
3. Set the element's dirty value flag to true.

4. Invoke the value sanitization algorithm[p526], if the element's `type`[p524] attribute's current state defines one.

5. If the element's value[p601] (after applying the value sanitization algorithm[p526]) is different from *oldValue*, and the element has a text entry cursor position[p622], move the text entry cursor position[p622] to the end of the text control, unselecting any selected text and resetting the selection direction[p623] to "none".

default

On getting, if the element has a `value`[p526] content attribute, return that attribute's value; otherwise, return the empty string.

On setting, set the value of the element's `value`[p526] content attribute to the new value.

default/on

On getting, if the element has a `value`[p526] content attribute, return that attribute's value; otherwise, return the string "on".

On setting, set the value of the element's `value`[p526] content attribute to the new value.

filename

On getting, return the string "C:\fakepath\" followed by the name of the first file in the list of selected files[p546], if any, or the empty string if the list is empty.

On setting, if the new value is the empty string, empty the list of selected files[p546]; otherwise, throw an `"InvalidStateError"` `DOMException`.

Note

This "fakepath" requirement is a sad accident of history. See the example in the File Upload state section[p547] for more information.

Note

Since path components[p546] are not permitted in filenames in the list of selected files[p546], the "\fakepath\" cannot be mistaken for a path component.

The **`checked`** IDL attribute allows scripts to manipulate the checkedness[p601] of an `input`[p521] element. On getting, it must return the current checkedness[p601] of the element; and on setting, it must set the element's checkedness[p601] to the new value and set the element's dirty checkedness flag[p526] to true.

The **`files`** IDL attribute allows scripts to access the element's selected files[p546].

On getting, if the IDL attribute applies[p524], it must return a `FileList` object that represents the current selected files[p546]. The same object must be returned until the list of selected files[p546] changes. If the IDL attribute does not apply[p525], then it must instead return null. [FILEAPI][p1496]

On setting, it must run these steps:

1. If the IDL attribute does not apply[p525] or the given value is null, then return.

2. Replace the element's selected files[p546] with the given value.

The **`valueAsDate`** IDL attribute represents the value[p601] of the element, interpreted as a date.

On getting, if the `valueAsDate`[p563] attribute does not apply[p525], as defined for the `input`[p521] element's `type`[p524] attribute's current state, then return null. Otherwise, run the algorithm to convert a string to a `Date` object[p526] defined for that state to the element's value[p601]; if the algorithm returned a `Date` object, then return it, otherwise, return null.

On setting, if the `valueAsDate`[p563] attribute does not apply[p525], as defined for the `input`[p521] element's `type`[p524] attribute's current state, then throw an `"InvalidStateError"` `DOMException`; otherwise, if the new value is not null and not a `Date` object throw a `TypeError` exception; otherwise, if the new value is null or a `Date` object representing the NaN time value, then set the value[p601] of the element to the empty string; otherwise, run the algorithm to convert a `Date` object to a string[p526], as defined for that state, on the new value, and set the value[p601] of the element to the resulting string.

The **`valueAsNumber`** IDL attribute represents the value[p601] of the element, interpreted as a number.

On getting, if the `valueAsNumber`[p564] attribute does not apply[p525], as defined for the `input`[p521] element's `type`[p524] attribute's current state, then return a Not-a-Number (NaN) value. Otherwise, run the algorithm to convert a string to a number[p526] defined for that state to the element's value[p601]; if the algorithm returned a number, then return it, otherwise, return a Not-a-Number (NaN) value.

On setting, if the new value is infinite, then throw a `TypeError` exception. Otherwise, if the `valueAsNumber`[p564] attribute does not apply[p525], as defined for the `input`[p521] element's `type`[p524] attribute's current state, then throw an `"InvalidStateError"` `DOMException`. Otherwise, if the new value is a Not-a-Number (NaN) value, then set the value[p601] of the element to the empty string. Otherwise, run the algorithm to convert a number to a string[p526], as defined for that state, on the new value, and set the value[p601] of the element to the resulting string.

The **`stepDown(n)`** and **`stepUp(n)`** methods, when invoked, must run the following algorithm:

1. If the `stepDown()`[p564] and `stepUp()`[p564] methods do not apply[p525], as defined for the `input`[p521] element's `type`[p524] attribute's current state, then throw an `"InvalidStateError"` `DOMException`.
2. If the element has no allowed value step[p558], then throw an `"InvalidStateError"` `DOMException`.
3. If the element has a minimum[p557] and a maximum[p557] and the minimum[p557] is greater than the maximum[p557], then return.
4. If the element has a minimum[p557] and a maximum[p557] and there is no value greater than or equal to the element's minimum[p557] and less than or equal to the element's maximum[p557] that, when subtracted from the step base[p558], is an integral multiple of the allowed value step[p558], then return.
5. If applying the algorithm to convert a string to a number[p526] to the string given by the element's value[p601] does not result in an error, then let *value* be the result of that algorithm. Otherwise, let *value* be zero.
6. Let *valueBeforeStepping* be *value*.
7. If *value* subtracted from the step base[p558] is not an integral multiple of the allowed value step[p558], then set *value* to the nearest value that, when subtracted from the step base[p558], is an integral multiple of the allowed value step[p558], and that is less than *value* if the method invoked was the `stepDown()`[p564] method, and more than *value* otherwise.

   Otherwise (*value* subtracted from the step base[p558] is an integral multiple of the allowed value step[p558]):

   1. Let *n* be the argument.
   2. Let *delta* be the allowed value step[p558] multiplied by *n*.
   3. If the method invoked was the `stepDown()`[p564] method, negate *delta*.
   4. Let *value* be the result of adding *delta* to *value*.
8. If the element has a minimum[p557], and *value* is less than that minimum[p557], then set *value* to the smallest value that, when subtracted from the step base[p558], is an integral multiple of the allowed value step[p558], and that is more than or equal to that minimum[p557].
9. If the element has a maximum[p557], and *value* is greater than that maximum[p557], then set *value* to the largest value that, when subtracted from the step base[p558], is an integral multiple of the allowed value step[p558], and that is less than or equal to that maximum[p557].
10. If either the method invoked was the `stepDown()`[p564] method and *value* is greater than *valueBeforeStepping*, or the method invoked was the `stepUp()`[p564] method and *value* is less than *valueBeforeStepping*, then return.

    Example

    This ensures that invoking the `stepUp()`[p564] method on the `input`[p521] element in the following example does not change the value[p601] of that element:

    ```
    <input type=number value=1 max=0>
    ```

11. Let *value as string* be the result of running the algorithm to convert a number to a string[p526], as defined for the `input`[p521] element's `type`[p524] attribute's current state, on *value*.
12. Set the value[p601] of the element to *value as string*.

The **`list`** IDL attribute must return the current suggestions source element[p558], if any, or null otherwise.

The `HTMLInputElement`[p523] **`showPicker()`** and `HTMLSelectElement`[p572] **`showPicker()`** method steps are:

1. If this is not mutable[p601], then throw an `"InvalidStateError"` `DOMException`.
2. If this's relevant settings object[p1098]'s origin[p1091] is not same origin[p910] with this's relevant settings object[p1098]'s top-level origin[p1091], and this is a `select`[p572] element, or this's `type`[p524] attribute is not in the File Upload[p546] state or Color[p542] state, then throw a `"SecurityError"` `DOMException`.

   Note

   File[p546] and Color[p542] inputs are exempted from this check for historical reason: their input activation behavior[p527] also shows their pickers, and has never been guarded by an origin check.
3. If this's relevant global object[p1098] does not have transient activation[p838], then throw a `"NotAllowedError"` `DOMException`.
4. If this is a `select`[p572] element, and this is not being rendered[p1406], then throw a `"NotSupportedError"` `DOMException`.
5. Show the picker, if applicable[p565], for this.

To **show the picker, if applicable** for an `input`[p521] or `select`[p572] element *element*:

1. If *element*'s relevant global object[p1098] does not have transient activation[p838], then return.
2. If *element* is not *mutable*[p601], then return.
3. Consume user activation[p839] given *element*'s relevant global object[p1098].
4. If *element* does not support a picker[p526], then return.
5. If *element* is an `input`[p521] element and *element*'s `type`[p524] attribute is in the File Upload[p546] state, then run these steps in parallel[p44]:
   1. Optionally, wait until any prior execution of this algorithm has terminated.
   2. Let *dismissed* be the result of WebDriver BiDi file dialog opened with *element*.
   3. If *dismissed* is false:
      1. Display a prompt to the user requesting that the user specify some files. If the `multiple`[p554] attribute is not set on *element*, there must be no more than one file selected; otherwise, any number may be selected. Files can be from the filesystem or created on the fly, e.g., a picture taken from a camera connected to the user's device.
      2. Wait for the user to have made their selection.
   4. If *dismissed* is true or if the user dismissed the prompt without changing their selection, then queue an element task[p1140] on the user interaction task source[p1149] given *element* to fire an event named `cancel`[p1489] at *element*, with the `bubbles` attribute initialized to true.
   5. Otherwise, update the file selection[p546] for *element*.

   Note

   As with all user interface specifications, user agents have a good deal of freedom in how they interpret these requirements. The above text implies that a user either dismisses the prompt or changes their selection; exactly one of these will be true. But the mapping of these possibilities to specific user interface elements is not mandated by the standard. For example, a user agent might interpret clicking the "Cancel" button when files were previously selected as a change of selection to select zero files, thus firing `input` and `change`[p1489]. Or it might interpret such a click as a dismissal that leaves the selection unchanged, thus firing `cancel`[p1489]. Similarly, it's up to the user agent whether re-selecting the same files as were previously selected counts as a dismissal, or as a change of selection.
6. Otherwise, the user agent should show the relevant user interface for selecting a value for *element*, in the way it normally would when the user interacts with the control.

   When showing such a user interface, it must respect the requirements stated in the relevant parts of the specification for how *element* behaves given its `type`[p524] attribute state. (For example, various sections describe restrictions on the resulting

value[p601] string.)

This step can have side effects, such as closing other pickers that were previously shown by this algorithm. (If this closes a file selection picker, then per the above that will lead to firing either input and change[p1489] events, or a cancel[p1489] event.)

4.10.5.5 Common event behaviors §[p566]

When the input and change[p1489] events apply[p524] (which is the case for all input[p521] controls other than buttons[p515] and those with the type[p524] attribute in the Hidden[p528] state), the events are fired to indicate that the user has interacted with the control. The input event fires whenever the user has modified the data of the control. The change[p1489] event fires when the value is committed, if that makes sense for the control, or else when the control loses focus[p852]. In all cases, the input event comes before the corresponding change[p1489] event (if any).

When an input[p521] element has a defined input activation behavior[p527], the rules for dispatching these events, if they apply[p524], are given in the section above that defines the type[p524] attribute's state. (This is the case for all input[p521] controls with the type[p524] attribute in the Checkbox[p544] state, the Radio Button[p544] state, or the File Upload[p546] state.)

For input[p521] elements without a defined input activation behavior[p527], but to which these events apply[p524], and for which the user interface involves both interactive manipulation and an explicit commit action, then when the user changes the element's value[p601], the user agent must queue an element task[p1140] on the user interaction task source[p1149] given the input[p521] element to fire an event named input at the input[p521] element, with the bubbles and composed attributes initialized to true, and any time the user commits the change, the user agent must queue an element task[p1140] on the user interaction task source[p1149] given the input[p521] element to set its user validity[p601] to true and fire an event named change[p1489] at the input[p521] element, with the bubbles attribute initialized to true.

Example

An example of a user interface involving both interactive manipulation and a commit action would be a Range[p540] controls that use a slider, when manipulated using a pointing device. While the user is dragging the control's knob, input events would fire whenever the position changed, whereas the change[p1489] event would only fire when the user let go of the knob, committing to a specific value.

For input[p521] elements without a defined input activation behavior[p527], but to which these events apply[p524], and for which the user interface involves an explicit commit action but no intermediate manipulation, then any time the user commits a change to the element's value[p601], the user agent must queue an element task[p1140] on the user interaction task source[p1149] given the input[p521] element to first fire an event named input at the input[p521] element, with the bubbles and composed attributes initialized to true, and then fire an event named change[p1489] at the input[p521] element, with the bubbles attribute initialized to true.

Example

An example of a user interface with a commit action would be a Color[p542] control that consists of a single button that brings up a color wheel: if the value[p601] only changes when the dialog is closed, then that would be the explicit commit action. On the other hand, if manipulating the control changes the color interactively, then there might be no commit action.

Example

Another example of a user interface with a commit action would be a Date[p533] control that allows both text-based user input and user selection from a drop-down calendar: while text input might not have an explicit commit step, selecting a date from the drop down calendar and then dismissing the drop down would be a commit action.

For input[p521] elements without a defined input activation behavior[p527], but to which these events apply[p524], any time the user causes the element's value[p601] to change without an explicit commit action, the user agent must queue an element task[p1140] on the user interaction task source[p1149] given the input[p521] element to fire an event named input at the input[p521] element, with the bubbles and composed attributes initialized to true. The corresponding change[p1489] event, if any, will be fired when the control loses focus[p852].

Example

Examples of a user changing the element's value[p601] would include the user typing into a text control, pasting a new value into the control, or undoing an edit in that control. Some user interactions do not cause changes to the value, e.g., hitting the "delete" key in an empty text control, or replacing some text in the control with text from the clipboard that happens to be exactly the same text.

Example

A Range[p540] control in the form of a slider that the user has focused[p845] and is interacting with using a keyboard would be another example of the user changing the element's value[p601] without a commit step.

In the case of tasks[p1139] that just fire an `input` event, user agents may wait for a suitable break in the user's interaction before queuing[p1140] the tasks; for example, a user agent could wait for the user to have not hit a key for 100ms, so as to only fire the event when the user pauses, instead of continuously for each keystroke.

When the user agent is to change an `input`[p521] element's value[p601] on behalf of the user (e.g. as part of a form prefilling feature), the user agent must queue an element task[p1140] on the user interaction task source[p1149] given the `input`[p521] element to first update the value[p601] accordingly, then fire an event named `input` at the `input`[p521] element, with the `bubbles` and `composed` attributes initialized to true, then fire an event named `change`[p1489] at the `input`[p521] element, with the `bubbles` attribute initialized to true.

Note

These events are not fired in response to changes made to the values of form controls by scripts. (This is to make it easier to update the values of form controls in response to the user manipulating the controls, without having to then filter out the script's own changes to avoid an infinite loop.)

Note

These events are also not fired when the browser changes the values of form controls as part of state restoration during navigation[p1070].

4.10.6 The `button` element §[p567]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Interactive content[p151].
Listed[p514], labelable[p515], submittable[p515], and autocapitalize-and-autocorrect inheriting[p515] form-associated element[p514].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151], but there must be no interactive content[p151] descendant and no descendant with the `tabindex`[p847] attribute specified.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
`command`[p568] — Indicates to the targeted element which action to take.
`commandfor`[p568] — Targets another element to be invoked.
`disabled`[p605] — Whether the form control is disabled
`form`[p601] — Associates the element with a `form`[p515] element
`formaction`[p606] — URL to use for form submission[p632]
`formenctype`[p607] — Entry list[p636] encoding type to use for form submission[p632]
`formmethod`[p606] — Variant to use for form submission[p632]
`formnovalidate`[p607] — Bypass form control validation for form submission[p632]
`formtarget`[p607] — Navigable[p1001] for form submission[p632]
`name`[p603] — Name of the element to use for form submission[p632] and in the `form.elements`[p517] API
`popovertarget`[p905] — Targets a popover element to toggle, show, or hide
`popovertargetaction`[p905] — Indicates whether a targeted popover element is to be toggled, shown, or hidden
`type`[p568] — Type of button
`value`[p570] — Value to be used for form submission[p632]

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLButtonElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString command;
  [CEReactions] attribute Element? commandForElement;
  [CEReactions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute USVString formAction;
  [CEReactions] attribute DOMString formEnctype;
  [CEReactions] attribute DOMString formMethod;
  [CEReactions] attribute boolean formNoValidate;
  [CEReactions] attribute DOMString formTarget;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute DOMString value;

  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  undefined setCustomValidity(DOMString error);

  readonly attribute NodeList labels;
};
HTMLButtonElement includes PopoverInvokerElement;
```

The button[p567] element represents[p142] a button labeled by its contents.

The element is a button[p515].

The **type** attribute controls the behavior of the button when it is activated. It is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
submit	**Submit Button**	Submits the form.
reset	**Reset Button**	Resets the form.
button	**Button**	Does nothing.

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the **Auto** state.

A button[p567] element is said to be a submit button[p515] if any of the following are true:

- the type[p568] attribute is in the Auto[p568] state and both the command[p568] and commandfor[p568] content attributes are not present; or
- the type[p568] attribute is in the Submit Button[p568] state.

Constraint validation: If the element is not a submit button[p515], the element is barred from constraint validation[p626].

If specified, the **commandfor** attribute value must be the ID of an element in the same tree as the button[p515] with the commandfor[p568] attribute.

The **command** attribute is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
`toggle-popover`	**Toggle Popover**	Shows or hides the targeted `popover`[p895] element.
`show-popover`	**Show Popover**	Shows the targeted `popover`[p895] element.
`hide-popover`	**Hide Popover**	Hides the targeted `popover`[p895] element.
`close`	**Close**	Closes the targeted `dialog`[p650] element.
`request-close`	**Request Close**	Requests to close the targeted `dialog`[p650] element.
`show-modal`	**Show Modal**	Opens the targeted `dialog`[p650] element as modal.
A custom command keyword[p569]	**Custom**	Only dispatches the `command`[p1489] event on the targeted element.

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the **Unknown** state.

A **custom command keyword** is a string that starts with "`--`".

A `button`[p567] element *element*'s activation behavior given *event* is:

1. If *element* is disabled[p605], then return.
2. If *element*'s node document is not fully active[p1017], then return.
3. If *element* has a form owner[p601]:
    1. If *element* is a submit button[p515], then submit[p633] *element*'s form owner[p601] from *element* with *userInvolvement*[p633] set to *event*'s user navigation involvement[p1028], and return.
    2. If *element*'s `type`[p568] attribute is in the Reset Button[p568] state, then reset[p641] *element*'s form owner[p601], and return.
    3. If *element*'s `type`[p568] attribute is in the Auto[p568] state, then return.
4. Let *target* be the result of running *element*'s get the `commandfor`-associated element[p109].
5. If *target* is not null:
    1. Let *command* be *element*'s `command`[p568] attribute.
    2. If *command* is in the Unknown[p569] state, then return.
    3. Let *isPopover* be true if *target*'s `popover`[p895] attribute is not in the No Popover[p896] state; otherwise false.
    4. If *isPopover* is false and *command* is not in the Custom[p569] state:
        1. Assert: *target*'s namespace is the HTML namespace.
        2. If this standard does not define is valid invoker command steps[p570] for *target*'s local name, then return.
        3. Otherwise, if the result of running *target*'s corresponding is valid invoker command steps[p570] given *command* is false, then return.
    5. Let *continue* be the result of firing an event named `command`[p1489] at *target*, using `CommandEvent`[p842], with its `command`[p842] attribute initialized to *command*, its `source`[p842] attribute initialized to *element*, and its `cancelable` and `composed` attributes initialized to true.

        DOM standard issue #1328 tracks how to better standardize associated event data in a way which makes sense on Events. Currently an event attribute initialized to a value cannot also have a getter, and so an internal slot (or map of additional fields) is required to properly specify this.

    6. If *continue* is false, then return.
    7. If *target* is not connected, then return.
    8. If *command* is in the Custom[p569] state, then return.
    9. If *command* is in the Hide Popover[p569] state:
        1. If the result of running check popover validity[p904] given *target*, true, false, and null is true, then run the hide popover algorithm[p900] given *target*, true, true, false, and *element*.
    10. Otherwise, if *command* is in the Toggle Popover[p569] state:

1. If the result of running check popover validity[p904] given *target*, false, false, and null is true, then run the show popover algorithm[p897] given *target*, false, and this.

2. Otherwise, if the result of running check popover validity[p904] given *target*, true, false, and null is true, then run the hide popover algorithm[p900] given *target*, true, true, false, and *element*.

11. Otherwise, if *command* is in the Show Popover[p569] state:

    1. If the result of running check popover validity[p904] given *target*, false, false, and null is true, then run the show popover algorithm[p897] given *target*, false, and this.

12. Otherwise, if this standard defines invoker command steps[p570] for *target*'s local name, then run the corresponding invoker command steps[p570] given *target*, *element*, and *command*.

6. Otherwise, run the popover target attribute activation behavior[p906] given *element* and *event*'s target.

An HTML element[p46] can have specific **is valid invoker command steps** and **invoker command steps** defined for the element's local name.

The `form`[p601] attribute is used to explicitly associate the `button`[p567] element with its form owner[p601]. The `name`[p603] attribute represents the element's name. The `disabled`[p605] attribute is used to make the control non-interactive and to prevent its value from being submitted. The `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], and `formtarget`[p607] attributes are attributes for form submission[p606].

Note

The `formnovalidate`[p607] attribute can be used to make submit buttons that do not trigger the constraint validation.

The `formaction`[p606], `formenctype`[p607], `formmethod`[p606], `formnovalidate`[p607], and `formtarget`[p607] must not be specified if the element is not a submit button[p515].

The **`commandForElement`** IDL attribute must reflect[p105] the element's `commandfor`[p568] content attribute.

The **`command`** getter steps are:

1. Let *command* be this's `command`[p568] attribute.

2. If *command* is in the Custom[p569] state, then return *command*'s value.

3. If *command* is in the Unknown[p569] state, then return the empty string.

4. Return the keyword corresponding to the value of *command*.

The `command`[p570] setter steps are to set the `command`[p568] content attribute to the given value.

The **`value`** attribute gives the element's value for the purposes of form submission. The element's value[p601] is the value of the element's `value`[p570] attribute, if there is one; otherwise the empty string. The element's optional value[p601] is the value of the element's `value`[p570] attribute, if there is one; otherwise null.

Note

A button (and its value) is only included in the form submission if the button itself was used to initiate the form submission.

The **`value`** IDL attribute must reflect[p105] the content attribute of the same name.

The **`type`** getter steps are:

1. If *this* is a submit button[p515], then return "`submit`".

2. Let *state* be this's `type`[p568] attribute.

3. Assert: *state* is not in the Submit Button[p568] state.

4. If *state* is in the Auto[p568] state, then return "`button`".

5. Return the keyword value corresponding to *state*.

The type[p570] setter steps are to set the type[p568] content attribute to the given value.

The willValidate[p629], validity[p629], and validationMessage[p631] IDL attributes, and the checkValidity()[p631], reportValidity()[p631], and setCustomValidity()[p629] methods, are part of the constraint validation API[p628]. The labels[p521] IDL attribute provides a list of the element's label[p519]s. The disabled[p606], form[p603], and name[p603] IDL attributes are part of the element's forms API.

Example

The following button is labeled "Show hint" and pops up a dialog box when activated:

```
<button type=button
        onclick="alert('This 15-20 minute piece was composed by George Gershwin.')">
 Show hint
</button>
```

Example

The following shows how buttons[p515] can use commandfor[p568] to show and hide an element with the popover[p895] attribute when activated:

```
<button type=button
        commandfor="the-popover"
        command="show-popover">
 Show menu
</button>
<div popover
     id="the-popover">
 <button commandfor="the-popover"
         command="hide-popover">
  Hide menu
 </button>
</div>
```

Example

The following shows how buttons can use commandfor[p568] with a custom command keyword[p569] on an element, demonstrating how one could use custom commands for unspecified behavior:

```
<button type=button
        commandfor="the-image"
        command="--rotate-landscape">
 Rotate Left
</button>
<button type=button
        commandfor="the-image"
        command="--rotate-portrait">
 Rotate Right
</button>
<img id="the-image"
     src="photo.jpg">
<script>
  const image = document.getElementById("the-image");
  image.addEventListener("command", (event) => {
   if ( event.command == "--rotate-landscape" ) {
    event.target.style.rotate = "-90deg"
   } else if ( event.command == "--rotate-portrait" ) {
    event.target.style.rotate = "0deg"
   }
  });
</script>
```

4.10.7 The select element §[p57]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Interactive content[p151].
Listed[p514], labelable[p515], submittable[p515], resettable[p515], and autocapitalize-and-autocorrect inheriting[p515] form-associated element[p514].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Zero or more option[p580], optgroup[p579], hr[p232], and script-supporting[p152] elements.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
autocomplete[p608] — Hint for form autofill feature
disabled[p605] — Whether the form control is disabled
form[p601] — Associates the element with a form[p515] element
multiple[p573] — Whether to allow multiple values
name[p603] — Name of the element to use for form submission[p632] and in the form.elements[p517] API
required[p573] — Whether the control is required for form submission[p632]
size[p573] — Size of the control

Accessibility considerations[p148]:

If the element has a multiple[p573] attribute or a size[p573] attribute with a value > 1: for authors; for implementers.
Otherwise: for authors; for implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLSelectElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString autocomplete;
  [CEReactions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute boolean multiple;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute boolean required;
  [CEReactions] attribute unsigned long size;

  readonly attribute DOMString type;

  [SameObject] readonly attribute HTMLOptionsCollection options;
  [CEReactions] attribute unsigned long length;
  getter HTMLOptionElement? item(unsigned long index);
  HTMLOptionElement? namedItem(DOMString name);
  [CEReactions] undefined add((HTMLOptionElement or HTMLOptGroupElement) element, optional
(HTMLElement or long)? before = null);
  [CEReactions] undefined remove(); // ChildNode overload
  [CEReactions] undefined remove(long index);
  [CEReactions] setter undefined (unsigned long index, HTMLOptionElement? option);

  [SameObject] readonly attribute HTMLCollection selectedOptions;
  attribute long selectedIndex;
  attribute DOMString value;
```

```
  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  undefined setCustomValidity(DOMString error);

  undefined showPicker();

  readonly attribute NodeList labels;
};
```

The select element represents a control for selecting amongst a set of options.

The **multiple** attribute is a boolean attribute. If the attribute is present, then the select element represents a control for selecting zero or more options from the list of options. If the attribute is absent, then the select element represents a control for selecting a single option from the list of options.

The **size** attribute gives the number of options to show to the user. The size attribute, if specified, must have a value that is a valid non-negative integer greater than zero.

The **display size** of a select element is the result of applying the rules for parsing non-negative integers to the value of element's size attribute, if it has one and parsing it is successful. If applying those rules to the attribute's value is not successful, or if the size attribute is absent, then the element's display size is 4 if the element's multiple content attribute is present, and 1 otherwise.

The **list of options** for a select element consists of all the option element children of the select element, and all the option element children of all the optgroup element children of the select element, in tree order.

The **required** attribute is a boolean attribute. When specified, the user will be required to select a value before submitting the form.

If a select element has a required attribute specified, does not have a multiple attribute specified, and has a display size of 1; and if the value of the first option element in the select element's list of options (if any) is the empty string, and that option element's parent node is the select element (and not an optgroup element), then that option is the select element's **placeholder label option**.

If a select element has a required attribute specified, does not have a multiple attribute specified, and has a display size of 1, then the select element must have a placeholder label option.

Note

In practice, the requirement stated in the paragraph above can only apply when a select element does not have a size attribute with a value greater than 1.

Constraint validation: If the element has its required attribute specified, and either none of the option elements in the select element's list of options have their selectedness set to true, or the only option element in the select element's list of options with its selectedness set to true is the placeholder label option, then the element is suffering from being missing.

If the multiple attribute is absent, and the element is not disabled, then the user agent should allow the user to pick an option element in its list of options that is itself not disabled. Upon this option element being **picked** (either through a click, or through unfocusing the element after changing its value, or through a menu command, or through any other mechanism), and before the relevant user interaction event is queued (e.g. before the click event), the user agent must set the selectedness of the picked option element to true, set its dirtiness to true, and then send select update notifications.

If the multiple attribute is absent, whenever an option element in the select element's list of options has its selectedness set to true, and whenever an option element with its selectedness set to true is added to the select element's list of options, the user agent must set the selectedness of all the other option elements in its list of options to false.

If the multiple attribute is absent and the element's display size is greater than 1, then the user agent should also allow the user to request that the option whose selectedness is true, if any, be unselected. Upon this request being conveyed to the user

agent, and before the relevant user interaction event is queued (e.g. before the `click` event), the user agent must set the selectedness[p582] of that `option`[p580] element to false, set its dirtiness[p582] to true, and then send `select` update notifications[p574].

The **selectedness setting algorithm**, given a `select`[p572] element *element*, is to run the following steps:

1. If *element*'s `multiple`[p573] attribute is absent, and *element*'s display size[p573] is 1, and no `option`[p580] elements in the *element*'s list of options[p573] have their selectedness[p582] set to true, then set the selectedness[p582] of the first `option`[p580] element in the list of options[p573] in tree order that is not disabled[p581], if any, to true, and return.

2. If *element*'s `multiple`[p573] attribute is absent, and two or more `option`[p580] elements in *element*'s list of options[p573] have their selectedness[p582] set to true, then set the selectedness[p582] of all but the last `option`[p580] element with its selectedness[p582] set to true in the list of options[p573] in tree order to false.

The `option`[p580] HTML element insertion steps[p46], given *insertedNode*, are:

1. If *insertedNode*'s parent is a `select`[p572] element, or *insertedNode*'s parent is an `optgroup`[p579] element whose parent is a `select`[p572] element, then run that `select`[p572] element's selectedness setting algorithm[p574].

The `option`[p580] HTML element removing steps[p46], given *removedNode* and *oldParent*, are:

1. If *oldParent* is a `select`[p572] element, or *oldParent* is an `optgroup`[p579] element whose parent is a `select`[p572] element, then run that `select`[p572] element's selectedness setting algorithm[p574].

The `option`[p580] HTML element moving steps[p46], given *movedNode* and *oldParent*, are:

1. Run the `option`[p580] HTML element removing steps[p46] given *movedNode* and *oldParent*.

2. Run the `option`[p580] HTML element insertion steps[p46] given *movedNode*.

The `optgroup`[p579] HTML element removing steps[p46], given *removedNode* and *oldParent*, are:

1. If *oldParent* is a `select`[p572] element and *removedNode* has an `option`[p580] child, then run *oldParent*'s selectedness setting algorithm[p574].

The `optgroup`[p579] HTML element moving steps[p46], given *movedNode* and *oldParent*, are:

1. Run the `optgroup`[p579] HTML element removing steps[p46] given *movedNode* and *oldParent*.

If an `option`[p580] element in the list of options[p573] **asks for a reset**, then run that `select`[p572] element's selectedness setting algorithm[p574].

If the `multiple`[p573] attribute is present, and the element is not disabled[p605], then the user agent should allow the user to **toggle** the selectedness[p582] of the `option`[p580] elements in its list of options[p573] that are themselves not disabled[p581]. Upon such an element being toggled[p574] (either through a click, or through a menu command[p649], or any other mechanism), and before the relevant user interaction event is queued (e.g. before a related `click` event), the selectedness[p582] of the `option`[p580] element must be changed (from true to false or false to true), the dirtiness[p582] of the element must be set to true, and the user agent must send `select` update notifications[p574].

When the user agent is to **send `select` update notifications**, queue an element task[p1140] on the user interaction task source[p1149] given the `select`[p572] element to run these steps:

1. Set the `select`[p572] element's user validity[p601] to true.

2. Fire an event named `input` at the `select`[p572] element, with the `bubbles` and `composed` attributes initialized to true.

3. Fire an event named `change`[p1489] at the `select`[p572] element, with the `bubbles` attribute initialized to true.

The reset algorithm[p641] for a `select`[p572] element *selectElement* is:

1. Set *selectElement*'s user validity[p601] to false.

2. For each *optionElement* of *selectElement*'s list of options[p573]:

    1. If *optionElement* has a `selected`[p582] attribute, then set *optionElement*'s selectedness[p582] to true; otherwise set it to false.

    2. Set *optionElement*'s dirtiness[p582] to false.

3. Run the selectedness setting algorithm[p574] given *selectElement*.

The `form`[p601] attribute is used to explicitly associate the `select`[p572] element with its form owner[p601]. The `name`[p603] attribute represents the element's name. The `disabled`[p605] attribute is used to make the control non-interactive and to prevent its value from being submitted. The `autocomplete`[p608] attribute controls how the user agent provides autofill behavior.

A `select`[p572] element that is not disabled[p605] is *mutable*[p601].

For web developers (non-normative)

***select*.type**[p575]

Returns "`select-multiple`" if the element has a `multiple`[p573] attribute, and "`select-one`" otherwise.

***select*.options**[p575]

Returns an `HTMLOptionsCollection`[p115] of the list of options[p573].

***select*.length**[p576] **[= *value*]**

Returns the number of elements in the list of options[p573].

When set to a smaller number, truncates the number of `option`[p580] elements in the `select`[p572].

When set to a greater number, adds new blank `option`[p580] elements to the `select`[p572].

***element* = *select*.item**[p576]**(*index*)**

***select*[*index*]**

Returns the item with index *index* from the list of options[p573]. The items are sorted in tree order.

***element* = *select*.namedItem**[p576]**(*name*)**

Returns the first item with ID or `name`[p1445] *name* from the list of options[p573].

Returns null if no element with that ID could be found.

***select*.add**[p576]**(*element* [, *before*])**

Inserts *element* before the node given by *before*.

The *before* argument can be a number, in which case *element* is inserted before the item with that number, or an element from the list of options[p573], in which case *element* is inserted before that element.

If *before* is omitted, null, or a number out of range, then *element* will be added at the end of the list.

This method will throw a "`HierarchyRequestError`" `DOMException` if *element* is an ancestor of the element into which it is to be inserted.

***select*.selectedOptions**[p576]

Returns an `HTMLCollection` of the list of options[p573] that are selected.

***select*.selectedIndex**[p576] **[= *value*]**

Returns the index of the first selected item, if any, or −1 if there is no selected item.

Can be set, to change the selection.

***select*.value**[p576] **[= *value*]**

Returns the value[p582] of the first selected item, if any, or the empty string if there is no selected item.

Can be set, to change the selection.

***select*.showPicker**[p565]**()**

Shows any applicable picker UI for *select*, so that the user can select a value.

Throws an "`InvalidStateError`" `DOMException` if *select* is not mutable[p601].

Throws a "`NotAllowedError`" `DOMException` if called without transient user activation[p838].

Throws a "`SecurityError`" `DOMException` if *select* is inside a cross-origin `iframe`[p391].

Throws a "`NotSupportedError`" `DOMException` if *select* is not being rendered[p1406].

The **`type`** IDL attribute, on getting, must return the string "`select-one`" if the `multiple`[p573] attribute is absent, and the string "`select-multiple`" if the `multiple`[p573] attribute is present.

The **`options`** IDL attribute must return an `HTMLOptionsCollection`[p115] rooted at the `select`[p572] node, whose filter matches the elements in the list of options[p573].

The options collection is also mirrored on the HTMLSelectElement object. The supported property indices at any instant are the indices supported by the object returned by the options attribute at that instant.

The **length** IDL attribute must return the number of nodes represented by the options collection. On setting, it must act like the attribute of the same name on the options collection.

The **item(*index*)** method must return the value returned by the method of the same name on the options collection, when invoked with the same argument.

The **namedItem(*name*)** method must return the value returned by the method of the same name on the options collection, when invoked with the same argument.

When the user agent is to set the value of a new indexed property or set the value of an existing indexed property for a select element, it must instead run the corresponding algorithm on the select element's options collection.

Similarly, the **add(*element*, *before*)** method must act like its namesake method on that same options collection.

The **remove()** method must act like its namesake method on that same options collection when it has arguments, and like its namesake method on the ChildNode interface implemented by the HTMLSelectElement ancestor interface Element when it has no arguments.

The **selectedOptions** IDL attribute must return an HTMLCollection rooted at the select node, whose filter matches the elements in the list of options that have their selectedness set to true.

The **selectedIndex** IDL attribute, on getting, must return the index of the first option element in the list of options in tree order that has its selectedness set to true, if any. If there isn't one, then it must return −1.

On setting, the selectedIndex attribute must set the selectedness of all the option elements in the list of options to false, and then the option element in the list of options whose index is the given new value, if any, must have its selectedness set to true and its dirtiness set to true.

Note

This can result in no element having a selectedness set to true even in the case of the select element having no multiple attribute and a display size of 1.

The **value** IDL attribute, on getting, must return the value of the first option element in the list of options in tree order that has its selectedness set to true, if any. If there isn't one, then it must return the empty string.

On setting, the value attribute must set the selectedness of all the option elements in the list of options to false, and then the first option element in the list of options, in tree order, whose value is equal to the given new value, if any, must have its selectedness set to true and its dirtiness set to true.

Note

This can result in no element having a selectedness set to true even in the case of the select element having no multiple attribute and a display size of 1.

The **multiple**, **required**, and **size** IDL attributes must reflect the respective content attributes of the same name. The size IDL attribute has a default value of 0.

Note

For historical reasons, the default value of the size IDL attribute does not return the actual size used, which, in the absence of the size content attribute, is either 1 or 4 depending on the presence of the multiple attribute.

The willValidate, validity, and validationMessage IDL attributes, and the checkValidity(), reportValidity(), and setCustomValidity() methods, are part of the constraint validation API. The labels IDL attribute provides a list of the element's label s. The disabled, form, and name IDL attributes are part of the element's forms API.

Example

The following example shows how a select element can be used to offer the user with a set of options from which the user can

select a single option. The default option is preselected.

```
<p>
 <label for="unittype">Select unit type:</label>
 <select id="unittype" name="unittype">
  <option value="1"> Miner </option>
  <option value="2"> Puffer </option>
  <option value="3" selected> Snipey </option>
  <option value="4"> Max </option>
  <option value="5"> Firebot </option>
 </select>
</p>
```

When there is no default option, a placeholder can be used instead:

```
<select name="unittype" required>
 <option value=""> Select unit type </option>
 <option value="1"> Miner </option>
 <option value="2"> Puffer </option>
 <option value="3"> Snipey </option>
 <option value="4"> Max </option>
 <option value="5"> Firebot </option>
</select>
```

Example

Here, the user is offered a set of options from which they can select any number. By default, all five options are selected.

```
<p>
 <label for="allowedunits">Select unit types to enable on this map:</label>
 <select id="allowedunits" name="allowedunits" multiple>
  <option value="1" selected> Miner </option>
  <option value="2" selected> Puffer </option>
  <option value="3" selected> Snipey </option>
  <option value="4" selected> Max </option>
  <option value="5" selected> Firebot </option>
 </select>
</p>
```

Example

Sometimes, a user has to select one or more items. This example shows such an interface.

```
<label>
 Select the songs from that you would like on your Act II Mix Tape:
 <select multiple required name="act2">
  <option value="s1">It Sucks to Be Me (Reprise)
  <option value="s2">There is Life Outside Your Apartment
  <option value="s3">The More You Ruv Someone
  <option value="s4">Schadenfreude
  <option value="s5">I Wish I Could Go Back to College
  <option value="s6">The Money Song
  <option value="s7">School for Monsters
  <option value="s8">The Money Song (Reprise)
  <option value="s9">There's a Fine, Fine Line (Reprise)
  <option value="s10">What Do You Do With a B.A. in English? (Reprise)
  <option value="s11">For Now
 </select>
</label>
```

Example

Occasionally it can be useful to have a separator:

```
<label>
 Select the song to play next:
 <select required name="next">
  <option value="sr">Random
  <hr>
  <option value="s1">It Sucks to Be Me (Reprise)
  <option value="s2">There is Life Outside Your Apartment
  …
```

4.10.8 The datalist element §[p578]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Either: phrasing content[p151].
Or: Zero or more option[p580] and script-supporting[p152] elements.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLDataListElement : HTMLElement {
  [HTMLConstructor] constructor();

  [SameObject] readonly attribute HTMLCollection options;
};
```

The datalist[p578] element represents a set of option[p580] elements that represent predefined options for other controls. In the rendering, the datalist[p578] element represents[p142] nothing and it, along with its children, should be hidden.

The datalist[p578] element can be used in two ways. In the simplest case, the datalist[p578] element has just option[p580] element children.

Example

```
<label>
 Animal:
 <input name=animal list=animals>
 <datalist id=animals>
  <option value="Cat">
  <option value="Dog">
 </datalist>
</label>
```

In the more elaborate case, the datalist element can be given contents that are to be displayed for down-level clients that don't support datalist. In this case, the option elements are provided inside a select element inside the datalist element.

Example

```
<label>
 Animal:
 <input name=animal list=animals>
</label>
<datalist id=animals>
 <label>
  or select from the list:
  <select name=animal>
   <option value="">
   <option>Cat
   <option>Dog
  </select>
 </label>
</datalist>
```

The datalist element is hooked up to an input element using the list attribute on the input element.

Each option element that is a descendant of the datalist element, that is not disabled, and whose value is a string that isn't the empty string, represents a suggestion. Each suggestion has a value and a label.

For web developers (non-normative)

***datalist*.options**

Returns an HTMLCollection of the option elements of the datalist element.

The **options** IDL attribute must return an HTMLCollection rooted at the datalist node, whose filter matches option elements.

Constraint validation: If an element has a datalist element ancestor, it is barred from constraint validation.

4.10.9 The optgroup element

Categories:

None.

Contexts in which this element can be used:

As a child of a select element.

Content model:

Zero or more option and script-supporting elements.

Tag omission in text/html:

An optgroup element's end tag can be omitted if the optgroup element is immediately followed by another optgroup element, if it is immediately followed by an hr element, or if there is no more content in the parent element.

Content attributes:

Global attributes
disabled — Whether the form control is disabled
label — User-visible label

Accessibility considerations:

For authors.
For implementers.

DOM interface:

IDL

```
[Exposed=Window]
```

```
interface HTMLOptGroupElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute boolean disabled;
  [CEReactions] attribute DOMString label;
};
```

The optgroup element represents a group of option elements with a common label.

The element's group of option elements consists of the option elements that are children of the optgroup element.

When showing option elements in select elements, user agents should show the option elements of such groups as being related to each other and separate from other option elements.

The **disabled** attribute is a boolean attribute and can be used to disable a group of option elements together.

The **label** attribute must be specified. Its value gives the name of the group, for the purposes of the user interface. User agents should use this attribute's value when labeling the group of option elements in a select element.

The **disabled** and **label** attributes must reflect the respective content attributes of the same name.

Note

There is no way to select an optgroup element. Only option elements can be selected. An optgroup element merely provides a label for a group of option elements.

Example

The following snippet shows how a set of lessons from three courses could be offered in a select drop-down widget:

```
<form action="courseselector.dll" method="get">
 <p>Which course would you like to watch today?
 <p><label>Course:
  <select name="c">
   <optgroup label="8.01 Physics I: Classical Mechanics">
    <option value="8.01.1">Lecture 01: Powers of Ten
    <option value="8.01.2">Lecture 02: 1D Kinematics
    <option value="8.01.3">Lecture 03: Vectors
   <optgroup label="8.02 Electricity and Magnetism">
    <option value="8.02.1">Lecture 01: What holds our world together?
    <option value="8.02.2">Lecture 02: Electric Field
    <option value="8.02.3">Lecture 03: Electric Flux
   <optgroup label="8.03 Physics III: Vibrations and Waves">
    <option value="8.03.1">Lecture 01: Periodic Phenomenon
    <option value="8.03.2">Lecture 02: Beats
    <option value="8.03.3">Lecture 03: Forced Oscillations with Damping
  </select>
 </label>
 <p><input type=submit value="▶ Play">
</form>
```

4.10.10 The option element

Categories:

None.

Contexts in which this element can be used:

As a child of a select element.
As a child of a datalist element.
As a child of an optgroup element.

Content model[p147]**:**

If the element has a `label`[p581] attribute and a `value`[p582] attribute: Nothing[p149].
If the element has a `label`[p581] attribute but no `value`[p582] attribute: Text[p151].
If the element has no `label`[p581] attribute and is not a child of a `datalist`[p578] element: Text[p151] that is not inter-element whitespace[p148].
If the element has no `label`[p581] attribute and is a child of a `datalist`[p578] element: Text[p151].

Tag omission in text/html[p148]**:**

An `option`[p580] element's end tag[p1280] can be omitted if the `option`[p580] element is immediately followed by another `option`[p580] element, if it is immediately followed by an `optgroup`[p579] element, if it is immediately followed by an `hr`[p232] element, or if there is no more content in the parent element.

Content attributes[p148]**:**

Global attributes[p155]
`disabled`[p581] — Whether the form control is disabled
`label`[p581] — User-visible label
`selected`[p582] — Whether the option is selected by default
`value`[p582] — Value to be used for form submission[p632]

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window,
 LegacyFactoryFunction=Option(optional DOMString text = "", optional DOMString value, optional
boolean defaultSelected = false, optional boolean selected = false)]
interface HTMLOptionElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute DOMString label;
  [CEReactions] attribute boolean defaultSelected;
  attribute boolean selected;
  [CEReactions] attribute DOMString value;

  [CEReactions] attribute DOMString text;
  readonly attribute long index;
};
```

The `option`[p580] element represents[p142] an option in a `select`[p572] element or as part of a list of suggestions in a `datalist`[p578] element.

In certain circumstances described in the definition of the `select`[p572] element, an `option`[p580] element can be a `select`[p572] element's placeholder label option[p573]. A placeholder label option[p573] does not represent an actual option, but instead represents a label for the `select`[p572] control.

The **`disabled`** attribute is a boolean attribute[p76]. An `option`[p580] element is **disabled** if its `disabled`[p581] attribute is present or if it is a child of an `optgroup`[p579] element whose `disabled`[p580] attribute is present.

An `option`[p580] element that is disabled[p581] must prevent any `click` events that are queued[p1139] on the user interaction task source[p1149] from being dispatched on the element.

Note

Being disabled[p581] does not prevent all modifications to the `option`[p580] element. For example, its selectedness[p582] could be modified programmatically from JavaScript. Or, it could be indirectly modified by user action, e.g., if other non-disabled `option`[p580] elements in the `select`[p572] element were modified.

The **`label`** attribute provides a label for element. The **label** of an `option`[p580] element is the value of the `label`[p581] content attribute, if there is one and its value is not the empty string, or, otherwise, the value of the element's `text`[p583] IDL attribute.

The label content attribute, if specified, must not be empty.

The **value** attribute provides a value for element. The **value** of an option element is the value of the value content attribute, if there is one, or, if there is not, the value of the element's text IDL attribute.

The **selected** attribute is a boolean attribute. It represents the default selectedness of the element.

The **dirtiness** of an option element is a boolean state, initially false. It controls whether adding or removing the selected content attribute has any effect.

The **selectedness** of an option element is a boolean state, initially false. Except where otherwise specified, when the element is created, its selectedness must be set to true if the element has a selected attribute. Whenever an option element's selected attribute is added, if its dirtiness is false, its selectedness must be set to true. Whenever an option element's selected attribute is *removed*, if its dirtiness is false, its selectedness must be set to false.

Note

The Option() constructor, when called with three or fewer arguments, overrides the initial state of the selectedness state to always be false even if the third argument is true (implying that a selected attribute is to be set). The fourth argument can be used to explicitly set the initial selectedness state when using the constructor.

A select element whose multiple attribute is not specified must not have more than one descendant option element with its selected attribute set.

An option element's **index** is the number of option elements that are in the same list of options but that come before it in tree order. If the option element is not in a list of options, then the option element's index is zero.

For web developers (non-normative)

***option*.selected**

Returns true if the element is selected, and false otherwise.

Can be set, to override the current state of the element.

***option*.index**

Returns the index of the element in its select element's options list.

***option*.form**

Returns the element's form element, if any, or null otherwise.

***option*.text**

Same as textContent, except that spaces are collapsed and script elements are skipped.

***option* = new Option([*text* [, *value* [, *defaultSelected* [, *selected*]]]])**

Returns a new option element.

The *text* argument sets the contents of the element.

The *value* argument sets the value attribute.

The *defaultSelected* argument sets the selected attribute.

The *selected* argument sets whether or not the element is selected. If it is omitted, even if the *defaultSelected* argument is true, the element is not selected.

The **disabled** IDL attribute must reflect the content attribute of the same name. The **defaultSelected** IDL attribute must reflect the selected content attribute.

The **label** IDL attribute, on getting, if there is a label content attribute, must return that attribute's value; otherwise, it must return the element's label. On setting, the element's label content attribute must be set to the new value.

The **value** IDL attribute, on getting, must return the element's value. On setting, the element's value content attribute must be set to the new value.

The **selected** IDL attribute, on getting, must return true if the element's selectedness is true, and false otherwise. On setting, it must set the element's selectedness to the new value, set its dirtiness to true, and then cause the element to ask for a reset.

The **index** IDL attribute must return the element's index.

The **text** IDL attribute, on getting, must return the result of stripping and collapsing ASCII whitespace from the concatenation of data of all the Text node descendants of the option[p580] element, in tree order, excluding any that are descendants of descendants of the option[p580] element that are themselves script[p660] or SVG script elements.

The text[p583] attribute's setter must string replace all with the given value within this element.

The **form** IDL attribute's behavior depends on whether the option[p580] element is in a select[p572] element or not. If the option[p580] has a select[p572] element as its parent, or has an optgroup[p579] element as its parent and that optgroup[p579] element has a select[p572] element as its parent, then the form[p583] IDL attribute must return the same value as the form[p603] IDL attribute on that select[p572] element. Otherwise, it must return null.

A legacy factory function is provided for creating HTMLOptionElement[p581] objects (in addition to the factory methods from DOM such as createElement()): **Option(*text*, *value*, *defaultSelected*, *selected*)**. When invoked, the legacy factory function must perform the following steps:

1. Let *document* be the current global object[p1098]'s associated Document[p935].
2. Let *option* be the result of creating an element given *document*, "option", and the HTML namespace.
3. If *text* is not the empty string, then append to *option* a new Text node whose data is *text*.
4. If *value* is given, then set an attribute value for *option* using "value[p582]" and *value*.
5. If *defaultSelected* is true, then set an attribute value for *option* using "selected[p582]" and the empty string.
6. If *selected* is true, then set *option*'s selectedness[p582] to true; otherwise set its selectedness[p582] to false (even if *defaultSelected* is true).
7. Return *option*.

4.10.11 The textarea element §[p583]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Interactive content[p151].
Listed[p514], labelable[p515], submittable[p515], resettable[p515], and autocapitalize-and-autocorrect inheriting[p515] form-associated element[p514].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Text[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
autocomplete[p608] — Hint for form autofill feature
cols[p585] — Maximum number of characters per line
dirname[p604] — Name of form control to use for sending the element's directionality[p161] in form submission[p632]
disabled[p605] — Whether the form control is disabled
form[p601] — Associates the element with a form[p515] element
maxlength[p586] — Maximum length of value
minlength[p586] — Minimum length of value
name[p603] — Name of the element to use for form submission[p632] and in the form.elements[p517] API
placeholder[p586] — User-visible label to be placed within the form control
readonly[p584] — Whether to allow the value to be edited by the user
required[p586] — Whether the control is required for form submission[p632]
rows[p585] — Number of lines to show

`wrap`[p586] — How the value of the form control is to be wrapped for form submission[p632]

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLTextAreaElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString autocomplete;
  [CEReactions] attribute unsigned long cols;
  [CEReactions] attribute DOMString dirName;
  [CEReactions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute long maxLength;
  [CEReactions] attribute long minLength;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString placeholder;
  [CEReactions] attribute boolean readOnly;
  [CEReactions] attribute boolean required;
  [CEReactions] attribute unsigned long rows;
  [CEReactions] attribute DOMString wrap;

  readonly attribute DOMString type;
  [CEReactions] attribute DOMString defaultValue;
  attribute [LegacyNullToEmptyString] DOMString value;
  readonly attribute unsigned long textLength;

  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  undefined setCustomValidity(DOMString error);

  readonly attribute NodeList labels;

  undefined select();
  attribute unsigned long selectionStart;
  attribute unsigned long selectionEnd;
  attribute DOMString selectionDirection;
  undefined setRangeText(DOMString replacement);
  undefined setRangeText(DOMString replacement, unsigned long start, unsigned long end, optional
SelectionMode selectionMode = "preserve");
  undefined setSelectionRange(unsigned long start, unsigned long end, optional DOMString
direction);
};
```

The `textarea`[p583] element represents[p142] a multiline plain text edit control for the element's **raw value**. The contents of the control represent the control's default value.

The raw value[p584] of a `textarea`[p583] control must be initially the empty string.

Note

This element has rendering requirements involving the bidirectional algorithm[p171]*.*

The **`readonly`** attribute is a boolean attribute[p76] used to control whether the text can be edited by the user or not.

Example

In this example, a text control is marked read-only because it represents a read-only file:

```
Filename: <code>/etc/bash.bashrc</code>
<textarea name="buffer" readonly>
# System-wide .bashrc file for interactive bash(1) shells.

# To enable the settings / commands in this file for login shells as well,
# this file has to be sourced in /etc/profile.

# If not running interactively, don't do anything
[ -z "$PS1" ] &amp;&amp; return

...</textarea>
```

Constraint validation: If the `readonly` attribute is specified on a `textarea` element, the element is barred from constraint validation.

A `textarea` element is mutable if it is neither disabled nor has a `readonly` attribute specified.

When a `textarea` is mutable, its raw value should be editable by the user: the user agent should allow the user to edit, insert, and remove text, and to insert and remove line breaks in the form of U+000A LINE FEED (LF) characters. Any time the user causes the element's raw value to change, the user agent must queue an element task on the user interaction task source given the `textarea` element to fire an event named `input` at the `textarea` element, with the `bubbles` and `composed` attributes initialized to true. User agents may wait for a suitable break in the user's interaction before queuing the task; for example, a user agent could wait for the user to have not hit a key for 100ms, so as to only fire the event when the user pauses, instead of continuously for each keystroke.

A `textarea` element's dirty value flag must be set to true whenever the user interacts with the control in a way that changes the raw value.

The cloning steps for `textarea` elements given *node*, *copy*, and *subtree* are to propagate the raw value and dirty value flag from *node* to *copy*.

The children changed steps for `textarea` elements must, if the element's dirty value flag is false, set the element's raw value to its child text content.

The reset algorithm for `textarea` elements is to set the user validity to false, the dirty value flag back to false, and the raw value to its child text content.

When a `textarea` element is popped off the stack of open elements of an HTML parser or XML parser, then the user agent must invoke the element's reset algorithm.

If the element is mutable, the user agent should allow the user to change the writing direction of the element, setting it either to a left-to-right writing direction or a right-to-left writing direction. If the user does so, the user agent must then run the following steps:

1. Set the element's `dir` attribute to "`ltr`" if the user selected a left-to-right writing direction, and "`rtl`" if the user selected a right-to-left writing direction.
2. Queue an element task on the user interaction task source given the `textarea` element to fire an event named `input` at the `textarea` element, with the `bubbles` and `composed` attributes initialized to true.

The **`cols`** attribute specifies the expected maximum number of characters per line. If the `cols` attribute is specified, its value must be a valid non-negative integer greater than zero. If applying the rules for parsing non-negative integers to the attribute's value results in a number greater than zero, then the element's **character width** is that value; otherwise, it is 20.

The user agent may use the `textarea` element's character width as a hint to the user as to how many characters the server prefers per line (e.g. for visual user agents by making the width of the control be that many characters). In visual renderings, the user agent should wrap the user's input in the rendering so that each line is no wider than this number of characters.

The **`rows`** attribute specifies the number of lines to show. If the `rows` attribute is specified, its value must be a valid non-negative integer greater than zero. If applying the rules for parsing non-negative integers to the attribute's value results in a number greater than zero, then the element's **character height** is that value; otherwise, it is 2.

Visual user agents should set the height of the control to the number of lines given by character height[p585].

The **wrap** attribute is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
soft	Soft	Text is not to be wrapped when submitted (though can still be wrapped in the rendering).
hard	Hard	Text is to have newlines added by the user agent so that the text is wrapped when it is submitted.

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the Soft[p586] state.

If the element's wrap[p586] attribute is in the Hard[p586] state, the cols[p585] attribute must be specified.

For historical reasons, the element's value is normalized in three different ways for three different purposes. The raw value[p584] is the value as it was originally set. It is not normalized. The API value[p601] is the value used in the value[p587] IDL attribute, textLength[p587] IDL attribute, and by the maxlength[p604] and minlength[p605] content attributes. It is normalized so that line breaks use U+000A LINE FEED (LF) characters. Finally, there is the value[p601], as used in form submission and other processing models in this specification. It is normalized as for the API value[p601], and in addition, if necessary given the element's wrap[p586] attribute, additional line breaks are inserted to wrap the text at the given width.

The algorithm for obtaining the element's API value[p601] is to return the element's raw value[p584], with newlines normalized.

The element's value[p601] is defined to be the element's API value[p584] with the textarea wrapping transformation[p586] applied. The **textarea wrapping transformation** is the following algorithm, as applied to a string:

1. If the element's wrap[p586] attribute is in the Hard[p586] state, insert U+000A LINE FEED (LF) characters into the string using an implementation-defined algorithm so that each line has no more than character width[p585] characters. For the purposes of this requirement, lines are delimited by the start of the string, the end of the string, and U+000A LINE FEED (LF) characters.

The **maxlength** attribute is a form control maxlength attribute[p604].

If the textarea[p583] element has a maximum allowed value length[p604], then the element's children must be such that the length of the value of the element's descendant text content with newlines normalized is less than or equal to the element's maximum allowed value length[p604].

The **minlength** attribute is a form control minlength attribute[p605].

The **required** attribute is a boolean attribute[p76]. When specified, the user will be required to enter a value before submitting the form.

Constraint validation: If the element has its required[p586] attribute specified, and the element is mutable[p601], and the element's value[p601] is the empty string, then the element is suffering from being missing[p626].

The **placeholder** attribute represents a *short* hint (a word or short phrase) intended to aid the user with data entry when the control has no value. A hint could be a sample value or a brief description of the expected format.

The placeholder[p586] attribute should not be used as an alternative to a label[p519]. For a longer hint or other advisory text, the title[p158] attribute is more appropriate.

Note

These mechanisms are very similar but subtly different: the hint given by the control's label[p519] is shown at all times; the short hint given in the placeholder[p586] attribute is shown before the user enters a value; and the hint in the title[p158] attribute is shown when the user requests further help.

User agents should present this hint to the user when the element's value[p601] is the empty string and the control is not focused[p845] (e.g. by displaying it inside a blank unfocused control). All U+000D CARRIAGE RETURN U+000A LINE FEED character pairs (CRLF) in the hint, as well as all other U+000D CARRIAGE RETURN (CR) and U+000A LINE FEED (LF) characters in the hint, must be treated as line breaks when rendering the hint.

If a user agent normally doesn't show this hint to the user when the control is focused[p845], then the user agent should nonetheless show the hint for the control if it was focused as a result of the autofocus[p857] attribute, since in that case the user will not have had an opportunity to examine the control before focusing it.

The name[p603] attribute represents the element's name. The dirname[p604] attribute controls how the element's directionality[p161] is submitted. The disabled[p605] attribute is used to make the control non-interactive and to prevent its value from being submitted. The

form[p601] attribute is used to explicitly associate the textarea[p583] element with its form owner[p601]. The autocomplete[p608] attribute controls how the user agent provides autofill behavior.

For web developers (non-normative)

***textarea*.type**[p587]

Returns the string "textarea".

***textarea*.value**[p587]

Returns the current value of the element.

Can be set, to change the value.

The **cols**, **placeholder**, **required**, **rows**, and **wrap** IDL attributes must reflect[p105] the respective content attributes of the same name. The cols[p587] and rows[p587] attributes are limited to only positive numbers with fallback[p108]. The cols[p587] IDL attribute's default value[p108] is 20. The rows[p587] IDL attribute's default value[p108] is 2. The **dirName** IDL attribute must reflect[p105] the dirname[p604] content attribute. The **maxLength** IDL attribute must reflect[p105] the maxlength[p586] content attribute, limited to only non-negative numbers[p108]. The **minLength** IDL attribute must reflect[p105] the minlength[p586] content attribute, limited to only non-negative numbers[p108]. The **readOnly** IDL attribute must reflect[p105] the readonly[p584] content attribute.

The **type** IDL attribute must return the value "textarea".

The **defaultValue** attribute's getter must return the element's child text content.

The defaultValue[p587] attribute's setter must string replace all with the given value within this element.

The **value** IDL attribute must, on getting, return the element's API value[p601]. On setting, it must perform the following steps:

1. Let *oldAPIValue* be this element's API value[p601].
2. Set this element's raw value[p584] to the new value.
3. Set this element's dirty value flag[p601] to true.
4. If the new API value[p601] is different from *oldAPIValue*, then move the text entry cursor position[p622] to the end of the text control, unselecting any selected text and resetting the selection direction[p623] to "none".

The **textLength** IDL attribute must return the length of the element's API value[p601].

The willValidate[p629], validity[p629], and validationMessage[p631] IDL attributes, and the checkValidity()[p631], reportValidity()[p631], and setCustomValidity()[p629] methods, are part of the constraint validation API[p628]. The labels[p521] IDL attribute provides a list of the element's label[p519]s. The select()[p623], selectionStart[p623], selectionEnd[p624], selectionDirection[p624], setRangeText()[p625], and setSelectionRange()[p624] methods and IDL attributes expose the element's text selection. The disabled[p606], form[p603], and name[p603] IDL attributes are part of the element's forms API.

Example

Here is an example of a textarea[p583] being used for unrestricted free-form text input in a form:

```
<p>If you have any comments, please let us know: <textarea cols=80 name=comments></textarea></p>
```

To specify a maximum length for the comments, one can use the maxlength[p586] attribute:

```
<p>If you have any short comments, please let us know: <textarea cols=80 name=comments
maxlength=200></textarea></p>
```

To give a default value, text can be included inside the element:

```
<p>If you have any comments, please let us know: <textarea cols=80 name=comments>You
rock!</textarea></p>
```

You can also give a minimum length. Here, a letter needs to be filled out by the user; a template (which is shorter than the minimum length) is provided, but is insufficient to submit the form:

```
<textarea required minlength="500">Dear Madam Speaker,

Regarding your letter dated ...

...

Yours Sincerely,

...</textarea>
```

A placeholder can be given as well, to suggest the basic form to the user, without providing an explicit template:

```
<textarea placeholder="Dear Francine,

They closed the parks this week, so we won't be able to
meet your there. Should we just have dinner?

Love,
Daddy"></textarea>
```

To have the browser submit the directionality[p161] of the element along with the value, the dirname[p604] attribute can be specified:

```
<p>If you have any comments, please let us know (you may use either English or Hebrew for your
comments):
<textarea cols=80 name=comments dirname=comments.dir></textarea></p>
```

4.10.12 The output element §[p588]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Listed[p514], labelable[p515], resettable[p515], and autocapitalize-and-autocorrect inheriting[p515] form-associated element[p514].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
for[p589] — Specifies controls from which the output was calculated
form[p601] — Associates the element with a form[p515] element
name[p603] — Name of the element to use in the form.elements[p517] API.

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL
```
[Exposed=Window]
interface HTMLOutputElement : HTMLElement {
  [HTMLConstructor] constructor();
```

```
  [SameObject, PutForwards=value] readonly attribute DOMTokenList htmlFor;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute DOMString name;

  readonly attribute DOMString type;
  [CEReactions] attribute DOMString defaultValue;
  [CEReactions] attribute DOMString value;

  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  undefined setCustomValidity(DOMString error);

  readonly attribute NodeList labels;
};
```

The output element represents the result of a calculation performed by the application, or the result of a user action.

Note

This element can be contrasted with the samp element, which is the appropriate element for quoting the output of other programs run previously.

The **for** content attribute allows an explicit relationship to be made between the result of a calculation and the elements that represent the values that went into the calculation or that otherwise influenced the calculation. The for attribute, if specified, must contain a string consisting of an unordered set of unique space-separated tokens, none of which are identical to another token and each of which must have the value of an ID of an element in the same tree.

The form attribute is used to explicitly associate the output element with its form owner. The name attribute represents the element's name. The output element is associated with a form so that it can be easily referenced from the event handlers of form controls; the element's value itself is not submitted when the form is submitted.

The element has a **default value override** (null or a string). Initially it must be null.

The element's **default value** is determined by the following steps:

1. If this element's default value override is non-null, then return it.
2. Return this element's descendant text content.

The reset algorithm for output elements is to run these steps:

1. String replace all with this element's default value within this element.
2. Set this element's default value override to null.

For web developers (non-normative)

***output*.value [= *value*]**

Returns the element's current value.

Can be set, to change the value.

***output*.defaultValue [= *value*]**

Returns the element's current default value.

Can be set, to change the default value.

***output*.type**

Returns the string "output".

The **value** getter steps are to return this's descendant text content.

The value[p589] setter steps are:

1. Set this's default value override[p589] to its default value[p589].
2. String replace all with the given value within this.

The **defaultValue** getter steps are to return the result of running this's default value[p589].

The defaultValue[p590] setter steps are:

1. If this's default value override[p589] is null, then string replace all with the given value within this and return.
2. Set this's default value override[p589] to the given value.

The **type** getter steps are to return "output".

The **htmlFor** IDL attribute must reflect[p105] the for[p589] content attribute.

The willValidate[p629], validity[p629], and validationMessage[p631] IDL attributes, and the checkValidity()[p631], reportValidity()[p631], and setCustomValidity()[p629] methods, are part of the constraint validation API[p628]. The labels[p521] IDL attribute provides a list of the element's label[p519]s. The form[p603] and name[p603] IDL attributes are part of the element's forms API.

Example

A simple calculator could use output[p588] for its display of calculated results:

```
<form onsubmit="return false" oninput="o.value = a.valueAsNumber + b.valueAsNumber">
 <input id=a type=number step=any> +
 <input id=b type=number step=any> =
 <output id=o for="a b"></output>
</form>
```

Example

In this example, an output[p588] element is used to report the results of a calculation performed by a remote server, as they come in:

```
<output id="result"></output>
<script>
 var primeSource = new WebSocket('ws://primes.example.net/');
 primeSource.onmessage = function (event) {
   document.getElementById('result').value = event.data;
 }
</script>
```

4.10.13 The progress element §[p590]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Labelable element[p515].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Phrasing content[p151], but there must be no progress[p590] element descendants.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]**:**

Global attributes[p155]
value[p591] — Current value of the element
max[p591] — Upper bound of range

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL
```
[Exposed=Window]
interface HTMLProgressElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute double value;
  [CEReactions] attribute double max;
  readonly attribute double position;
  readonly attribute NodeList labels;
};
```

The progress[p590] element represents[p142] the completion progress of a task. The progress is either indeterminate, indicating that progress is being made but that it is not clear how much more work remains to be done before the task is complete (e.g. because the task is waiting for a remote host to respond), or the progress is a number in the range zero to a maximum, giving the fraction of work that has so far been completed.

There are two attributes that determine the current task completion represented by the element. The **value** attribute specifies how much of the task has been completed, and the **max** attribute specifies how much work the task requires in total. The units are arbitrary and not specified.

Note

To make a determinate progress bar, add a value[p591] attribute with the current progress (either a number from 0.0 to 1.0, or, if the max[p591] attribute is specified, a number from 0 to the value of the max[p591] attribute). To make an indeterminate progress bar, remove the value[p591] attribute.

Authors are encouraged to also include the current value and the maximum value inline as text inside the element, so that the progress is made available to users of legacy user agents.

Example

Here is a snippet of a web application that shows the progress of some automated task:

```
<section>
 <h2>Task Progress</h2>
 <p>Progress: <progress id=p max=100><span>0</span>%</progress></p>
 <script>
  var progressBar = document.getElementById('p');
  function updateProgress(newValue) {
    progressBar.value = newValue;
    progressBar.getElementsByTagName('span')[0].textContent = newValue;
  }
 </script>
</section>
```

(The `updateProgress()` method in this example would be called by some other code on the page to update the actual progress bar as the task progressed.)

The value[p591] and max[p591] attributes, when present, must have values that are valid floating-point numbers[p78]. The value[p591] attribute, if present, must have a value greater than or equal to zero, and less than or equal to the value of the max[p591] attribute, if present, or 1.0, otherwise. The max[p591] attribute, if present, must have a value greater than zero.

Note

The progress element is the wrong element to use for something that is just a gauge, as opposed to task progress. For instance, indicating disk space usage using progress would be inappropriate. Instead, the meter element is available for such use cases.

User agent requirements: If the value attribute is omitted, then the progress bar is an indeterminate progress bar. Otherwise, it is a determinate progress bar.

If the progress bar is a determinate progress bar and the element has a max attribute, the user agent must parse the max attribute's value according to the rules for parsing floating-point number values. If this does not result in an error, and if the parsed value is greater than zero, then the **maximum value** of the progress bar is that value. Otherwise, if the element has no max attribute, or if it has one but parsing it resulted in an error, or if the parsed value was less than or equal to zero, then the maximum value of the progress bar is 1.0.

If the progress bar is a determinate progress bar, user agents must parse the value attribute's value according to the rules for parsing floating-point number values. If this does not result in an error and the parsed value is greater than zero, then the **value** of the progress bar is that parsed value. Otherwise, if parsing the value attribute's value resulted in an error or a number less than or equal to zero, then the value of the progress bar is zero.

If the progress bar is a determinate progress bar, then the **current value** is the maximum value, if value is greater than the maximum value, and value otherwise.

UA requirements for showing the progress bar: When representing a progress element to the user, the UA should indicate whether it is a determinate or indeterminate progress bar, and in the former case, should indicate the relative position of the current value relative to the maximum value.

For web developers (non-normative)

***progress*.position**

For a determinate progress bar (one with known current and maximum values), returns the result of dividing the current value by the maximum value.

For an indeterminate progress bar, returns −1.

If the progress bar is an indeterminate progress bar, then the **position** IDL attribute must return −1. Otherwise, it must return the result of dividing the current value by the maximum value.

If the progress bar is an indeterminate progress bar, then the **value** IDL attribute, on getting, must return 0. Otherwise, it must return the current value. On setting, the given value must be converted to the best representation of the number as a floating-point number and then the value content attribute must be set to that string.

Note

Setting the value IDL attribute to itself when the corresponding content attribute is absent would change the progress bar from an indeterminate progress bar to a determinate progress bar with no progress.

The **max** IDL attribute must reflect the content attribute of the same name, limited to only positive numbers. The default value for max is 1.0.

The labels IDL attribute provides a list of the element's labels.

4.10.14 The meter element

Categories:

Flow content.
Phrasing content.
Labelable element.
Palpable content.

Contexts in which this element can be used:

Where phrasing content is expected.

Content model[p147]**:**

Phrasing content[p151], but there must be no meter[p592] element descendants.

Tag omission in text/html[p148]**:**

Neither tag is omissible.

Content attributes[p148]**:**

Global attributes[p155]
value[p593] — Current value of the element
min[p593] — Lower bound of range
max[p593] — Upper bound of range
low[p593] — High limit of low range
high[p593] — Low limit of high range
optimum[p593] — Optimum value in gauge

Accessibility considerations[p148]**:**

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLMeterElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute double value;
  [CEReactions] attribute double min;
  [CEReactions] attribute double max;
  [CEReactions] attribute double low;
  [CEReactions] attribute double high;
  [CEReactions] attribute double optimum;
  readonly attribute NodeList labels;
};
```

The meter[p592] element represents[p142] a scalar measurement within a known range, or a fractional value; for example disk usage, the relevance of a query result, or the fraction of a voting population to have selected a particular candidate.

This is also known as a gauge.

The meter[p592] element should not be used to indicate progress (as in a progress bar). For that role, HTML provides a separate progress[p590] element.

Note

The meter[p592] element also does not represent a scalar value of arbitrary range — for example, it would be wrong to use this to report a weight, or height, unless there is a known maximum value.

There are six attributes that determine the semantics of the gauge represented by the element.

The **min** attribute specifies the lower bound of the range, and the **max** attribute specifies the upper bound. The **value** attribute specifies the value to have the gauge indicate as the "measured" value.

The other three attributes can be used to segment the gauge's range into "low", "medium", and "high" parts, and to indicate which part of the gauge is the "optimum" part. The **low** attribute specifies the range that is considered to be the "low" part, and the **high** attribute specifies the range that is considered to be the "high" part. The **optimum** attribute gives the position that is "optimum"; if that is higher than the "high" value then this indicates that the higher the value, the better; if it's lower than the "low" mark then it indicates that lower values are better, and naturally if it is in between then it indicates that neither high nor low values are good.

Authoring requirements: The value[p593] attribute must be specified. The value[p593], min[p593], low[p593], high[p593], max[p593], and optimum[p593] attributes, when present, must have values that are valid floating-point numbers[p78].

In addition, the attributes' values are further constrained:

Let *value* be the value[p593] attribute's number.

If the min[p593] attribute is specified, then let *minimum* be that attribute's value; otherwise, let it be 0.

If the max[p593] attribute is specified, then let *maximum* be that attribute's value; otherwise, let it be 1.0.

The following inequalities must hold, as applicable:

- *minimum* ≤ *value* ≤ *maximum*
- *minimum* ≤ low[p593] ≤ *maximum* (if low[p593] is specified)
- *minimum* ≤ high[p593] ≤ *maximum* (if high[p593] is specified)
- *minimum* ≤ optimum[p593] ≤ *maximum* (if optimum[p593] is specified)
- low[p593] ≤ high[p593] (if both low[p593] and high[p593] are specified)

Note

If no minimum or maximum is specified, then the range is assumed to be 0..1, and the value thus has to be within that range.

Authors are encouraged to include a textual representation of the gauge's state in the element's contents, for users of user agents that do not support the meter[p592] element.

When used with microdata[p796], the meter[p592] element's value[p593] attribute provides the element's machine-readable value.

Example

The following examples show three gauges that would all be three-quarters full:

```
Storage space usage: <meter value=6 max=8>6 blocks used (out of 8 total)</meter>
```

```
Voter turnout: <meter value=0.75><img alt="75%" src="graph75.png"></meter>
```

```
Tickets sold: <meter min="0" max="100" value="75"></meter>
```

The following example is incorrect use of the element, because it doesn't give a range (and since the default maximum is 1, both of the gauges would end up looking maxed out):

```
<p>The grapefruit pie had a radius of <meter value=12>12cm</meter>
and a height of <meter value=2>2cm</meter>.</p> <!-- BAD! -->
```

Instead, one would either not include the meter element, or use the meter element with a defined range to give the dimensions in context compared to other pies:

```
<p>The grapefruit pie had a radius of 12cm and a height of
2cm.</p>
<dl>
 <dt>Radius: <dd> <meter min=0 max=20 value=12>12cm</meter>
 <dt>Height: <dd> <meter min=0 max=10 value=2>2cm</meter>
</dl>
```

There is no explicit way to specify units in the meter[p592] element, but the units may be specified in the title[p158] attribute in free-form text.

Example

The example above could be extended to mention the units:

```
<dl>
 <dt>Radius: <dd> <meter min=0 max=20 value=12 title="centimeters">12cm</meter>
 <dt>Height: <dd> <meter min=0 max=10 value=2 title="centimeters">2cm</meter>
</dl>
```

User agent requirements: User agents must parse the min[p593], max[p593], value[p593], low[p593], high[p593], and optimum[p593] attributes using the rules for parsing floating-point number values[p79].

User agents must then use all these numbers to obtain values for six points on the gauge, as follows. (The order in which these are evaluated is important, as some of the values refer to earlier ones.)

The *minimum value*

If the min[p593] attribute is specified and a value could be parsed out of it, then the minimum value is that value. Otherwise, the minimum value is zero.

The *maximum value*

If the max[p593] attribute is specified and a value could be parsed out of it, then the candidate maximum value is that value. Otherwise, the candidate maximum value is 1.0.

If the candidate maximum value is greater than or equal to the minimum value, then the maximum value is the candidate maximum value. Otherwise, the maximum value is the same as the minimum value.

The *actual value*

If the value[p593] attribute is specified and a value could be parsed out of it, then that value is the candidate actual value. Otherwise, the candidate actual value is zero.

If the candidate actual value is less than the minimum value, then the actual value is the minimum value.

Otherwise, if the candidate actual value is greater than the maximum value, then the actual value is the maximum value.

Otherwise, the actual value is the candidate actual value.

The *low boundary*

If the low[p593] attribute is specified and a value could be parsed out of it, then the candidate low boundary is that value. Otherwise, the candidate low boundary is the same as the minimum value.

If the candidate low boundary is less than the minimum value, then the low boundary is the minimum value.

Otherwise, if the candidate low boundary is greater than the maximum value, then the low boundary is the maximum value.

Otherwise, the low boundary is the candidate low boundary.

The *high boundary*

If the high[p593] attribute is specified and a value could be parsed out of it, then the candidate high boundary is that value. Otherwise, the candidate high boundary is the same as the maximum value.

If the candidate high boundary is less than the low boundary, then the high boundary is the low boundary.

Otherwise, if the candidate high boundary is greater than the maximum value, then the high boundary is the maximum value.

Otherwise, the high boundary is the candidate high boundary.

The *optimum point*

If the optimum[p593] attribute is specified and a value could be parsed out of it, then the candidate optimum point is that value. Otherwise, the candidate optimum point is the midpoint between the minimum value and the maximum value.

If the candidate optimum point is less than the minimum value, then the optimum point is the minimum value.

Otherwise, if the candidate optimum point is greater than the maximum value, then the optimum point is the maximum value.

Otherwise, the optimum point is the candidate optimum point.

All of which will result in the following inequalities all being true:

- minimum value ≤ actual value ≤ maximum value
- minimum value ≤ low boundary ≤ high boundary ≤ maximum value
- minimum value ≤ optimum point ≤ maximum value

UA requirements for regions of the gauge: If the optimum point is equal to the low boundary or the high boundary, or anywhere in between them, then the region between the low and high boundaries of the gauge must be treated as the optimum region, and the low and high parts, if any, must be treated as suboptimal. Otherwise, if the optimum point is less than the low boundary, then the region between the minimum value and the low boundary must be treated as the optimum region, the region from the low boundary up to the high boundary must be treated as a suboptimal region, and the remaining region must be treated as an even less good region. Finally, if the optimum point is higher than the high boundary, then the situation is reversed; the region between the high boundary and the maximum value must be treated as the optimum region, the region from the high boundary down to the low boundary must be treated as a suboptimal region, and the remaining region must be treated as an even less good region.

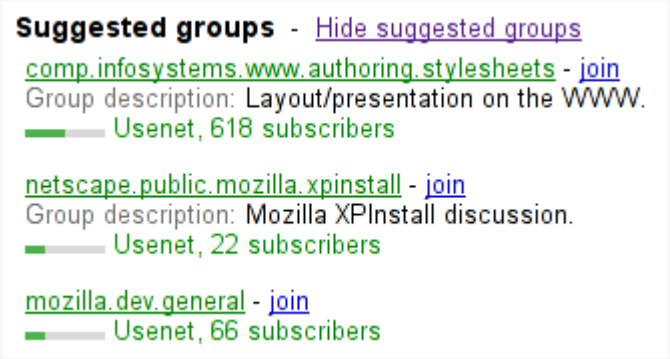
UA requirements for showing the gauge: When representing a meter[p592] element to the user, the UA should indicate the relative position of the actual value to the minimum and maximum values, and the relationship between the actual value and the three regions of the gauge.

Example

The following markup:

```
<h3>Suggested groups</h3>
<menu>
 <li><a href="?cmd=hsg" onclick="hideSuggestedGroups()">Hide suggested groups</a></li>
</menu>
<ul>
 <li>
  <p><a href="/group/comp.infosystems.www.authoring.stylesheets/
view">comp.infosystems.www.authoring.stylesheets</a> -
     <a href="/group/comp.infosystems.www.authoring.stylesheets/subscribe">join</a></p>
  <p>Group description: <strong>Layout/presentation on the WWW.</strong></p>
  <p><meter value="0.5">Moderate activity,</meter> Usenet, 618 subscribers</p>
 </li>
 <li>
  <p><a href="/group/netscape.public.mozilla.xpinstall/view">netscape.public.mozilla.xpinstall</a>
-
     <a href="/group/netscape.public.mozilla.xpinstall/subscribe">join</a></p>
  <p>Group description: <strong>Mozilla XPInstall discussion.</strong></p>
  <p><meter value="0.25">Low activity,</meter> Usenet, 22 subscribers</p>
 </li>
 <li>
  <p><a href="/group/mozilla.dev.general/view">mozilla.dev.general</a> -
     <a href="/group/mozilla.dev.general/subscribe">join</a></p>
  <p><meter value="0.25">Low activity,</meter> Usenet, 66 subscribers</p>
 </li>
</ul>
```

Might be rendered as follows:



User agents may combine the value of the title[p158] attribute and the other attributes to provide context-sensitive help or inline text detailing the actual values.

Example

For example, the following snippet:

```
<meter min=0 max=60 value=23.2 title=seconds></meter>
```

...might cause the user agent to display a gauge with a tooltip saying "Value: 23.2 out of 60." on one line and "seconds" on a second line.

The **value** IDL attribute, on getting, must return the actual value[p595]. On setting, the given value must be converted to the best representation of the number as a floating-point number[p79] and then the value[p593] content attribute must be set to that string.

The **min** IDL attribute, on getting, must return the minimum value[p595]. On setting, the given value must be converted to the best representation of the number as a floating-point number[p79] and then the min[p593] content attribute must be set to that string.

The **max** IDL attribute, on getting, must return the maximum value[p595]. On setting, the given value must be converted to the best representation of the number as a floating-point number[p79] and then the max[p593] content attribute must be set to that string.

The **low** IDL attribute, on getting, must return the low boundary[p595]. On setting, the given value must be converted to the best representation of the number as a floating-point number[p79] and then the low[p593] content attribute must be set to that string.

The **high** IDL attribute, on getting, must return the high boundary[p595]. On setting, the given value must be converted to the best representation of the number as a floating-point number[p79] and then the high[p593] content attribute must be set to that string.

The **optimum** IDL attribute, on getting, must return the optimum value[p595]. On setting, the given value must be converted to the best representation of the number as a floating-point number[p79] and then the optimum[p593] content attribute must be set to that string.

The labels[p521] IDL attribute provides a list of the element's label[p519]s.

Example

The following example shows how a gauge could fall back to localized or pretty-printed text.

```
<p>Disk usage: <meter min=0 value=170261928 max=233257824>170 261 928 bytes used
out of 233 257 824 bytes available</meter></p>
```

4.10.15 The fieldset element §[p597]

Categories[p147]:

Flow content[p150].
Listed[p514] and autocapitalize-and-autocorrect inheriting[p515] form-associated element[p514].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

Optionally, a legend[p600] element, followed by flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
disabled[p598] — Whether the descendant form controls, except any inside legend[p600], are disabled
form[p601] — Associates the element with a form[p515] element
name[p603] — Name of the element to use in the form.elements[p517] API.

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]**:**

IDL

```
[Exposed=Window]
interface HTMLFieldSetElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  [CEReactions] attribute DOMString name;

  readonly attribute DOMString type;

  [SameObject] readonly attribute HTMLCollection elements;

  readonly attribute boolean willValidate;
  [SameObject] readonly attribute ValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  undefined setCustomValidity(DOMString error);
};
```

The fieldset[p597] element represents[p142] a set of form controls (or other content) grouped together, optionally with a caption. The caption is given by the first legend[p600] element that is a child of the fieldset[p597] element, if any. The remainder of the descendants form the group.

The **disabled** attribute, when specified, causes all the form control descendants of the fieldset[p597] element, excluding those that are descendants of the fieldset[p597] element's first legend[p600] element child, if any, to be disabled[p605].

A fieldset[p597] element is a **disabled fieldset** if it matches any of the following conditions:

- Its disabled[p598] attribute is specified
- It is a descendant of another fieldset[p597] element whose disabled[p598] attribute is specified, and is *not* a descendant of that fieldset[p597] element's first legend[p600] element child, if any.

The form[p601] attribute is used to explicitly associate the fieldset[p597] element with its form owner[p601]. The name[p603] attribute represents the element's name.

For web developers (non-normative)

***fieldset*.type**[p598]

Returns the string "fieldset".

***fieldset*.elements**[p598]

Returns an HTMLCollection of the form controls in the element.

The **disabled** IDL attribute must reflect[p105] the content attribute of the same name.

The **type** IDL attribute must return the string "`fieldset`".

The **elements** IDL attribute must return an HTMLCollection rooted at the fieldset[p597] element, whose filter matches listed elements[p514].

The willValidate[p629], validity[p629], and validationMessage[p631] attributes, and the checkValidity()[p631], reportValidity()[p631], and setCustomValidity()[p629] methods, are part of the constraint validation API[p628]. The form[p603] and name[p603] IDL attributes are part of the element's forms API.

Example

This example shows a fieldset[p597] element being used to group a set of related controls:

```
<fieldset>
```

```
 <legend>Display</legend>
 <p><label><input type=radio name=c value=0 checked> Black on White</label>
 <p><label><input type=radio name=c value=1> White on Black</label>
 <p><label><input type=checkbox name=g> Use grayscale</label>
 <p><label>Enhance contrast <input type=range name=e list=contrast min=0 max=100 value=0
step=1></label>
 <datalist id=contrast>
  <option label=Normal value=0>
  <option label=Maximum value=100>
 </datalist>
</fieldset>
```

Example

The following snippet shows a fieldset with a checkbox in the legend that controls whether or not the fieldset is enabled. The contents of the fieldset consist of two required text controls and an optional year/month control.

```
<fieldset name="clubfields" disabled>
 <legend> <label>
  <input type=checkbox name=club onchange="form.clubfields.disabled = !checked">
  Use Club Card
 </label> </legend>
 <p><label>Name on card: <input name=clubname required></label></p>
 <p><label>Card number: <input name=clubnum required pattern="[-0-9]+"></label></p>
 <p><label>Expiry date: <input name=clubexp type=month></label></p>
</fieldset>
```

Example

You can also nest fieldset[p597] elements. Here is an example expanding on the previous one that does so:

```
<fieldset name="clubfields" disabled>
 <legend> <label>
  <input type=checkbox name=club onchange="form.clubfields.disabled = !checked">
  Use Club Card
 </label> </legend>
 <p><label>Name on card: <input name=clubname required></label></p>
 <fieldset name="numfields">
  <legend> <label>
   <input type=radio checked name=clubtype onchange="form.numfields.disabled = !checked">
   My card has numbers on it
  </label> </legend>
  <p><label>Card number: <input name=clubnum required pattern="[-0-9]+"></label></p>
 </fieldset>
 <fieldset name="letfields" disabled>
  <legend> <label>
   <input type=radio name=clubtype onchange="form.letfields.disabled = !checked">
   My card has letters on it
  </label> </legend>
  <p><label>Card code: <input name=clublet required pattern="[A-Za-z]+"></label></p>
 </fieldset>
</fieldset>
```

In this example, if the outer "Use Club Card" checkbox is not checked, everything inside the outer fieldset[p597], including the two radio buttons in the legends of the two nested fieldset[p597]s, will be disabled. However, if the checkbox is checked, then the radio buttons will both be enabled and will let you select which of the two inner fieldset[p597]s is to be enabled.

Example

This example shows a grouping of controls where the legend element both labels the grouping, and the nested heading element surfaces the grouping in the document outline:

```
<fieldset>
 <legend> <h2>
  How can we best reach you?
 </h2> </legend>
 <p> <label>
 <input type=radio checked name=contact_pref>
  Phone
 </label> </p>
 <p> <label>
  <input type=radio name=contact_pref>
  Text
 </label> </p>
 <p> <label>
  <input type=radio name=contact_pref>
  Email
 </label> </p>
</fieldset>
```

4.10.16 The legend element

Categories:

None.

Contexts in which this element can be used:

As the first child of a fieldset element.

Content model:

Phrasing content, optionally intermixed with heading content.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes

Accessibility considerations:

For authors.
For implementers.

DOM interface:

IDL

```
[Exposed=Window]
interface HTMLLegendElement : HTMLElement {
  [HTMLConstructor] constructor();

  readonly attribute HTMLFormElement? form;

  // also has obsolete members
};
```

The legend element represents a caption for the rest of the contents of the legend element's parent fieldset element, if any.

For web developers (non-normative)

***legend*.form**

Returns the element's form element, if any, or null otherwise.

The **form** IDL attribute's behavior depends on whether the legend element is in a fieldset element or not. If the legend has a fieldset element as its parent, then the form IDL attribute must return the same value as the form IDL attribute on that fieldset element. Otherwise, it must return null.

4.10.17 Form control infrastructure

4.10.17.1 A form control's value

Most form controls have a **value** and a **checkedness**. (The latter is only used by input elements.) These are used to describe how the user interacts with the control.

A control's value is its internal state. As such, it might not match the user's current input.

Example

For instance, if a user enters the word "three" into a numeric field that expects digits, the user's input would be the string "three" but the control's value would remain unchanged. Or, if a user enters the email address " awesome@example.com" (with leading whitespace) into an email field, the user's input would be the string " awesome@example.com" but the browser's UI for email fields might translate that into a value of "awesome@example.com" (without the leading whitespace).

input and textarea elements have a **dirty value flag**. This is used to track the interaction between the value and default value. If it is false, value mirrors the default value. If it is true, the default value is ignored.

Some form controls also have an **optional value** this largely mirrors the value but doesn't normalize to an empty string.
Note *This ought to be used sparingly, you generally want value.*

input, textarea, and select elements have a **user validity** boolean. It is initially set to false.

To define the behavior of constraint validation in the face of the input element's multiple attribute, input elements can also have separately defined **values**.

To define the behavior of the maxlength and minlength attributes, as well as other APIs specific to the textarea element, all form control with a value also have an algorithm for obtaining an **API value**. By default this algorithm is to simply return the control's value.

The select element does not have a value; the selectedness of its option elements is what is used instead.

4.10.17.2 Mutability

A form control can be designated as ***mutable***.

Note

This determines (by means of definitions and requirements in this specification that rely on whether an element is so designated) whether or not the user can modify the value or checkedness of a form control, or whether or not a control can be automatically prefilled.

4.10.17.3 Association of controls and forms

A form-associated element can have a relationship with a form element, which is called the element's **form owner**. If a form-associated element is not associated with a form element, its form owner is said to be null.

A form-associated element has an associated **parser inserted flag**.

A form-associated element is, by default, associated with its nearest ancestor form element (as described below), but, if it is listed, may have a **form** attribute specified to override this.

Note

This feature allows authors to work around the lack of support for nested `form` elements.

If a listed form-associated element has a `form` attribute specified, then that attribute's value must be the ID of a `form` element in the element's tree.

Note

The rules in this section are complicated by the fact that although conforming documents or trees will never contain nested `form` elements, it is quite possible (e.g., using a script that performs DOM manipulation) to generate trees that have such nested elements. They are also complicated by rules in the HTML parser that, for historical reasons, can result in a form-associated element being associated with a `form` element that is not its ancestor.

When a form-associated element is created, its form owner must be initialized to null (no owner).

When a form-associated element is to be **associated** with a form, its form owner must be set to that form.

When a listed form-associated element's `form` attribute is set, changed, or removed, then the user agent must reset the form owner of that element.

When a listed form-associated element has a `form` attribute and the ID of any of the elements in the tree changes, then the user agent must reset the form owner of that form-associated element.

When a listed form-associated element has a `form` attribute and an element with an ID is inserted into or removed from the `Document`, or its HTML element moving steps are run, then the user agent must reset the form owner of that form-associated element.

Note

The form owner is also reset by the HTML element insertion steps, HTML element removing steps, and HTML element moving steps.

To **reset the form owner** of a form-associated element *element*:

1. Unset *element*'s parser inserted flag.
2. If all of the following are true:
   - *element*'s form owner is not null;
   - *element* is not listed or its `form` content attribute is not present; and
   - *element*'s form owner is its nearest `form` element ancestor after the change to the ancestor chain,

   then return.
3. Set *element*'s form owner to null.
4. If *element* is listed, has a `form` content attribute, and is connected, then:
   1. If the first element in *element*'s tree, in tree order, to have an ID that is identical to *element*'s `form` content attribute's value, is a `form` element, then associate the *element* with that `form` element.
5. Otherwise, if *element* has an ancestor `form` element, then associate *element* with the nearest such ancestor `form` element.

Example

In the following non-conforming snippet

```
...
 <form id="a">
  <div id="b"></div>
 </form>
 <script>
```

```
  document.getElementById('b').innerHTML =
     '<table><tr><td></form><form id="c"><input id="d"></table>' +
     '<input id="e">';
 </script>
...
```

the form owner[p601] of "d" would be the inner nested form "c", while the form owner[p601] of "e" would be the outer form "a".

This happens as follows: First, the "e" node gets associated with "c" in the HTML parser[p1289]. Then, the `innerHTML`[p1172] algorithm moves the nodes from the temporary document to the "b" element. At this point, the nodes see their ancestor chain change, and thus all the "magic" associations done by the parser are reset to normal ancestor associations.

This example is a non-conforming document, though, as it is a violation of the content models to nest `form`[p515] elements, and there is a parse error[p1291] for the `</form>` tag.

For web developers (non-normative)

***element*.form**[p603]

Returns the element's form owner[p601].

Returns null if there isn't one.

Listed[p514] form-associated elements[p514] except for form-associated custom elements[p767] have a **form** IDL attribute, which, on getting, must return the element's form owner[p601], or null if there isn't one.

Form-associated custom elements[p767] don't have `form`[p603] IDL attribute. Instead, their `ElementInternals`[p779] object has a **form** IDL attribute. On getting, it must throw a `"NotSupportedError"` `DOMException` if the target element[p780] is not a form-associated custom element[p767]. Otherwise, it must return the element's form owner[p601], or null if there isn't one.

4.10.18 Attributes common to form controls §[p603]

4.10.18.1 Naming form controls: the `name`[p603] attribute §[p603]

The **name** content attribute gives the name of the form control, as used in form submission[p632] and in the `form`[p515] element's `elements`[p517] object. If the attribute is specified, its value must not be the empty string or `isindex`.

Note

A number of user agents historically implemented special support for first-in-form text controls with the name `isindex`, and this specification previously defined related user agent requirements for it. However, some user agents subsequently dropped that special support, and the related requirements were removed from this specification. So, to avoid problematic reinterpretations in legacy user agents, the name `isindex` is no longer allowed.

Other than `isindex`, any non-empty value for `name`[p516] is allowed. An ASCII case-insensitive match for the name **_charset_** is special: if used as the name of a Hidden[p528] control with no `value`[p526] attribute, then during submission the `value`[p526] attribute is automatically given a value consisting of the submission character encoding.

The **name** IDL attribute must reflect[p105] the `name`[p603] content attribute.

Note

DOM clobbering is a common cause of security issues. Avoid using the names of built-in form properties with the `name`[p603] content attribute.

In this example, the `input`[p521] element overrides the built-in `method`[p606] property:

```
let form = document.createElement("form");
let input = document.createElement("input");
form.appendChild(input);
```

```
form.method;           // => "get"
input.name = "method"; // DOM clobbering occurs here
form.method === input; // => true
```

Since the input name takes precedence over built-in form properties, the JavaScript reference `form.method` *will point to the* input[p521] *element named "method" instead of the built-in* method[p606] *property.*

4.10.18.2 Submitting element directionality: the dirname[p604] attribute §[p60 4]

The **dirname** attribute on a form control element enables the submission of the directionality[p161] of the element, and gives the name of the control that contains this value during form submission[p632]. If such an attribute is specified, its value must not be the empty string.

Example

In this example, a form contains a text control and a submission button:

```
<form action="addcomment.cgi" method=post>
 <p><label>Comment: <input type=text name="comment" dirname="comment.dir" required></label></p>
 <p><button name="mode" type=submit value="add">Post Comment</button></p>
</form>
```

When the user submits the form, the user agent includes three fields, one called "comment", one called "comment.dir", and one called "mode"; so if the user types "Hello", the submission body might be something like:

```
comment=Hello&comment.dir=ltr&mode=add
```

If the user manually switches to a right-to-left writing direction and enters "مرحبا", the submission body might be something like:

```
comment=%D9%85%D8%B1%D8%AD%D8%A8%D8%A7&comment.dir=rtl&mode=add
```

4.10.18.3 Limiting user input length: the maxlength[p604] attribute §[p60 4]

A **form control maxlength attribute**, controlled by the dirty value flag[p601], declares a limit on the number of characters a user can input. The number of characters is measured using length and, in the case of textarea[p583] elements, with all newlines normalized to a single character (as opposed to CRLF pairs).

If an element has its form control maxlength attribute[p604] specified, the attribute's value must be a valid non-negative integer[p78]. If the attribute is specified and applying the rules for parsing non-negative integers[p78] to its value results in a number, then that number is the element's **maximum allowed value length**. If the attribute is omitted or parsing its value results in an error, then there is no maximum allowed value length[p604].

Constraint validation: If an element has a maximum allowed value length[p604], its dirty value flag[p601] is true, its value[p601] was last changed by a user edit (as opposed to a change made by a script), and the length of the element's API value[p601] is greater than the element's maximum allowed value length[p604], then the element is suffering from being too long[p627].

User agents may prevent the user from causing the element's API value[p601] to be set to a value whose length is greater than the element's maximum allowed value length[p604].

Note

In the case of textarea[p583] *elements, the API value[p601] and value[p601] differ. In particular, newline normalization is applied before the maximum allowed value length[p604] is checked (whereas the textarea wrapping transformation[p586] is not applied).*

4.10.18.4 Setting minimum input length requirements: the `minlength` attribute

A **form control `minlength` attribute**, controlled by the dirty value flag, declares a lower bound on the number of characters a user can input. The "number of characters" is measured using length and, in the case of `textarea` elements, with all newlines normalized to a single character (as opposed to CRLF pairs).

Note

The `minlength` attribute does not imply the `required` attribute. If the form control has no `required` attribute, then the value can still be omitted; the `minlength` attribute only kicks in once the user has entered a value at all. If the empty string is not allowed, then the `required` attribute also needs to be set.

If an element has its form control `minlength` attribute specified, the attribute's value must be a valid non-negative integer. If the attribute is specified and applying the rules for parsing non-negative integers to its value results in a number, then that number is the element's **minimum allowed value length**. If the attribute is omitted or parsing its value results in an error, then there is no minimum allowed value length.

If an element has both a maximum allowed value length and a minimum allowed value length, the minimum allowed value length must be smaller than or equal to the maximum allowed value length.

Constraint validation: If an element has a minimum allowed value length, its dirty value flag is true, its value was last changed by a user edit (as opposed to a change made by a script), its value is not the empty string, and the length of the element's API value is less than the element's minimum allowed value length, then the element is suffering from being too short.

Example

In this example, there are four text controls. The first is required, and has to be at least 5 characters long. The other three are optional, but if the user fills one in, the user has to enter at least 10 characters.

```
<form action="/events/menu.cgi" method="post">
 <p><label>Name of Event: <input required minlength=5 maxlength=50 name=event></label></p>
 <p><label>Describe what you would like for breakfast, if anything:
    <textarea name="breakfast" minlength="10"></textarea></label></p>
 <p><label>Describe what you would like for lunch, if anything:
    <textarea name="lunch" minlength="10"></textarea></label></p>
 <p><label>Describe what you would like for dinner, if anything:
    <textarea name="dinner" minlength="10"></textarea></label></p>
 <p><input type=submit value="Submit Request"></p>
</form>
```

4.10.18.5 Enabling and disabling form controls: the `disabled` attribute

The **`disabled`** content attribute is a boolean attribute.

Note

The `disabled` attribute for `option` elements and the `disabled` attribute for `optgroup` elements are defined separately.

A form control is **disabled** if any of the following are true:

- the element is a `button`, `input`, `select`, `textarea`, or form-associated custom element, and the `disabled` attribute is specified on this element (regardless of its value); or
- the element is a descendant of a `fieldset` element whose `disabled` attribute is specified, and is *not* a descendant of that `fieldset` element's first `legend` element child, if any.

A form control that is disabled must prevent any `click` events that are queued on the user interaction task source from being dispatched on the element.

Note

Being disabled[p605] does not prevent all modifications to the form control. For example, the control's value[p601] or checkedness[p601] could be modified programmatically from JavaScript. Or, they could be indirectly modified by user action, e.g., if other non-disabled elements in the control's radio button group[p544] were modified.

Constraint validation: If an element is disabled[p605], it is barred from constraint validation[p626].

The **disabled** IDL attribute must reflect[p105] the disabled[p605] content attribute.

4.10.18.6 Form submission attributes §[p606]

Attributes for form submission can be specified both on form[p515] elements and on submit buttons[p515] (elements that represent buttons that submit forms, e.g. an input[p521] element whose type[p524] attribute is in the Submit Button[p548] state).

The attributes for form submission[p606] that may be specified on form[p515] elements are action[p606], enctype[p607], method[p606], novalidate[p607], and target[p607].

The corresponding attributes for form submission[p606] that may be specified on submit buttons[p515] are formaction[p606], formenctype[p607], formmethod[p606], formnovalidate[p607], and formtarget[p607]. When omitted, they default to the values given on the corresponding attributes on the form[p515] element.

The **action** and **formaction** content attributes, if specified, must have a value that is a valid non-empty URL potentially surrounded by spaces[p97].

The **action** of an element is the value of the element's formaction[p606] attribute, if the element is a submit button[p515] and has such an attribute, or the value of its form owner[p601]'s action[p606] attribute, if *it* has one, or else the empty string.

The **method** and **formmethod** content attributes are enumerated attributes[p77] with the following keywords and states:

Keyword	State	Brief description
get	**GET**	Indicates the form[p515] will use the HTTP GET method.
post	**POST**	Indicates the form[p515] will use the HTTP POST method.
dialog	**Dialog**	Indicates the form[p515] is intended to close the dialog[p650] box in which the form finds itself, if any, and otherwise not submit.

The method[p606] attribute's *missing value default*[p77] and *invalid value default*[p77] are both the GET[p606] state.

The formmethod[p606] attribute has no *missing value default*[p77], and its *invalid value default*[p77] is the GET[p606] state.

The **method** of an element is one of those states. If the element is a submit button[p515] and has a formmethod[p606] attribute, then the element's method[p606] is that attribute's state; otherwise, it is the form owner[p601]'s method[p606] attribute's state.

Example

Here the method[p606] attribute is used to explicitly specify the default value, "get[p606]", so that the search query is submitted in the URL:

```
<form method="get" action="/search.cgi">
 <p><label>Search terms: <input type=search name=q></label></p>
 <p><input type=submit></p>
</form>
```

Example

On the other hand, here the method[p606] attribute is used to specify the value "post[p606]", so that the user's message is submitted in the HTTP request's body:

```
<form method="post" action="/post-message.cgi">
 <p><label>Message: <input type=text name=m></label></p>
```

```
 <p><input type=submit value="Submit message"></p>
</form>
```

Example

In this example, a form[p515] is used with a dialog[p650]. The method[p606] attribute's "dialog[p606]" keyword is used to have the dialog automatically close when the form is submitted.

```
<dialog id="ship">
 <form method=dialog>
  <p>A ship has arrived in the harbour.</p>
  <button type=submit value="board">Board the ship</button>
  <button type=submit value="call">Call to the captain</button>
 </form>
</dialog>
<script>
 var ship = document.getElementById('ship');
 ship.showModal();
 ship.onclose = function (event) {
   if (ship.returnValue == 'board') {
     // ...
   } else {
     // ...
   }
 };
</script>
```

The **enctype** and **formenctype** content attributes are enumerated attributes[p77] with the following keywords and states:

- The "**application/x-www-form-urlencoded**" keyword and corresponding state.
- The "**multipart/form-data**" keyword and corresponding state.
- The "**text/plain**" keyword and corresponding state.

The attribute's *missing value default*[p77] and *invalid value default*[p77] are both the application/x-www-form-urlencoded[p607] state.

The formenctype[p607] attribute has no *missing value default*[p77], and its *invalid value default*[p77] is the application/x-www-form-urlencoded[p607] state.

The **enctype** of an element is one of those three states. If the element is a submit button[p515] and has a formenctype[p607] attribute, then the element's enctype[p607] is that attribute's state; otherwise, it is the form owner[p601]'s enctype[p607] attribute's state.

The **target** and **formtarget** content attributes, if specified, must have values that are valid navigable target names or keywords[p1009].

The **novalidate** and **formnovalidate** content attributes are boolean attributes[p76]. If present, they indicate that the form is not to be validated during submission.

The **no-validate state** of an element is true if the element is a submit button[p515] and the element's formnovalidate[p607] attribute is present, or if the element's form owner[p601]'s novalidate[p607] attribute is present, and false otherwise.

Example

This attribute is useful to include "save" buttons on forms that have validation constraints, to allow users to save their progress even though they haven't fully entered the data in the form. The following example shows a simple form that has two required fields. There are three buttons: one to submit the form, which requires both fields to be filled in; one to save the form so that the user can come back and fill it in later; and one to cancel the form altogether.

```
<form action="editor.cgi" method="post">
 <p><label>Name: <input required name=fn></label></p>
 <p><label>Essay: <textarea required name=essay></textarea></label></p>
 <p><input type=submit name=submit value="Submit essay"></p>
 <p><input type=submit formnovalidate name=save value="Save essay"></p>
 <p><input type=submit formnovalidate name=cancel value="Cancel"></p>
</form>
```

The **action** IDL attribute must reflect[p105] the content attribute of the same name, except that on getting, when the content attribute is missing or its value is the empty string, the element's node document's URL must be returned instead. The **target** IDL attribute must reflect[p105] the content attribute of the same name. The **method** and **enctype** IDL attributes must reflect[p105] the respective content attributes of the same name, limited to only known values[p106]. The **encoding** IDL attribute must reflect[p105] the enctype[p607] content attribute, limited to only known values[p106]. The **noValidate** IDL attribute must reflect[p105] the novalidate[p607] content attribute. The **formAction** IDL attribute must reflect[p105] the formaction[p606] content attribute, except that on getting, when the content attribute is missing or its value is the empty string, the element's node document's URL must be returned instead. The **formEnctype** IDL attribute must reflect[p105] the formenctype[p607] content attribute, limited to only known values[p106]. The **formMethod** IDL attribute must reflect[p105] the formmethod[p606] content attribute, limited to only known values[p106]. The **formNoValidate** IDL attribute must reflect[p105] the formnovalidate[p607] content attribute. The **formTarget** IDL attribute must reflect[p105] the formtarget[p607] content attribute.

4.10.18.7 Autofill §[p608]

4.10.18.7.1 Autofilling form controls: the autocomplete[p608] attribute §[p608]

User agents sometimes have features for helping users fill forms in, for example prefilling the user's address based on earlier user input. The **autocomplete** content attribute can be used to hint to the user agent how to, or indeed whether to, provide such a feature.

There are two ways this attribute is used. When wearing the **autofill expectation mantle**, the autocomplete[p608] attribute describes what input is expected from users. When wearing the **autofill anchor mantle**, the autocomplete[p608] attribute describes the meaning of the given value.

On an input[p521] element whose type[p524] attribute is in the Hidden[p528] state, the autocomplete[p608] attribute wears the autofill anchor mantle[p608]. In all other cases, it wears the autofill expectation mantle[p608].

When wearing the autofill expectation mantle[p608], the autocomplete[p608] attribute, if specified, must have a value that is an ordered set of space-separated tokens[p96] consisting of either a single token that is an ASCII case-insensitive match for the string "off[p610]", or a single token that is an ASCII case-insensitive match for the string "on[p610]", or autofill detail tokens[p608].

When wearing the autofill anchor mantle[p608], the autocomplete[p608] attribute, if specified, must have a value that is an ordered set of space-separated tokens[p96] consisting of just autofill detail tokens[p608] (i.e. the "on[p610]" and "off[p610]" keywords are not allowed).

Autofill detail tokens are the following, in the order given below:

1. Optionally, a token whose first eight characters are an ASCII case-insensitive match for the string "**section-**", meaning that the field belongs to the named group.

   Example

   For example, if there are two shipping addresses in the form, then they could be marked up as:

   ```
   <fieldset>
    <legend>Ship the blue gift to...</legend>
    <p> <label> Address:     <textarea name=ba autocomplete="section-blue shipping street-
   address"></textarea> </label>
    <p> <label> City:        <input name=bc autocomplete="section-blue shipping address-
   level2"> </label>
    <p> <label> Postal Code: <input name=bp autocomplete="section-blue shipping postal-code">
   </label>
   </fieldset>
   <fieldset>
   ```

```
 <legend>Ship the red gift to...</legend>
 <p> <label> Address:     <textarea name=ra autocomplete="section-red shipping street-
address"></textarea> </label>
 <p> <label> City:        <input name=rc autocomplete="section-red shipping address-
level2"> </label>
 <p> <label> Postal Code: <input name=rp autocomplete="section-red shipping postal-code">
</label>
</fieldset>
```

2. Optionally, a token that is an ASCII case-insensitive match for one of the following strings:

    - "**shipping**", meaning the field is part of the shipping address or contact information
    - "**billing**", meaning the field is part of the billing address or contact information

3. Either of the following two options:

    - A token that is an ASCII case-insensitive match for one of the following autofill field[p610] names, excluding those that are inappropriate for the control[p611]:

        - "name[p611]"
        - "honorific-prefix[p611]"
        - "given-name[p611]"
        - "additional-name[p611]"
        - "family-name[p611]"
        - "honorific-suffix[p611]"
        - "nickname[p611]"
        - "username[p611]"
        - "new-password[p611]"
        - "current-password[p611]"
        - "one-time-code[p611]"
        - "organization-title[p611]"
        - "organization[p611]"
        - "street-address[p611]"
        - "address-line1[p611]"
        - "address-line2[p611]"
        - "address-line3[p611]"
        - "address-level4[p611]"
        - "address-level3[p611]"
        - "address-level2[p611]"
        - "address-level1[p611]"
        - "country[p611]"
        - "country-name[p612]"
        - "postal-code[p612]"
        - "cc-name[p612]"
        - "cc-given-name[p612]"
        - "cc-additional-name[p612]"
        - "cc-family-name[p612]"
        - "cc-number[p612]"
        - "cc-exp[p612]"
        - "cc-exp-month[p612]"
        - "cc-exp-year[p612]"
        - "cc-csc[p612]"
        - "cc-type[p612]"
        - "transaction-currency[p612]"
        - "transaction-amount[p612]"
        - "language[p612]"
        - "bday[p612]"
        - "bday-day[p612]"
        - "bday-month[p612]"
        - "bday-year[p612]"
        - "sex[p612]"
        - "url[p612]"
        - "photo[p612]"

      (See the table below for descriptions of these values.)

    - The following, in the given order:

        1. Optionally, a token that is an ASCII case-insensitive match for one of the following strings:

            - "**home**", meaning the field is for contacting someone at their residence
            - "**work**", meaning the field is for contacting someone at their workplace

- "**mobile**", meaning the field is for contacting someone regardless of location
- "**fax**", meaning the field describes a fax machine's contact details
- "**pager**", meaning the field describes a pager's or beeper's contact details

2. A token that is an ASCII case-insensitive match for one of the following autofill field[p610] names, excluding those that are inappropriate for the control[p611]:

   - "tel[p612]"
   - "tel-country-code[p612]"
   - "tel-national[p612]"
   - "tel-area-code[p612]"
   - "tel-local[p612]"
   - "tel-local-prefix[p612]"
   - "tel-local-suffix[p613]"
   - "tel-extension[p613]"
   - "email[p613]"
   - "impp[p613]"

   (See the table below for descriptions of these values.)

4. Optionally, a token that is an ASCII case-insensitive match for the string "**webauthn**", meaning the user agent should show public key credentials available via conditional mediation when the user interacts with the form control. webauthn[p610] is only valid for input[p521] and textarea[p583] elements.

As noted earlier, the meaning of the attribute and its keywords depends on the mantle that the attribute is wearing.

↪ **When wearing the autofill expectation mantle[p608]...**

The "**off**" keyword indicates either that the control's input data is particularly sensitive (for example the activation code for a nuclear weapon); or that it is a value that will never be reused (for example a one-time-key for a bank login) and the user will therefore have to explicitly enter the data each time, instead of being able to rely on the UA to prefill the value for them; or that the document provides its own autocomplete mechanism and does not want the user agent to provide autocompletion values.

The "**on**" keyword indicates that the user agent is allowed to provide the user with autocompletion values, but does not provide any further information about what kind of data the user might be expected to enter. User agents would have to use heuristics to decide what autocompletion values to suggest.

The autofill field[p610] listed above indicate that the user agent is allowed to provide the user with autocompletion values, and specifies what kind of value is expected. The meaning of each such keyword is described in the table below.

If the autocomplete[p608] attribute is omitted, the default value corresponding to the state of the element's form owner[p601]'s autocomplete[p516] attribute is used instead (either "on[p610]" or "off[p610]"). If there is no form owner[p601], then the value "on[p610]" is used.

↪ **When wearing the autofill anchor mantle[p608]...**

The autofill field[p610] listed above indicate that the value of the particular kind of value specified is that value provided for this element. The meaning of each such keyword is described in the table below.

Example

In this example the page has explicitly specified the currency and amount of the transaction. The form requests a credit card and other billing details. The user agent could use this information to suggest a credit card that it knows has sufficient balance and that supports the relevant currency.

```
<form method=post action="step2.cgi">
 <input type=hidden autocomplete=transaction-currency value="CHF">
 <input type=hidden autocomplete=transaction-amount value="15.00">
 <p><label>Credit card number: <input type=text inputmode=numeric autocomplete=cc-
number></label>
 <p><label>Expiry Date: <input type=month autocomplete=cc-exp></label>
 <p><input type=submit value="Continue...">
</form>
```

The **autofill field** keywords relate to each other as described in the table below. Each field name listed on a row of this table corresponds to the meaning given in the cell for that row in the column labeled "Meaning". Some fields correspond to subparts of other fields; for example, a credit card expiry date can be expressed as one field giving both the month and year of expiry ("cc-exp[p612]"), or as two fields, one giving the month ("cc-exp-month[p612]") and one the year ("cc-exp-year[p612]"). In such cases, the names of the

broader fields cover multiple rows, in which the narrower fields are defined.

Note

Generally, authors are encouraged to use the broader fields rather than the narrower fields, as the narrower fields tend to expose Western biases. For example, while it is common in some Western cultures to have a given name and a family name, in that order (and thus often referred to as a first name *and a* surname*), many cultures put the family name first and the given name second, and many others simply have one name (a* mononym*). Having a single field is therefore more flexible.*

Some fields are only appropriate for certain form controls. An autofill field[p610] name is **inappropriate for a control** if the control does not belong to the group listed for that autofill field[p610] in the fifth column of the first row describing that autofill field[p610] in the table below. What controls fall into each group is described below the table.

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"**name**"	Full name	Free-form text, no newlines	Sir Timothy John Berners-Lee, OM, KBE, FRS, FREng, FRSA	Text[p613]
"**honorific-prefix**"	Prefix or title (e.g. "Mr.", "Ms.", "Dr.", "M^{lle}")	Free-form text, no newlines	Sir	Text[p613]
"**given-name**"	Given name (in some Western cultures, also known as the *first name*)	Free-form text, no newlines	Timothy	Text[p613]
"**additional-name**"	Additional names (in some Western cultures, also known as *middle names*, forenames other than the first name)	Free-form text, no newlines	John	Text[p613]
"**family-name**"	Family name (in some Western cultures, also known as the *last name* or *surname*)	Free-form text, no newlines	Berners-Lee	Text[p613]
"**honorific-suffix**"	Suffix (e.g. "Jr.", "B.Sc.", "MBASW", "II")	Free-form text, no newlines	OM, KBE, FRS, FREng, FRSA	Text[p613]
"**nickname**"	Nickname, screen name, handle: a typically short name used instead of the full name	Free-form text, no newlines	Tim	Text[p613]
"**organization-title**"	Job title (e.g. "Software Engineer", "Senior Vice President", "Deputy Managing Director")	Free-form text, no newlines	Professor	Text[p613]
"**username**"	A username	Free-form text, no newlines	timbl	Username[p613]
"**new-password**"	A new password (e.g. when creating an account or changing a password)	Free-form text, no newlines	GUMFXbadyrS3	Password[p613]
"**current-password**"	The current password for the account identified by the username[p611] field (e.g. when logging in)	Free-form text, no newlines	qwerty	Password[p613]
"**one-time-code**"	One-time code used for verifying user identity	Free-form text, no newlines	123456	Password[p613]
"**organization**"	Company name corresponding to the person, address, or contact information in the other fields associated with this field	Free-form text, no newlines	World Wide Web Consortium	Text[p613]
"**street-address**"	Street address (multiple lines, newlines preserved)	Free-form text	32 Vassar Street MIT Room 32-G524	Multiline[p613]
"**address-line1**"	Street address (one line per field)	Free-form text, no newlines	32 Vassar Street	Text[p613]
"**address-line2**"		Free-form text, no newlines	MIT Room 32-G524	Text[p613]
"**address-line3**"		Free-form text, no newlines		Text[p613]
"**address-level4**"	The most fine-grained administrative level[p614], in addresses with four administrative levels	Free-form text, no newlines		Text[p613]
"**address-level3**"	The third administrative level[p614], in addresses with three or more administrative levels	Free-form text, no newlines		Text[p613]
"**address-level2**"	The second administrative level[p614], in addresses with two or more administrative levels; in the countries with two administrative levels, this would typically be the city, town, village, or other locality within which the relevant street address is found	Free-form text, no newlines	Cambridge	Text[p613]
"**address-level1**"	The broadest administrative level[p614] in the address, i.e. the province within which the locality is found; for example, in the US, this would be the state; in Switzerland it would be the canton; in the UK, the post town	Free-form text, no newlines	MA	Text[p613]
"**country**"	Country code	Valid ISO 3166-1-alpha-2 country code [ISO3166][p1497]	US	Text[p613]

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"country-name"	Country name	Free-form text, no newlines; derived from country in some cases[p619]	US	Text[p613]
"postal-code"	Postal code, post code, ZIP code, CEDEX code (if CEDEX, append "CEDEX", and the *arrondissement*, if relevant, to the address-level2[p611] field)	Free-form text, no newlines	02139	Text[p613]
"cc-name"	Full name as given on the payment instrument	Free-form text, no newlines	Tim Berners-Lee	Text[p613]
"cc-given-name"	Given name as given on the payment instrument (in some Western cultures, also known as the *first name*)	Free-form text, no newlines	Tim	Text[p613]
"cc-additional-name"	Additional names given on the payment instrument (in some Western cultures, also known as *middle names*, forenames other than the first name)	Free-form text, no newlines		Text[p613]
"cc-family-name"	Family name given on the payment instrument (in some Western cultures, also known as the *last name* or *surname*)	Free-form text, no newlines	Berners-Lee	Text[p613]
"cc-number"	Code identifying the payment instrument (e.g. the credit card number)	ASCII digits	4114360123456785	Text[p613]
"cc-exp"	Expiration date of the payment instrument	Valid month string[p83]	2014-12	Month[p614]
"cc-exp-month"	Month component of the expiration date of the payment instrument	Valid integer[p78] in the range 1..12	12	Numeric[p613]
"cc-exp-year"	Year component of the expiration date of the payment instrument	Valid integer[p78] greater than zero	2014	Numeric[p613]
"cc-csc"	Security code for the payment instrument (also known as the card security code (CSC), card validation code (CVC), card verification value (CVV), signature panel code (SPC), credit card ID (CCID), etc.)	ASCII digits	419	Text[p613]
"cc-type"	Type of payment instrument	Free-form text, no newlines	Visa	Text[p613]
"transaction-currency"	The currency that the user would prefer the transaction to use	ISO 4217 currency code [ISO4217][p1497]	GBP	Text[p613]
"transaction-amount"	The amount that the user would like for the transaction (e.g. when entering a bid or sale price)	Valid floating-point number[p78]	401.00	Numeric[p613]
"language"	Preferred language	Valid BCP 47 language tag [BCP47][p1493]	en	Text[p613]
"bday"	Birthday	Valid date string[p84]	1955-06-08	Date[p614]
"bday-day"	Day component of birthday	Valid integer[p78] in the range 1..31	8	Numeric[p613]
"bday-month"	Month component of birthday	Valid integer[p78] in the range 1..12	6	Numeric[p613]
"bday-year"	Year component of birthday	Valid integer[p78] greater than zero	1955	Numeric[p613]
"sex"	Gender identity (e.g. Female, Fa'afafine)	Free-form text, no newlines	Male	Text[p613]
"url"	Home page or other web page corresponding to the company, person, address, or contact information in the other fields associated with this field	Valid URL string	https://www.w3.org/People/Berners-Lee/	URL[p613]
"photo"	Photograph, icon, or other image corresponding to the company, person, address, or contact information in the other fields associated with this field	Valid URL string	https://www.w3.org/Press/Stock/Berners-Lee/2001-europaeum-eighth.jpg	URL[p613]
"tel"	Full telephone number, including country code	ASCII digits and U+0020 SPACE characters, prefixed by a U+002B PLUS SIGN character (+)	+1 617 253 5702	Tel[p613]
"tel-country-code"	Country code component of the telephone number	ASCII digits prefixed by a U+002B PLUS SIGN character (+)	+1	Text[p613]
"tel-national"	Telephone number without the county code component, with a country-internal prefix applied if applicable	ASCII digits and U+0020 SPACE characters	617 253 5702	Text[p613]
"tel-area-code"	Area code component of the telephone number, with a country-internal prefix applied if applicable	ASCII digits	617	Text[p613]
"tel-local"	Telephone number without the country code and area code components	ASCII digits	2535702	Text[p613]
"tel-local-"	First part of the component of the telephone number that follows the area code, when that component is split into two components	ASCII digits	253	Text[p613]

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"prefix"				
"tel-local-suffix"	Second part of the component of the telephone number that follows the area code, when that component is split into two components	ASCII digits	5702	Text[p613]
"tel-extension"	Telephone number internal extension code	ASCII digits	1000	Text[p613]
"email"	Email address	Valid email address[p532]	timbl@w3.org	Username[p613]
"impp"	URL representing an instant messaging protocol endpoint (for example, "aim:goim?screenname=example" or "xmpp:fred@example.net")	Valid URL string	irc://example.org/timbl,isuser	URL[p613]

The groups correspond to controls as follows:

Text

input[p521] elements with a type[p524] attribute in the Hidden[p528] state
input[p521] elements with a type[p524] attribute in the Text[p529] state
input[p521] elements with a type[p524] attribute in the Search[p529] state
textarea[p583] elements
select[p572] elements

Multiline

input[p521] elements with a type[p524] attribute in the Hidden[p528] state
textarea[p583] elements
select[p572] elements

Password

input[p521] elements with a type[p524] attribute in the Hidden[p528] state
input[p521] elements with a type[p524] attribute in the Text[p529] state

Address levels: The "address-level1[p611]" – "address-level4[p611]" fields are used to describe the locality of the street address. Different locales have different numbers of levels. For example, the US uses two levels (state and town), the UK uses one or two depending on the address (the post town, and in some cases the locality), and China can use three (province, city, district). The "address-level1[p611]" field represents the widest administrative division. Different locales order the fields in different ways; for example, in the US the town (level 2) precedes the state (level 1); while in Japan the prefecture (level 1) precedes the city (level 2) which precedes the district (level 3). Authors are encouraged to provide forms that are presented in a way that matches the country's conventions (hiding, showing, and rearranging fields accordingly as the user changes the country).

4.10.18.7.2 Processing model §[p614]

Each input[p521] element to which the autocomplete[p608] attribute applies[p524], each select[p572] element, and each textarea[p583] element, has an **autofill hint set**, an **autofill scope**, an **autofill field name**, a **non-autofill credential type**, and an **IDL-exposed autofill value**.

The autofill field name[p614] specifies the specific kind of data expected in the field, e.g. "street-address[p611]" or "cc-exp[p612]".

The autofill hint set[p614] identifies what address or contact information type the user agent is to look at, e.g. "shipping[p609] fax[p610]" or "billing[p609]".

The non-autofill credential type[p614] identifies a type of credential that may be offered by the user agent when the user interacts with the field alongside other autofill field[p610] values. If this value is "webauthn" instead of null, selecting a credential of that type will resolve a pending conditional mediation navigator.credentials.get() request, instead of autofilling the field.

Example

For example, a sign-in page could instruct the user agent to either autofill a saved password, or show a public key credential that will resolve a pending navigator.credentials.get() request. A user can select either to sign-in.

```
<input name=password type=password autocomplete="current-password webauthn">
```

The autofill scope[p614] identifies the group of fields whose information concerns the same subject, and consists of the autofill hint set[p614] with, if applicable, the "section-*" prefix, e.g. "billing", "section-parent shipping", or "section-child shipping home".

These values are defined as the result of running the following algorithm:

1. If the element has no autocomplete[p608] attribute, then jump to the step labeled *default*.
2. Let *tokens* be the result of splitting the attribute's value on ASCII whitespace.
3. If *tokens* is empty, then jump to the step labeled *default*.
4. Let *index* be the index of the last token in *tokens*.
5. Let *field* be the *index*th token in *tokens*.
6. Set the *category*, *maximum tokens* pair to the result of determining a field's category[p616] given *field*.

7. If *category* is null, then jump to the step labeled *default*.
8. If the number of tokens in *tokens* is greater than *maximum tokens*, then jump to the step labeled *default*.
9. If *category* is Off or Automatic but the element's `autocomplete`[p608] attribute is wearing the autofill anchor mantle[p608], then jump to the step labeled *default*.
10. If *category* is Off, set the element's autofill field name[p614] to the string "`off`", set its autofill hint set[p614] to empty, and set its IDL-exposed autofill value[p614] to the string "`off`". Then, return.
11. If *category* is Automatic, set the element's autofill field name[p614] to the string "`on`", set its autofill hint set[p614] to empty, and set its IDL-exposed autofill value[p614] to the string "`on`". Then, return.
12. Let *scope tokens* be an empty list.
13. Let *hint tokens* be an empty set.
14. Let *credential type* be null.
15. Let *IDL value* have the same value as *field*.
16. If *category* is Credential and the *index*th token in *tokens* is an ASCII case-insensitive match for "`webauthn`[p610]", then run the substeps that follow:
    1. Set *credential type* to "`webauthn`".
    2. If the *index*th token in *tokens* is the first entry, then skip to the step labeled *done*.
    3. Decrement *index* by one.
    4. Set the *category*, *maximum tokens* pair to the result of determining a field's category[p616] given the *index*th token in *tokens*.
    5. If *category* is not Normal and *category* is not Contact, then jump to the step labeled *default*.
    6. If *index* is greater than *maximum tokens* minus one (i.e. if the number of remaining tokens is greater than *maximum tokens*), then jump to the step labeled *default*.
    7. Set *IDL value* to the concatenation of the *index*th token in *tokens*, a U+0020 SPACE character, and the previous value of *IDL value*.
17. If the *index*th token in *tokens* is the first entry, then skip to the step labeled *done*.
18. Decrement *index* by one.
19. If *category* is Contact and the *index*th token in *tokens* is an ASCII case-insensitive match for one of the strings in the following list, then run the substeps that follow:
    - "`home`[p609]"
    - "`work`[p609]"
    - "`mobile`[p610]"
    - "`fax`[p610]"
    - "`pager`[p610]"

    The substeps are:
    1. Let *contact* be the matching string from the list above.
    2. Insert *contact* at the start of *scope tokens*.
    3. Add *contact* to *hint tokens*.
    4. Let *IDL value* be the concatenation of *contact*, a U+0020 SPACE character, and the previous value of *IDL value*.
    5. If the *index*th entry in *tokens* is the first entry, then skip to the step labeled *done*.
    6. Decrement *index* by one.
20. If the *index*th token in *tokens* is an ASCII case-insensitive match for one of the strings in the following list, then run the substeps that follow:
    - "`shipping`[p609]"
    - "`billing`[p609]"

The substeps are:

1. Let *mode* be the matching string from the list above.
2. Insert *mode* at the start of *scope tokens*.
3. Add *mode* to *hint tokens*.
4. Let *IDL value* be the concatenation of *mode*, a U+0020 SPACE character, and the previous value of *IDL value*.
5. If the *index*th entry in *tokens* is the first entry, then skip to the step labeled *done*.
6. Decrement *index* by one.

21. If the *index*th entry in *tokens* is not the first entry, then jump to the step labeled *default*.
22. If the first eight characters of the *index*th token in *tokens* are not an ASCII case-insensitive match for the string "section-[p608]", then jump to the step labeled *default*.
23. Let *section* be the *index*th token in *tokens*, converted to ASCII lowercase.
24. Insert *section* at the start of *scope tokens*.
25. Let *IDL value* be the concatenation of *section*, a U+0020 SPACE character, and the previous value of *IDL value*.
26. *Done*: Set the element's autofill hint set[p614] to *hint tokens*.
27. Set the element's non-autofill credential type[p614] to *credential type*.
28. Set the element's autofill scope[p614] to *scope tokens*.
29. Set the element's autofill field name[p614] to *field*.
30. Set the element's IDL-exposed autofill value[p614] to *IDL value*.
31. Return.
32. *Default*: Set the element's IDL-exposed autofill value[p614] to the empty string, and its autofill hint set[p614] and autofill scope[p614] to empty.
33. If the element's autocomplete[p608] attribute is wearing the autofill anchor mantle[p608], then set the element's autofill field name[p614] to the empty string and return.
34. Let *form* be the element's form owner[p601], if any, or null otherwise.
35. If *form* is not null and *form*'s autocomplete[p516] attribute is in the Off[p516] state, then set the element's autofill field name[p614] to "off[p610]".

    Otherwise, set the element's autofill field name[p614] to "on[p610]".

To **determine a field's category**, given *field*:

1. If the *field* is not an ASCII case-insensitive match for one of the tokens given in the first column of the following table, return the pair (null, null).

Token	Maximum number of tokens	Category
"off[p610]"	1	Off
"on[p610]"	1	Automatic
"name[p611]"	3	Normal
"honorific-prefix[p611]"	3	Normal
"given-name[p611]"	3	Normal
"additional-name[p611]"	3	Normal
"family-name[p611]"	3	Normal

"tel-area-code[p612]"	4	Contact
"tel-local[p612]"	4	Contact
"tel-local-prefix[p612]"	4	Contact
"tel-local-suffix[p613]"	4	Contact
"tel-extension[p613]"	4	Contact
"email[p613]"	4	Contact
"impp[p613]"	4	Contact
"webauthn[p610]"	5	Credential

2. Otherwise, let *maximum tokens* and *category* be the values of the cells in the second and third columns of that row respectively.

3. Return the pair (*category*, *maximum tokens*).

For the purposes of autofill, a **control's data** depends on the kind of control:

An input[p521] element with its type[p524] attribute in the Email[p531] state and with the multiple[p554] attribute specified

The element's values[p601].

Any other `input` element

A `textarea` element

The element's value.

A `select` element with its `multiple` attribute specified

The `option` elements in the `select` element's list of options that have their selectedness set to true.

Any other `select` element

The `option` element in the `select` element's list of options that has its selectedness set to true.

How to process the autofill hint set, autofill scope, and autofill field name depends on the mantle that the `autocomplete` attribute is wearing.

↪ **When wearing the autofill expectation mantle...**

When an element's autofill field name is "`off`", the user agent should not remember the control's data, and should not offer past values to the user.

Note

In addition, when an element's autofill field name is "`off`", values are reset when reactivating a document.

Example

Banks frequently do not want UAs to prefill login information:

```
<p><label>Account: <input type="text" name="ac" autocomplete="off"></label></p>
<p><label>PIN: <input type="password" name="pin" autocomplete="off"></label></p>
```

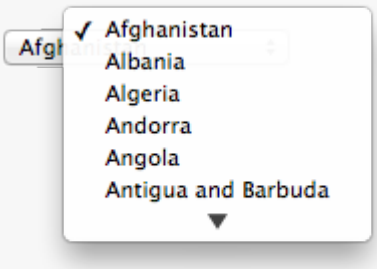
When an element's autofill field name is *not* "`off`", the user agent may store the control's data, and may offer previously stored values to the user.

Example

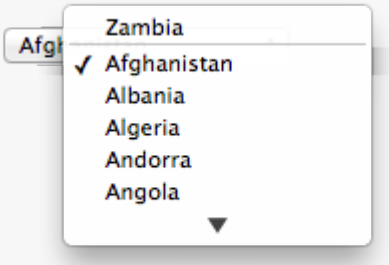
For example, suppose a user visits a page with this control:

```
<select name="country">
 <option>Afghanistan
 <option>Albania
 <option>Algeria
 <option>Andorra
 <option>Angola
 <option>Antigua and Barbuda
 <option>Argentina
 <option>Armenia
 <!-- ... -->
 <option>Yemen
 <option>Zambia
 <option>Zimbabwe
</select>
```

This might render as follows:



Suppose that on the first visit to this page, the user selects "Zambia". On the second visit, the user agent could duplicate the entry for Zambia at the top of the list, so that the interface instead looks like this:



When the autofill field name[p614] is "on[p610]", the user agent should attempt to use heuristics to determine the most appropriate values to offer the user, e.g. based on the element's name[p603] value, the position of the element in its tree, what other fields exist in the form, and so forth.

When the autofill field name[p614] is one of the names of the autofill fields[p610] described above, the user agent should provide suggestions that match the meaning of the field name as given in the table earlier in this section. The autofill hint set[p614] should be used to select amongst multiple possible suggestions.

Example

For example, if a user once entered one address into fields that used the "shipping[p609]" keyword, and another address into fields that used the "billing[p609]" keyword, then in subsequent forms only the first address would be suggested for form controls whose autofill hint set[p614] contains the keyword "shipping[p609]". Both addresses might be suggested, however, for address-related form controls whose autofill hint set[p614] does not contain either keyword.

↪ **When wearing the autofill anchor mantle[p608]...**

When the autofill field name[p614] is not the empty string, then the user agent must act as if the user had specified the control's data[p617] for the given autofill hint set[p614], autofill scope[p614], and autofill field name[p614] combination.

When the user agent **autofills form controls**, elements with the same form owner[p601] and the same autofill scope[p614] must use data relating to the same person, address, payment instrument, and contact details. When a user agent autofills "country[p611]" and "country-name[p612]" fields with the same form owner[p601] and autofill scope[p614], and the user agent has a value for the country[p611]" field(s), then the "country-name[p612]" field(s) must be filled using a human-readable name for the same country. When a user agent fills in multiple fields at once, all fields with the same autofill field name[p614], form owner[p601], and autofill scope[p614] must be filled with the same value.

Example

Suppose a user agent knows of two phone numbers, +1 555 123 1234 and +1 555 666 7777. It would not be conforming for the user agent to fill a field with `autocomplete="shipping tel-local-prefix"` with the value "123" and another field in the same form with `autocomplete="shipping tel-local-suffix"` with the value "7777". The only valid prefilled values given the aforementioned information would be "123" and "1234", or "666" and "7777", respectively.

Example

Similarly, if a form for some reason contained both a "cc-exp[p612]" field and a "cc-exp-month[p612]" field, and the user agent prefilled the form, then the month component of the former would have to match the latter.

Example

This requirement interacts with the autofill anchor mantle[p608] also. Consider the following markup snippet:

```
<form>
 <input type=hidden autocomplete="nickname" value="TreePlate">
 <input type=text autocomplete="nickname">
</form>
```

The only value that a conforming user agent could suggest in the text control is "TreePlate", the value given by the hidden input[p521] element.

The "section-*" tokens in the autofill scope[p614] are opaque; user agents must not attempt to derive meaning from the precise values of these tokens.

Example

For example, it would not be conforming if the user agent decided that it should offer the address it knows to be the user's daughter's address for "section-child" and the addresses it knows to be the user's spouses' addresses for "section-spouse".

The autocompletion mechanism must be implemented by the user agent acting as if the user had modified the control's data[p617], and must be done at a time where the element is *mutable*[p601] (e.g. just after the element has been inserted into the document, or when the user agent stops parsing[p1376]). User agents must only prefill controls using values that the user could have entered.

Example

For example, if a select[p572] element only has option[p580] elements with values "Steve" and "Rebecca", "Jay", and "Bob", and has an autofill field name[p614] "given-name[p611]", but the user agent's only idea for what to prefill the field with is "Evan", then the user agent cannot prefill the field. It would not be conforming to somehow set the select[p572] element to the value "Evan", since the user could not have done so themselves.

A user agent prefilling a form control must not discriminate between form controls that are in a document tree and those that are connected; that is, it is not conforming to make the decision on whether or not to autofill based on whether the element's root is a shadow root versus a Document[p131].

A user agent prefilling a form control's value[p601] must not cause that control to suffer from a type mismatch[p626], suffer from being too long[p627], suffer from being too short[p627], suffer from an underflow[p627], suffer from an overflow[p627], or suffer from a step mismatch[p627]. A user agent prefilling a form control's value[p601] must not cause that control to suffer from a pattern mismatch[p626] either. Where possible given the control's constraints, user agents must use the format given as canonical in the aforementioned table. Where it's not possible for the canonical format to be used, user agents should use heuristics to attempt to convert values so that they can be used.

Example

For example, if the user agent knows that the user's middle name is "Ines", and attempts to prefill a form control that looks like this:

```
<input name=middle-initial maxlength=1 autocomplete="additional-name">
```

...then the user agent could convert "Ines" to "I" and prefill it that way.

Example

A more elaborate example would be with month values. If the user agent knows that the user's birthday is the 27th of July 2012, then it might try to prefill all of the following controls with slightly different values, all driven from this information:

`<input name=b type=month autocomplete="bday">`	2012-07	The day is dropped since the Month[p534] state only accepts a month/year combination. (Note that this example is non-conforming, because the autofill field name[p614] bday[p612] is not allowed with the Month[p534] state.)

`<select name=c autocomplete="bday"> <option>Jan <option>Feb ... <option>Jul <option>Aug ... </select>`	July	The user agent picks the month from the listed options, either by noticing there are twelve options and picking the 7th, or by recognizing that one of the strings (three characters "Jul" followed by a newline and a space) is a close match for the name of the month (July) in one of the user agent's supported languages, or through some other similar mechanism.
`<input name=a type=number min=1 max=12 autocomplete="bday-month">`	7	User agent converts "July" to a month number in the range 1..12, like the field.
`<input name=a type=number min=0 max=11 autocomplete="bday-month">`	6	User agent converts "July" to a month number in the range 0..11, like the field.
`<input name=a type=number min=1 max=11 autocomplete="bday-month">`		User agent doesn't fill in the field, since it can't make a good guess as to what the form expects.

A user agent may allow the user to override an element's autofill field name[p614], e.g. to change it from "off[p610]" to "on[p610]" to allow values to be remembered and prefilled despite the page author's objections, or to always "off[p610]", never remembering values.

More specifically, user agents may in particular consider replacing the autofill field name[p614] of form controls that match the description given in the first column of the following table, when their autofill field name[p614] is either "on[p610]" or "off[p610]", with the value given in the second cell of that row. If this table is used, the replacements must be done in tree order, since all but the first row references the autofill field name[p614] of earlier elements. When the descriptions below refer to form controls being preceded or followed by others, they mean in the list of listed elements[p514] that share the same form owner[p601].

Form control	New autofill field name[p614]
an input[p521] element whose type[p524] attribute is in the Text[p529] state that is followed by an input[p521] element whose type[p524] attribute is in the Password[p533] state	"username[p611]"
an input[p521] element whose type[p524] attribute is in the Password[p533] state that is preceded by an input[p521] element whose autofill field name[p614] is "username[p611]"	"current-password[p611]"
an input[p521] element whose type[p524] attribute is in the Password[p533] state that is preceded by an input[p521] element whose autofill field name[p614] is "current-password[p611]"	"new-password[p611]"
an input[p521] element whose type[p524] attribute is in the Password[p533] state that is preceded by an input[p521] element whose autofill field name[p614] is "new-password[p611]"	"new-password[p611]"

The **autocomplete** IDL attribute, on getting, must return the element's IDL-exposed autofill value[p614], and on setting, must reflect[p105] the content attribute of the same name.

4.10.19 APIs for the text control selections §[p62] 1

The input[p521] and textarea[p583] elements define several attributes and methods for handling their selection. Their shared algorithms are defined here.

For web developers (non-normative)

***element*.select[p623]()**

Selects everything in the text control.

***element*.selectionStart [= *value*]**

Returns the offset to the start of the selection.

Can be set, to change the start of the selection.

***element*.selectionEnd [= *value*]**

Returns the offset to the end of the selection.

Can be set, to change the end of the selection.

***element*.selectionDirection [= *value*]**

Returns the current direction of the selection.

Can be set, to change the direction of the selection.

The possible values are "`forward`", "`backward`", and "`none`".

***element*.setSelectionRange(*start*, *end* [, *direction*])**

Changes the selection to cover the given substring in the given direction. If the direction is omitted, it will be reset to be the platform default (none or forward).

***element*.setRangeText(*replacement* [, *start*, *end* [, *selectionMode*]])**

Replaces a range of text with the new text. If the *start* and *end* arguments are not provided, the range is assumed to be the selection.

The final argument determines how the selection will be set after the text has been replaced. The possible values are:

"select"
: Selects the newly inserted text.

"start"
: Moves the selection to just before the inserted text.

"end"
: Moves the selection to just after the selected text.

"preserve"
: Attempts to preserve the selection. This is the default.

All `input` elements to which these APIs apply, and all `textarea` elements, have either a **selection** or a **text entry cursor position** at all times (even for elements that are not being rendered), measured in offsets into the code units of the control's relevant value. The initial state must consist of a text entry cursor at the beginning of the control.

For `input` elements, these APIs must operate on the element's value. For `textarea` elements, these APIs must operate on the element's API value. In the below algorithms, we call the value string being operated on the **relevant value**.

Example

The use of API value instead of raw value for `textarea` elements means that U+000D (CR) characters are normalized away. For example,

```
<textarea id="demo"></textarea>
<script>
 demo.value = "A\r\nB";
 demo.setRangeText("replaced", 0, 2);
 assert(demo.value === "replacedB");
</script>
```

If we had operated on the raw value of "`A\r\nB`", then we would have replaced the characters "`A\r`", ending up with a result of "`replaced\nB`". But since we used the API value of "`A\nB`", we replaced the characters "`A\n`", giving "`replacedB`".

Note

Characters with no visible rendering, such as U+200D ZERO WIDTH JOINER, still count as characters. Thus, for instance, the selection can include just an invisible character, and the text insertion cursor can be placed to one side or another of such a character.

Whenever the relevant value changes for an element to which these APIs apply, run these steps:

1. If the element has a selection[p622]:

    1. If the start of the selection is now past the end of the relevant value[p622], set it to the end of the relevant value[p622].

    2. If the end of the selection is now past the end of the relevant value[p622], set it to the end of the relevant value[p622].

    3. If the user agent does not support empty selection, and both the start and end of the selection are now pointing to the end of the relevant value[p622], then instead set the element's text entry cursor position[p622] to the end of the relevant value[p622], removing any selection.

2. Otherwise, the element must have a text entry cursor position[p622] position. If it is now past the end of the relevant value[p622], set it to the end of the relevant value[p622].

Note

In some cases where the relevant value[p622] changes, other parts of the specification will also modify the text entry cursor position[p622], beyond just the clamping steps above. For example, see the `value`[p587] setter for `textarea`[p583].

Where possible, user interface features for changing the text selection[p622] in `input`[p521] and `textarea`[p583] elements must be implemented using the set the selection range[p624] algorithm so that, e.g., all the same events fire.

The selections[p622] of `input`[p521] and `textarea`[p583] elements have a **selection direction**, which is either "`forward`", "`backward`", or "`none`". The exact meaning of the selection direction depends on the platform. This direction is set when the user manipulates the selection. The initial selection direction[p623] must be "`none`" if the platform supports that direction, or "`forward`" otherwise.

To **set the selection direction** of an element to a given direction, update the element's selection direction[p623] to the given direction, unless the direction is "`none`" and the platform does not support that direction; in that case, update the element's selection direction[p623] to "`forward`".

Note

On Windows, the direction indicates the position of the caret relative to the selection: a "`forward`" selection has the caret at the end of the selection and a "`backward`" selection has the caret at the start of the selection. Windows has no "`none`" direction.

On Mac, the direction indicates which end of the selection is affected when the user adjusts the size of the selection using the arrow keys with the Shift modifier: the "`forward`" direction means the end of the selection is modified, and the "`backward`" direction means the start of the selection is modified. The "`none`" direction is the default on Mac, it indicates that no particular direction has yet been selected. The user sets the direction implicitly when first adjusting the selection, based on which directional arrow key was used.

The **`select()`** method, when invoked, must run the following steps:

1. If this element is an `input`[p521] element, and either `select()`[p623] does not apply[p525] to this element or the corresponding control has no selectable text, return.

    Example

    For instance, in a user agent where `<input type=color>`[p542] is rendered as a color well with a picker, as opposed to a text control accepting a hexadecimal color code, there would be no selectable text, and thus calls to the method are ignored.

2. Set the selection range[p624] with 0 and infinity.

The **`selectionStart`** attribute's getter must run the following steps:

1. If this element is an `input`[p521] element, and `selectionStart`[p623] does not apply[p525] to this element, return null.

2. If there is no selection[p622], return the code unit offset within the relevant value[p622] to the character that immediately follows the text entry cursor[p622].

3. Return the code unit offset within the relevant value[p622] to the character that immediately follows the start of the selection[p622].

The `selectionStart`[p623] attribute's setter must run the following steps:

1. If this element is an `input`[p521] element, and `selectionStart`[p623] does not apply[p525] to this element, throw an "`InvalidStateError`" `DOMException`.

2. Let *end* be the value of this element's selectionEnd[p624] attribute.
3. If *end* is less than the given value, set *end* to the given value.
4. Set the selection range[p624] with the given value, *end*, and the value of this element's selectionDirection[p624] attribute.

The **selectionEnd** attribute's getter must run the following steps:

1. If this element is an input[p521] element, and selectionEnd[p624] does not apply[p525] to this element, return null.
2. If there is no selection[p622], return the code unit offset within the relevant value[p622] to the character that immediately follows the text entry cursor[p622].
3. Return the code unit offset within the relevant value[p622] to the character that immediately follows the end of the selection[p622].

The selectionEnd[p624] attribute's setter must run the following steps:

1. If this element is an input[p521] element, and selectionEnd[p624] does not apply[p525] to this element, throw an "InvalidStateError" DOMException.
2. Set the selection range[p624] with the value of this element's selectionStart[p623] attribute, the given value, and the value of this element's selectionDirection[p624] attribute.

The **selectionDirection** attribute's getter must run the following steps:

1. If this element is an input[p521] element, and selectionDirection[p624] does not apply[p525] to this element, return null.
2. Return this element's selection direction[p623].

The selectionDirection[p624] attribute's setter must run the following steps:

1. If this element is an input[p521] element, and selectionDirection[p624] does not apply[p525] to this element, throw an "InvalidStateError" DOMException.
2. Set the selection range[p624] with the value of this element's selectionStart[p623] attribute, the value of this element's selectionEnd[p624] attribute, and the given value.

The **setSelectionRange(*start*, *end*, *direction*)** method, when invoked, must run the following steps:

1. If this element is an input[p521] element, and setSelectionRange()[p624] does not apply[p525] to this element, throw an "InvalidStateError" DOMException.
2. Set the selection range[p624] with *start*, *end*, and *direction*.

To **set the selection range** with an integer or null *start*, an integer or null or the special value infinity *end*, and optionally a string *direction*, run the following steps:

1. If *start* is null, let *start* be 0.
2. If *end* is null, let *end* be 0.
3. Set the selection[p622] of the text control to the sequence of code units within the relevant value[p622] starting with the code unit at the *start*th position (in logical order) and ending with the code unit at the (*end*-1)th position. Arguments greater than the length of the relevant value[p622] of the text control (including the special value infinity) must be treated as pointing at the end of the text control. If *end* is less than or equal to *start*, then the start of the selection and the end of the selection must both be placed immediately before the character with offset *end*. In UAs where there is no concept of an empty selection, this must set the cursor to be just before the character with offset *end*.
4. If *direction* is not identical to either "backward" or "forward", or if the *direction* argument was not given, set *direction* to "none".
5. Set the selection direction[p623] of the text control to *direction*.
6. If the previous steps caused the selection[p622] of the text control to be modified (in either extent or direction[p623]), then queue an element task[p1140] on the user interaction task source[p1149] given the element to fire an event named select[p1490] at the element, with the bubbles attribute initialized to true.

The **`setRangeText(replacement, start, end, selectMode)`** method, when invoked, must run the following steps:

1. If this element is an `input`[p521] element, and `setRangeText()`[p625] does not apply[p525] to this element, throw an `"InvalidStateError"` `DOMException`.
2. Set this element's dirty value flag[p601] to true.
3. If the method has only one argument, then let *start* and *end* have the values of the `selectionStart`[p623] attribute and the `selectionEnd`[p624] attribute respectively.

   Otherwise, let *start*, *end* have the values of the second and third arguments respectively.
4. If *start* is greater than *end*, then throw an `"IndexSizeError"` `DOMException`.
5. If *start* is greater than the length of the relevant value[p622] of the text control, then set it to the length of the relevant value[p622] of the text control.
6. If *end* is greater than the length of the relevant value[p622] of the text control, then set it to the length of the relevant value[p622] of the text control.
7. Let *selection start* be the current value of the `selectionStart`[p623] attribute.
8. Let *selection end* be the current value of the `selectionEnd`[p624] attribute.
9. If *start* is less than *end*, delete the sequence of code units within the element's relevant value[p622] starting with the code unit at the *start*th position and ending with the code unit at the (*end*-1)th position.
10. Insert the value of the first argument into the text of the relevant value[p622] of the text control, immediately before the *start*th code unit.
11. Let *new length* be the length of the value of the first argument.
12. Let *new end* be the sum of *start* and *new length*.
13. Run the appropriate set of substeps from the following list:

    ↪ **If the fourth argument's value is "`select`"**
    Let *selection start* be *start*.

    Let *selection end* be *new end*.

    ↪ **If the fourth argument's value is "`start`"**
    Let *selection start* and *selection end* be *start*.

    ↪ **If the fourth argument's value is "`end`"**
    Let *selection start* and *selection end* be *new end*.

    ↪ **If the fourth argument's value is "`preserve`"**
    ↪ **If the method has only one argument**

    1. Let *old length* be *end* minus *start*.
    2. Let *delta* be *new length* minus *old length*.
    3. If *selection start* is greater than *end*, then increment it by *delta*. (If *delta* is negative, i.e. the new text is shorter than the old text, then this will *decrease* the value of *selection start*.)

       Otherwise: if *selection start* is greater than *start*, then set it to *start*. (This snaps the start of the selection to the start of the new text if it was in the middle of the text that it replaced.)
    4. If *selection end* is greater than *end*, then increment it by *delta* in the same way.

       Otherwise: if *selection end* is greater than *start*, then set it to *new end*. (This snaps the end of the selection to the end of the new text if it was in the middle of the text that it replaced.)
14. Set the selection range[p624] with *selection start* and *selection end*.

The `setRangeText()`[p625] method uses the following enumeration:

IDL

```
enum SelectionMode {
  "select",
  "start",
  "end",
  "preserve" // default
};
```

Example

To obtain the currently selected text, the following JavaScript suffices:

```
var selectionText = control.value.substring(control.selectionStart, control.selectionEnd);
```

...where *control* is the input[p521] or textarea[p583] element.

Example

To add some text at the start of a text control, while maintaining the text selection, the three attributes must be preserved:

```
var oldStart = control.selectionStart;
var oldEnd = control.selectionEnd;
var oldDirection = control.selectionDirection;
var prefix = "http://";
control.value = prefix + control.value;
control.setSelectionRange(oldStart + prefix.length, oldEnd + prefix.length, oldDirection);
```

...where *control* is the input[p521] or textarea[p583] element.

4.10.20 Constraints §[p626]

4.10.20.1 Definitions §[p626]

A submittable element[p515] is a **candidate for constraint validation** except when a condition has **barred the element from constraint validation**. (For example, an element is barred from constraint validation[p626] if it has a datalist[p578] element ancestor.)

An element can have a **custom validity error message** defined. Initially, an element must have its custom validity error message[p626] set to the empty string. When its value is not the empty string, the element is suffering from a custom error[p627]. It can be set using the setCustomValidity()[p629] method, except for form-associated custom elements[p767]. Form-associated custom elements[p767] can have a custom validity error message[p626] set via their ElementInternals[p779] object's setValidity()[p782] method. The user agent should use the custom validity error message[p626] when alerting the user to the problem with the control.

An element can be constrained in various ways. The following is the list of **validity states** that a form control can be in, making the control invalid for the purposes of constraint validation. (The definitions below are non-normative; other parts of this specification define more precisely when each state applies or does not.)

Suffering from being missing

When a control has no value[p601] but has a `required` attribute (input[p521] required[p554], textarea[p583] required[p586]); or, more complicated rules for select[p572] elements and controls in radio button groups[p544], as specified in their sections.

When the setValidity()[p782] method sets `valueMissing` flag to true for a form-associated custom element[p767].

Suffering from a type mismatch

When a control that allows arbitrary user input has a value[p601] that is not in the correct syntax (Email[p531], URL[p530]).

When the setValidity()[p782] method sets `typeMismatch` flag to true for a form-associated custom element[p767].

Suffering from a pattern mismatch

When a control has a value[p601] that doesn't satisfy the pattern[p555] attribute.

When the setValidity()[p782] method sets patternMismatch flag to true for a form-associated custom element[p767].

Suffering from being too long

When a control has a value[p601] that is too long for the form control maxlength attribute[p604] (input[p521] maxlength[p552], textarea[p583] maxlength[p586]).

When the setValidity()[p782] method sets tooLong flag to true for a form-associated custom element[p767].

Suffering from being too short

When a control has a value[p601] that is too short for the form control minlength attribute[p605] (input[p521] minlength[p552], textarea[p583] minlength[p586]).

When the setValidity()[p782] method sets tooShort flag to true for a form-associated custom element[p767].

Suffering from an underflow

When a control has a value[p601] that is not the empty string and is too low for the min[p557] attribute.

When the setValidity()[p782] method sets rangeUnderflow flag to true for a form-associated custom element[p767].

Suffering from an overflow

When a control has a value[p601] that is not the empty string and is too high for the max[p557] attribute.

When the setValidity()[p782] method sets rangeOverflow flag to true for a form-associated custom element[p767].

Suffering from a step mismatch

When a control has a value[p601] that doesn't fit the rules given by the step[p558] attribute.

When the setValidity()[p782] method sets stepMismatch flag to true for a form-associated custom element[p767].

Suffering from bad input

When a control has incomplete input and the user agent does not think the user ought to be able to submit the form in its current state.

When the setValidity()[p782] method sets badInput flag to true for a form-associated custom element[p767].

Suffering from a custom error

When a control's custom validity error message[p626] (as set by the element's setCustomValidity()[p629] method or ElementInternals[p779]'s setValidity()[p782] method) is not the empty string.

Note

An element can still suffer from these states even when the element is disabled[p605]; thus these states can be represented in the DOM even if validating the form during submission wouldn't indicate a problem to the user.

An element **satisfies its constraints** if it is not suffering from any of the above validity states[p626].

4.10.20.2 Constraint validation [§ 7][p627]

When the user agent is required to **statically validate the constraints** of form[p515] element *form*, it must run the following steps, which return either a *positive* result (all the controls in the form are valid) or a *negative* result (there are invalid controls) along with a (possibly empty) list of elements that are invalid and for which no script has claimed responsibility:

1. Let *controls* be a list of all the submittable elements[p515] whose form owner[p601] is *form*, in tree order.
2. Let *invalid controls* be an initially empty list of elements.
3. For each element *field* in *controls*, in tree order:
    1. If *field* is not a candidate for constraint validation[p626], then move on to the next element.
    2. Otherwise, if *field* satisfies its constraints[p627], then move on to the next element.
    3. Otherwise, add *field* to *invalid controls*.

4. If *invalid controls* is empty, then return a *positive* result.
5. Let *unhandled invalid controls* be an initially empty list of elements.
6. For each element *field* in *invalid controls*, if any, in tree order:
    1. Let *notCanceled* be the result of firing an event named `invalid`[p1490] at *field*, with the `cancelable` attribute initialized to true.
    2. If *notCanceled* is true, then add *field* to *unhandled invalid controls*.
7. Return a *negative* result with the list of elements in the *unhandled invalid controls* list.

If a user agent is to **interactively validate the constraints** of `form`[p515] element *form*, then the user agent must run the following steps:

1. Statically validate the constraints[p627] of *form*, and let *unhandled invalid controls* be the list of elements returned if the result was *negative*.
2. If the result was *positive*, then return that result.
3. Report the problems with the constraints of at least one of the elements given in *unhandled invalid controls* to the user.
    - User agents may focus one of those elements in the process, by running the focusing steps[p851] for that element, and may change the scrolling position of the document, or perform some other action that brings the element to the user's attention. For elements that are form-associated custom elements[p767], user agents should use their validation anchor[p782] instead, for the purposes of these actions.
    - User agents may report more than one constraint violation.
    - User agents may coalesce related constraint violation reports if appropriate (e.g. if multiple radio buttons in a group[p544] are marked as required, only one error need be reported).
    - If one of the controls is not being rendered[p1406] (e.g. it has the `hidden`[p832] attribute set), then user agents may report a script error.
4. Return a *negative* result.

4.10.20.3 The constraint validation API [§](p628)

For web developers (non-normative)

***element*.willValidate**[p629]

Returns true if the element will be validated when the form is submitted; false otherwise.

***element*.setCustomValidity**[p629]**(*message*)**

Sets a custom error, so that the element would fail to validate. The given message is the message to be shown to the user when reporting the problem to the user.

If the argument is the empty string, clears the custom error.

***element*.validity**[p629]**.valueMissing**[p630]

Returns true if the element has no value but is a required field; false otherwise.

***element*.validity**[p629]**.typeMismatch**[p630]

Returns true if the element's value is not in the correct syntax; false otherwise.

***element*.validity**[p629]**.patternMismatch**[p630]

Returns true if the element's value doesn't match the provided pattern; false otherwise.

***element*.validity**[p629]**.tooLong**[p630]

Returns true if the element's value is longer than the provided maximum length; false otherwise.

***element*.validity**[p629]**.tooShort**[p630]

Returns true if the element's value, if it is not the empty string, is shorter than the provided minimum length; false otherwise.

***element*.validity[p629].rangeUnderflow[p630]**

Returns true if the element's value is lower than the provided minimum; false otherwise.

***element*.validity[p629].rangeOverflow[p630]**

Returns true if the element's value is higher than the provided maximum; false otherwise.

***element*.validity[p629].stepMismatch[p630]**

Returns true if the element's value doesn't fit the rules given by the step[p558] attribute; false otherwise.

***element*.validity[p629].badInput[p630]**

Returns true if the user has provided input in the user interface that the user agent is unable to convert to a value; false otherwise.

***element*.validity[p629].customError[p630]**

Returns true if the element has a custom error; false otherwise.

***element*.validity[p629].valid[p630]**

Returns true if the element's value has no validity problems; false otherwise.

***valid* = *element*.checkValidity[p631]()**

Returns true if the element's value has no validity problems; false otherwise. Fires an invalid[p1490] event at the element in the latter case.

***valid* = *element*.reportValidity[p631]()**

Returns true if the element's value has no validity problems; otherwise, returns false, fires an invalid[p1490] event at the element, and (if the event isn't canceled) reports the problem to the user.

***element*.validationMessage[p631]**

Returns the error message that would be shown to the user if the element was to be checked for validity.

The **willValidate** attribute's getter must return true, if this element is a candidate for constraint validation[p626], and false otherwise (i.e., false if any conditions are barring it from constraint validation[p626]).

The **willValidate** attribute of ElementInternals[p779] interface, on getting, must throw a "NotSupportedError" DOMException if the target element[p780] is not a form-associated custom element[p767]. Otherwise, it must return true if the target element[p780] is a candidate for constraint validation[p626], and false otherwise.

The **setCustomValidity(*error*)** method steps are:

1. Set *error* to the result of normalizing newlines given *error*.
2. Set the custom validity error message[p626] to *error*.

Example

In the following example, a script checks the value of a form control each time it is edited, and whenever it is not a valid value, uses the setCustomValidity()[p629] method to set an appropriate message.

```
<label>Feeling: <input name=f type="text" oninput="check(this)"></label>
<script>
 function check(input) {
   if (input.value == "good" ||
       input.value == "fine" ||
       input.value == "tired") {
     input.setCustomValidity('"' + input.value + '" is not a feeling.');
   } else {
     // input is fine -- reset the error message
     input.setCustomValidity('');
   }
 }
</script>
```

The **validity** attribute's getter must return a ValidityState[p630] object that represents the validity states[p626] of this element. This

object is live[p48].

The **validity** attribute of ElementInternals[p779] interface, on getting, must throw a "NotSupportedError" DOMException if the target element[p780] is not a form-associated custom element[p767]. Otherwise, it must return a ValidityState[p630] object that represents the validity states[p626] of the target element[p780]. This object is live[p48].

IDL

```
[Exposed=Window]
interface ValidityState {
  readonly attribute boolean valueMissing;
  readonly attribute boolean typeMismatch;
  readonly attribute boolean patternMismatch;
  readonly attribute boolean tooLong;
  readonly attribute boolean tooShort;
  readonly attribute boolean rangeUnderflow;
  readonly attribute boolean rangeOverflow;
  readonly attribute boolean stepMismatch;
  readonly attribute boolean badInput;
  readonly attribute boolean customError;
  readonly attribute boolean valid;
};
```

A ValidityState[p630] object has the following attributes. On getting, they must return true if the corresponding condition given in the following list is true, and false otherwise.

valueMissing
: The control is suffering from being missing[p626].

typeMismatch
: The control is suffering from a type mismatch[p626].

patternMismatch
: The control is suffering from a pattern mismatch[p626].

tooLong
: The control is suffering from being too long[p627].

tooShort
: The control is suffering from being too short[p627].

rangeUnderflow
: The control is suffering from an underflow[p627].

rangeOverflow
: The control is suffering from an overflow[p627].

stepMismatch
: The control is suffering from a step mismatch[p627].

badInput
: The control is suffering from bad input[p627].

customError
: The control is suffering from a custom error[p627].

valid
: None of the other conditions are true.

The **check validity steps** for an element *element* are:

1. If *element* is a candidate for constraint validation[p626] and does not satisfy its constraints[p627], then:
    1. Fire an event named invalid[p1490] at *element*, with the cancelable attribute initialized to true (though canceling

has no effect).

2. Return false.

2. Return true.

The **checkValidity()** method, when invoked, must run the check validity steps[p630] on this element.

The **checkValidity()** method of the ElementInternals[p779] interface must run these steps:

1. Let *element* be this ElementInternals[p779]'s target element[p780].
2. If *element* is not a form-associated custom element[p767], then throw a "NotSupportedError" DOMException.
3. Run the check validity steps[p630] on *element*.

The **report validity steps** for an element *element* are:

1. If *element* is a candidate for constraint validation[p626] and does not satisfy its constraints[p627], then:
    1. Let *report* be the result of firing an event named invalid[p1490] at *element*, with the cancelable attribute initialized to true.
    2. If *report* is true, then report the problems with the constraints of this element to the user. When reporting the problem with the constraints to the user, the user agent may run the focusing steps[p851] for *element*, and may change the scrolling position of the document, or perform some other action that brings *element* to the user's attention. User agents may report more than one constraint violation, if *element* suffers from multiple problems at once.
    3. Return false.
2. Return true.

The **reportValidity()** method, when invoked, must run the report validity steps[p631] on this element.

The **reportValidity()** method of the ElementInternals[p779] interface must run these steps:

1. Let *element* be this ElementInternals[p779]'s target element[p780].
2. If *element* is not a form-associated custom element[p767], then throw a "NotSupportedError" DOMException.
3. Run the report validity steps[p631] on *element*.

The **validationMessage** attribute's getter must run these steps:

1. If this element is not a candidate for constraint validation[p626] or if this element satisfies its constraints[p627], then return the empty string.
2. Return a suitably localized message that the user agent would show the user if this were the only form control with a validity constraint problem. If the user agent would not actually show a textual message in such a situation (e.g., it would show a graphical cue instead), then return a suitably localized message that expresses (one or more of) the validity constraint(s) that the control does not satisfy. If the element is a candidate for constraint validation[p626] and is suffering from a custom error[p627], then the custom validity error message[p626] should be present in the return value.

4.10.20.4 Security [p631]

Servers should not rely on client-side validation. Client-side validation can be intentionally bypassed by hostile users, and unintentionally bypassed by users of older user agents or automated tools that do not implement these features. The constraint validation features are only intended to improve the user experience, not to provide any kind of security mechanism.

4.10.21 Form submission §[p632]

4.10.21.1 Introduction §[p632]

This section is non-normative.

When a form is submitted, the data in the form is converted into the structure specified by the enctype[p607], and then sent to the destination specified by the action[p606] using the given method[p606].

For example, take the following form:

```
<form action="/find.cgi" method=get>
 <input type=text name=t>
 <input type=search name=q>
 <input type=submit>
</form>
```

If the user types in "cats" in the first field and "fur" in the second, and then hits the submit button, then the user agent will load `/find.cgi?t=cats&q=fur`.

On the other hand, consider this form:

```
<form action="/find.cgi" method=post enctype="multipart/form-data">
 <input type=text name=t>
 <input type=search name=q>
 <input type=submit>
</form>
```

Given the same user input, the result on submission is quite different: the user agent instead does an HTTP POST to the given URL, with as the entity body something like the following text:

```
------kYFrd4jNJEgCervE
Content-Disposition: form-data; name="t"

cats
------kYFrd4jNJEgCervE
Content-Disposition: form-data; name="q"

fur
------kYFrd4jNJEgCervE--
```

4.10.21.2 Implicit submission §[p632]

A `form`[p515] element's **default button** is the first submit button[p515] in tree order whose form owner[p601] is that `form`[p515] element.

If the user agent supports letting the user submit a form implicitly (for example, on some platforms hitting the "enter" key while a text control is focused[p845] implicitly submits the form), then doing so for a form, whose default button[p632] has activation behavior and is not disabled[p605], must cause the user agent to fire a `click` event[p1162] at that default button[p632].

Note

There are pages on the web that are only usable if there is a way to implicitly submit forms, so user agents are strongly encouraged to support this.

If the form has no submit button[p515], then the implicit submission mechanism must perform the following steps:

1. If the form has more than one field that blocks implicit submission[p632], then return.
2. Submit[p633] the `form`[p515] element from the `form`[p515] element itself with *userInvolvement*[p633] set to "`activation`[p1028]".

For the purpose of the previous paragraph, an element is a **field that blocks implicit submission** of a `form`[p515] element if it is an `input`[p521] element whose form owner[p601] is that `form`[p515] element and whose `type`[p524] attribute is in one of the following states: Text[p529],

Search[p529], Telephone[p529], URL[p530], Email[p531], Password[p533], Date[p533], Month[p534], Week[p535], Time[p536], Local Date and Time[p537], Number[p538]

4.10.21.3 Form submission algorithm §[p633]

Each `form`[p515] element has a **constructing entry list** boolean, initially false.

Each `form`[p515] element has a **firing submission events** boolean, initially false.

To **submit** a `form`[p515] element *form* from an element *submitter* (typically a button), given an optional boolean ***submitted from `submit()` method*** (default false) and an optional user navigation involvement[p1028] ***userInvolvement*** (default "none[p1028]"):

1. If *form* cannot navigate[p310], then return.
2. If *form*'s constructing entry list[p633] is true, then return.
3. Let *form document* be *form*'s node document.
4. If *form document*'s active sandboxing flag set[p928] has its sandboxed forms browsing context flag[p927] set, then return.
5. If *submitted from* `submit()`[p518] *method* is false, then:
    1. If *form*'s firing submission events[p633] is true, then return.
    2. Set *form*'s firing submission events[p633] to true.
    3. For each element *field* in the list of submittable elements[p515] whose form owner[p601] is *form*, set *field*'s user validity[p601] to true.
    4. If the *submitter* element's no-validate state[p607] is false, then interactively validate the constraints[p628] of *form* and examine the result. If the result is negative (i.e., the constraint validation concluded that there were invalid fields and probably informed the user of this), then:
        1. Set *form*'s firing submission events[p633] to false.
        2. Return.
    5. Let *submitterButton* be null if *submitter* is *form*. Otherwise, let *submitterButton* be *submitter*.
    6. Let *shouldContinue* be the result of firing an event named `submit`[p1490] at *form* using `SubmitEvent`[p640], with the `submitter`[p640] attribute initialized to *submitterButton*, the `bubbles` attribute initialized to true, and the `cancelable` attribute initialized to true.
    7. Set *form*'s firing submission events[p633] to false.
    8. If *shouldContinue* is false, then return.
    9. If *form* cannot navigate[p310], then return.

    Note

    Cannot navigate[p310] is run again as dispatching the `submit`[p1490] event could have changed the outcome.
6. Let *encoding* be the result of picking an encoding for the form[p638].
7. Let *entry list* be the result of constructing the entry list[p636] with *form*, *submitter*, and *encoding*.
8. Assert: *entry list* is not null.
9. If *form* cannot navigate[p310], then return.

    Note

    Cannot navigate[p310] is run again as dispatching the `formdata`[p1490] event in constructing the entry list[p636] could have changed the outcome.
10. Let *method* be the *submitter* element's method[p606].
11. If *method* is dialog[p606], then:

1. If *form* does not have an ancestor `dialog`[p650] element, then return.
2. Let *subject* be *form*'s nearest ancestor `dialog`[p650] element.
3. Let *result* be null.
4. If *submitter* is an `input`[p521] element whose `type`[p524] attribute is in the Image Button[p548] state, then:
    1. Let (*x*, *y*) be the selected coordinate[p550].
    2. Set *result* to the concatenation of *x*, ",", and *y*.
5. Otherwise, if *submitter* is a submit button[p515], then set *result* to *submitter*'s optional value[p601].
6. Close the dialog[p657] *subject* with *result* and null.
7. Return.

12. Let *action* be the *submitter* element's action[p606].
13. If *action* is the empty string, let *action* be the URL of the *form document*.
14. Let *parsed action* be the result of encoding-parsing a URL[p98] given *action*, relative to *submitter*'s node document.
15. If *parsed action* is failure, then return.
16. Let *scheme* be the scheme of *parsed action*.
17. Let *enctype* be the *submitter* element's enctype[p607].
18. Let *formTarget* be null.
19. If the *submitter* element is a submit button[p515] and it has a `formtarget`[p607] attribute, then set *formTarget* to the `formtarget`[p607] attribute value.
20. Let *target* be the result of getting an element's target[p177] given *submitter*'s form owner[p601] and *formTarget*.
21. Let *noopener* be the result of getting an element's noopener[p310] with *form*, *parsed action*, and *target*.
22. Let *targetNavigable* be the first return value of applying the rules for choosing a navigable[p1010] given *target*, *form*'s node navigable[p1002], and *noopener*.
23. If *targetNavigable* is null, then return.
24. Let *historyHandling* be "`auto`[p1027]".
25. If *form document* equals *targetNavigable*'s active document[p1002], and *form document* has not yet completely loaded[p1078], then set *historyHandling* to "`replace`[p1027]".
26. Select the appropriate row in the table below based on *scheme* as given by the first cell of each row. Then, select the appropriate cell on that row based on *method* as given in the first cell of each column. Then, jump to the steps named in that cell and defined below the table.

	GET[p606]	**POST**[p606]
`http`	Mutate action URL[p635]	Submit as entity body[p635]
`https`	Mutate action URL[p635]	Submit as entity body[p635]
`ftp`	Get action URL[p635]	Get action URL[p635]
`javascript`	Get action URL[p635]	Get action URL[p635]
`data`	Mutate action URL[p635]	Get action URL[p635]
`mailto`	Mail with headers[p636]	Mail as body[p636]

If *scheme* is not one of those listed in this table, then the behavior is not defined by this specification. User agents should, in the absence of another specification defining this, act in a manner analogous to that defined in this specification for similar schemes.

Each `form`[p515] element has a **planned navigation**, which is either null or a task[p1139]; when the `form`[p515] is first created, its planned navigation[p634] must be set to null. In the behaviors described below, when the user agent is required to **plan to navigate** to a URL *url* given an optional POST resource[p1020]-or-null *postResource* (default null), it must run the following steps:

1. Let *referrerPolicy* be the empty string.
2. If the `form`[p515] element's link types[p315] include the `noreferrer`[p326] keyword, then set *referrerPolicy* to "`no-referrer`".
3. If the `form`[p515] has a non-null planned navigation[p634], remove it from its task queue[p1138].
4. Queue an element task[p1140] on the DOM manipulation task source[p1149] given the `form`[p515] element and the following steps:
    1. Set the `form`[p515]'s planned navigation[p634] to null.
    2. Navigate[p1028] *targetNavigable* to *url* using the `form`[p515] element's node document, with *historyHandling*[p1028] set to *historyHandling*, *userInvolvement*[p1028] set to *userInvolvement*, *sourceElement*[p1028] set to *submitter*, *referrerPolicy*[p1028] set to *referrerPolicy*, *documentResource*[p1028] set to *postResource*, and *formDataEntryList*[p1028] set to *entry list*.
5. Set the `form`[p515]'s planned navigation[p634] to the just-queued task[p1139].

The behaviors are as follows:

Mutate action URL

Let *pairs* be the result of converting to a list of name-value pairs[p638] with *entry list*.

Let *query* be the result of running the `application/x-www-form-urlencoded` serializer with *pairs* and *encoding*.

Set *parsed action*'s query component to *query*.

Plan to navigate[p634] to *parsed action*.

Submit as entity body

Assert: *method* is POST[p606].

Switch on *enctype*:

↪ **`application/x-www-form-urlencoded`**[p607]

Let *pairs* be the result of converting to a list of name-value pairs[p638] with *entry list*.

Let *body* be the result of running the `application/x-www-form-urlencoded` serializer with *pairs* and *encoding*.

Set *body* to the result of encoding *body*.

Let *mimeType* be `` `application/x-www-form-urlencoded` ``.

↪ **`multipart/form-data`**[p607]

Let *body* be the result of running the `multipart/form-data` encoding algorithm[p639] with *entry list* and *encoding*.

Let *mimeType* be the isomorphic encoding of the concatenation of "`multipart/form-data; boundary=`" and the `multipart/form-data` boundary string[p639] generated by the `multipart/form-data` encoding algorithm[p639].

↪ **`text/plain`**[p607]

Let *pairs* be the result of converting to a list of name-value pairs[p638] with *entry list*.

Let *body* be the result of running the `text/plain` encoding algorithm[p639] with *pairs*.

Set *body* to the result of encoding *body* using *encoding*.

Let *mimeType* be `` `text/plain` ``.

Plan to navigate[p634] to *parsed action* given a POST resource[p1020] whose request body[p1020] is *body* and request content-type[p1020] is *mimeType*.

Get action URL

Plan to navigate[p634] to *parsed action*.

Note

entry list *is discarded.*

Mail with headers

Let *pairs* be the result of converting to a list of name-value pairs[p638] with *entry list*.

Let *headers* be the result of running the application/x-www-form-urlencoded serializer with *pairs* and *encoding*.

Replace occurrences of U+002B PLUS SIGN characters (+) in *headers* with the string "%20".

Set *parsed action*'s query to *headers*.

Plan to navigate[p634] to *parsed action*.

Mail as body

Let *pairs* be the result of converting to a list of name-value pairs[p638] with *entry list*.

Switch on *enctype*:

↪ **text/plain**[p607]

Let *body* be the result of running the text/plain encoding algorithm[p639] with *pairs*.

Set *body* to the result of running UTF-8 percent-encode on *body* using the default encode set. [URL][p1501]

↪ **Otherwise**

Let *body* be the result of running the application/x-www-form-urlencoded serializer with *pairs* and *encoding*.

If *parsed action*'s query is null, then set it to the empty string.

If *parsed action*'s query is not the empty string, then append a single U+0026 AMPERSAND character (&) to it.

Append "body=" to *parsed action*'s query.

Append *body* to *parsed action*'s query.

Plan to navigate[p634] to *parsed action*.

4.10.21.4 Constructing the entry list §[p636]

An **entry list** is a list of entries[p636], typically representing the contents of a form. An **entry** is a tuple consisting of a **name** (a scalar value string) and a **value** (either a scalar value string or a File object).

To **create an entry** given a string *name*, a string or Blob object *value*, and optionally a scalar value string *filename*:

1. Set *name* to the result of converting *name* into a scalar value string.
2. If *value* is a string, then set *value* to the result of converting *value* into a scalar value string.
3. Otherwise:
    1. If *value* is not a File object, then set *value* to a new File object, representing the same bytes, whose name attribute value is "blob".
    2. If *filename* is given, then set *value* to a new File object, representing the same bytes, whose name attribute is *filename*.

Note

These operations will create a new File object if either filename *is given or the passed Blob is not a File object. In those cases, the identity of the passed Blob object is not kept.*

4. Return an entry[p636] whose name[p636] is *name* and whose value[p636] is *value*.

To **construct the entry list** given a *form*, an optional *submitter* (default null), and an optional *encoding* (default UTF-8):

1. If *form*'s constructing entry list[p633] is true, then return null.
2. Set *form*'s constructing entry list[p633] to true.
3. Let *controls* be a list of all the submittable elements[p515] whose form owner[p601] is *form*, in tree order.
4. Let *entry list* be a new empty entry list[p636].
5. For each element *field* in *controls*, in tree order:
    1. If any of the following are true:
        - *field* has a `datalist`[p578] element ancestor;
        - *field* is disabled[p605];
        - *field* is a button[p515] but it is not *submitter*;
        - *field* is an `input`[p521] element whose `type`[p524] attribute is in the Checkbox[p544] state and whose checkedness[p601] is false; or
        - *field* is an `input`[p521] element whose `type`[p524] attribute is in the Radio Button[p544] state and whose checkedness[p601] is false,

        then continue.
    2. If the *field* element is an `input`[p521] element whose `type`[p524] attribute is in the Image Button[p548] state, then:
        1. If the *field* element is not *submitter*, then continue.
        2. If the *field* element has a `name`[p603] attribute specified and its value is not the empty string, let *name* be that value followed by U+002E (.). Otherwise, let *name* be the empty string.
        3. Let $name_x$ be the concatenation of *name* and U+0078 (x).
        4. Let $name_y$ be the concatenation of *name* and U+0079 (y).
        5. Let (x, y) be the selected coordinate[p550].
        6. Create an entry[p636] with $name_x$ and x, and append it to *entry list*.
        7. Create an entry[p636] with $name_y$ and y, and append it to *entry list*.
        8. Continue.
    3. If the *field* is a form-associated custom element[p767], then perform the entry construction algorithm[p782] given *field* and *entry list*, then continue.
    4. If either the *field* element does not have a `name`[p603] attribute specified, or its `name`[p603] attribute's value is the empty string, then continue.
    5. Let *name* be the value of the *field* element's `name`[p603] attribute.
    6. If the *field* element is a `select`[p572] element, then for each `option`[p580] element in the `select`[p572] element's list of options[p573] whose selectedness[p582] is true and that is not disabled[p581], create an entry[p636] with *name* and the value[p582] of the `option`[p580] element, and append it to *entry list*.
    7. Otherwise, if the *field* element is an `input`[p521] element whose `type`[p524] attribute is in the Checkbox[p544] state or the Radio Button[p544] state, then:
        1. If the *field* element has a `value`[p526] attribute specified, then let *value* be the value of that attribute; otherwise, let *value* be the string "`on`".
        2. Create an entry[p636] with *name* and *value*, and append it to *entry list*.
    8. Otherwise, if the *field* element is an `input`[p521] element whose `type`[p524] attribute is in the File Upload[p546] state, then:
        1. If there are no selected files[p546], then create an entry[p636] with *name* and a new `File` object with an empty name, `application/octet-stream` as type, and an empty body, and append it to *entry list*.
        2. Otherwise, for each file in selected files[p546], create an entry[p636] with *name* and a `File` object representing

the file, and append it to *entry list*.

9. Otherwise, if the *field* element is an input element whose type attribute is in the Hidden state and *name* is an ASCII case-insensitive match for "_charset_":

    1. Let *charset* be the name of *encoding*.

    2. Create an entry with *name* and *charset*, and append it to *entry list*.

10. Otherwise, create an entry with *name* and the value of the *field* element, and append it to *entry list*.

11. If the element has a dirname attribute, that attribute's value is not the empty string, and the element is an auto-directionality form-associated element:

    1. Let *dirname* be the value of the element's dirname attribute.

    2. Let *dir* be the string "ltr" if the directionality of the element is 'ltr', and "rtl" otherwise (i.e., when the directionality of the element is 'rtl').

    3. Create an entry with *dirname* and *dir*, and append it to *entry list*.

6. Let *form data* be a new FormData object associated with *entry list*.

7. Fire an event named formdata at *form* using FormDataEvent, with the formData attribute initialized to *form data* and the bubbles attribute initialized to true.

8. Set *form*'s constructing entry list to false.

9. Return a clone of *entry list*.

4.10.21.5 Selecting a form submission encoding

If the user agent is to **pick an encoding for a form**, it must run the following steps:

1. Let *encoding* be the document's character encoding.

2. If the form element has an accept-charset attribute, set *encoding* to the return value of running these substeps:

    1. Let *input* be the value of the form element's accept-charset attribute.

    2. Let *candidate encoding labels* be the result of splitting *input* on ASCII whitespace.

    3. Let *candidate encodings* be an empty list of character encodings.

    4. For each token in *candidate encoding labels* in turn (in the order in which they were found in *input*), get an encoding for the token and, if this does not result in failure, append the encoding to *candidate encodings*.

    5. If *candidate encodings* is empty, return UTF-8.

    6. Return the first encoding in *candidate encodings*.

3. Return the result of getting an output encoding from *encoding*.

4.10.21.6 Converting an entry list to a list of name-value pairs

The application/x-www-form-urlencoded and text/plain encoding algorithms take a list of name-value pairs, where the values must be strings, rather than an entry list where the value can be a File. The following algorithm performs the conversion.

To **convert to a list of name-value pairs** an entry list *entry list*, run these steps:

1. Let *list* be an empty list of name-value pairs.

2. For each *entry* of *entry list*:

    1. Let *name* be *entry*'s name, with every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), replaced by a string consisting of U+000D (CR) and

U+000A (LF).

2. If *entry*'s value[p636] is a `File` object, then let *value* be *entry*'s value[p636]'s `name`. Otherwise, let *value* be *entry*'s value[p636].

3. Replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), in *value*, by a string consisting of U+000D (CR) and U+000A (LF).

4. Append to *list* a new name-value pair whose name is *name* and whose value is *value*.

3. Return *list*.

4.10.21.7 URL-encoded form data §[p639]

See *URL* for details on `application/x-www-form-urlencoded`. [URL][p1501]

4.10.21.8 Multipart form data §[p639]

The **`multipart/form-data` encoding algorithm**, given an entry list[p636] *entry list* and an encoding *encoding*, is as follows:

1. For each *entry* of *entry list*:

    1. Replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), in *entry*'s name[p636], by a string consisting of a U+000D (CR) and U+000A (LF).

    2. If *entry*'s value[p636] is not a `File` object, then replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), in *entry*'s value[p636], by a string consisting of a U+000D (CR) and U+000A (LF).

2. Return the byte sequence resulting from encoding the *entry list* using the rules described by RFC 7578, *Returning Values from Forms:* `multipart/form-data`, given the following conditions: [RFC7578][p1500]

    - Each entry[p636] in *entry list* is a *field*, the name[p636] of the entry is the *field name* and the value[p636] of the entry is the *field value*.

    - The order of parts must be the same as the order of fields in *entry list*. Multiple entries with the same name must be treated as distinct fields.

    - Field names, field values for non-file fields, and filenames for file fields, in the generated `multipart/form-data`[p1492] resource must be set to the result of encoding the corresponding entry's name or value with *encoding*, converted to a byte sequence.

    - For field names and filenames for file fields, the result of the encoding in the previous bullet point must be escaped by replacing any 0x0A (LF) bytes with the byte sequence `` `%0A` ``, 0x0D (CR) with `` `%0D` `` and 0x22 (") with `` `%22` ``. The user agent must not perform any other escapes.

    - The parts of the generated `multipart/form-data`[p1492] resource that correspond to non-file fields must not have a `` `Content-Type`[p100] `` header specified.

    - The boundary used by the user agent in generating the return value of this algorithm is the **`multipart/form-data` boundary string**. (This value is used to generate the MIME type of the form submission payload generated by this algorithm.)

For details on how to interpret `multipart/form-data`[p1492] payloads, see RFC 7578. [RFC7578][p1500]

4.10.21.9 Plain text form data §[p639]

The **`text/plain` encoding algorithm**, given a list of name-value pairs *pairs*, is as follows:

1. Let *result* be the empty string.

2. For each *pair* in *pairs*:

1. Append *pair*'s name to *result*.
2. Append a single U+003D EQUALS SIGN character (=) to *result*.
3. Append *pair*'s value to *result*.
4. Append a U+000D CARRIAGE RETURN (CR) U+000A LINE FEED (LF) character pair to *result*.

3. Return *result*.

Payloads using the text/plain format are intended to be human readable. They are not reliably interpretable by computer, as the format is ambiguous (for example, there is no way to distinguish a literal newline in a value from the newline at the end of the value).

4.10.21.10 The SubmitEvent[p640] interface [§p64 0]

IDL

```
[Exposed=Window]
interface SubmitEvent : Event {
  constructor(DOMString type, optional SubmitEventInit eventInitDict = {});

  readonly attribute HTMLElement? submitter;
};

dictionary SubmitEventInit : EventInit {
  HTMLElement? submitter = null;
};
```

For web developers (non-normative)

***event*.submitter[p640]**

Returns the element representing the submit button[p515] that triggered the form submission[p632], or null if the submission was not triggered by a button.

The **submitter** attribute must return the value it was initialized to.

4.10.21.11 The FormDataEvent[p640] interface [§p64 0]

IDL

```
[Exposed=Window]
interface FormDataEvent : Event {
  constructor(DOMString type, FormDataEventInit eventInitDict);

  readonly attribute FormData formData;
};

dictionary FormDataEventInit : EventInit {
  required FormData formData;
};
```

For web developers (non-normative)

***event*.formData[p640]**

Returns a FormData object representing names and values of elements associated to the target form[p515]. Operations on the FormData object will affect form data to be submitted.

The **formData** attribute must return the value it was initialized to. It represents a FormData object associated to the entry list[p636] that is constructed[p636] when the form[p515] is submitted.

4.10.22 Resetting a form §[p64]

When a `form`[p515] element *form* is **reset**, run these steps:

1. Let *reset* be the result of firing an event named `reset`[p1490] at *form*, with the `bubbles` and `cancelable` attributes initialized to true.
2. If *reset* is true, then invoke the reset algorithm[p641] of each resettable element[p515] whose form owner[p601] is *form*.

Each resettable element[p515] defines its own **reset algorithm**. Changes made to form controls as part of these algorithms do not count as changes caused by the user (and thus, e.g., do not cause `input` events to fire).

4.11 Interactive elements §[p64]

4.11.1 The `details` element §[p64]

Categories[p147]:

Flow content[p150].
Interactive content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where flow content[p150] is expected.

Content model[p147]:

One `summary`[p647] element followed by flow content[p150].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
`name`[p642] — Name of group of mutually-exclusive `details`[p641] elements
`open`[p642] — Whether the details are visible

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLDetailsElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString name;
  [CEReactions] attribute boolean open;
};
```

The `details`[p641] element represents[p142] a disclosure widget from which the user can obtain additional information or controls.

Note

As with all HTML elements, it is not conforming to use the `details`[p641] element when attempting to represent another type of control. For example, tab widgets and menu widgets are not disclosure widgets, so abusing the `details`[p641] element to implement these patterns is incorrect.

Note

The `details`[p641] element is not appropriate for footnotes. Please see the section on footnotes[p787] for details on how to mark up footnotes.

The first summary[p647] element child of the element, if any, represents[p142] the summary or legend of the details. If there is no child summary[p647] element, the user agent should provide its own legend (e.g. "Details").

The rest of the element's contents represents[p142] the additional information or controls.

The **name** content attribute gives the name of the group of related details[p641] elements that the element is a member of. Opening one member of this group causes other members of the group to close. If the attribute is specified, its value must not be the empty string.

Before using this feature, authors should consider whether this grouping of related details[p641] elements into an exclusive accordion is helpful or harmful to users. While using an exclusive accordion can reduce the maximum amount of space that a set of content can occupy, it can also frustrate users who have to open many items to find what they want or users who want to look at the contents of multiple items at the same time.

A document must not contain more than one details[p641] element in the same details name group[p642] that has the open[p642] attribute present. Authors must not use script to add details[p641] elements to a document in a way that would cause a details name group[p642] to have more than one details[p641] element with the open[p642] attribute present.

Note

The group of elements that is created by a common name[p642] attribute is exclusive, meaning that at most one of the details[p641] elements can be open at once. While this exclusivity is enforced by user agents, the resulting enforcement immediately changes the open[p642] attributes in the markup. This requirement on authors forbids such misleading markup.

A document must not contain a details[p641] element that is a descendant of another details[p641] element in the same details name group[p642].

Documents that use the name[p642] attribute to group multiple related details[p641] elements should keep those related elements together in a containing element (such as a section[p210] element or article[p207] element). When it makes sense for the group to be introduced with a heading, authors should put that heading in a heading[p225] element at the start of the containing element.

Note

Visually and programmatically grouping related elements together can be important for accessible user experiences. This can help users understand the relationship between such elements. When related elements are in disparate sections of a web page rather than being grouped, the elements' relationships to each other can be less discoverable or understandable.

The **open** content attribute is a boolean attribute[p76]. If present, it indicates that both the summary and the additional information is to be shown to the user. If the attribute is absent, only the summary is to be shown.

When the element is created, if the attribute is absent, the additional information should be hidden; if the attribute is present, that information should be shown. Subsequently, if the attribute is removed, then the information should be hidden; if the attribute is added, the information should be shown.

The user agent should allow the user to request that the additional information be shown or hidden. To honor a request for the details to be shown, the user agent must set the open[p642] attribute on the element to the empty string. To honor a request for the information to be hidden, the user agent must remove the open[p642] attribute from the element.

Note

This ability to request that additional information be shown or hidden may simply be the activation behavior of the appropriate summary[p647] element, in the case such an element exists. However, if no such element exists, user agents can still provide this ability through some other user interface affordance.

The **details name group** that contains a details[p641] element *a* also contains all the other details[p641] elements *b* that fulfill all of the following conditions:

- Both *a* and *b* are in the same tree.
- They both have a name[p642] attribute, their name[p642] attributes are not the empty string, and the value of *a*'s name[p642] attribute equals the value of *b*'s name[p642] attribute.

Every details[p641] element has a **details toggle task tracker**, which is a toggle task tracker[p842] or null, initially null.

The following attribute change steps, given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used for all details[p641] elements:

1. If *namespace* is not null, then return.
2. If *localName* is `name`[p642], then ensure details exclusivity by closing the given element if needed[p643] given *element*.
3. If *localName* is `open`[p642], then:
    1. If one of *oldValue* or *value* is null and the other is not null, run the following steps, which are known as the **details notification task steps**, for this `details`[p641] element:

        Note

        When the `open`[p642] attribute is toggled several times in succession, the resulting tasks essentially get coalesced so that only one event is fired.

        1. If *oldValue* is null, queue a details toggle event task[p643] given the `details`[p641] element, "`closed`", and "`open`".
        2. Otherwise, queue a details toggle event task[p643] given the `details`[p641] element, "`open`", and "`closed`".
    2. If *oldValue* is null and *value* is not null, then ensure details exclusivity by closing other elements if needed[p643] given *element*.

The `details`[p641] HTML element insertion steps[p46], given *insertedNode*, are:

1. Ensure details exclusivity by closing the given element if needed[p643] given *insertedNode*.

Note

To be clear, these attribute change and insertion steps also run when an attribute or element is inserted via the parser.

To **queue a details toggle event task** given a `details`[p641] element *element*, a string *oldState*, and a string *newState*:

1. If *element*'s details toggle task tracker[p642] is not null, then:
    1. Set *oldState* to *element*'s details toggle task tracker[p642]'s old state[p842].
    2. Remove *element*'s details toggle task tracker[p642]'s task[p842] from its task queue[p1138].
    3. Set *element*'s details toggle task tracker[p642] to null.
2. Queue an element task[p1140] given the DOM manipulation task source[p1149] and *element* to run the following steps:
    1. Fire an event named `toggle`[p1491] at *element*, using `ToggleEvent`[p841], with the `oldState`[p841] attribute initialized to *oldState* and the `newState`[p841] attribute initialized to *newState*.
    2. Set *element*'s details toggle task tracker[p642] to null.
3. Set *element*'s details toggle task tracker[p642] to a struct with task[p842] set to the just-queued task[p1139] and old state[p842] set to *oldState*.

To **ensure details exclusivity by closing other elements if needed** given a `details`[p641] element *element*:

1. Assert: *element* has an `open`[p642] attribute.
2. If *element* does not have a `name`[p642] attribute, or its `name`[p642] attribute is the empty string, then return.
3. Let *groupMembers* be a list of elements, containing all elements in *element*'s details name group[p642] except for *element*, in tree order.
4. For each element *otherElement* of *groupMembers*:
    1. If the `open`[p642] attribute is set on *otherElement*, then:
        1. Assert: *otherElement* is the only element in *groupMembers* that has the `open`[p642] attribute set.
        2. Remove the `open`[p642] attribute on *otherElement*.
        3. Break.

To **ensure details exclusivity by closing the given element if needed** given a `details`[p641] element *element*:

1. If *element* does not have an `open` attribute, then return.
2. If *element* does not have a `name` attribute, or its `name` attribute is the empty string, then return.
3. Let *groupMembers* be a list of elements, containing all elements in *element*'s details name group except for *element*, in tree order.
4. For each element *otherElement* of *groupMembers*:
    1. If the `open` attribute is set on *otherElement*, then:
        1. Remove the `open` attribute on *element*.
        2. Break.

The **`name`** and **`open`** IDL attributes must reflect the respective content attributes of the same name.

The **ancestor details revealing algorithm** is to run the following steps on *currentNode*:

1. While *currentNode* has a parent node within the flat tree:
    1. If *currentNode* is slotted into the second slot of a `details` element:
        1. Set *currentNode* to the `details` element which *currentNode* is slotted into.
        2. If the `open` attribute is not set on *currentNode*, then set the `open` attribute on *currentNode* to the empty string.
    2. Otherwise, set *currentNode* to the parent node of *currentNode* within the flat tree.

Example

The following example shows the `details` element being used to hide technical details in a progress report.

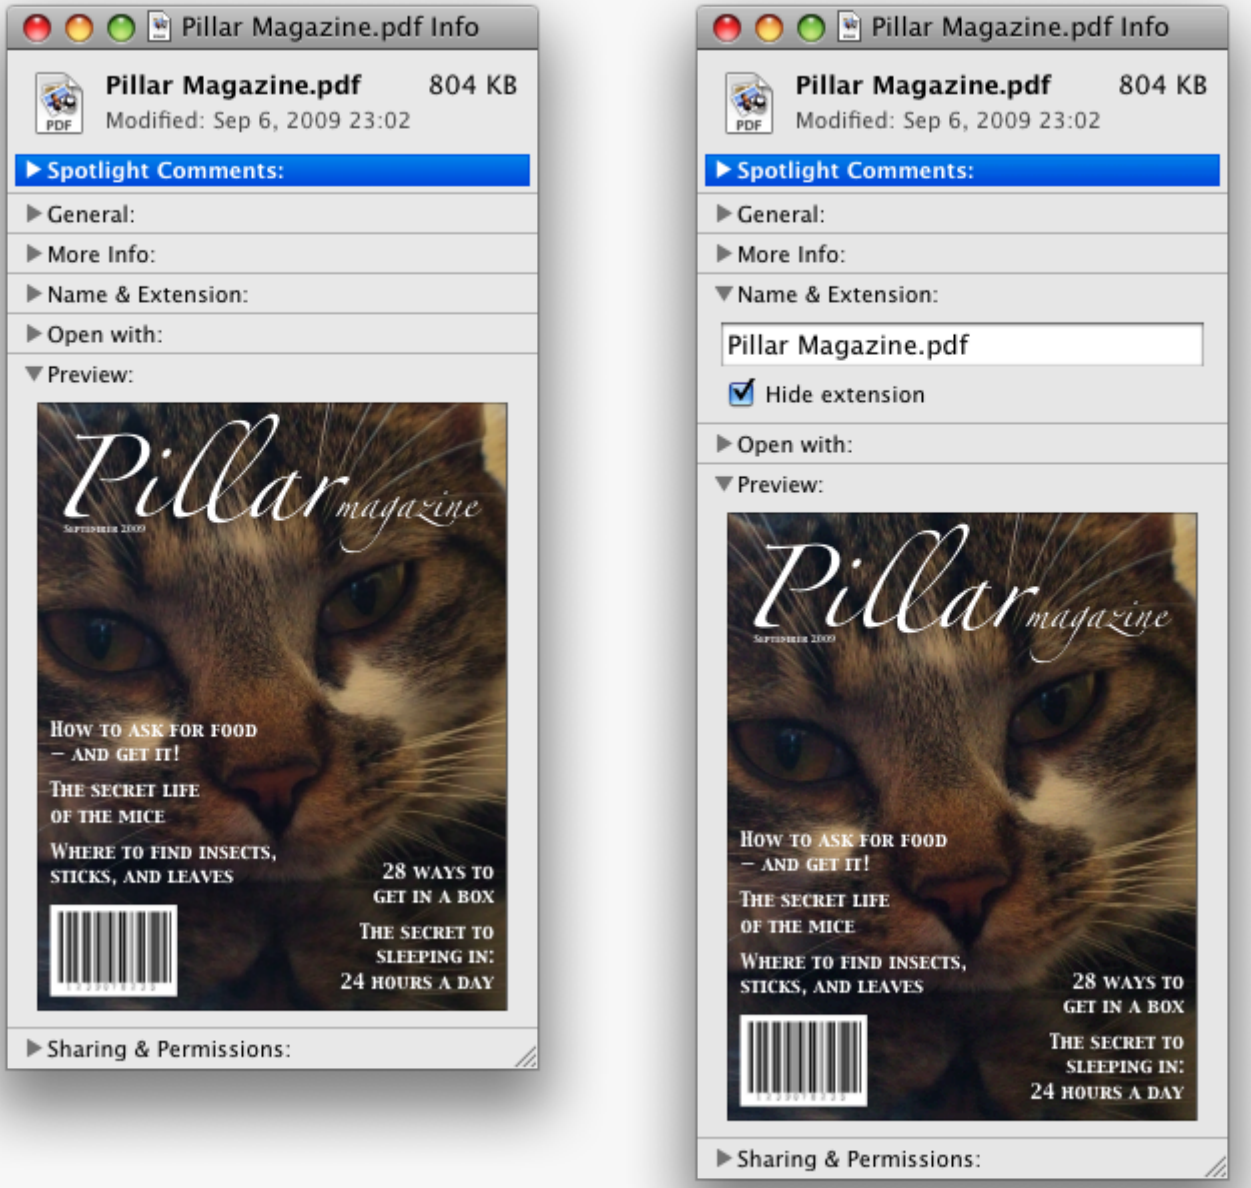
```
<section class="progress window">
 <h1>Copying "Really Achieving Your Childhood Dreams"</h1>
 <details>
  <summary>Copying... <progress max="375505392" value="97543282"></progress> 25%</summary>
  <dl>
   <dt>Transfer rate:</dt> <dd>452KB/s</dd>
   <dt>Local filename:</dt> <dd>/home/rpausch/raycd.m4v</dd>
   <dt>Remote filename:</dt> <dd>/var/www/lectures/raycd.m4v</dd>
   <dt>Duration:</dt> <dd>01:16:27</dd>
   <dt>Color profile:</dt> <dd>SD (6-1-6)</dd>
   <dt>Dimensions:</dt> <dd>320×240</dd>
  </dl>
 </details>
</section>
```

Example

The following shows how a `details` element can be used to hide some controls by default:

```
<details>
 <summary><label for=fn>Name & Extension:</label></summary>
 <p><input type=text id=fn name=fn value="Pillar Magazine.pdf">
 <p><label><input type=checkbox name=ext checked> Hide extension</label>
</details>
```

One could use this in conjunction with other `details` in a list to allow the user to collapse a set of fields down to a small set of headings, with the ability to open each one.



In these examples, the summary really just summarizes what the controls can change, and not the actual values, which is less than ideal.

¶ p64 5

Example

The following example shows the name p642 attribute of the details p641 element being used to create an exclusive accordion, a set of details p641 elements where a user action to open one details p641 element causes any open details p641 to close.

```
<section class="characteristics">
 <details name="frame-characteristics">
  <summary>Material</summary>
  The picture frame is made of solid oak wood.
 </details>
 <details name="frame-characteristics">
  <summary>Size</summary>
  The picture frame fits a photo 40cm tall and 30cm wide.
```

```
  The frame is 45cm tall, 35cm wide, and 2cm thick.
 </details>
 <details name="frame-characteristics">
  <summary>Color</summary>
  The picture frame is available in its natural wood
  color, or with black stain.
 </details>
</section>
```

¶ p64 6 **Example**

The following example shows what happens when the open p642 attribute is set on a details p641 element that is part of a set of elements using the name p642 attribute to create an exclusive accordion.

Given the initial markup:

```
<section class="characteristics">
 <details name="frame-characteristics" id="d1" open>...</details>
 <details name="frame-characteristics" id="d2">...</details>
 <details name="frame-characteristics" id="d3">...</details>
</section>
```

and the script:

```
document.getElementById("d2").setAttribute("open", "");
```

then the resulting tree after the script executes will be equivalent to the markup:

```
<section class="characteristics">
 <details name="frame-characteristics" id="d1">...</details>
 <details name="frame-characteristics" id="d2" open>...</details>
 <details name="frame-characteristics" id="d3">...</details>
</section>
```

because setting the open p642 attribute on `d2` removes it from `d1`.

The same happens when the user activates the summary p647 element inside of `d2`.

Example

Because the open p642 attribute is added and removed automatically as the user interacts with the control, it can be used in CSS to style the element differently based on its state. Here, a style sheet is used to animate the color of the summary when the element is opened or closed:

```
<style>
 details > summary { transition: color 1s; color: black; }
 details[open] > summary { color: red; }
</style>
<details>
 <summary>Automated Status: Operational</summary>
 <p>Velocity: 12m/s</p>
 <p>Direction: North</p>
</details>
```

4.11.2 The summary element §[p647]

Categories[p147]:

None.

Contexts in which this element can be used[p147]:

As the first child of a details[p641] element.

Content model[p147]:

Phrasing content[p151], optionally intermixed with heading content[p151].

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The summary[p647] element represents[p142] a summary, caption, or legend for the rest of the contents of the summary[p647] element's parent details[p641] element, if any.

A summary[p647] element is a **summary for its parent details** if the following algorithm returns true:

1. If this summary[p647] element has no parent, then return false.
2. Let *parent* be this summary[p647] element's parent.
3. If *parent* is not a details[p641] element, then return false.
4. If *parent*'s first summary[p647] element child is not this summary[p647] element, then return false.
5. Return true.

The activation behavior of summary[p647] elements is to run the following steps:

1. If this summary[p647] element is not the summary for its parent details[p647], then return.
2. Let *parent* be this summary[p647] element's parent.
3. If the open[p642] attribute is present on *parent*, then remove it. Otherwise, set *parent*'s open[p642] attribute to the empty string.

Note

This will then run the details notification task steps[p643].

4.11.3 Commands §[p647]

4.11.3.1 Facets §[p647]

A **command** is the abstraction behind menu items, buttons, and links. Once a command is defined, other parts of the interface can refer to the same command, allowing many access points to a single feature to share facets such as the Disabled State[p648].

Commands are defined to have the following **facets**:

Label

The name of the command as seen by the user.

Access Key

A key combination selected by the user agent that triggers the command. A command might not have an Access Key.

Hidden State

Whether the command is hidden or not (basically, whether it should be shown in menus).

Disabled State

Whether the command is relevant and can be triggered or not.

Action

The actual effect that triggering the command will have. This could be a scripted event handler, a URL to which to navigate[p1028], or a form submission.

User agents may expose the commands[p647] that match the following criteria:

- The Hidden State[p648] facet is false (visible)
- The element is in a document with a non-null browsing context[p1012].
- Neither the element nor any of its ancestors has a `hidden`[p832] attribute specified.

User agents are encouraged to do this especially for commands that have Access Keys[p647], as a way to advertise those keys to the user.

Example

For example, such commands could be listed in the user agent's menu bar.

4.11.3.2 Using the `a` element to define a command §[p648]

An `a`[p258] element with an `href`[p304] attribute defines a command[p647].

The Label[p647] of the command is the element's descendant text content.

The Access Key[p647] of the command is the element's assigned access key[p861], if any.

The Hidden State[p648] of the command is true (hidden) if the element has a `hidden`[p832] attribute, and false otherwise.

The Disabled State[p648] facet of the command is true if the element or one of its ancestors is inert[p835], and false otherwise.

The Action[p648] of the command is to fire a `click` event[p1162] at the element.

4.11.3.3 Using the `button` element to define a command §[p648]

A `button`[p567] element always defines a command[p647].

The Label[p647], Access Key[p647], Hidden State[p648], and Action[p648] facets of the command are determined as for a elements[p648] (see the previous section).

The Disabled State[p648] of the command is true if the element or one of its ancestors is inert[p835], or if the element's disabled[p605] state is set, and false otherwise.

4.11.3.4 Using the `input` element to define a command §[p648]

An `input`[p521] element whose `type`[p524] attribute is in one of the Submit Button[p548], Reset Button[p551], Image Button[p548], Button[p551], Radio Button[p544], or Checkbox[p544] states defines a command[p647].

The Label[p647] of the command is determined as follows:

- If the `type`[p524] attribute is in one of the Submit Button[p548], Reset Button[p551], Image Button[p548], or Button[p551] states, then the Label[p647] is the string given by the `value`[p526] attribute, if any, and a UA-dependent, locale-dependent value that the UA uses to label the button itself if the attribute is absent.

- Otherwise, if the element is a labeled control, then the Label is the descendant text content of the first `label` element in tree order whose labeled control is the element in question. (In JavaScript terms, this is given by *element*`.labels[0].textContent`.)
- Otherwise, if the `value` attribute is present, then the Label is the value of that attribute.
- Otherwise, the Label is the empty string.

Note

Even though the `value` attribute on `input` elements in the Image Button state is non-conformant, the attribute can still contribute to the Label determination, if it is present and the Image Button's `alt` attribute is missing.

The Access Key of the command is the element's assigned access key, if any.

The Hidden State of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The Disabled State of the command is true if the element or one of its ancestors is inert, or if the element's disabled state is set, and false otherwise.

The Action of the command is to fire a `click` event at the element.

4.11.3.5 Using the `option` element to define a command

An `option` element with an ancestor `select` element and either no `value` attribute or a `value` attribute that is not the empty string defines a command.

The Label of the command is the value of the `option` element's `label` attribute, if there is one, or else the `option` element's descendant text content, with ASCII whitespace stripped and collapsed.

The Access Key of the command is the element's assigned access key, if any.

The Hidden State of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The Disabled State of the command is true if the element is disabled, or if its nearest ancestor `select` element is disabled, or if it or one of its ancestors is inert, and false otherwise.

If the `option`'s nearest ancestor `select` element has a `multiple` attribute, the Action of the command is to toggle the `option` element. Otherwise, the Action is to pick the `option` element.

4.11.3.6 Using the `accesskey` attribute on a `legend` element to define a command

A `legend` element defines a command if all of the following are true:

- It has an assigned access key.
- It is a child of a `fieldset` element.
- Its parent has a descendant that defines a command that is neither a `label` element nor a `legend` element. This element, if it exists, is **the `legend` element's `accesskey` delegatee**.

The Label of the command is the element's descendant text content.

The Access Key of the command is the element's assigned access key.

The Hidden State, Disabled State, and Action facets of the command are the same as the respective facets of the `legend` element's `accesskey` delegatee.

Example

In this example, the `legend` element specifies an `accesskey`, which, when activated, will delegate to the `input` element

inside the legend element.

```
<fieldset>
 <legend accesskey=p>
  <label>I want <input name=pizza type=number step=1 value=1 min=0>
   pizza(s) with these toppings</label>
 </legend>
 <label><input name=pizza-cheese type=checkbox checked> Cheese</label>
 <label><input name=pizza-ham type=checkbox checked> Ham</label>
 <label><input name=pizza-pineapple type=checkbox> Pineapple</label>
</fieldset>
```

4.11.3.7 Using the accesskey attribute to define a command on other elements

An element that has an assigned access key defines a command.

If one of the earlier sections that define elements that define commands define that this element defines a command, then that section applies to this element, and this section does not. Otherwise, this section applies to that element.

The Label of the command depends on the element. If the element is a labeled control, the descendant text content of the first label element in tree order whose labeled control is the element in question is the Label (in JavaScript terms, this is given by *element*`.labels[0].textContent`). Otherwise, the Label is the element's descendant text content.

The Access Key of the command is the element's assigned access key.

The Hidden State of the command is true (hidden) if the element has a hidden attribute, and false otherwise.

The Disabled State of the command is true if the element or one of its ancestors is inert, and false otherwise.

The Action of the command is to run the following steps:

1. Run the focusing steps for the element.
2. Fire a `click` event at the element.

4.11.4 The dialog element

Categories:

Flow content.

Contexts in which this element can be used:

Where flow content is expected.

Content model:

Flow content.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes

`closedby` — Which user actions will close the dialog

`open` — Whether the dialog box is showing

Accessibility considerations:

For authors.

For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLDialogElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute boolean open;
  attribute DOMString returnValue;
  [CEReactions] attribute DOMString closedBy;
  [CEReactions] undefined show();
  [CEReactions] undefined showModal();
  [CEReactions] undefined close(optional DOMString returnValue);
  [CEReactions] undefined requestClose(optional DOMString returnValue);
};
```

The dialog[p650] element represents a transitory part of an application, in the form of a small window ("dialog box"), which the user interacts with to perform a task or gather information. Once the user is done, the dialog can be automatically closed by the application, or manually closed by the user.

Especially for modal dialogs, which are a familiar pattern across all types of applications, authors should work to ensure that dialogs in their web applications behave in a way that is familiar to users of non-web applications.

Note

As with all HTML elements, it is not conforming to use the dialog[p650] element when attempting to represent another type of control. For example, context menus, tooltips, and popup listboxes are not dialog boxes, so abusing the dialog[p650] element to implement these patterns is incorrect.

An important part of user-facing dialog behavior is the placement of initial focus. The dialog focusing steps[p658] attempt to pick a good candidate for initial focus when a dialog is shown, but might not be a substitute for authors carefully thinking through the correct choice to match user expectations for a specific dialog. As such, authors should use the autofocus[p857] attribute on the descendant element of the dialog that the user is expected to immediately interact with after the dialog opens. If there is no such element, then authors should use the autofocus[p857] attribute on the dialog[p650] element itself.

Example

In the following example, a dialog is used for editing the details of a product in an inventory management web application.

```
<dialog>
  <label>Product Number <input type="text" readonly></label>
  <label>Product Name <input type="text" autofocus></label>
</dialog>
```

If the autofocus[p857] attribute was not present, the Product Number field would have been focused by the dialog focusing steps. Although that is reasonable behavior, the author determined that the more relevant field to focus was the Product Name field, as the Product Number field is readonly and expects no user input. So, the author used autofocus to override the default.

Even if the author wants to focus the Product Number field by default, they are best off explicitly specifying that by using autofocus on that input[p521] element. This makes the intent obvious to future readers of the code, and ensures the code stays robust in the face of future updates. (For example, if another developer added a close button, and positioned it in the node tree before the Product Number field).

Another important aspect of user behavior is whether dialogs are scrollable or not. In some cases, overflow (and thus scrollability) cannot be avoided, e.g., when it is caused by the user's high text zoom settings. But in general, scrollable dialogs are not expected by users. Adding large text nodes directly to dialog elements is particularly bad as this is likely to cause the dialog element itself to overflow. Authors are best off avoiding them.

Example

The following terms of service dialog respects the above suggestions.

```
<dialog style="height: 80vh;">
```

```
  <div style="overflow: auto; height: 60vh;" autofocus>
    <p>By placing an order via this Web site on the first day of the fourth month of the year
    2010 Anno Domini, you agree to grant Us a non-transferable option to claim, for now and for
    ever more, your immortal soul.</p>
    <p>Should We wish to exercise this option, you agree to surrender your immortal soul,
    and any claim you may have on it, within 5 (five) working days of receiving written
    notification from  this site or one of its duly authorized minions.</p>
    <!-- ... etc., with many more <p> elements ... -->
  </div>
  <form method="dialog">
    <button type="submit" value="agree">Agree</button>
    <button type="submit" value="disagree">Disagree</button>
  </form>
</dialog>
```

Note how the dialog focusing steps[p658] would have picked the scrollable div[p257] element by default, but similarly to the previous example, we have placed autofocus[p857] on the div[p257] so as to be more explicit and robust against future changes.

In contrast, if the p[p230] elements expressing the terms of service did not have such a wrapper div[p257] element, then the dialog[p650] itself would become scrollable, violating the above advice. Furthermore, in the absence of any autofocus[p857] attribute, such a markup pattern would have violated the above advice and tripped up the dialog focusing steps[p658]'s default behavior, and caused focus to jump to the Agree button[p567], which is a bad user experience.

Example

This dialog box has some small print. The strong[p262] element is used to draw the user's attention to the more important part.

```
<dialog>
 <h1>Add to Wallet</h1>
 <p><strong><label for=amt>How many gold coins do you want to add to your
wallet?</label></strong></p>
 <p><input id=amt name=amt type=number min=0 step=0.01 value=100></p>
 <p><small>You add coins at your own risk.</small></p>
 <p><label><input name=round type=checkbox> Only add perfectly round coins</label></p>
 <p><input type=button onclick="submit()" value="Add Coins"></p>
</dialog>
```

The **open** attribute is a boolean attribute[p76]. When specified, it indicates that the dialog[p650] element is active and that the user can interact with it.

The **closedby** content attribute is an enumerated attribute[p77] with the following keywords and states:

Keyword	State	Brief description
any	**Any**	Close requests[p872] or clicks outside close the dialog.
closerequest	**Close Request**	Close requests[p872] close the dialog.
none	**None**	No user actions automatically close the dialog.

The closedby[p652] attribute's *invalid value default*[p77] and *missing value default*[p77] are both the **Auto** state.

Note

The Auto[p652] state behaves as Close Request[p652] state when the dialog[p650] was shown using its showModal()[p654] method; otherwise the None[p652] state.

A dialog[p650] element without an open[p652] attribute specified should not be shown to the user. This requirement may be implemented indirectly through the style layer. For example, user agents that support the suggested default rendering[p49] implement this requirement using the CSS rules described in the Rendering section[p1406].

¶ p65 3

Note

Removing the open p652 attribute will usually hide the dialog. However, doing so has a number of strange additional consequences:

- *The close p1489 event will not be fired.*
- *The close() p654 method, and any close requests p872, will no longer be able to close the dialog.*
- *If the dialog was shown using its showModal() p654 method, the Document p131 will still be blocked p836.*

For these reasons, it is generally better to never remove the open p652 attribute manually. Instead, use the requestClose() p654 or close() p654 methods to close the dialog, or the hidden p832 attribute to hide it.

The tabindex p847 attribute must not be specified on dialog p650 elements.

For web developers (non-normative)

***dialog*.show p653()**

Displays the dialog p650 element.

***dialog*.showModal p654()**

Displays the dialog p650 element and makes it the top-most modal dialog.

This method honors the autofocus p857 attribute.

***dialog*.close p654([*result*])**

Closes the dialog p650 element.

The argument, if provided, provides a return value.

***dialog*.requestClose p654([*result*])**

Acts as if a close request p872 was sent targeting *dialog*, by first firing a cancel p1489 event, and if that event is not canceled with preventDefault(), proceeding to close the *dialog* in the same way as the close() p654 method (including firing a close p1489 event).

This is a helper utility that can be used to consolidate cancelation and closing logic into the cancel p1489 and close p1489 event handlers, by having all non-close request p872 closing affordances call this method.

Note that this method ignores the closedby p652 attribute: that is, even if closedby p652 is set to "none p652", the same behavior will apply.

The argument, if provided, provides a return value.

***dialog*.returnValue p654 [= *result*]**

Returns the dialog p650's return value.

Can be set, to update the return value.

The **show()** method steps are:

1. If this has an open p652 attribute and is modal p655 of this is false, then return.
2. If this has an open p652 attribute, then throw an "InvalidStateError" DOMException.
3. If the result of firing an event named beforetoggle p1489, using ToggleEvent p841, with the cancelable attribute initialized to true, the oldState p841 attribute initialized to "closed", and the newState p841 attribute initialized to "open" at this is false, then return.
4. If this has an open p652 attribute, then return.
5. Queue a dialog toggle event task p658 given this, "closed", "open", and null.
6. Add an open p652 attribute to this, whose value is the empty string.
7. Assert: this's node document's open dialogs list p132 does not contain this.
8. Add this to this's node document's open dialogs list p132.
9. Set the dialog close watcher p656 with this.
10. Set this's previously focused element p654 to the focused p845 element.

11. Let *document* be this's node document.

12. Let *hideUntil* be the result of running topmost popover ancestor[p902] given this, *document*'s showing hint popover list[p905], null, and false.

13. If *hideUntil* is null, then set *hideUntil* to the result of running topmost popover ancestor[p902] given this, *document*'s showing auto popover list[p904], null, and false.

14. If *hideUntil* is null, then set *hideUntil* to *document*.

15. Run hide all popovers until[p901] given *hideUntil*, false, and true.

16. Run the dialog focusing steps[p658] given this.

The **showModal()** method steps are to show a modal dialog[p655] given this and null.

The **close(*returnValue*)** method steps are:

1. If *returnValue* is not given, then set it to null.

2. Close the dialog[p657] this with *returnValue* and null.

The **requestClose(*returnValue*)** method steps are:

1. If *returnValue* is not given, then set it to null.

2. Request to close the dialog[p657] this with *returnValue* and null.

¶[p654] 4

Note

We use show/close as the verbs for `dialog`[p650] elements, as opposed to verb pairs that are more commonly thought of as antonyms such as show/hide or open/close, due to the following constraints:

- *Hiding a dialog is different from closing one. Closing a dialog gives it a return value, fires an event, unblocks the page for other dialogs, and so on. Whereas hiding a dialog is a purely visual property, and is something you can already do with the `hidden`[p832] attribute or by removing the `open`[p652] attribute. (See also the note above[p653] about removing the `open`[p652] attribute, and how hiding the dialog in that way is generally not desired.)*

- *Showing a dialog is different from opening one. Opening a dialog consists of creating and showing that dialog (similar to how `window.open()`[p937] both creates and shows a new window). Whereas showing the dialog is the process of taking a `dialog`[p650] element that is already in the DOM, and making it interactive and visible to the user.*

- *If we were to have a `dialog.open()` method despite the above, it would conflict with the `dialog.open`[p654] property.*

Furthermore, a survey of many other UI frameworks contemporary to the original design of the `dialog`[p650] element made it clear that the show/close verb pair was reasonably common.

In summary, it turns out that the implications of certain verbs, and how they are used in technology contexts, mean that paired actions such as showing and closing a dialog are not always expressible as antonyms.

The **returnValue** IDL attribute, on getting, must return the last value to which it was set. On setting, it must be set to the new value. When the element is created, it must be set to the empty string.

The **closedBy** getter steps are to return the keyword corresponding to the computed closed-by state[p658] given this.

The `closedBy`[p654] setter steps are to set the `closedby`[p652] content attribute to the given value.

The **open** IDL attribute must reflect[p105] the `open`[p652] content attribute.

Each `Document`[p131] has a **dialog pointerdown target**, which is an HTML dialog element[p651] or null, initially null.

Each HTML element[p46] has a **previously focused element** which is null or an element, and it is initially null. When `showModal()`[p654] and `show()`[p653] are called, this element is set to the currently focused[p845] element before running the dialog focusing steps[p658]. Elements with the `popover`[p895] attribute set this element to the currently focused[p845] element during the show popover algorithm[p897].

Each `dialog`[p650] element has a **dialog toggle task tracker**, which is a toggle task tracker[p842] or null, initially null.

Each dialog element has a **close watcher**, which is a close watcher or null, initially null.

Each dialog element has a **request close return value**, which is a string or null, initially null.

Each dialog element has a **request close source element**, which is an Element or null, initially null.

Each dialog element has an **enable close watcher for request close** boolean, initially false.

Note

dialog's enable close watcher for request close is used to force enable the dialog's close watcher while requesting to close it. A dialog whose computed closed-by state is the None state would otherwise have a disabled close watcher.

Each dialog element has an **is modal** boolean, initially false.

The dialog HTML element removing steps, given *removedNode* and *oldParent*, are:

1. If *removedNode*'s close watcher is not null, then:
    1. Destroy *removedNode*'s close watcher.
    2. Set *removedNode*'s close watcher to null.
2. If *removedNode*'s node document's top layer contains *removedNode*, then remove an element from the top layer immediately given *removedNode*.
3. Set is modal of *removedNode* to false.
4. Remove *removedNode* from *removedNode*'s node document's open dialogs list.

To **show a modal dialog** given a dialog element *subject* and an Element or null *source*:

1. If *subject* has an open attribute and is modal of *subject* is true, then return.
2. If *subject* has an open attribute, then throw an "InvalidStateError" DOMException.
3. If *subject*'s node document is not fully active, then throw an "InvalidStateError" DOMException.
4. If *subject* is not connected, then throw an "InvalidStateError" DOMException.
5. If *subject* is in the popover showing state, then throw an "InvalidStateError" DOMException.
6. If the result of firing an event named beforetoggle, using ToggleEvent, with the cancelable attribute initialized to true, the oldState attribute initialized to "closed", the newState attribute initialized to "open", and the source attribute initialized to *source* at *subject* is false, then return.
7. If *subject* has an open attribute, then return.
8. If *subject* is not connected, then return.
9. If *subject* is in the popover showing state, then return.
10. Queue a dialog toggle event task given *subject*, "closed", "open", and *source*.
11. Add an open attribute to *subject*, whose value is the empty string.
12. Set is modal of *subject* to true.
13. Assert: *subject*'s node document's open dialogs list does not contain *subject*.
14. Add *subject* to *subject*'s node document's open dialogs list.
15. Set *subject*'s node document to be blocked by the modal dialog *subject*.

¶ 5 Note

This will cause the focused area of the document to become inert (unless that currently focused area is a shadow-including descendant of subject*). In such cases, the focused area of the document will soon be reset to the viewport. In a couple steps we will attempt to find a better candidate to focus.*

16. If *subject*'s node document's top layer does not already contain *subject*, then add an element to the top layer given *subject*.
17. Set the dialog close watcher[p656] with *subject*.
18. Set *subject*'s previously focused element[p654] to the focused[p845] element.
19. Let *document* be *subject*'s node document.
20. Let *hideUntil* be the result of running topmost popover ancestor[p902] given *subject*, *document*'s showing hint popover list[p905], null, and false.
21. If *hideUntil* is null, then set *hideUntil* to the result of running topmost popover ancestor[p902] given *subject*, *document*'s showing auto popover list[p904], null, and false.
22. If *hideUntil* is null, then set *hideUntil* to *document*.
23. Run hide all popovers until[p901] given *hideUntil*, false, and true.
24. Run the dialog focusing steps[p658] given *subject*.

To **set the dialog close watcher**, given a `dialog`[p650] element *dialog*:

1. Set *dialog*'s close watcher[p655] to the result of establishing a close watcher[p874] given *dialog*'s relevant global object[p1098], with:
    - *cancelAction*[p874] given *canPreventClose* being to return the result of firing an event named `cancel`[p1489] at *dialog*, with the `cancelable` attribute initialized to *canPreventClose*.
    - *closeAction*[p874] being to close the dialog[p657] given *dialog*, *dialog*'s request close return value[p655], and *dialog*'s request close source element[p655].
    - *getEnabledState*[p874] being to return true if *dialog*'s enable close watcher for request close[p655] is true or *dialog*'s computed closed-by state[p658] is not None[p652]; otherwise false.

The is valid invoker command steps[p570] for `dialog`[p650] elements, given a `command`[p568] attribute *command*, are:

1. If *command* is in the Close[p569] state, the Request Close[p569] state, or the Show Modal[p569] state, then return true.
2. Return false.

The invoker command steps[p570] for `dialog`[p650] elements, given an element *element*, an element *invoker*, and a `command`[p568] attribute *command*, are:

1. If *element* is in the popover showing[p896] state, then return.
2. If *command* is in the Close[p569] state and *element* has an `open`[p652] attribute, then close the dialog[p657] *element* with *invoker*'s optional value[p601] and *invoker*.
3. If *command* is in the Request Close[p569] state and *element* has an `open`[p652] attribute, then request to close the dialog[p657] *element* with *invoker*'s optional value[p601] and *invoker*.
4. If *command* is the Show Modal[p569] state and *element* does not have an `open`[p652] attribute, then show a modal dialog[p655] given *element* and *invoker*.

Example

The following buttons use `commandfor`[p568] to open and close a "confirm" `dialog`[p650] as modal when activated:

```
<button type=button
        commandfor="the-dialog"
        command="show-modal">
 Delete
</button>
<dialog id="the-dialog">
 <form action="/delete" method="POST">
  <button type="submit">
   Delete
  </button>
```

```
  <button commandfor="the-dialog"
          command="close">
   Cancel
  </button>
 </form>
</dialog>
```

When a dialog[p650] element *subject* is to be **closed**, with null or a string *result* and an Element or null *source*, run these steps:

1. If *subject* does not have an open[p652] attribute, then return.
2. Fire an event named beforetoggle[p1489], using ToggleEvent[p841], with the oldState[p841] attribute initialized to "open", the newState[p841] attribute initialized to "closed", and the source[p841] attribute initialized to *source* at *subject*.
3. If *subject* does not have an open[p652] attribute, then return.
4. Queue a dialog toggle event task[p658] given *subject*, "open", "closed", and *source*.
5. Remove *subject*'s open[p652] attribute.
6. If is modal[p655] of *subject* is true, then request an element to be removed from the top layer given *subject*.
7. Let *wasModal* be the value of *subject*'s is modal[p655] flag.
8. Set is modal[p655] of *subject* to false.
9. Remove *subject* from *subject*'s node document's open dialogs list[p132].
10. If *result* is not null, then set *subject*'s returnValue[p654] attribute to *result*.
11. Set *subject*'s request close return value[p655] to null.
12. Set *subject*'s request close source element[p655] to null.
13. If *subject*'s previously focused element[p654] is not null, then:
    1. Let *element* be *subject*'s previously focused element[p654].
    2. Set *subject*'s previously focused element[p654] to null.
    3. If *subject*'s node document's focused area of the document[p845]'s DOM anchor[p843] is a shadow-including inclusive descendant of *subject*, or *wasModal* is true, then run the focusing steps[p851] for *element*; the viewport should not be scrolled by doing this step.
14. Queue an element task[p1140] on the user interaction task source[p1149] given the *subject* element to fire an event named close[p1489] at *subject*.
15. If *subject*'s close watcher[p655] is not null, then:
    1. Destroy[p875] *subject*'s close watcher[p655].
    2. Set *subject*'s close watcher[p655] to null.

To **request to close** dialog[p650] element *subject*, given null or a string *returnValue* and null or an Element *source*:

1. If *subject* does not have an open[p652] attribute, then return.
2. Assert: *subject*'s close watcher[p655] is not null.
3. Set *subject*'s enable close watcher for request close[p655] to true.
4. Set *subject*'s request close return value[p655] to *returnValue*.
5. Set *subject*'s request close source element[p655] to *source*.
6. Request to close[p875] *subject*'s close watcher[p655] with false.

7. Set *subject*'s enable close watcher for request close[p655] to false.

To **queue a dialog toggle event task** given a `dialog`[p650] element *element*, a string *oldState*, a string *newState*, and an `Element` or null *source*:

1. If *element*'s dialog toggle task tracker[p654] is not null, then:
    1. Set *oldState* to *element*'s dialog toggle task tracker[p654]'s old state[p842].
    2. Remove *element*'s dialog toggle task tracker[p654]'s task[p842] from its task queue[p1138].
    3. Set *element*'s dialog toggle task tracker[p654] to null.
2. Queue an element task[p1140] given the DOM manipulation task source[p1149] and *element* to run the following steps:
    1. Fire an event named `toggle`[p1491] at *element*, using `ToggleEvent`[p841], with the `oldState`[p841] attribute initialized to *oldState*, the `newState`[p841] attribute initialized to *newState*, and the `source`[p841] attribute initialized to *source*.
    2. Set *element*'s dialog toggle task tracker[p654] to null.
3. Set *element*'s dialog toggle task tracker[p654] to a struct with task[p842] set to the just-queued task[p1139] and old state[p842] set to *oldState*.

To retrieve a dialog's **computed closed-by state**, given a `dialog`[p650] *dialog*:

1. If the state of *dialog*'s `closedby`[p652] attribute is Auto[p652]:
    1. If *dialog*'s is modal[p655] is true, then return Close Request[p652].
    2. Return None[p652].
2. Return the state of *dialog*'s `closedby`[p652] attribute.

The **dialog focusing steps**, given a `dialog`[p650] element *subject*, are as follows:

1. If the allow focus steps[p857] given *subject*'s node document return false, then return.
2. Let *control* be null.
3. If *subject* has the `autofocus`[p857] attribute, then set *control* to *subject*.
4. If *control* is null, then set *control* to the focus delegate[p850] of *subject*.
5. If *control* is null, then set *control* to *subject*.
6. Run the focusing steps[p851] for *control*.

> **Note**
> *If* control *is not focusable[p845], this will do nothing. This would only happen if subject had no focus delegate, and the user agent decided that* `dialog`[p650] *elements were not generally focusable. In that case, any earlier modifications[p655] to the focused area of the document[p845] will apply.*

7. Let *topDocument* be *control*'s node navigable[p1002]'s top-level traversable[p1003]'s active document[p1002].
8. If *control*'s node document's origin is not the same[p910] as the origin of *topDocument*, then return.
9. Empty *topDocument*'s autofocus candidates[p857].
10. Set *topDocument*'s autofocus processed flag[p857] to true.

4.11.5 Dialog light dismiss §[p658]

> **Note**
> *"Light dismiss" means that clicking outside of a* `dialog`[p650] *element whose* `closedby`[p652] *attribute is in the Any[p652] state will close the* `dialog`[p650] *element. This is in addition to how such* `dialog`[p650]*s respond to close requests[p872].*

To **light dismiss open dialogs**, given a PointerEvent *event*:

1. Assert: *event*'s isTrusted attribute is true.
2. Let *document* be *event*'s target's node document.
3. If *document*'s open dialogs list[p132] is empty, then return.
4. Let *ancestor* be the result of running nearest clicked dialog[p659] given *event*.
5. If *event*'s type is "pointerdown", then set *document*'s dialog pointerdown target[p654] to *ancestor*.
6. If *event*'s type is "pointerup", then:
    1. Let *sameTarget* be true if *ancestor* is *document*'s dialog pointerdown target[p654].
    2. Set *document*'s dialog pointerdown target[p654] to null.
    3. If *sameTarget* is false, then return.
    4. Let *topmostDialog* be the last element of *document*'s open dialogs list[p132].
    5. If *ancestor* is *topmostDialog*, then return.
    6. If *topmostDialog*'s computed closed-by state[p658] is not Any[p652], then return.
    7. Assert: *topmostDialog*'s close watcher[p655] is not null.
    8. Request to close[p875] *topmostDialog*'s close watcher[p655] with false.

To **run light dismiss activities**, given a PointerEvent *event*:

1. Run light dismiss open popovers[p907] with *event*.
2. Run light dismiss open dialogs[p659] with *event*.

Run light dismiss activities[p659] will be called by the Pointer Events spec when the user clicks or touches anywhere on the page.

To find the **nearest clicked dialog**, given a PointerEvent *event*:

1. Let *target* be *event*'s target.
2. If *target* is a dialog[p650] element, *target* has an open[p652] attribute, *target*'s is modal[p655] is true, and *event*'s clientX and clientY are outside the bounds of *target*, then return null.

    Note

    The check for clientX and clientY is because a pointer event that hits the ::backdrop *pseudo element of a dialog will result in* event *having a target of the dialog element itself.*
3. Let *currentNode* be *target*.
4. While *currentNode* is not null:
    1. If *currentNode* is a dialog[p650] element and *currentNode* has an open[p652] attribute, then return *currentNode*.
    2. Set *currentNode* to *currentNode*'s parent in the flat tree.
5. Return null.

4.12 Scripting §[p659]

Scripts allow authors to add interactivity to their documents.

Authors are encouraged to use declarative alternatives to scripting where possible, as declarative mechanisms are often more maintainable, and many users disable scripting.

Example

For example, instead of using a script to show or hide a section to show more details, the `details` element could be used.

Authors are also encouraged to make their applications degrade gracefully in the absence of scripting support.

Example

For example, if an author provides a link in a table header to dynamically resort the table, the link could also be made to function without scripts by requesting the sorted table from the server.

4.12.1 The `script` element

Categories:

Metadata content.
Flow content.
Phrasing content.
Script-supporting element.

Contexts in which this element can be used:

Where metadata content is expected.
Where phrasing content is expected.
Where script-supporting elements are expected.

Content model:

If there is no `src` attribute, depends on the value of the `type` attribute, but must match script content restrictions.
If there *is* a `src` attribute, the element must be either empty or contain only script documentation that also matches script content restrictions.

Tag omission in text/html:

Neither tag is omissible.

Content attributes:

Global attributes
`type` — Type of script
`src` — Address of the resource
`nomodule` — Prevents execution in user agents that support module scripts
`async` — Execute script when available, without blocking while fetching
`defer` — Defer script execution
`blocking` — Whether the element is potentially render-blocking
`crossorigin` — How the element handles crossorigin requests
`referrerpolicy` — Referrer policy for fetches initiated by the element
`integrity` — Integrity metadata used in *Subresource Integrity* checks [SRI]
`fetchpriority` — Sets the priority for fetches initiated by the element

Accessibility considerations:

For authors.
For implementers.

DOM interface:

IDL

```
[Exposed=Window]
interface HTMLScriptElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString type;
  [CEReactions] attribute USVString src;
  [CEReactions] attribute boolean noModule;
  [CEReactions] attribute boolean async;
  [CEReactions] attribute boolean defer;
  [SameObject, PutForwards=value] readonly attribute DOMTokenList blocking;
  [CEReactions] attribute DOMString? crossOrigin;
```

```
  [CEReactions] attribute DOMString referrerPolicy;
  [CEReactions] attribute DOMString integrity;
  [CEReactions] attribute DOMString fetchPriority;

  [CEReactions] attribute DOMString text;

  static boolean supports(DOMString type);

  // also has obsolete members
};
```

The script[p660] element allows authors to include dynamic script, instructions to the user agent, and data blocks in their documents. The element does not represent[p142] content for the user.

The script element has two core attributes. The **type** attribute allows customization of the type of script represented:

- Omitting the attribute, setting it to the empty string, or setting it to a JavaScript MIME type essence match means that the script is a classic script[p1100], to be interpreted according to the JavaScript *Script* top-level production. Authors should omit the type[p661] attribute instead of redundantly setting it.
- Setting the attribute to an ASCII case-insensitive match for "`module`" means that the script is a JavaScript module script[p1100], to be interpreted according to the JavaScript *Module* top-level production.
- Setting the attribute to an ASCII case-insensitive match for "`importmap`" means that the script is an import map[p1122], containing JSON that will be used to control the behavior of module specifier resolution[p1116].
- Setting the attribute to any other value means that the script is a **data block**, which is not processed by the user agent, but instead by author script or other tools. Authors must use a valid MIME type string that is not a JavaScript MIME type essence match to denote data blocks.

> **Note**
>
> *The requirement that data blocks[p661] must be denoted using a valid MIME type string is in place to avoid potential future collisions. Values for the type[p661] attribute that are not MIME types, like "`module`" or "`importmap`", are used by the standard to denote types of scripts which have special behavior in user agents. By using a valid MIME type string now, you ensure that your data block will not ever be reinterpreted as a different script type, even in future user agents.*

The second core attribute is the **src** attribute. It must only be specified for classic scripts[p1100] and JavaScript module scripts[p1100], and denotes that instead of using the element's child text content as the script content, the script will be fetched from the specified URL. If src[p661] is specified, it must be a valid non-empty URL potentially surrounded by spaces[p97].

Which other attributes may be specified on a given script[p660] element is determined by the following table:

	nomodule[p662]	async[p662]	defer[p662]	blocking[p662]	crossorigin[p662]	referrerpolicy[p662]	integrity[p663]	fetchpriority[p663]
External classic scripts	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Inline classic scripts	Yes	·	·	·	Yes*	Yes*	·	·†
External module scripts	·	Yes	·	Yes	Yes	Yes	Yes	Yes
Inline module scripts	·	Yes	·	·	Yes*	Yes*	·	·†
Import maps	·	·	·	·	·	·	·	·
Data blocks	·	·	·	·	·	·	·	·

* Although inline scripts have no initial fetches, the crossorigin[p662] and referrerpolicy[p662] attribute on inline scripts affects the credentials mode and referrer policy used by module imports, including dynamic `import()`.

† Unlike crossorigin[p662] and referrerpolicy[p662], fetchpriority[p663] does not affect module imports. See some discussion in issue #10276.

The contents of inline script[p660] elements, or the external script resource, must conform with the requirements of the JavaScript specification's *Script* or *Module* productions, for classic scripts[p1100] and JavaScript module scripts[p1100] respectively. [JAVASCRIPT][p1497]

The contents of inline script[p660] elements for import maps[p1122] must conform with the import map authoring requirements[p1121].

When used to include data blocks[p661], the data must be embedded inline, the format of the data must be given using the type[p661] attribute, and the contents of the script[p660] element must conform to the requirements defined for the format used.

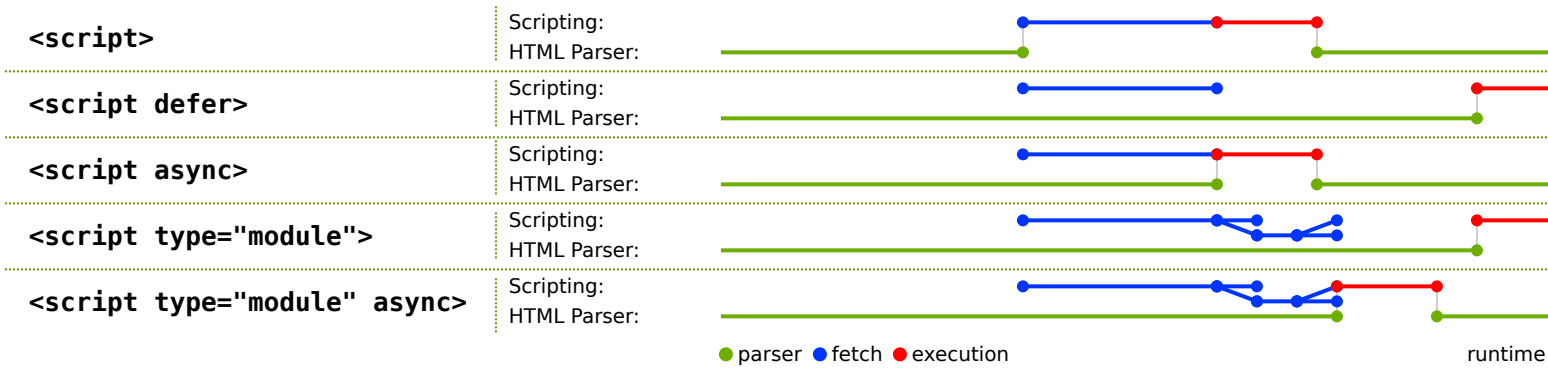
The **nomodule** attribute is a boolean attribute[p76] that prevents a script from being executed in user agents that support module scripts[p1100]. This allows selective execution of module scripts[p1100] in modern user agents and classic scripts[p1100] in older user agents, as shown below[p665].

The **async** and **defer** attributes are boolean attributes[p76] that indicate how the script should be evaluated. There are several possible modes that can be selected using these attributes, depending on the script's type.

For external classic scripts[p1100], if the async[p662] attribute is present, then the classic script will be fetched in parallel[p44] to parsing and evaluated as soon as it is available (potentially before parsing completes). If the async[p662] attribute is not present but the defer[p662] attribute is present, then the classic script will be fetched in parallel[p44] and evaluated when the page has finished parsing. If neither attribute is present, then the script is fetched and evaluated immediately, blocking parsing until these are both complete.

For module scripts[p1100], if the async[p662] attribute is present, then the module script and all its dependencies will be fetched in parallel[p44] to parsing, and the module script will be evaluated as soon as it is available (potentially before parsing completes). Otherwise, the module script and its dependencies will be fetched in parallel[p44] to parsing and evaluated when the page has finished parsing. (The defer[p662] attribute has no effect on module scripts.)

This is all summarized in the following schematic diagram:



Note

The exact processing details for these attributes are, for mostly historical reasons, somewhat non-trivial, involving a number of aspects of HTML. The implementation requirements are therefore by necessity scattered throughout the specification. The algorithms below[p666] describe the core of this processing, but these algorithms reference and are referenced by the parsing rules for script[p660] start[p1346] and end[p1360] tags in HTML, in foreign content[p1375], and in XML[p1403], the rules for the document.write()[p1168] method, the handling of scripting[p1087], etc.

Note

When inserted using the document.write()[p1168] method, script[p660] elements usually[p1347] execute (typically blocking further script execution or HTML parsing). When inserted using the innerHTML[p1172] and outerHTML[p1173] attributes, they do not execute at all.

The defer[p662] attribute may be specified even if the async[p662] attribute is specified, to cause legacy web browsers that only support defer[p662] (and not async[p662]) to fall back to the defer[p662] behavior instead of the blocking behavior that is the default.

The **blocking** attribute is a blocking attribute[p104].

The **crossorigin** attribute is a CORS settings attribute[p101]. For external classic scripts[p1100], it controls whether error information will be exposed, when the script is obtained from other origins[p909]. For external module scripts[p1100], it controls the credentials mode used for the initial fetch of the module source, if cross-origin. For both classic[p1100] and module scripts[p1100], it controls the credentials mode used for cross-origin module imports.

Note

Unlike classic scripts[p1100], module scripts[p1100] require the use of the CORS protocol for cross-origin fetching.

The **referrerpolicy** attribute is a referrer policy attribute[p101]. Its sets the referrer policy used for the initial fetch of an external script, as well as the fetching of any imported module scripts. [REFERRERPOLICY][p1499]

Example

An example of a script element's referrer policy being used when fetching imported scripts but not other subresources:

```
<script referrerpolicy="origin">
  fetch('/api/data');    // not fetched with <script>'s referrer policy
  import('./utils.mjs'); // is fetched with <script>'s referrer policy ("origin" in this case)
</script>
```

The **integrity** attribute sets the integrity metadata used for the initial fetch of an external script. The value must match the requirements of the integrity attribute. [SRI]

The **fetchpriority** attribute is a fetch priority attribute. Its sets the priority used for the initial fetch of an external script.

Changing any of these attributes dynamically has no direct effect; these attributes are only used at specific times described in the processing model.

The IDL attributes **src**, **type**, **defer**, **integrity**, and **blocking** must each reflect the respective content attributes of the same name.

The **noModule** IDL attribute must reflect the nomodule content attribute.

The **crossOrigin** IDL attribute must reflect the crossorigin content attribute, limited to only known values.

The **referrerPolicy** IDL attribute must reflect the referrerpolicy content attribute, limited to only known values.

The **fetchPriority** IDL attribute must reflect the fetchpriority content attribute, limited to only known values.

The **async** getter steps are:

1. If this's force async is true, then return true.
2. If this's async content attribute is present, then return true.
3. Return false.

The async setter steps are:

1. Set this's force async to false.
2. If the given value is true, then set this's async content attribute to the empty string.
3. Otherwise, remove this's async content attribute.

For web developers (non-normative)

***script*.text [= *value*]**

Returns the child text content of the element.

script*.text = *value

Replaces the element's children with the text given by *value*.

HTMLScriptElement.supports(*type*)

Returns true if the given *type* is a script type supported by the user agent. The possible script types in this specification are "classic", "module", and "importmap", but others might be added in the future.

The **text** getter steps are to return this's child text content.

The text setter steps are to string replace all with the given value within this.

The static **supports(*type*)** method steps are:

1. If *type* is "classic", then return true.
2. If *type* is "module", then return true.

3. If *type* is "`importmap`", then return true.

4. Return false.

Note

The type *argument has to exactly match these values; we do not perform an ASCII case-insensitive match. This is different from how* `type`[p661] *content attribute values are treated, and how* `DOMTokenList`'s `supports()` *method works, but it aligns with the* `WorkerType`[p1254] *enumeration used in the* `Worker()`[p1254] *constructor.*

Example

In this example, two `script`[p660] elements are used. One embeds an external classic script[p1100], and the other includes some data as a data block[p661].

```
<script src="game-engine.js"></script>
<script type="text/x-game-map">
........U.........e
o............A....e
.....A.....AAA....e
.A..AAA...AAAAA...e
</script>
```

The data in this case might be used by the script to generate the map of a video game. The data doesn't have to be used that way, though; maybe the map data is actually embedded in other parts of the page's markup, and the data block here is just used by the site's search engine to help users who are looking for particular features in their game maps.

Example

The following sample shows how a `script`[p660] element can be used to define a function that is then used by other parts of the document, as part of a classic script[p1100]. It also shows how a `script`[p660] element can be used to invoke script while the document is being parsed, in this case to initialize the form's output.

```
<script>
 function calculate(form) {
   var price = 52000;
   if (form.elements.brakes.checked)
     price += 1000;
   if (form.elements.radio.checked)
     price += 2500;
   if (form.elements.turbo.checked)
     price += 5000;
   if (form.elements.sticker.checked)
     price += 250;
   form.elements.result.value = price;
 }
</script>
<form name="pricecalc" onsubmit="return false" onchange="calculate(this)">
 <fieldset>
  <legend>Work out the price of your car</legend>
  <p>Base cost: £52000.</p>
  <p>Select additional options:</p>
  <ul>
   <li><label><input type=checkbox name=brakes> Ceramic brakes (£1000)</label></li>
   <li><label><input type=checkbox name=radio> Satellite radio (£2500)</label></li>
   <li><label><input type=checkbox name=turbo> Turbo charger (£5000)</label></li>
   <li><label><input type=checkbox name=sticker> "XZ" sticker (£250)</label></li>
  </ul>
  <p>Total: £<output name=result></output></p>
 </fieldset>
 <script>
  calculate(document.forms.pricecalc);
```

```
 </script>
</form>
```

¶ p665 Example

The following sample shows how a script element can be used to include an external JavaScript module script.

```
<script type="module" src="app.mjs"></script>
```

This module, and all its dependencies (expressed through JavaScript `import` statements in the source file), will be fetched. Once the entire resulting module graph has been imported, and the document has finished parsing, the contents of `app.mjs` will be evaluated.

Additionally, if code from another script element in the same Window imports the module from `app.mjs` (e.g. via `import "./app.mjs";`), then the same JavaScript module script created by the former script element will be imported.

¶ p665 Example

This example shows how to include a JavaScript module script for modern user agents, and a classic script for older user agents:

```
<script type="module" src="app.mjs"></script>
<script nomodule defer src="classic-app-bundle.js"></script>
```

In modern user agents that support JavaScript module scripts, the script element with the nomodule attribute will be ignored, and the script element with a type of "`module`" will be fetched and evaluated (as a JavaScript module script). Conversely, older user agents will ignore the script element with a type of "`module`", as that is an unknown script type for them — but they will have no problem fetching and evaluating the other script element (as a classic script), since they do not implement the nomodule attribute.

¶ p665 Example

The following sample shows how a script element can be used to write an inline JavaScript module script that performs a number of substitutions on the document's text, in order to make for a more interesting reading experience (e.g. on a news site): [XKCD1288]

```
<script type="module">
 import { walkAllTextNodeDescendants } from "./dom-utils.mjs";

 const substitutions = new Map([
   ["witnesses", "these dudes I know"]
   ["allegedly", "kinda probably"]
   ["new study", "Tumblr post"]
   ["rebuild", "avenge"]
   ["space", "spaaace"]
   ["Google glass", "Virtual Boy"]
   ["smartphone", "Pokédex"]
   ["electric", "atomic"]
   ["Senator", "Elf-Lord"]
   ["car", "cat"]
   ["election", "eating contest"]
   ["Congressional leaders", "river spirits"]
   ["homeland security", "Homestar Runner"]
   ["could not be reached for comment", "is guilty and everyone knows it"]
 ]);

 function substitute(textNode) {
   for (const [before, after] of substitutions.entries()) {
     textNode.data = textNode.data.replace(new RegExp(`\\b${before}\\b`, "ig"), after);
```

```
    }
  }

  walkAllTextNodeDescendants(document.body, substitute);
</script>
```

Some notable features gained by using a JavaScript module script include the ability to import functions from other JavaScript modules, strict mode by default, and how top-level declarations do not introduce new properties onto the global object[p1092]. Also note that no matter where this script[p660] element appears in the document, it will not be evaluated until both document parsing has complete and its dependency (`dom-utils.mjs`) has been fetched and evaluated.

¶[p666] Example

The following sample shows how a JSON module script[p1100] can be imported from inside a JavaScript module script[p1100]:

```
<script type="module">
  import peopleInSpace from "http://api.open-notify.org/astros.json" with { type: "json" };

  const list = document.querySelector("#people-in-space");
  for (const { craft, name } of peopleInSpace.people) {
    const li = document.createElement("li");
    li.textContent = `${name} / ${craft}`;
    list.append(li);
  }
</script>
```

MIME type checking for module scripts is strict. In order for the fetch of the JSON module script[p1100] to succeed, the HTTP response must have a JSON MIME type, for example `Content-Type: text/json`. On the other hand, if the `with { type: "json" }` part of the statement is omitted, it is assumed that the intent is to import a JavaScript module script[p1100], and the fetch will fail if the HTTP response has a MIME type that is not a JavaScript MIME type.

4.12.1.1 Processing model §[p666]

A script[p660] element has several associated pieces of state.

A script[p660] element has a **parser document**, which is either null or a Document[p131], initially null. It is set by the HTML parser[p1289] and the XML parser[p1402] on script[p660] elements they insert, and affects the processing of those elements. script[p660] elements with non-null parser documents[p666] are known as **parser-inserted**.

A script[p660] element has a **preparation-time document**, which is either null or a Document[p131], initially null. It is used to prevent scripts that move between documents during preparation[p668] from executing[p673].

A script[p660] element has a **force async** boolean, initially true. It is set to false by the HTML parser[p1289] and the XML parser[p1402] on script[p660] elements they insert, and when the element gets an async[p662] content attribute added.

A script[p660] element has a **from an external file** boolean, initially false. It is determined when the script is prepared[p668], based on the src[p661] attribute of the element at that time.

A script[p660] element has a **ready to be parser-executed** boolean, initially false. This is used only used for elements that are also parser-inserted[p666], to let the parser know when to execute the script.

A script[p660] element has an **already started** boolean, initially false.

A script[p660] element has a **delaying the load event** boolean, initially false.

A script[p660] element has a **type**, which is either null, "`classic`", "`module`", or "`importmap`", initially null. It is determined when the element is prepared[p668], based on the type[p661] attribute of the element at that time.

A script[p660] element has a **result**, which is either "`uninitialized`", null (representing an error), a script[p1099], or an import map parse

result[p1116]. It is initially "uninitialized".

A script[p660] element has **steps to run when the result is ready**, which are a series of steps or null, initially null. To **mark as ready** a script[p660] element *el* given a script[p1099], import map parse result[p1116], or null *result*:

1. Set *el*'s result[p666] to *result*.
2. If *el*'s steps to run when the result is ready[p667] are not null, then run them.
3. Set *el*'s steps to run when the result is ready[p667] to null.
4. Set *el*'s delaying the load event[p666] to false.

A script[p660] element *el* is implicitly potentially render-blocking[p105] if *el*'s type[p666] is "classic", *el* is parser-inserted[p666], and *el* does not have an async[p662] or defer[p662] attribute.

The cloning steps for script[p660] elements given *node*, *copy*, and *subtree* are to set *copy*'s already started[p666] to *node*'s already started[p666].

When an async[p662] attribute is added to a script[p660] element *el*, the user agent must set *el*'s force async[p666] to false.

Whenever a script[p660] element *el*'s delaying the load event[p666] is true, the user agent must delay the load event[p1377] of *el*'s preparation-time document[p666].

The script[p660] HTML element post-connection steps[p46], given *insertedNode*, are:

1. If *insertedNode* is not connected, then return.

   Example

   This can happen in the case where an earlier-inserted script[p660] removes a later-inserted script[p660]. For instance:

   ```
   <script>
   const script1 = document.createElement('script');
   script1.innerText = `
     document.querySelector('#script2').remove();
   `;

   const script2 = document.createElement('script');
   script2.id = 'script2';
   script2.textContent = `console.log('script#2 running')`;

   document.body.append(script1, script2);
   </script>
   ```

   Nothing is printed to the console in this example. By the time the HTML element post-connection steps[p46] run for the first script[p660] that was atomically inserted by append(), it can observe that the second script[p660] is already connected to the DOM. It removes the second script[p660], so that by the time *its* HTML element post-connection steps[p46] run, it is no longer connected, and does not get prepared[p668].

2. If *insertedNode* is parser-inserted[p666], then return.
3. Prepare the script element[p668] given *insertedNode*.

The script[p660] children changed steps are:

1. Run the script[p660] HTML element post-connection steps[p46], given the script[p660] element.

Example

This has an interesting implication on the execution order of a script[p660] element and any newly-inserted child script[p660] elements. Consider the following snippet:

```
<script id=outer-script></script>

<script>
  const outerScript = document.querySelector('#outer-script');

  const start = new Text('console.log(1);');
  const innerScript = document.createElement('script');
  innerScript.textContent = `console.log('inner script executing')`;
  const end = new Text('console.log(2);');

  outerScript.append(start, innerScript, end);

  // Logs:
  // 1
  // 2
  // inner script executing
</script>
```

By the time the second script block executes, the `outer-script` has already been prepared[p668], but because it is empty, it did not execute and therefore is not marked as already started[p666]. The atomic insertion of the `Text` nodes and nested `script`[p660] element have the following effects:

1. All three child nodes get atomically inserted as children of `outer-script`; all of their insertion steps run, which have no observable consequences in this case.
2. The `outer-script`'s children changed steps run, which prepares[p668] that script; because its body is now non-empty, this executes the contents of the two `Text` nodes, in order.
3. The `script`[p660] HTML element post-connection steps[p46] finally run for `innerScript`, causing its body to execute.

The following attribute change steps, given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used for all `script`[p660] elements:

1. If *namespace* is not null, then return.
2. If *localName* is `src`[p661], then run the `script`[p660] HTML element post-connection steps[p46], given *element*.

To **prepare the script element** given a `script`[p660] element *el*:

1. If *el*'s already started[p666] is true, then return.
2. Let *parser document* be *el*'s parser document[p666].
3. Set *el*'s parser document[p666] to null.

   Note

   This is done so that if parser-inserted `script`[p660] elements fail to run when the parser tries to run them, e.g. because they are empty or specify an unsupported scripting language, another script can later mutate them and cause them to run again.

4. If *parser document* is non-null and *el* does not have an `async`[p662] attribute, then set *el*'s force async[p666] to true.

   Note

   This is done so that if a parser-inserted `script`[p660] element fails to run when the parser tries to run it, but it is later executed after a script dynamically updates it, it will execute in an async fashion even if the `async`[p662] attribute isn't set.

5. Let *source text* be *el*'s child text content.
6. If *el* has no `src`[p661] attribute, and *source text* is the empty string, then return.
7. If *el* is not connected, then return.
8. If any of the following are true:

- *el* has a `type`[p661] attribute whose value is the empty string;
- *el* has no `type`[p661] attribute but it has a `language`[p1447] attribute and *that* attribute's value is the empty string; or
- *el* has neither a `type`[p661] attribute nor a `language`[p1447] attribute,

then let *the script block's type string* for this `script`[p660] element be "`text/javascript`".

Otherwise, if *el* has a `type`[p661] attribute, then let *the script block's type string* be the value of that attribute with leading and trailing ASCII whitespace stripped.

Otherwise, *el* has a non-empty `language`[p1447] attribute; let *the script block's type string* be the concatenation of "`text/`" and the value of *el*'s `language`[p1447] attribute.

Note

The `language`[p1447] attribute is never conforming, and is always ignored if there is a `type`[p661] attribute present.

9. If *the script block's type string* is a JavaScript MIME type essence match, then set *el*'s type[p666] to "`classic`".
10. Otherwise, if *the script block's type string* is an ASCII case-insensitive match for the string "`module`", then set *el*'s type[p666] to "`module`".
11. Otherwise, if *the script block's type string* is an ASCII case-insensitive match for the string "`importmap`", then set *el*'s type[p666] to "`importmap`".
12. Otherwise, return. (No script is executed, and *el*'s type[p666] is left as null.)
13. If *parser document* is non-null, then set *el*'s parser document[p666] back to *parser document* and set *el*'s force async[p666] to false.
14. Set *el*'s already started[p666] to true.
15. Set *el*'s preparation-time document[p666] to its node document.
16. If *parser document* is non-null, and *parser document* is not equal to *el*'s preparation-time document[p666], then return.
17. If scripting is disabled[p1099] for *el*, then return.

Note

The definition of scripting is disabled[p1099] means that, amongst others, the following scripts will not execute: scripts in `XMLHttpRequest`'s `responseXML` documents, scripts in `DOMParser`[p1169]-created documents, scripts in documents created by `XSLTProcessor`[p53]'s `transformToDocument`[p53] feature, and scripts that are first inserted by a script into a `Document`[p131] that was created using the `createDocument()` API. [XHR][p1502] [DOMPARSING][p1496] [XSLTP][p1502] [DOM][p1496]

18. If *el* has a `nomodule`[p662] content attribute and its type[p666] is "`classic`", then return.

Note

This means specifying `nomodule`[p662] on a module script[p1100] has no effect; the algorithm continues onward.

19. If *el* does not have a `src`[p661] content attribute, and the Should element's inline behavior be blocked by Content Security Policy? algorithm returns "`Blocked`" when given *el*, "`script`", and *source text*, then return. [CSP][p1494]
20. If *el* has an `event`[p1447] attribute and a `for`[p1447] attribute, and *el*'s type[p666] is "`classic`", then:
    1. Let *for* be the value of *el*'s `for`[p1447] attribute.
    2. Let *event* be the value of *el*'s `event`[p1447] attribute.
    3. Strip leading and trailing ASCII whitespace from *event* and *for*.
    4. If *for* is not an ASCII case-insensitive match for the string "`window`", then return.
    5. If *event* is not an ASCII case-insensitive match for either the string "`onload`" or the string "`onload()`", then return.
21. If *el* has a `charset`[p1445] attribute, then let *encoding* be the result of getting an encoding from the value of the `charset`[p1445] attribute.

    If *el* does not have a `charset`[p1445] attribute, or if getting an encoding failed, then let *encoding* be *el*'s node document's the

encoding.

Note

If el's *type*[p666] *is* "module"*, this encoding will be ignored.*

22. Let *classic script CORS setting* be the current state of *el*'s crossorigin[p662] content attribute.

23. Let *module script credentials mode* be the CORS settings attribute credentials mode[p101] for *el*'s crossorigin[p662] content attribute.

24. Let *cryptographic nonce* be *el*'s [[CryptographicNonce]][p102] internal slot's value.

25. If *el* has an integrity[p663] attribute, then let *integrity metadata* be that attribute's value.

    Otherwise, let *integrity metadata* be the empty string.

26. Let *referrer policy* be the current state of *el*'s referrerpolicy[p662] content attribute.

27. Let *fetch priority* be the current state of *el*'s fetchpriority[p663] content attribute.

28. Let *parser metadata* be "parser-inserted" if *el* is parser-inserted[p666], and "not-parser-inserted" otherwise.

29. Let *options* be a script fetch options[p1101] whose cryptographic nonce[p1101] is *cryptographic nonce*, integrity metadata[p1101] is *integrity metadata*, parser metadata[p1101] is *parser metadata*, credentials mode[p1101] is *module script credentials mode*, referrer policy[p1101] is *referrer policy*, and fetch priority[p1101] is *fetch priority*.

30. Let *settings object* be *el*'s node document's relevant settings object[p1098].

31. If *el* has a src[p661] content attribute, then:

    1. If *el*'s type[p666] is "importmap", then queue an element task[p1140] on the DOM manipulation task source[p1149] given *el* to fire an event named error[p1489] at *el*, and return.

       Note

       External import map scripts are not currently supported. See WICG/import-maps issue #235 for discussions on adding support.

    2. Let *src* be the value of *el*'s src[p661] attribute.

    3. If *src* is the empty string, then queue an element task[p1140] on the DOM manipulation task source[p1149] given *el* to fire an event named error[p1489] at *el*, and return.

    4. Set *el*'s from an external file[p666] to true.

    5. Let *url* be the result of encoding-parsing a URL[p98] given *src*, relative to *el*'s node document.

    6. If *url* is failure, then queue an element task[p1140] on the DOM manipulation task source[p1149] given *el* to fire an event named error[p1489] at *el*, and return.

    7. If *el* is potentially render-blocking[p105], then block rendering[p135] on *el*.

    8. Set *el*'s delaying the load event[p666] to true.

    9. If *el* is currently render-blocking[p135], then set *options*'s render-blocking[p1101] to true.

    10. Let *onComplete* given *result* be the following steps:

        1. Mark as ready[p667] *el* given *result*.

    11. Switch on *el*'s type[p666]:

        ↪ "classic"

        Fetch a classic script[p1102] given *url*, *settings object*, *options*, *classic script CORS setting*, *encoding*, and *onComplete*.

        ↪ "module"

        If *el* does not have an integrity[p663] attribute, then set *options*'s integrity metadata[p1101] to the result of resolving a module integrity metadata[p1101] with *url* and *settings object*.

Fetch an external module script graph[p1104] given *url*, *settings object*, *options*, and *onComplete*.

For performance reasons, user agents may start fetching the classic script or module graph (as defined above) as soon as the `src`[p661] attribute is set, instead, in the hope that *el* will become connected (and that the `crossorigin`[p662] attribute won't change value in the meantime). Either way, once *el* becomes connected[p47], the load must have started as described in this step. If the UA performs such prefetching, but *el* never becomes connected, or the `src`[p661] attribute is dynamically changed, or the `crossorigin`[p662] attribute is dynamically changed, then the user agent will not execute the script so obtained, and the fetching process will have been effectively wasted.

32. If *el* does not have a `src`[p661] content attribute:

    1. Let *base URL* be *el*'s node document's document base URL[p98].

    2. Switch on *el*'s type[p666]:

       ↪ "`classic`"

       1. Let *script* be the result of creating a classic script[p1108] using *source text*, *settings object*, *base URL*, and *options*.

       2. Mark as ready[p667] *el* given *script*.

       ↪ "`module`"

       1. Set *el*'s delaying the load event[p666] to true.

       2. If *el* is potentially render-blocking[p105], then:

          1. Block rendering[p135] on *el*.

          2. Set *options*'s render-blocking[p1101] to true.

       3. Fetch an inline module script graph[p1104], given *source text*, *base URL*, *settings object*, *options*, and with the following steps given *result*:

          1. Queue an element task[p1140] on the networking task source[p1149] given *el* to perform the following steps:

             1. Mark as ready[p667] *el* given *result*.

          Note

          Queueing a task here means that, even if the inline module script has no dependencies or synchronously results in a parse error, we won't proceed to execute the script element[p673] synchronously.

       ↪ "`importmap`"

       1. Let *result* be the result of creating an import map parse result[p1116] given *source text* and *base URL*.

       2. Mark as ready[p667] *el* given *result*.

33. If *el*'s type[p666] is "`classic`" and *el* has a `src`[p661] attribute, or *el*'s type[p666] is "`module`":

    1. Assert: *el*'s result[p666] is "`uninitialized`".

    2. If *el* has an `async`[p662] attribute or *el*'s force async[p666] is true:

       1. Let *scripts* be *el*'s preparation-time document[p666]'s set of scripts that will execute as soon as possible[p672].

       2. Append *el* to *scripts*.

       3. Set *el*'s steps to run when the result is ready[p667] to the following:

          1. Execute the script element[p673] *el*.

          2. Remove *el* from *scripts*.

    3. Otherwise, if *el* is not parser-inserted[p666]:

1. Let *scripts* be *el*'s preparation-time document[p666]'s list of scripts that will execute in order as soon as possible[p672].
2. Append *el* to *scripts*.
3. Set *el*'s steps to run when the result is ready[p667] to the following:
    1. If *scripts*[0] is not *el*, then abort these steps.
    2. While *scripts* is not empty, and *scripts*[0]'s result[p666] is not "`uninitialized`":
        1. Execute the script element[p673] *scripts*[0].
        2. Remove *scripts*[0].

4. Otherwise, if *el* has a `defer`[p662] attribute or *el*'s type[p666] is "`module`":
    1. Append *el* to its parser document[p666]'s list of scripts that will execute when the document has finished parsing[p672].
    2. Set *el*'s steps to run when the result is ready[p667] to the following: set *el*'s ready to be parser-executed[p666] to true. (The parser will handle executing the script.)

5. Otherwise:
    1. Set *el*'s parser document[p666]'s pending parsing-blocking script[p672] to *el*.
    2. Block rendering[p135] on *el*.
    3. Set *el*'s steps to run when the result is ready[p667] to the following: set *el*'s ready to be parser-executed[p666] to true. (The parser will handle executing the script.)

34. Otherwise:
    1. Assert: *el*'s result[p666] is *not* "`uninitialized`".
    2. If all of the following are true:
        - *el*'s type[p666] is "`classic`";
        - *el* is parser-inserted[p666];
        - *el*'s parser document[p666] has a style sheet that is blocking scripts[p205]; and
        - either the parser that created *el* is an XML parser[p1402], or it's an HTML parser[p1289] whose script nesting level[p1291] is not greater than one,

        then:
        1. Set *el*'s parser document[p666]'s pending parsing-blocking script[p672] to *el*.
        2. Set *el*'s ready to be parser-executed[p666] to true. (The parser will handle executing the script.)
    3. Otherwise, immediately[p44] execute the script element[p673] *el*, even if other scripts are already executing.

Each Document[p131] has a **pending parsing-blocking script**, which is a `script`[p660] element or null, initially null.

Each Document[p131] has a **set of scripts that will execute as soon as possible**, which is a set of `script`[p660] elements, initially empty.

Each Document[p131] has a **list of scripts that will execute in order as soon as possible**, which is a list of `script`[p660] elements, initially empty.

Each Document[p131] has a **list of scripts that will execute when the document has finished parsing**, which is a list of `script`[p660] elements, initially empty.

Note

If a `script`[p660] element that blocks a parser gets moved to another Document[p131] before it would normally have stopped blocking that parser, it nonetheless continues blocking that parser until the condition that causes it to be blocking the parser no longer

applies (e.g., if the script is a pending parsing-blocking script because the original Document has a style sheet that is blocking scripts when it was parsed, but then the script is moved to another Document before the blocking style sheet(s) loaded, the script still blocks the parser until the style sheets are all loaded, at which time the script executes and the parser is unblocked).

To **execute the script element** given a `script` element *el*:

1. Let *document* be *el*'s node document.
2. If *el*'s preparation-time document is not equal to *document*, then return.
3. Unblock rendering on *el*.
4. If *el*'s result is null, then fire an event named `error` at *el*, and return.
5. If *el*'s from an external file is true, or *el*'s type is "`module`", then increment *document*'s ignore-destructive-writes counter.
6. Switch on *el*'s type:

   ↪ **"`classic`"**

   1. Let *oldCurrentScript* be the value to which *document*'s `currentScript` object was most recently set.
   2. If *el*'s root is *not* a shadow root, then set *document*'s `currentScript` attribute to *el*. Otherwise, set it to null.

      Note

      This does not use the in a document tree check, as el *could have been removed from the document prior to execution, and in that scenario `currentScript` still needs to point to it.*

   3. Run the classic script given by *el*'s result.
   4. Set *document*'s `currentScript` attribute to *oldCurrentScript*.

   ↪ **"`module`"**

   1. Assert: *document*'s `currentScript` attribute is null.
   2. Run the module script given by *el*'s result.

   ↪ **"`importmap`"**

   1. Register an import map given *el*'s relevant global object and *el*'s result.
7. Decrement the ignore-destructive-writes counter of *document*, if it was incremented in the earlier step.
8. If *el*'s from an external file is true, then fire an event named `load` at *el*.

4.12.1.2 Scripting languages §

User agents are not required to support JavaScript. This standard needs to be updated if a language other than JavaScript comes along and gets similar wide adoption by web browsers. Until such a time, implementing other languages is in conflict with this standard, given the processing model defined for the `script` element.

Servers should use `text/javascript` for JavaScript resources, in accordance with *Updates to ECMAScript Media Types*. Servers should not use other JavaScript MIME types for JavaScript resources, and must not use non-JavaScript MIME types. [RFC9239]

For external JavaScript resources, MIME type parameters in `` `Content-Type` `` headers are generally ignored. (In some cases the `` `charset` `` parameter has an effect.) However, for the `script` element's `type` attribute they are significant; it uses the JavaScript MIME type essence match concept.

Note

For example, scripts with their `type` attribute set to "`text/javascript; charset=utf-8`" *will not be evaluated, even though*

that is a valid JavaScript MIME type when parsed.

Furthermore, again for external JavaScript resources, special considerations apply around `Content-Type` header processing as detailed in the prepare the script element algorithm and *Fetch*. [FETCH]

4.12.1.3 Restrictions for contents of `script` elements

Note

The easiest and safest way to avoid the rather strange restrictions described in this section is to always escape an ASCII case-insensitive match for "<!--" as "\x3C!--", "<script" as "\x3Cscript", and "</script" as "\x3C/script" when these sequences appear in literals in scripts (e.g. in strings, regular expressions, or comments), and to avoid writing code that uses such constructs in expressions. Doing so avoids the pitfalls that the restrictions in this section are prone to triggering: namely, that, for historical reasons, parsing of `script` blocks in HTML is a strange and exotic practice that acts unintuitively in the face of these sequences.

The `script` element's descendant text content must match the `script` production in the following ABNF, the character set for which is Unicode. [ABNF]

```
script        = outer *( comment-open inner comment-close outer )

outer         = < any string that doesn't contain a substring that matches not-in-outer >
not-in-outer  = comment-open
inner         = < any string that doesn't contain a substring that matches not-in-inner >
not-in-inner  = comment-close / script-open

comment-open  = "<!--"
comment-close = "-->"
script-open   = "<" s c r i p t tag-end

s             =  %x0053 ; U+0053 LATIN CAPITAL LETTER S
s             =/ %x0073 ; U+0073 LATIN SMALL LETTER S
c             =  %x0043 ; U+0043 LATIN CAPITAL LETTER C
c             =/ %x0063 ; U+0063 LATIN SMALL LETTER C
r             =  %x0052 ; U+0052 LATIN CAPITAL LETTER R
r             =/ %x0072 ; U+0072 LATIN SMALL LETTER R
i             =  %x0049 ; U+0049 LATIN CAPITAL LETTER I
i             =/ %x0069 ; U+0069 LATIN SMALL LETTER I
p             =  %x0050 ; U+0050 LATIN CAPITAL LETTER P
p             =/ %x0070 ; U+0070 LATIN SMALL LETTER P
t             =  %x0054 ; U+0054 LATIN CAPITAL LETTER T
t             =/ %x0074 ; U+0074 LATIN SMALL LETTER T

tag-end       =  %x0009 ; U+0009 CHARACTER TABULATION (tab)
tag-end       =/ %x000A ; U+000A LINE FEED (LF)
tag-end       =/ %x000C ; U+000C FORM FEED (FF)
tag-end       =/ %x0020 ; U+0020 SPACE
tag-end       =/ %x002F ; U+002F SOLIDUS (/)
tag-end       =/ %x003E ; U+003E GREATER-THAN SIGN (>)
```

When a `script` element contains script documentation, there are further restrictions on the contents of the element, as described in the section below.

Example

The following script illustrates this issue. Suppose you have a script that contains a string, as in:

```
const example = 'Consider this string: <!-- <script>';
console.log(example);
```

If one were to put this string directly in a script[p660] block, it would violate the restrictions above:

```
<script>
  const example = 'Consider this string: <!-- <script>';
  console.log(example);
</script>
```

The bigger problem, though, and the reason why it would violate those restrictions, is that actually the script would get parsed weirdly: *the script block above is not terminated*. That is, what looks like a "</script>" end tag in this snippet is actually still part of the script[p660] block. The script doesn't execute (since it's not terminated); if it somehow were to execute, as it might if the markup looked as follows, it would fail because the script (highlighted here) is not valid JavaScript:

```
<script>
  const example = 'Consider this string: <!-- <script>';
  console.log(example);
</script>
<!-- despite appearances, this is actually part of the script still! -->
<script>
 ... // this is the same script block still...
</script>
```

What is going on here is that for legacy reasons, "<!--" and "<script" strings in script[p660] elements in HTML need to be balanced in order for the parser to consider closing the block.

By escaping the problematic strings as mentioned at the top of this section, the problem is avoided entirely:

```
<script>
  // Note: `\x3C` is an escape sequence for `<`.
  const example = 'Consider this string: \x3C!-- \x3Cscript>';
  console.log(example);
</script>
<!-- this is just a comment between script blocks -->
<script>
 ... // this is a new script block
</script>
```

It is possible for these sequences to naturally occur in script expressions, as in the following examples:

```
if (x<!--y) { ... }
if ( player<script ) { ... }
```

In such cases the characters cannot be escaped, but the expressions can be rewritten so that the sequences don't occur, as in:

```
if (x < !--y) { ... }
if (!--y > x) { ... }
if (!(--y) > x) { ... }
if (player < script) { ... }
if (script > player) { ... }
```

Doing this also avoids a different pitfall as well: for related historical reasons, the string "<!--" in classic scripts[p1100] is actually treated as a line comment start, just like "//".

4.12.1.4 Inline documentation for external scripts §[p675]

If a script[p660] element's src[p661] attribute is specified, then the contents of the script[p660] element, if any, must be such that the value of the text[p663] IDL attribute, which is derived from the element's contents, matches the `documentation` production in the following ABNF, the character set for which is Unicode. [ABNF][p1493]

```
documentation = *( *( space / tab / comment ) [ line-comment ] newline )
comment       = slash star *( not-star / star not-slash ) 1*star slash
line-comment  = slash slash *not-newline

; characters
tab           = %x0009 ; U+0009 CHARACTER TABULATION (tab)
newline       = %x000A ; U+000A LINE FEED (LF)
space         = %x0020 ; U+0020 SPACE
star          = %x002A ; U+002A ASTERISK (*)
slash         = %x002F ; U+002F SOLIDUS (/)
not-newline   = %x0000-0009 / %x000B-10FFFF
                ; a scalar value other than U+000A LINE FEED (LF)
not-star      = %x0000-0029 / %x002B-10FFFF
                ; a scalar value other than U+002A ASTERISK (*)
not-slash     = %x0000-002E / %x0030-10FFFF
                ; a scalar value other than U+002F SOLIDUS (/)
```

Note

This corresponds to putting the contents of the element in JavaScript comments.

Note

This requirement is in addition to the earlier restrictions on the syntax of contents of script[p660] elements.

Example

This allows authors to include documentation, such as license information or API information, inside their documents while still referring to external script files. The syntax is constrained so that authors don't accidentally include what looks like valid script while also providing a src[p661] attribute.

```
<script src="cool-effects.js">
 // create new instances using:
 //    var e = new Effect();
 // start the effect using .play, stop using .stop:
 //    e.play();
 //    e.stop();
</script>
```

4.12.1.5 Interaction of script[p660] elements and XSLT §[p676]

This section is non-normative.

This specification does not define how XSLT interacts with the script[p660] element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, based on existing implementations:

- When an XSLT transformation program is triggered by an `<?xml-stylesheet?>` processing instruction and the browser implements a direct-to-DOM transformation, script[p660] elements created by the XSLT processor need to have its parser document[p666] set correctly, and run in document order (modulo scripts marked defer[p662] or async[p662]), immediately[p44], as the transformation is occurring.

- The XSLTProcessor[p53] transformToDocument()[p53] method adds elements to a Document[p131] object with a null browsing context[p1012], and, accordingly, any script[p660] elements they create need to have their already started[p666] set to true in the prepare the script element[p668] algorithm and never get executed (scripting is disabled[p1098]). Such script[p660] elements still need to have their parser document[p666] set, though, such that their async[p663] IDL attribute will return false in the absence of an async[p662] content attribute.

- The XSLTProcessor[p53] transformToFragment()[p53] method needs to create a fragment that is equivalent to one built manually by creating the elements using document.createElementNS(). For instance, it needs to create script[p660] elements with null parser document[p666] and with their already started[p666] set to false, so that they will execute when the fragment is inserted into a document.

The main distinction between the first two cases and the last case is that the first two operate on Document[p131]s and the last operates on a fragment.

4.12.2 The noscript element §[p677]

Categories[p147]:

Metadata content[p150].
Flow content[p150].
Phrasing content[p151].

Contexts in which this element can be used[p147]:

In a head[p174] element of an HTML document, if there are no ancestor noscript[p677] elements.
Where phrasing content[p151] is expected in HTML documents, if there are no ancestor noscript[p677] elements.

Content model[p147]:

When scripting is disabled[p1099], in a head[p174] element: in any order, zero or more link[p178] elements, zero or more style[p201] elements, and zero or more meta[p190] elements.
When scripting is disabled[p1099], not in a head[p174] element: transparent[p152], but there must be no noscript[p677] element descendants.
Otherwise: text that conforms to the requirements given in the prose.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

Uses HTMLElement[p143].

The noscript[p677] element represents[p142] nothing if scripting is enabled[p1098], and represents[p142] its children if scripting is disabled[p1099]. It is used to present different markup to user agents that support scripting and those that don't support scripting, by affecting how the document is parsed.

When used in HTML documents, the allowed content model is as follows:

In a head[p174] element, if scripting is disabled[p1099] for the noscript[p677] element

The noscript[p677] element must contain only link[p178], style[p201], and meta[p190] elements.

In a head[p174] element, if scripting is enabled[p1098] for the noscript[p677] element

The noscript[p677] element must contain only text, except that invoking the HTML fragment parsing algorithm[p1391] with the noscript[p677] element as the *context*[p1391] element and the text contents as the *input* must result in a list of nodes that consists only of link[p178], style[p201], and meta[p190] elements that would be conforming if they were children of the noscript[p677] element, and no parse errors[p1291].

Outside of head[p174] elements, if scripting is disabled[p1099] for the noscript[p677] element

The noscript[p677] element's content model is transparent[p152], with the additional restriction that a noscript[p677] element must not have a noscript[p677] element as an ancestor (that is, noscript[p677] can't be nested).

Outside of head[p174] elements, if scripting is enabled[p1098] for the noscript[p677] element

The noscript[p677] element must contain only text, except that the text must be such that running the following algorithm results in a conforming document with no noscript[p677] elements and no script[p660] elements, and such that no step in the algorithm throws an exception or causes an HTML parser[p1289] to flag a parse error[p1291]:

1. Remove every script[p660] element from the document.
2. Make a list of every noscript[p677] element in the document. For every noscript[p677] element in that list, perform the following steps:

1. Let *s* be the child text content of the noscript element.
2. Set the outerHTML attribute of the noscript element to the value of *s*. (This, as a side-effect, causes the noscript element to be removed from the document.)

Note

All these contortions are required because, for historical reasons, the noscript element is handled differently by the HTML parser based on whether scripting was enabled or not when the parser was invoked.

The noscript element must not be used in XML documents.

Note

The noscript element is only effective in the HTML syntax, it has no effect in the XML syntax. This is because the way it works is by essentially "turning off" the parser when scripts are enabled, so that the contents of the element are treated as pure text and not as real elements. XML does not define a mechanism by which to do this.

The noscript element has no other requirements. In particular, children of the noscript element are not exempt from form submission, scripting, and so forth, even when scripting is enabled for the element.

Example

In the following example, a noscript element is used to provide fallback for a script.

```
<form action="calcSquare.php">
 <p>
  <label for=x>Number</label>:
  <input id="x" name="x" type="number">
 </p>
 <script>
  var x = document.getElementById('x');
  var output = document.createElement('p');
  output.textContent = 'Type a number; it will be squared right then!';
  x.form.appendChild(output);
  x.form.onsubmit = function () { return false; }
  x.oninput = function () {
    var v = x.valueAsNumber;
    output.textContent = v + ' squared is ' + v * v;
  };
 </script>
 <noscript>
  <input type=submit value="Calculate Square">
 </noscript>
</form>
```

When script is disabled, a button appears to do the calculation on the server side. When script is enabled, the value is computed on-the-fly instead.

The noscript element is a blunt instrument. Sometimes, scripts might be enabled, but for some reason the page's script might fail. For this reason, it's generally better to avoid using noscript, and to instead design the script to change the page from being a scriptless page to a scripted page on the fly, as in the next example:

```
<form action="calcSquare.php">
 <p>
  <label for=x>Number</label>:
  <input id="x" name="x" type="number">
 </p>
 <input id="submit" type=submit value="Calculate Square">
 <script>
  var x = document.getElementById('x');
  var output = document.createElement('p');
```

```
  output.textContent = 'Type a number; it will be squared right then!';
  x.form.appendChild(output);
  x.form.onsubmit = function () { return false; }
  x.oninput = function () {
    var v = x.valueAsNumber;
    output.textContent = v + ' squared is ' + v * v;
  };
  var submit = document.getElementById('submit');
  submit.parentNode.removeChild(submit);
 </script>
</form>
```

The above technique is also useful in XML documents, since `noscript` [p677] is not allowed there.

4.12.3 The `template` element §[p67] 9

Categories [p147]**:**

Metadata content [p150].
Flow content [p150].
Phrasing content [p151].
Script-supporting element [p152].

Contexts in which this element can be used [p147]**:**

Where metadata content [p150] is expected.
Where phrasing content [p151] is expected.
Where script-supporting elements [p152] are expected.
As a child of a `colgroup` [p488] element that doesn't have a `span` [p489] attribute.

Content model [p147]**:**

Nothing [p149] (for clarification, see example [p680]).

Tag omission in text/html [p148]**:**

Neither tag is omissible.

Content attributes [p148]**:**

Global attributes [p155]
`shadowrootmode` [p680] — Enables streaming declarative shadow roots
`shadowrootdelegatesfocus` [p680] — Sets delegates focus on a declarative shadow root
`shadowrootclonable` [p680] — Sets clonable on a declarative shadow root
`shadowrootserializable` [p680] — Sets serializable [p118] on a declarative shadow root
`shadowrootcustomelementregistry` [p680] — Enables declarative shadow roots to indicate they will use a custom element registry

Accessibility considerations [p148]**:**

For authors.
For implementers.

DOM interface [p148]**:**

IDL

```
[Exposed=Window]
interface HTMLTemplateElement : HTMLElement {
  [HTMLConstructor] constructor();

  readonly attribute DocumentFragment content;
  [CEReactions] attribute DOMString shadowRootMode;
  [CEReactions] attribute boolean shadowRootDelegatesFocus;
  [CEReactions] attribute boolean shadowRootClonable;
  [CEReactions] attribute boolean shadowRootSerializable;
  [CEReactions] attribute DOMString shadowRootCustomElementRegistry;
};
```

The template element is used to declare fragments of HTML that can be cloned and inserted in the document by script.

In a rendering, the template element represents nothing.

The **shadowrootmode** content attribute is an enumerated attribute with the following keywords and states:

Keyword	State	Brief description
open	**Open**	The template element represents an open declarative shadow root.
closed	**Closed**	The template element represents a closed declarative shadow root.

The shadowrootmode attribute's *invalid value default* and *missing value default* are both the **None** state.

The **shadowrootdelegatesfocus** content attribute is a boolean attribute.

The **shadowrootclonable** content attribute is a boolean attribute.

The **shadowrootserializable** content attribute is a boolean attribute.

The **shadowrootcustomelementregistry** content attribute is a boolean attribute.

The template contents of a template element are not children of the element itself.

Note

It is also possible, as a result of DOM manipulation, for a template element to contain Text nodes and element nodes; however, having any is a violation of the template element's content model, since its content model is defined as nothing.

¶ 680

Example

For example, consider the following document:

```
<!doctype html>
<html lang="en">
 <head>
  <title>Homework</title>
 <body>
  <template id="template"><p>Smile!</p></template>
  <script>
   let num = 3;
   const fragment = document.getElementById('template').content.cloneNode(true);
   while (num-- > 1) {
     fragment.firstChild.before(fragment.firstChild.cloneNode(true));
     fragment.firstChild.textContent += fragment.lastChild.textContent;
   }
   document.body.appendChild(fragment);
  </script>
</html>
```

The p element in the template element is *not* a child of the template element in the DOM; it is a child of the DocumentFragment returned by the template element's content IDL attribute.

If the script were to call appendChild() on the template element, that would add a child to the template element (as for any other element); however, doing so is a violation of the template element's content model.

For web developers (non-normative)

***template*.content**

Returns the template contents (a DocumentFragment).

Each template element has an associated DocumentFragment object that is its **template contents**. The template contents have no conformance requirements. When a template element is created, the user agent must run the following steps to establish the template contents:

1. Let *doc* be the `template`[p679] element's node document's appropriate template contents owner document[p681].
2. Create a `DocumentFragment` object whose node document is *doc* and host is the `template`[p679] element.
3. Set the `template`[p679] element's template contents[p680] to the newly created `DocumentFragment` object.

A `Document`[p131] *doc*'s **appropriate template contents owner document** is the `Document`[p131] returned by the following algorithm:

1. If *doc* is not a `Document`[p131] created by this algorithm, then:
    1. If *doc* does not yet have an **associated inert template document**, then:
        1. Let *new doc* be a new `Document`[p131] (whose browsing context[p1012] is null). This is "a `Document`[p131] created by this algorithm" for the purposes of the step above.
        2. If *doc* is an HTML document, mark *new doc* as an HTML document also.
        3. Set *doc*'s associated inert template document[p681] to *new doc*.
    2. Set *doc* to *doc*'s associated inert template document[p681].

    Note

    Each `Document`[p131] not created by this algorithm thus gets a single `Document`[p131] to act as its proxy for owning the template contents[p680] of all its `template`[p679] elements, so that they aren't in a browsing context[p1011] and thus remain inert (e.g. scripts do not run). Meanwhile, `template`[p679] elements inside `Document`[p131] objects that are created by this algorithm just reuse the same `Document`[p131] owner for their contents.
2. Return *doc*.

The adopting steps (with *node* and *oldDocument* as parameters) for `template`[p679] elements are the following:

1. Let *doc* be *node*'s node document's appropriate template contents owner document[p681].

    Note

    node's *node document* *is the* `Document`[p131] *object that* node *was just adopted* into.
2. Adopt *node*'s template contents[p680] (a `DocumentFragment` object) into *doc*.

The **`content`** getter steps are to return `template`[p679]'s template contents[p680], if the template contents[p680] is not a `ShadowRoot` node; otherwise null.

The **`shadowRootMode`** IDL attribute must reflect[p105] the `shadowrootmode`[p680] content attribute, limited to only known values[p106].

The **`shadowRootDelegatesFocus`** IDL attribute must reflect[p105] the `shadowrootdelegatesfocus`[p680] content attribute.

The **`shadowRootClonable`** IDL attribute must reflect[p105] the `shadowrootclonable`[p680] content attribute.

The **`shadowRootSerializable`** IDL attribute must reflect[p105] the `shadowrootserializable`[p680] content attribute.

The **`shadowRootCustomElementRegistry`** IDL attribute must reflect[p105] the `shadowrootcustomelementregistry`[p680] content attribute.

Note

The IDL attribute does intentionally not have a boolean type so it can be extended.

The cloning steps for `template`[p679] elements given *node*, *copy*, and *subtree* are:

1. If *subtree* is false, then return.
2. For each *child* of *node*'s template contents[p680]'s children, in tree order: clone a node given *child* with *document* set to *copy*'s template contents[p680]'s node document, *subtree* set to true, and *parent* set to *copy*'s template contents[p680].

Example

In this example, a script populates a table four-column with data from a data structure, using a `template`[p679] to provide the

element structure instead of manually generating the structure from markup.

```
<!DOCTYPE html>
<html lang='en'>
<title>Cat data</title>
<script>
 // Data is hard-coded here, but could come from the server
 var data = [
   { name: 'Pillar', color: 'Ticked Tabby', sex: 'Female (neutered)', legs: 3 },
   { name: 'Hedral', color: 'Tuxedo', sex: 'Male (neutered)', legs: 4 },
 ];
</script>
<table>
 <thead>
  <tr>
   <th>Name <th>Color <th>Sex <th>Legs
 <tbody>
  <template id="row">
   <tr><td><td><td><td>
  </template>
</table>
<script>
 var template = document.querySelector('#row');
 for (var i = 0; i < data.length; i += 1) {
   var cat = data[i];
   var clone = template.content.cloneNode(true);
   var cells = clone.querySelectorAll('td');
   cells[0].textContent = cat.name;
   cells[1].textContent = cat.color;
   cells[2].textContent = cat.sex;
   cells[3].textContent = cat.legs;
   template.parentNode.appendChild(clone);
 }
</script>
```

This example uses `cloneNode()` on the `template`[p679]'s contents; it could equivalently have used `document.importNode()`, which does the same thing. The only difference between these two APIs is when the node document is updated: with `cloneNode()` it is updated when the nodes are appended with `appendChild()`, with `document.importNode()` it is updated when the nodes are cloned.

4.12.3.1 Interaction of `template`[p679] elements with XSLT and XPath §[p68]

This section is non-normative.

This specification does not define how XSLT and XPath interact with the `template`[p679] element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, which are intended to be consistent with other processing described in this specification:

- An XSLT processor based on an XML parser that acts as described in this specification[p1402] needs to act as if `template`[p679] elements contain as descendants their template contents[p680] for the purposes of the transform.
- An XSLT processor that outputs a DOM needs to ensure that nodes that would go into a `template`[p679] element are instead placed into the element's template contents[p680].
- XPath evaluation using the XPath DOM API when applied to a `Document`[p131] parsed using the HTML parser[p1289] or the XML parser[p1402] described in this specification needs to ignore template contents[p680].

4.12.4 The slot element §[p683]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].

Contexts in which this element can be used[p147]:

Where phrasing content[p151] is expected.

Content model[p147]:

Transparent[p152]

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
name[p683] — Name of shadow tree slot

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
[Exposed=Window]
interface HTMLSlotElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString name;
  sequence<Node> assignedNodes(optional AssignedNodesOptions options = {});
  sequence<Element> assignedElements(optional AssignedNodesOptions options = {});
  undefined assign((Element or Text)... nodes);
};

dictionary AssignedNodesOptions {
  boolean flatten = false;
};
```

The slot[p683] element defines a slot. It is typically used in a shadow tree. A slot[p683] element represents[p142] its assigned nodes, if any, and its contents otherwise.

The **name** content attribute may contain any string value. It represents a slot's name.

Note

The name[p683] attribute is used to assign slots to other elements: a slot[p683] element with a name[p683] attribute creates a named slot to which any element is assigned if that element has a slot[p156] attribute whose value matches that name[p683] attribute's value, and the slot[p683] element is a child of the shadow tree whose root's host has that corresponding slot[p156] attribute value.

For web developers (non-normative)

***slot*.name[p684]**

Can be used to get and set *slot*'s name.

***slot*.assignedNodes[p684]()**

Returns *slot*'s assigned nodes.

***slot*.assignedNodes[p684]({ flatten: true })**

Returns *slot*'s assigned nodes, if any, and *slot*'s children otherwise, and does the same for any slot[p683] elements encountered therein, recursively, until there are no slot[p683] elements left.

***slot*.assignedElements[p684]()**

Returns *slot*'s assigned nodes, limited to elements.

***slot*.assignedElements[p684]({ flatten: true })**

Returns the same as assignedNodes({ flatten: true })[p684], limited to elements.

***slot*.assign[p684](...*nodes*)**

Sets *slot*'s manually assigned nodes[p684] to the given *nodes*.

The **name** IDL attribute must reflect[p105] the content attribute of the same name.

The slot[p683] element has **manually assigned nodes**, which is an ordered set of slottables set by assign()[p684]. This set is initially empty.

Note

The manually assigned nodes[p684] set can be implemented using weak references to the slottables, because this set is not directly accessible from script.

The **assignedNodes(*options*)** method steps are:

1. If *options*["flatten[p683]"] is false, then return this's assigned nodes.
2. Return the result of finding flattened slottables with this.

The **assignedElements(*options*)** method steps are:

1. If *options*["flatten[p683]"] is false, then return this's assigned nodes, filtered to contain only Element nodes.
2. Return the result of finding flattened slottables with this, filtered to contain only Element nodes.

The **assign(...*nodes*)** method steps are:

1. For each *node* of this's manually assigned nodes[p684], set *node*'s manual slot assignment to null.
2. Let *nodesSet* be a new ordered set.
3. For each *node* of *nodes*:
    1. If *node*'s manual slot assignment refers to a slot[p683], then remove *node* from that slot[p683]'s manually assigned nodes[p684].
    2. Set *node*'s manual slot assignment to this.
    3. Append *node* to *nodesSet*.
4. Set this's manually assigned nodes[p684] to *nodesSet*.
5. Run assign slottables for a tree for this's root.

4.12.5 The canvas element §[p684]

Categories[p147]:

Flow content[p150].
Phrasing content[p151].
Embedded content[p151].
Palpable content[p151].

Contexts in which this element can be used[p147]:

Where embedded content[p151] is expected.

Content model[p147]:

Transparent[p152], but with no interactive content[p151] descendants except for a[p258] elements, img[p347] elements with usemap[p474] attributes, button[p567] elements, input[p521] elements whose type[p524] attribute are in the Checkbox[p544] or Radio Button[p544] states, input[p521] elements that are buttons[p515], and select[p572] elements with a multiple[p573] attribute or a display size[p573] greater than 1.

Tag omission in text/html[p148]:

Neither tag is omissible.

Content attributes[p148]:

Global attributes[p155]
width[p686] — Horizontal dimension
height[p686] — Vertical dimension

Accessibility considerations[p148]:

For authors.
For implementers.

DOM interface[p148]:

IDL

```
typedef (CanvasRenderingContext2D or ImageBitmapRenderingContext or WebGLRenderingContext or
WebGL2RenderingContext or GPUCanvasContext) RenderingContext;

[Exposed=Window]
interface HTMLCanvasElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute unsigned long width;
  [CEReactions] attribute unsigned long height;

  RenderingContext? getContext(DOMString contextId, optional any options = null);

  USVString toDataURL(optional DOMString type = "image/png", optional any quality);
  undefined toBlob(BlobCallback _callback, optional DOMString type = "image/png", optional any
quality);
  OffscreenCanvas transferControlToOffscreen();
};

callback BlobCallback = undefined (Blob? blob);
```

The canvas[p684] element provides scripts with a resolution-dependent bitmap canvas, which can be used for rendering graphs, game graphics, art, or other visual images on the fly.

Authors should not use the canvas[p684] element in a document when a more suitable element is available. For example, it is inappropriate to use a canvas[p684] element to render a page heading: if the desired presentation of the heading is graphically intense, it should be marked up using appropriate elements (typically h1[p217]) and then styled using CSS and supporting technologies such as shadow trees.

When authors use the canvas[p684] element, they must also provide content that, when presented to the user, conveys essentially the same function or purpose as the canvas[p684]'s bitmap. This content may be placed as content of the canvas[p684] element. The contents of the canvas[p684] element, if any, are the element's fallback content[p151].

In interactive visual media, if scripting is enabled[p1098] for the canvas[p684] element, and if support for canvas[p684] elements has been enabled, then the canvas[p684] element represents[p142] embedded content[p151] consisting of a dynamically created image, the element's bitmap.

In non-interactive, static, visual media, if the canvas[p684] element has been previously associated with a rendering context (e.g. if the page was viewed in an interactive visual medium and is now being printed, or if some script that ran during the page layout process painted on the element), then the canvas[p684] element represents[p142] embedded content[p151] with the element's current bitmap and size. Otherwise, the element represents its fallback content[p151] instead.

In non-visual media, and in visual media if scripting is disabled[p1099] for the canvas[p684] element or if support for canvas[p684] elements has been disabled, the canvas[p684] element represents[p142] its fallback content[p151] instead.

When a canvas[p684] element represents[p142] embedded content[p151], the user can still focus descendants of the canvas[p684] element (in the fallback content[p151]). When an element is focused[p845], it is the target of keyboard interaction events (even though the element itself is not visible). This allows authors to make an interactive canvas keyboard-accessible: authors should have a one-to-one mapping of interactive regions to *focusable areas*[p843] in the fallback content[p151]. (Focus has no effect on mouse interaction events.) [UIEVENTS][p1500]

An element whose nearest canvas element ancestor is being rendered and represents embedded content is an element that is **being used as relevant canvas fallback content**.

The canvas element has two attributes to control the size of the element's bitmap: **width** and **height**. These attributes, when specified, must have values that are valid non-negative integers. The rules for parsing non-negative integers must be used to **obtain their numeric values**. If an attribute is missing, or if parsing its value returns an error, then the default value must be used instead. The width attribute defaults to 300, and the height attribute defaults to 150.

When setting the value of the width or height attribute, if the context mode of the canvas element is set to placeholder, the user agent must throw an "InvalidStateError" DOMException and leave the attribute's value unchanged.

The natural dimensions of the canvas element when it represents embedded content are equal to the dimensions of the element's bitmap.

The user agent must use a square pixel density consisting of one pixel of image data per coordinate space unit for the bitmaps of a canvas and its rendering contexts.

Note

A canvas element can be sized arbitrarily by a style sheet, its bitmap is then subject to the 'object-fit' CSS property.

The bitmaps of canvas elements, the bitmaps of ImageBitmap objects, as well as some of the bitmaps of rendering contexts, such as those described in the sections on the CanvasRenderingContext2D, OffscreenCanvasRenderingContext2D, and ImageBitmapRenderingContext objects below, have an **origin-clean** flag, which can be set to true or false. Initially, when the canvas element or ImageBitmap object is created, its bitmap's origin-clean flag must be set to true.

A canvas element can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, a canvas also has a **canvas context mode**, which is initially **none** but can be changed to either **placeholder**, **2d**, **bitmaprenderer**, **webgl**, **webgl2**, or **webgpu** by algorithms defined in this specification.

When its canvas context mode is none, a canvas element has no rendering context, and its bitmap must be transparent black with a natural width equal to the numeric value of the element's width attribute and a natural height equal to the numeric value of the element's height attribute, those values being interpreted in CSS pixels, and being updated as the attributes are set, changed, or removed.

When its canvas context mode is placeholder, a canvas element has no rendering context. It serves as a placeholder for an OffscreenCanvas object, and the content of the canvas element is updated by the OffscreenCanvas object's rendering context.

When a canvas element represents embedded content, it provides a paint source whose width is the element's natural width, whose height is the element's natural height, and whose appearance is the element's bitmap.

Whenever the width and height content attributes are set, removed, changed, or redundantly set to the value they already have, then the user agent must perform the action from the row of the following table that corresponds to the canvas element's context mode.

Context Mode	Action
2d	Follow the steps to set bitmap dimensions to the numeric values of the width and height content attributes.
webgl or **webgl2**	Follow the behavior defined in the WebGL specifications. [WEBGL]
webgpu	Follow the behavior defined in *WebGPU*. [WEBGPU]
bitmaprenderer	If the context's bitmap mode is set to blank, run the steps to set an ImageBitmapRenderingContext's output bitmap, passing the canvas element's rendering context.

Context Mode[p686]	Action
placeholder[p686]	Do nothing.
none[p686]	Do nothing.

The **width** and **height** IDL attributes must reflect[p105] the respective content attributes of the same name, with the same defaults.

For web developers (non-normative)

***context* = *canvas*.getContext[p687](*contextId* [, *options*])**

Returns an object that exposes an API for drawing on the canvas. *contextId* specifies the desired API: "2d[p687]", "bitmaprenderer[p687]", "webgl[p687]", "webgl2[p687]", or "webgpu[p688]". *options* is handled by that API.

This specification defines the "2d[p687]" and "bitmaprenderer[p687]" contexts below. The WebGL specifications define the "webgl[p687]" and "webgl2[p687]" contexts. *WebGPU* defines the "webgpu[p688]" context. [WEBGL][p1501] [WEBGPU][p1501]

Returns null if *contextId* is not supported, or if the canvas has already been initialized with another context type (e.g., trying to get a "2d[p687]" context after getting a "webgl[p687]" context).

The **getContext(*contextId*, *options*)** method of the canvas[p684] element, when invoked, must run these steps:

1. If *options* is not an object, then set *options* to null.
2. Set *options* to the result of converting *options* to a JavaScript value.
3. Run the steps in the cell of the following table whose column header matches this canvas[p684] element's canvas context mode[p686] and whose row header matches *contextId*:

	none[p686]	2d[p686]	bitmaprenderer[p686]	webgl[p686] or webgl2[p686]	webgpu[p686]	placeholder[p686]
"2d"	1. Let *context* be the result of running the 2D context creation algorithm[p695] given this and *options*. 2. Set this's context mode[p686] to 2d[p686]. 3. Return *context*.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Return null.	Throw an "InvalidStateError" DOMException.
"bitmaprenderer"	1. Let *context* be the result of running the ImageBitmapRenderingContext creation algorithm[p747] given this and *options*. 2. Set this's context mode[p686] to bitmaprenderer[p686]. 3. Return *context*.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Throw an "InvalidStateError" DOMException.
"webgl" or "webgl2", if the user agent supports the WebGL feature in its current configuration	1. Let *context* be the result of following the instructions given in the WebGL specifications' *Context Creation* sections. [WEBGL][p1501] 2. If *context* is null, then return null; otherwise set this's context mode[p686] to webgl[p686] or	Return null.	Return null.	Return the same object as was returned the last time the method was invoked	Return null.	Throw an "InvalidStateError" DOMException.

	none[p686]	2d[p686]	bitmaprenderer[p686]	webgl[p686] or webgl2[p686]	webgpu[p686]	placeholder[p686]
	webgl2[p686]. 3. Return *context*.			with this same first argument.		
"webgpu", if the user agent supports the WebGPU feature in its current configuration	1. Let *context* be the result of following the instructions given in *WebGPU*'s Canvas Rendering section. [WEBGPU][p1501] 2. If *context* is null, then return null; otherwise set this's context mode[p686] to webgpu[p686]. 3. Return *context*.	Return null.	Return null.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Throw an "InvalidStateError" DOMException.
An unsupported value*	Return null.	Return null.	Return null.	Return null.	Return null.	Throw an "InvalidStateError" DOMException.

* For example, the "webgl[p687]" or "webgl2[p687]" value in the case of a user agent having exhausted the graphics hardware's abilities and having no software fallback implementation.

For web developers (non-normative)

***url* = *canvas*.toDataURL[p688]([*type* [, *quality*]])**

Returns a data: URL for the image in the canvas.

The first argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "image/png[p1492]"; that type is also used if the given type isn't supported. The second argument applies if the type is an image format that supports variable quality (such as "image/jpeg[p1492]"), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

When trying to use types other than "image/png[p1492]", authors can check if the image was really returned in the requested format by checking to see if the returned string starts with one of the exact strings "data:image/png," or "data:image/png;". If it does, the image is PNG, and thus the requested type was not supported. (The one exception to this is if the canvas has either no height or no width, in which case the result might simply be "data:,".)

***canvas*.toBlob[p689](*callback* [, *type* [, quality]])**

Creates a Blob object representing a file containing the image in the canvas, and invokes a callback with a handle to that object.

The second argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "image/png[p1492]"; that type is also used if the given type isn't supported. The third argument applies if the type is an image format that supports variable quality (such as "image/jpeg[p1492]"), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

***canvas*.transferControlToOffscreen[p689]()**

Returns a newly created OffscreenCanvas[p748] object that uses the canvas[p684] element as a placeholder. Once the canvas[p684] element has become a placeholder for an OffscreenCanvas[p748] object, its natural size can no longer be changed, and it cannot have a rendering context. The content of the placeholder canvas is updated on the OffscreenCanvas[p748]'s relevant agent[p1088]'s event loop[p1138]'s update the rendering[p1143] steps.

The **toDataURL(*type*, *quality*)** method, when invoked, must run these steps:

1. If this canvas[p684] element's bitmap's origin-clean[p686] flag is set to false, then throw a "SecurityError" DOMException.
2. If this canvas[p684] element's bitmap has no pixels (i.e. either its horizontal dimension or its vertical dimension is zero), then return the string "data:,". (This is the shortest data: URL; it represents the empty string in a text/plain resource.)
3. Let *file* be a serialization of this canvas element's bitmap as a file[p753], passing *type* and *quality* if given.
4. If *file* is null, then return "data:,".
5. Return a data: URL representing *file*. [RFC2397][p1499]

The **toBlob(*callback*, *type*, *quality*)** method, when invoked, must run these steps:

1. If this canvas element's bitmap's origin-clean flag is set to false, then throw a "SecurityError" DOMException.
2. Let *result* be null.
3. If this canvas element's bitmap has pixels (i.e., neither its horizontal dimension nor its vertical dimension is zero), then set *result* to a copy of this canvas element's bitmap.
4. Run these steps in parallel:
    1. If *result* is non-null, then set *result* to a serialization of *result* as a file with *type* and *quality* if given.
    2. Queue an element task on the **canvas blob serialization task source** given the canvas element to run these steps:
        1. If *result* is non-null, then set *result* to a new Blob object, created in the relevant realm of this canvas element, representing *result*. [FILEAPI]
        2. Invoke *callback* with « *result* » and "report".

The **transferControlToOffscreen()** method, when invoked, must run these steps:

1. If this canvas element's context mode is not set to none, throw an "InvalidStateError" DOMException.
2. Let *offscreenCanvas* be a new OffscreenCanvas object with its width and height equal to the values of the width and height content attributes of this canvas element.
3. Set the *offscreenCanvas*'s placeholder canvas element to a weak reference to this canvas element.
4. Set this canvas element's context mode to placeholder.
5. Set the *offscreenCanvas*'s inherited language to the language of this canvas element.
6. Set the *offscreenCanvas*'s inherited direction to the directionality of this canvas element.
7. Return *offscreenCanvas*.

Note

To maintain compatibility with existing web content, user agents need to enumerate methods defined in CanvasUserInterface[p691] immediately after the stroke()[p728] method on CanvasRenderingContext2D[p690] objects.

For web developers (non-normative)

***context* = *canvas*.getContext[p687]('2d' [, { [alpha[p697]: true] [, desynchronized[p697]: false] [, colorSpace[p697]: 'srgb'] [, willReadFrequently[p697]: false]}])**

Returns a CanvasRenderingContext2D[p690] object that is permanently bound to a particular canvas[p684] element.

If the alpha[p697] member is false, then the context is forced to always be opaque.

If the desynchronized[p697] member is true, then the context might be desynchronized[p697].

The colorSpace[p697] member specifies the color space[p697] of the rendering context.

The colorType[p697] member specifies the color type[p697] of the rendering context.

If the willReadFrequently[p697] member is true, then the context is marked for readback optimization[p697].

***context*.canvas[p695]**

Returns the canvas[p684] element.

***attributes* = *context*.getContextAttributes[p697]()**

Returns an object whose:

- alpha[p696] member is true if the context has an alpha component that is not 1.0; otherwise false.
- desynchronized[p697] member is true if the context can be desynchronized[p697].
- colorSpace[p697] member is a string indicating the context's color space[p697].
- colorType[p697] member is a string indicating the context's color type[p697].
- willReadFrequently[p697] member is true if the context is marked for readback optimization[p697].

The CanvasRenderingContext2D[p690] 2D rendering context represents a flat linear Cartesian surface whose origin (0,0) is at the top left corner, with the coordinate space having *x* values increasing when going right, and *y* values increasing when going down. The *x*-coordinate of the right-most edge is equal to the width of the rendering context's output bitmap[p696] in CSS pixels; similarly, the *y*-coordinate of the bottom-most edge is equal to the height of the rendering context's output bitmap[p696] in CSS pixels.

The size of the coordinate space does not necessarily represent the size of the actual bitmaps that the user agent will use internally or during rendering. On high-definition displays, for instance, the user agent may internally use bitmaps with four device pixels per unit in the coordinate space, so that the rendering remains at high quality throughout. Anti-aliasing can similarly be implemented using oversampling with bitmaps of a higher resolution than the final image on the display.

Example

Using CSS pixels to describe the size of a rendering context's output bitmap[p696] does not mean that when rendered the canvas will cover an equivalent area in CSS pixels. CSS pixels are reused for ease of integration with CSS features, such as text layout.

In other words, the canvas element below's rendering context has a 200x200 output bitmap (which internally uses CSS pixels as a unit for ease of integration with CSS) and is rendered as 100x100 CSS pixels:

```
<canvas width=200 height=200 style=width:100px;height:100px>
```

The **2D context creation algorithm**, which is passed a *target* (a canvas element) and *options*, consists of running these steps:

1. Let *settings* be the result of converting *options* to the dictionary type CanvasRenderingContext2DSettings. (This can throw an exception.)
2. Let *context* be a new CanvasRenderingContext2D object.
3. Initialize *context*'s canvas attribute to point to *target*.
4. Set *context*'s output bitmap to the same bitmap as *target*'s bitmap (so that they are shared).
5. Set bitmap dimensions to the numeric values of *target*'s width and height content attributes.
6. Run the canvas settings output bitmap initialization algorithm, given *context* and *settings*.
7. Return *context*.

When the user agent is to **set bitmap dimensions** to *width* and *height*, it must run these steps:

1. Reset the rendering context to its default state.
2. Resize the output bitmap to the new *width* and *height*.
3. Let *canvas* be the canvas element to which the rendering context's canvas attribute was initialized.
4. If the numeric value of *canvas*'s width content attribute differs from *width*, then set *canvas*'s width content attribute to the shortest possible string representing *width* as a valid non-negative integer.
5. If the numeric value of *canvas*'s height content attribute differs from *height*, then set *canvas*'s height content attribute to the shortest possible string representing *height* as a valid non-negative integer.

Example

Only one square appears to be drawn in the following example:

```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');
context.fillRect(0,0,50,50);
canvas.setAttribute('width', '300'); // clears the canvas
context.fillRect(0,100,50,50);
canvas.width = canvas.width; // clears the canvas
context.fillRect(100,0,50,50); // only this square remains
```

The **canvas** attribute must return the value it was initialized to when the object was created.

The PredefinedColorSpace enumeration is used to specify the color space of the canvas's backing store.

The "**srgb**" value indicates the 'srgb' color space.

The "**display-p3**" value indicates the 'display-p3' color space.

Note

The algorithm for converting between color spaces can be found in the Converting Colors section of CSS Color. *[CSSCOLOR]*

The CanvasColorType[p689] enumeration is used to specify the color type[p697] of the canvas's backing store.

The "**unorm8**" value indicates that the type for all color components is 8-bit unsigned normalized.

The "**float16**" value indicates that the type for all color components is 16-bit floating point.

The CanvasFillRule[p689] enumeration is used to select the **fill rule** algorithm by which to determine if a point is inside or outside a path.

The "**nonzero**" value indicates the nonzero winding rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path going in one direction is equal to the number of times it crosses the path going in the other direction.

The "**evenodd**" value indicates the even-odd rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path is even.

If a point is not outside a shape, it is inside the shape.

The ImageSmoothingQuality[p690] enumeration is used to express a preference for the interpolation quality to use when smoothing images.

The "**low**" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "**medium**" value indicates a preference for a medium level of image interpolation quality.

The "**high**" value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

Note

Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-smoothing algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used.

4.12.5.1.1 Implementation notes §[p696]

This section is non-normative.

The output bitmap[p696], when it is not directly displayed by the user agent, implementations can, instead of updating this bitmap, merely remember the sequence of drawing operations that have been applied to it until such time as the bitmap's actual data is needed (for example because of a call to drawImage()[p731], or the createImageBitmap()[p1200] factory method). In many cases, this will be more memory efficient.

The bitmap of a canvas[p684] element is the one bitmap that's pretty much always going to be needed in practice. The output bitmap[p696] of a rendering context, when it has one, is always just an alias to a canvas[p684] element's bitmap.

Additional bitmaps are sometimes needed, e.g. to enable fast drawing when the canvas is being painted at a different size than its natural size, or to enable double buffering so that graphics updates, like page scrolling for example, can be processed concurrently while canvas draw commands are being executed.

4.12.5.1.2 The canvas settings §[p696]

A CanvasSettings[p690] object has an **output bitmap** that is initialized when the object is created.

The output bitmap[p696] has an origin-clean[p686] flag, which can be set to true or false. Initially, when one of these bitmaps is created, its origin-clean[p686] flag must be set to true.

The CanvasSettings[p690] object also has an **alpha** boolean. When a CanvasSettings[p690] object's alpha[p696] is false, then its alpha

component must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

Note

Thus, the bitmap of such a context starts off as opaque black instead of transparent black; `clearRect()`[p724] always results in opaque black pixels, every fourth byte from `getImageData()`[p734] is always 255, the `putImageData()`[p734] method effectively ignores every fourth byte in its input, and so on. However, the alpha component of styles and images drawn onto the canvas are still honoured up to the point where they would impact the output bitmap[p696]'s alpha component; for instance, drawing a 50% transparent white square on a freshly created output bitmap[p696] with its alpha[p696] set to false will result in a fully-opaque gray square.

The `CanvasSettings`[p690] object also has a **desynchronized** boolean. When a `CanvasSettings`[p690] object's desynchronized[p697] is true, then the user agent may optimize the rendering of the canvas to reduce the latency, as measured from input events to rasterization, by desynchronizing the canvas paint cycle from the event loop, bypassing the ordinary user agent rendering algorithm, or both. Insofar as this mode involves bypassing the usual paint mechanisms, rasterization, or both, it might introduce visible tearing artifacts.

Note

The user agent usually renders on a buffer which is not being displayed, quickly swapping it and the one being scanned out for presentation; the former buffer is called back buffer and the latter front buffer*. A popular technique for reducing latency is called front buffer rendering, also known as* single buffer *rendering, where rendering happens in parallel and racily with the scanning out process. This technique reduces the latency at the price of potentially introducing tearing artifacts and can be used to implement in total or part of the desynchronized[p697] boolean. [MULTIPLEBUFFERING][p1498]*

Note

The desynchronized[p697] boolean can be useful when implementing certain kinds of applications, such as drawing applications, where the latency between input and rasterization is critical.

The `CanvasSettings`[p690] object also has a **will read frequently** boolean. When a `CanvasSettings`[p690] object's will read frequently[p697] is true, the user agent may optimize the canvas for readback operations.

Note

On most devices the user agent needs to decide whether to store the canvas's output bitmap[p696] on the GPU (this is also called "hardware accelerated"), or on the CPU (also called "software"). Most rendering operations are more performant for accelerated canvases, with the major exception being readback with `getImageData()`[p734], `toDataURL()`[p688], or `toBlob()`[p689]. `CanvasSettings`[p690] objects with will read frequently[p697] equal to true tell the user agent that the webpage is likely to perform many readback operations and that it is advantageous to use a software canvas.

The `CanvasSettings`[p690] object also has a **color space** setting of type `PredefinedColorSpace`[p689]. The `CanvasSettings`[p690] object's color space[p697] indicates the color space for the output bitmap[p696].

The `CanvasSettings`[p690] object also has a **color type** setting of type `CanvasColorType`[p689]. The `CanvasSettings`[p690] object's color type[p697] indicates the data type of the color and alpha components of the pixels of the output bitmap[p696].

To **initialize a `CanvasSettings` output bitmap**, given a `CanvasSettings`[p690] *context* and a `CanvasRenderingContext2DSettings`[p689] *settings*:

1. Set *context*'s alpha[p696] to *settings*["**`alpha`**"].
2. Set *context*'s desynchronized[p697] to *settings*["**`desynchronized`**"].
3. Set *context*'s color space[p697] to *settings*["**`colorSpace`**"].
4. Set *context*'s color type[p697] to *settings*["**`colorType`**"].
5. Set *context*'s will read frequently[p697] to *settings*["**`willReadFrequently`**"].

The **`getContextAttributes()`** method steps are to return «["`alpha`[p697]" → this's alpha[p696], "`desynchronized`[p697]" → this's desynchronized[p697], "`colorSpace`[p697]" → this's color space[p697], "`colorType`[p697]" → this's color type[p697], "`willReadFrequently`[p697]" → this's will read frequently[p697]]».

4.12.5.1.3 The canvas state §p698

Objects that implement the CanvasState[p690] interface maintain a stack of drawing states. **Drawing states** consist of:

- The current transformation matrix[p717].
- The current clipping region[p728].
- The current letter spacing[p705], word spacing[p705], fill style[p720], stroke style[p720], filter[p739], global alpha[p737], compositing and blending operator[p737], and shadow color[p738].
- The current values of the following attributes: lineWidth[p699], lineCap[p699], lineJoin[p699], miterLimit[p700], lineDashOffset[p700], shadowOffsetX[p738], shadowOffsetY[p738], shadowBlur[p739], lang[p705], font[p704], textAlign[p705], textBaseline[p705], direction[p705], fontKerning[p706], fontStretch[p706], fontVariantCaps[p706], textRendering[p706], imageSmoothingEnabled[p738], imageSmoothingQuality[p738].
- The current dash list[p700].

Note

The rendering context's bitmaps are not part of the drawing state, as they depend on whether and how the rendering context is bound to a canvas[p684] element.

Objects that implement the CanvasState[p690] mixin have a **context lost** boolean, that is initialized to false when the object is created. The context lost[p698] value is updated in the context lost steps[p1144].

For web developers (non-normative)

***context*.save[p698]()**

Pushes the current state onto the stack.

***context*.restore[p698]()**

Pops the top state on the stack, restoring the context to that state.

***context*.reset[p698]()**

Resets the rendering context, which includes the backing buffer, the drawing state stack, path, and styles.

***context*.isContextLost[p698]()**

Returns true if the rendering context was lost. Context loss can occur due to driver crashes, running out of memory, etc. In these cases, the canvas loses its backing storage and takes steps to reset the rendering context to its default state[p698].

The **save()** method steps are to push a copy of the current drawing state onto the drawing state stack.

The **restore()** method steps are to pop the top entry in the drawing state stack, and reset the drawing state it describes. If there is no saved state, then the method must do nothing.

The **reset()** method steps are to reset the rendering context to its default state[p698].

To **reset the rendering context to its default state**:

1. Clear canvas's bitmap to transparent black.
2. Empty the list of subpaths in context's current default path[p727].
3. Clear the context's drawing state stack.
4. Reset everything that drawing state[p698] consists of to their initial values.

The **isContextLost()** method steps are to return this's context lost[p698].

4.12.5.1.4 Line styles §p698

For web developers (non-normative)

***context*.lineWidth** [= *value*]
***styles*.lineWidth** [= *value*]

Returns the current line width.

Can be set, to change the line width. Values that are not finite values greater than zero are ignored.

***context*.lineCap** [= *value*]
***styles*.lineCap** [= *value*]

Returns the current line cap style.

Can be set, to change the line cap style.

The possible line cap styles are "`butt`", "`round`", and "`square`". Other values are ignored.

***context*.lineJoin** [= *value*]
***styles*.lineJoin** [= *value*]

Returns the current line join style.

Can be set, to change the line join style.

The possible line join styles are "`bevel`", "`round`", and "`miter`". Other values are ignored.

***context*.miterLimit** [= *value*]
***styles*.miterLimit** [= *value*]

Returns the current miter limit ratio.

Can be set, to change the miter limit ratio. Values that are not finite values greater than zero are ignored.

***context*.setLineDash**(*segments*)
***styles*.setLineDash**(*segments*)

Sets the current line dash pattern (as used when stroking). The argument is a list of distances for which to alternately have the line on and the line off.

segments = *context*.getLineDash()**
segments = *styles*.getLineDash()**

Returns a copy of the current line dash pattern. The array returned will always have an even number of entries (i.e. the pattern is normalized).

***context*.lineDashOffset**
***styles*.lineDashOffset**

Returns the phase offset (in the same units as the line dash pattern).

Can be set, to change the phase offset. Values that are not finite values are ignored.

Objects that implement the CanvasPathDrawingStyles interface have attributes and methods (defined in this section) that control how lines are treated by the object.

The **lineWidth** attribute gives the width of lines, in coordinate space units. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the CanvasPathDrawingStyles interface is created, the lineWidth attribute must initially have the value 1.0.

The **lineCap** attribute defines the type of endings that UAs will place on the end of lines. The three valid values are "`butt`", "`round`", and "`square`".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the CanvasPathDrawingStyles interface is created, the lineCap attribute must initially have the value "`butt`".

The **lineJoin** attribute defines the type of corners that UAs will place where two lines meet. The three valid values are "`bevel`", "`round`", and "`miter`".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the CanvasPathDrawingStyles[p692] interface is created, the lineJoin[p699] attribute must initially have the value "miter".

When the lineJoin[p699] attribute has the value "miter", strokes use the miter limit ratio to decide how to render joins. The miter limit ratio can be explicitly set using the **miterLimit** attribute. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the CanvasPathDrawingStyles[p692] interface is created, the miterLimit[p700] attribute must initially have the value 10.0.

Each CanvasPathDrawingStyles[p692] object has a **dash list**, which is either empty or consists of an even number of non-negative numbers. Initially, the dash list[p700] must be empty.

The **setLineDash(*segments*)** method, when invoked, must run these steps:

1. If any value in *segments* is not finite (e.g. an Infinity or a NaN value), or if any value is negative (less than zero), then return (without throwing an exception; user agents could show a message on a developer console, though, as that would be helpful for debugging).
2. If the number of elements in *segments* is odd, then let *segments* be the concatenation of two copies of *segments*.
3. Set the object's dash list[p700] to *segments*.

When the **getLineDash()** method is invoked, it must return a sequence whose values are the values of the object's dash list[p700], in the same order.

It is sometimes useful to change the "phase" of the dash pattern, e.g. to achieve a "marching ants" effect. The phase can be set using the **lineDashOffset** attribute. On getting, it must return the current value. On setting, infinite and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the CanvasPathDrawingStyles[p692] interface is created, the lineDashOffset[p700] attribute must initially have the value 0.0.

When a user agent is to **trace a path**, given an object *style* that implements the CanvasPathDrawingStyles[p692] interface, it must run the following algorithm. This algorithm returns a new path[p710].

1. Let *path* be a copy of the path being traced.
2. Prune all zero-length line segments[p710] from *path*.
3. Remove from *path* any subpaths containing no lines (i.e. subpaths with just one point).
4. Replace each point in each subpath of *path* other than the first point and the last point of each subpath by a *join* that joins the line leading to that point to the line leading out of that point, such that the subpaths all consist of two points (a starting point with a line leading out of it, and an ending point with a line leading into it), one or more lines (connecting the points and the joins), and zero or more joins (each connecting one line to another), connected together such that each subpath is a series of one or more lines with a join between each one and a point on each end.
5. Add a straight closing line to each closed subpath in *path* connecting the last point and the first point of that subpath; change the last point to a join (from the previously last line to the newly added closing line), and change the first point to a join (from the newly added closing line to the first line).
6. If *style*'s dash list[p700] is empty, then jump to the step labeled *convert*.
7. Let *pattern width* be the concatenation of all the entries of *style*'s dash list[p700], in coordinate space units.
8. For each subpath *subpath* in *path*, run the following substeps. These substeps mutate the subpaths in *path in vivo*.
    1. Let *subpath width* be the length of all the lines of *subpath*, in coordinate space units.
    2. Let *offset* be the value of *style*'s lineDashOffset[p700], in coordinate space units.

3. While *offset* is greater than *pattern width*, decrement it by *pattern width*.

   While *offset* is less than zero, increment it by *pattern width*.

4. Define *L* to be a linear coordinate line defined along all lines in *subpath*, such that the start of the first line in the subpath is defined as coordinate 0, and the end of the last line in the subpath is defined as coordinate *subpath width*.

5. Let *position* be 0 minus *offset*.

6. Let *index* be 0.

7. Let *current state* be *off* (the other states being *on* and *zero-on*).

8. *Dash on*: Let *segment length* be the value of *style*'s dash list[p700]'s *index*th entry.

9. Increment *position* by *segment length*.

10. If *position* is greater than *subpath width*, then end these substeps for this subpath and start them again for the next subpath; if there are no more subpaths, then jump to the step labeled *convert* instead.

11. If *segment length* is nonzero, then let *current state* be *on*.

12. Increment *index* by one.

13. *Dash off*: Let *segment length* be the value of *style*'s dash list[p700]'s *index*th entry.

14. Let *start* be the offset *position* on *L*.

15. Increment *position* by *segment length*.

16. If *position* is less than zero, then jump to the step labeled *post-cut*.

17. If *start* is less than zero, then let *start* be zero.

18. If *position* is greater than *subpath width*, then let *end* be the offset *subpath width* on *L*. Otherwise, let *end* be the offset *position* on *L*.

19. Jump to the first appropriate step:

    ↪ **If *segment length* is zero and *current state* is *off***

    Do nothing, just continue to the next step.

    ↪ **If *current state* is *off***

    Cut the line on which *end* finds itself short at *end* and place a point there, cutting in two the subpath that it was in; remove all line segments, joins, points, and subpaths that are between *start* and *end*; and finally place a single point at *start* with no lines connecting to it.

    The point has a *directionality* for the purposes of drawing line caps (see below). The directionality is the direction that the original line had at that point (i.e. when *L* was defined above).

    ↪ **Otherwise**

    Cut the line on which *start* finds itself into two at *start* and place a point there, cutting in two the subpath that it was in, and similarly cut the line on which *end* finds itself short at *end* and place a point there, cutting in two the subpath that *it* was in, and then remove all line segments, joins, points, and subpaths that are between *start* and *end*.

    If *start* and *end* are the same point, then this results in just the line being cut in two and two points being inserted there, with nothing being removed, unless a join also happens to be at that point, in which case the join must be removed.

20. *Post-cut*: If *position* is greater than *subpath width*, then jump to the step labeled *convert*.

21. Increment *index* by one. If it is equal to the number of entries in *style*'s dash list[p700], then let *index* be 0.

22. Return to the step labeled *dash on*.

9. *Convert*: This is the step that converts the path to a new path that represents its stroke.

   Create a new path[p710] that describes the edge of the areas that would be covered if a straight line of length equal to *style*'s

lineWidth[p699] was swept along each subpath in *path* while being kept at an angle such that the line is orthogonal to the path being swept, replacing each point with the end cap necessary to satisfy *style*'s lineCap[p699] attribute as described previously and elaborated below, and replacing each join with the join necessary to satisfy *style*'s lineJoin[p699] type, as defined below.

Caps: Each point has a flat edge perpendicular to the direction of the line coming out of it. This is then augmented according to the value of *style*'s lineCap[p699]. The "butt" value means that no additional line cap is added. The "round" value means that a semi-circle with the diameter equal to *style*'s lineWidth[p699] width must additionally be placed on to the line coming out of each point. The "square" value means that a rectangle with the length of *style*'s lineWidth[p699] width and the width of half *style*'s lineWidth[p699] width, placed flat against the edge perpendicular to the direction of the line coming out of the point, must be added at each point.

Points with no lines coming out of them must have two caps placed back-to-back as if it was really two points connected to each other by an infinitesimally short straight line in the direction of the point's *directionality* (as defined above).

Joins: In addition to the point where a join occurs, two additional points are relevant to each join, one for each line: the two corners found half the line width away from the join point, one perpendicular to each line, each on the side furthest from the other line.

A triangle connecting these two opposite corners with a straight line, with the third point of the triangle being the join point, must be added at all joins. The lineJoin[p699] attribute controls whether anything else is rendered. The three aforementioned values have the following meanings:

The "bevel" value means that this is all that is rendered at joins.

The "round" value means that an arc connecting the two aforementioned corners of the join, abutting (and not overlapping) the aforementioned triangle, with the diameter equal to the line width and the origin at the point of the join, must be added at joins.

The "miter" value means that a second triangle must (if it can given the miter length) be added at the join, with one line being the line between the two aforementioned corners, abutting the first triangle, and the other two being continuations of the outside edges of the two joining lines, as long as required to intersect without going over the miter length.

The miter length is the distance from the point where the join occurs to the intersection of the line edges on the outside of the join. The miter limit ratio is the maximum allowed ratio of the miter length to half the line width. If the miter length would cause the miter limit ratio (as set by *style*'s miterLimit[p700] attribute) to be exceeded, then this second triangle must not be added.

The subpaths in the newly created path must be oriented such that for any point, the number of times a half-infinite straight line drawn from that point crosses a subpath is even if and only if the number of times a half-infinite straight line drawn from that same point crosses a subpath going in one direction is equal to the number of times it crosses a subpath going in the other direction.

10. Return the newly created path.

4.12.5.1.5 Text styles §[p702]

For web developers (non-normative)

***context*.lang**[p705] **[= *value*]**

***styles*.lang**[p705] **[= *value*]**

Returns the current language setting.

Can be set to a BCP 47 language tag, the empty string, or "inherit[p705]", to change the language used when resolving fonts. "inherit[p705]" takes the language from the canvas[p684] element's language, or the associated document element when there is no canvas[p684] element.

The default is "inherit[p705]".

***context*.font**[p704] **[= *value*]**

***styles*.font**[p704] **[= *value*]**

Returns the current font settings.

Can be set, to change the font. The syntax is the same as for the CSS 'font' property; values that cannot be parsed as CSS font values are ignored. The default is "10px sans-serif".

Relative keywords and lengths are computed relative to the font of the canvas[p684] element.

***context*.textAlign** [= *value*]

***styles*.textAlign** [= *value*]

Returns the current text alignment settings.

Can be set, to change the alignment. The possible values are and their meanings are given below. Other values are ignored. The default is "`start`".

***context*.textBaseline** [= *value*]

***styles*.textBaseline** [= *value*]

Returns the current baseline alignment settings.

Can be set, to change the baseline alignment. The possible values and their meanings are given below. Other values are ignored. The default is "`alphabetic`".

***context*.direction** [= *value*]

***styles*.direction** [= *value*]

Returns the current directionality.

Can be set, to change the directionality. The possible values and their meanings are given below. Other values are ignored. The default is "`inherit`".

***context*.letterSpacing** [= *value*]

***styles*.letterSpacing** [= *value*]

Returns the current spacing between characters in the text.

Can be set, to change spacing between characters. Values that cannot be parsed as a CSS <length> are ignored. The default is "`0px`".

***context*.fontKerning** [= *value*]

***styles*.fontKerning** [= *value*]

Returns the current font kerning settings.

Can be set, to change the font kerning. The possible values and their meanings are given below. Other values are ignored. The default is "`auto`".

***context*.fontStretch** [= *value*]

***styles*.fontStretch** [= *value*]

Returns the current font stretch settings.

Can be set, to change the font stretch. The possible values and their meanings are given below. Other values are ignored. The default is "`normal`".

***context*.fontVariantCaps** [= *value*]

***styles*.fontVariantCaps** [= *value*]

Returns the current font variant caps settings.

Can be set, to change the font variant caps. The possible values and their meanings are given below. Other values are ignored. The default is "`normal`".

***context*.textRendering** [= *value*]

***styles*.textRendering** [= *value*]

Returns the current text rendering settings.

Can be set, to change the text rendering. The possible values and their meanings are given below. Other values are ignored. The default is "`auto`".

***context*.wordSpacing** [= *value*]

***styles*.wordSpacing** [= *value*]

Returns the current spacing between words in the text.

Can be set, to change spacing between words. Values that cannot be parsed as a CSS <length> are ignored. The default is "`0px`".

Objects that implement the `CanvasTextDrawingStyles` interface have attributes (defined in this section) that control how text is laid out (rasterized or outlined) by the object. Such objects can also have a **font style source object**. For `CanvasRenderingContext2D` objects, this is the `canvas` element given by the value of the context's `canvas` attribute. For `OffscreenCanvasRenderingContext2D` objects, this is the associated `OffscreenCanvas` object.

Font resolution for the font style source object[p703] requires a font source. This is determined for a given *object* implementing CanvasTextDrawingStyles[p692] by the following steps: [CSSFONTLOAD][p1494]

1. If *object*'s font style source object[p703] is a canvas[p684] element, return the element's node document.
2. Otherwise, *object*'s font style source object[p703] is an OffscreenCanvas[p748] object:
    1. Let *global* be *object*'s relevant global object[p1098].
    2. If *global* is a Window[p934] object, then return *global*'s associated Document[p935].
    3. Assert: *global* implements WorkerGlobalScope[p1246].
    4. Return *global*.

Example

This is an example of font resolution with a regular canvas[p684] element with ID `c1`.

```
const font = new FontFace("MyCanvasFont", "url(mycanvasfont.ttf)");
documents.fonts.add(font);

const context = document.getElementById("c1").getContext("2d");
document.fonts.ready.then(function() {
  context.font = "64px MyCanvasFont";
  context.fillText("hello", 0, 0);
});
```

In this example, the canvas will display text using `mycanvasfont.ttf` as its font.

Example

This is an example of how font resolution can happen using OffscreenCanvas[p748]. Assuming a canvas[p684] element with ID `c2` which is transferred to a worker like so:

```
const offscreenCanvas = document.getElementById("c2").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker:

```
self.onmessage = function(ev) {
  const transferredCanvas = ev.data;
  const context = transferredCanvas.getContext("2d");
  const font = new FontFace("MyFont", "url(myfont.ttf)");
  self.fonts.add(font);
  self.fonts.ready.then(function() {
    context.font = "64px MyFont";
    context.fillText("hello", 0, 0);
  });
};
```

In this example, the canvas will display a text using `myfont.ttf`. Notice that the font is only loaded inside the worker, and not in the document context.

The **font** IDL attribute, on setting, must be parsed as a CSS <'font'> value (but without supporting property-independent style sheet syntax like 'inherit'), and the resulting font must be assigned to the context, with the 'line-height' component forced to 'normal', with the 'font-size' component converted to CSS pixels, and with system fonts being computed to explicit values. If the new value is syntactically incorrect (including using property-independent style sheet syntax like 'inherit' or 'initial'), then it must be ignored, without assigning a new font value. [CSS][p1494]

Font family names must be interpreted in the context of the font style source object[p703] when the font is to be used; any fonts embedded using `@font-face` or loaded using FontFace[p68] objects that are visible to the font style source object[p703] must therefore be available once they are loaded. (Each font style source object[p703] has a font source, which determines what fonts are available.) If a font is used before it is fully loaded, or if the font style source object[p703] does not have that font in scope at the time the font is to be

used, then it must be treated as if it was an unknown font, falling back to another as described by the relevant CSS specifications. [CSSFONTS]p1494 [CSSFONTLOAD]p1494

On getting, the font p704 attribute must return the serialized form of the current font of the context (with no 'line-height' component). [CSSOM]p1495

Example

For example, after the following statement:

```
context.font = 'italic 400 12px/2 Unknown Font, sans-serif';
```

...the expression `context.font` would evaluate to the string "`italic 12px "Unknown Font", sans-serif`". The "400" font-weight doesn't appear because that is the default value. The line-height doesn't appear because it is forced to "normal", the default value.

When the object implementing the CanvasTextDrawingStyles p692 interface is created, the font of the context must be set to 10px sans-serif. When the 'font-size' component is set to lengths using percentages, 'em' or 'ex' units, or the 'larger' or 'smaller' keywords, these must be interpreted relative to the computed value of the 'font-size' property of the font style source object p703 at the time that the attribute is set, if it is an element. When the 'font-weight' component is set to the relative values 'bolder' and 'lighter', these must be interpreted relative to the computed value of the 'font-weight' property of the font style source object p703 at the time that the attribute is set, if it is an element. If the computed values are undefined for a particular case (e.g. because the font style source object p703 is not an element or is not being rendered p1406), then the relative keywords must be interpreted relative to the normal-weight 10px sans-serif default.

The **textAlign** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles p692 interface is created, the textAlign p705 attribute must initially have the value start p706.

The **textBaseline** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles p692 interface is created, the textBaseline p705 attribute must initially have the value alphabetic p707.

Objects that implement the CanvasTextDrawingStyles p692 interface have an associated **language** value used to localize font rendering. Valid values are a BCP 47 language tag, the empty string, or "**inherit**" where the language comes from the canvas p684 element's language, or the associated document element when there is no canvas p684 element. Initially, the language p705 must be "inherit p705".

The **lang** getter steps are to return this's language p705.

The lang p705 setter steps are to set this's language p705 to the given value.

The **direction** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles p692 interface is created, the direction p705 attribute must initially have the value "inherit p707".

Objects that implement the CanvasTextDrawingStyles p692 interface have attributes that control the spacing between letters and words. Such objects have associated **letter spacing** and **word spacing** values, which are CSS <length> values. Initially, both must be the result of parsing "`0px`" as a CSS <length>.

The **letterSpacing** getter steps are to return the serialized form of this's letter spacing p705.

The letterSpacing p705 setter steps are:

1. Let *parsed* be the result of parsing the given value as a CSS <length>.
2. If *parsed* is failure, then return.
3. Set this's letter spacing p705 to *parsed*.

The **wordSpacing** getter steps are to return the serialized form of this's word spacing p705.

The wordSpacing p705 setter steps are:

1. Let *parsed* be the result of parsing the given value as a CSS <length>.

2. If *parsed* is failure, then return.

3. Set this's word spacing[p705] to *parsed*.

The **fontKerning** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles[p692] interface is created, the fontKerning[p706] attribute must initially have the value "auto[p707]".

The **fontStretch** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles[p692] interface is created, the fontStretch[p706] attribute must initially have the value "normal[p707]".

The **fontVariantCaps** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles[p692] interface is created, the fontVariantCaps[p706] attribute must initially have the value "normal[p708]".

The **textRendering** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles[p692] interface is created, the textRendering[p706] attribute must initially have the value "auto[p708]".

The textAlign[p705] attribute's allowed keywords are as follows:

start
: Align to the start edge of the text (left side in left-to-right text, right side in right-to-left text).

end
: Align to the end edge of the text (right side in left-to-right text, left side in right-to-left text).

left
: Align to the left.

right
: Align to the right.

center
: Align to the center.

The textBaseline[p705] attribute's allowed keywords correspond to alignment points in the font:

The keywords map to these alignment points as follows:

top
: The em-over baseline

hanging

The hanging baseline

middle

Halfway between the em-over baseline and the em-under baseline

alphabetic

The alphabetic baseline

ideographic

The ideographic-under baseline

bottom

The em-under baseline

The `direction`[p705] attribute's allowed keywords are as follows:

ltr

Treat input to the text preparation algorithm[p708] as left-to-right text.

rtl

Treat input to the text preparation algorithm[p708] as right-to-left text.

inherit

Use the process in the text preparation algorithm[p708] to obtain the text direction from the `canvas`[p684] element, placeholder `canvas` element[p748], or document element.

The `fontKerning`[p706] attribute's allowed keywords are as follows:

auto

Kerning is applied at the discretion of the user agent.

normal

Kerning is applied.

none

Kerning is not applied.

The `fontStretch`[p706] attribute's allowed keywords are as follows:

ultra-condensed

Same as CSS 'font-stretch' 'ultra-condensed' setting.

extra-condensed

Same as CSS 'font-stretch' 'extra-condensed' setting.

condensed

Same as CSS 'font-stretch' 'condensed' setting.

semi-condensed

Same as CSS 'font-stretch' 'semi-condensed' setting.

normal

The default setting, where width of the glyphs is at 100%.

semi-expanded

Same as CSS 'font-stretch' 'semi-expanded' setting.

expanded

Same as CSS 'font-stretch' 'expanded' setting.

extra-expanded

Same as CSS 'font-stretch' 'extra-expanded' setting.

ultra-expanded
Same as CSS 'font-stretch' 'ultra-expanded' setting.

The fontVariantCaps[p706] attribute's allowed keywords are as follows:

normal
None of the features listed below are enabled.

small-caps
Same as CSS 'font-variant-caps' 'small-caps' setting.

all-small-caps
Same as CSS 'font-variant-caps' 'all-small-caps' setting.

petite-caps
Same as CSS 'font-variant-caps' 'petite-caps' setting.

all-petite-caps
Same as CSS 'font-variant-caps' 'all-petite-caps' setting.

unicase
Same as CSS 'font-variant-caps' 'unicase' setting.

titling-caps
Same as CSS 'font-variant-caps' 'titling-caps' setting.

The textRendering[p706] attribute's allowed keywords are as follows:

auto
Same as 'auto' in SVG text-rendering property.

optimizeSpeed
Same as 'optimizeSpeed' in SVG text-rendering property.

optimizeLegibility
Same as 'optimizeLegibility' in SVG text-rendering property.

geometricPrecision
Same as 'geometricPrecision' in SVG text-rendering property.

The **text preparation algorithm** is as follows. It takes as input a string *text*, a CanvasTextDrawingStyles[p692] object *target*, and an optional length *maxWidth*. It returns an array of glyph shapes, each positioned on a common coordinate space, a *physical alignment* whose value is one of *left*, *right*, and *center*, and an inline box. (Most callers of this algorithm ignore the *physical alignment* and the inline box.)

1. If *maxWidth* was provided but is less than or equal to zero or equal to NaN, then return an empty array.
2. Replace all ASCII whitespace in *text* with U+0020 SPACE characters.
3. Let *font* be the current font of *target*, as given by that object's font[p704] attribute.
4. Let *language* be the *target*'s language[p705].
5. If *language* is "inherit[p705]":
    1. Let *sourceObject* be *object*'s font style source object[p703].
    2. If *sourceObject* is a canvas[p684] element, then set *language* to the *sourceObject*'s language[p159].
    3. Otherwise:
        1. Assert: *sourceObject* is an OffscreenCanvas[p748] object.
